T103 Evaluating particle size of dry and wet forages using the Ro-Tap separator and Penn State Particle Size Separator method. A. D. Kmicikewycz,* D. D. Maulfair, and A. J. Heinrichs, *Pennsylvania State University, University Park.*

Adequate particle length of forages is an important part of a total ration feeding program and is necessary for proper rumen function. There has been considerable effort exerted to developing laboratory and field-based particle sizing techniques that accurately determine particle size (PS) distribution. The objective of this experiment was to compare 3 different methods used by various laboratories to analyze PS distributions of samples of corn silage (CS) and haylage (H). Method 1 involved utilizing the Ro-Tap separator (W. S. Tyler, Mentor, OH) in determining dry CS and H PS. Method 2 utilized the Penn State Particle Size Separator (PSPS; NASCO, Inc. Fort Atkinson, WI) in determining the PS of wet samples of CS and H. Lastly, method 3 utilized the PSPS in determining the PS of dry samples of CS and H. Three replicates were evaluated for each sample, and the log of the mean cumulative percentage for each sieve was analyzed using GLM procedure in SAS. The 3 methods produced different PS distributions for both CS and H ($P < 0.01$), evidenced by differences in the slope of the distributions. The percentage of particles ≥1.18 mm was determined to be 89.8%, 98%, and 92% for CS and 81.4%, 96.9%, and 89.9% for H for method 1, 2, and 3 respectively. Each system of particle sizing of forages yields a different distribution, and results from different methods are not interchangeable.

Key Words: particle size, forage, analysis

T104 In vitro evaluation of *Miscanthus sacchariflorus* var. as a roughage source for ruminants. S. J. Oh,* J. H. Yang, A. R. Lee, C. H. Ryu, J. H. Lim, S. B. Cho, and N. J. Choi, *Department of Animal Science, Chonbuk National University, Jeonju, Korea.*

This study was conducted to evaluate newly developed germtype *Miscanthus sacchariflorus* var. as a roughage for ruminants. *Miscanthus* has been regarded as an environment friend and carbon neutral plant because it does not require nitrogen fertilizer during its growth. *Miscanthus* has been extensively researched in various industry areas such as paper, energy, building materials, and geotextiles, but there are few studies concerning *Miscanthus* as feed for ruminants. In this study, *Miscanthus* from 2 stages of growth (mid and late) was evaluated using in vitro rumen fermentation and rice straw was used as a reference roughage. So, 3 different roughage sources were used to examine their effect on rumen fermentation. All of experiment was conducted in triplicates with same rumen fluid and in vitro fermentative condition, and the results were analyzed using general linear model with SPSS program In vitro rumen fermentation was prepared with rumen fluid from a Korean native steer equipped with cannula. Total gas production, volatile fatty acid production, pH and ammonia nitrogen concentration were investigated during fermentation until 72 h. In acetic acid production, *Miscanthus* in mid growth stages (MM) showed similar patterns with that of rice straw (RS) but *Miscanthus* in late growth stage (ML) was significantly lower than RS ($P < 0.05$). The propionic acid production in RS was significantly higher than *Miscanthus* regardless of growth stages ($P < 0.05$). In butyric acid production, iso-butyrate production in MM was significantly higher than RS, particularly in 72 h of fermentation ($P < 0.05$). Valeric acid production patterns showed similar with butyric acid production across treatments. In pH profiles, MM showed significantly higher than RS ($P < 0.05$). No difference was found in ammonia nitrogen production between MM and RS but that of ML was significantly lower than MM and RS ($P < 0.05$). Total gas production from MM and RS showed same each other but total gas in ML was significantly low ($P < 0.05$). As a result, *Miscanthus* in mid growth stage could be replaced with RS as roughage for ruminants.

Key Words: *Miscanthus sacchariflorus*, roughage, ruminant

T105 Relationship between dynamic degradation and 48-hour degradation of alfalfa hay in Holstein heifers. Y. Tian*[1], Z. Cao[1], S. Li[1], and S. Yan[2], [1]*State Key Laboratory of Animal Nutrition, College of Animal Science and Technology, China Agricultural University, Beijing, China,* [2]*College of Animal Science, Inner Mongolia Agricultural University, Huhhot, China.*

The objective of this study was to determine the relationship between dynamic degradation and 48 h degradation of alfalfa hay in Holstein heifers. Four Chinese Holstein heifers of average weight 600 ± 30 kg fitted with ruminal cannula were selected. Alfalfa hay samples (n = 9) were incubated in the rumen for 4, 8, 16, 24, 36, 48 and 72h by in situ nylon bag technique. The diet was formulated at a 4:6 (DM basis) concentrate to forage ratio according to 1.3 × maintenance nutrients level. Data were analyzed by ANOVA and Regression analysis procedures (SAS 9.0). The results showed that the Crude protein (CP) degradation rate after 16 h tended to be stable ($P = 0.08$), and degradation rate of DM ($P = 0.08$), NDF (Neutral Detergent Fiber, NDF) ($P = 0.06$) and ADF (Acid Detergent Fiber, NDF) ($P = 0.09$) after 24 h tended to be stable. There was significant correlation between nutrient effective degradation rate and the degradation rate at 48 h in Holstein heifers ($P < 0.001$) (Table 1). In summary, the degradation rate at 48 h for alfalfa hay can be used to predict effective degradation rate.

Table 1. Regression analysis between effective degradation and degradation at 48 h of alfalfa[1]

Index	Regression Equation	R^2	*P*-value
DM	y = 0.804x+1.990	0.978	<0.001
CP	y = 0.898x-4.645	0.995	<0.001
NDF	y = 0.767x-1.964	0.927	<0.001
ADF	y = 1.050x-12.346	0.929	<0.001

[1]Where y = representative effective degradation rate, x = 48-h degradation rate, $P < 0.05$ showed significant difference.

Key Words: alfalfa hay, degradation

T106 In vitro organic matter and nitrogen disappearance of Kenyan browse using rumen from goats ingesting grass versus browse. A. McEwin*[1], C. Wambui[3], J. P. Muir[2], J. Githiori[4], and B. D. Lambert[1,2], [1]*Tarleton State University, Stephenville, TX,* [2]*Texas Agrilife Research, Stephenville,* [3]*Edgerton University, Kenya,* [4]*International Livestock Research Institute, Kenya.*

In vitro organic matter disappearances (IVOMD) of browse species are often thought to be artificially low because of the presence of secondary plant compounds such as condensed tannins (CT). This project investigated how the diet of the wether donating the rumen fluid affected (IVOMD) and in vitro nitrogen disappearance (IVND) results of 11 Kenyan browse species with CT concentrations ranging from 0.2 to 11.9%. The trial consisted of comparing IVOMD and IVND using rumen liquor donated from ruminally cannulated goats that were either fed a Bermudagrass hay diet (no CT) or were allowed to graze freely on natural Texas browse (high CT levels). For 7 of the species, leaf IVOMD was greater ($P < 0.05$) for samples incubated in rumen liquor of goats fed hay but there were no differences ($P > 0.05$) for 2 species without CT or 3 species with CT. Nitrogen in vitro disappearance (as a proportion of the original N) was greater ($P < 0.05$) for 3 species when hay was fed the donor animal, greater 4 species when browse was used, and made no difference ($P > 0.05$) in 4 species, including those without CT. No consistent pattern was discernible between CT concentration and proportion of N disappearing in vitro. These results suggest that when looking IVMD and IVND in browse species that contain secondary compounds, which may interfere with rumen microorganisms, the diet of the rumen fluid donors sometimes but not always make a difference. Further research in needed into determining what factors in the CT or additional factors beyond CT produce differences in IVOMD and IVND.

Key Words: condensed tannins, organic matter disappearances, ruminant

T107 Chemical composition and in vitro gas production of mulberry (*Morus alba* sp.) leaves during regrowth. R. A. Gomes[1], M. H. M. R. Fernandes*[1], I. A. M. A. Teixeira[1], K. T. Resende[1], R. A. Reis[1], F. S. B. Rey[2], and D. C. Soares[1], [1]*UNESP/Sao Paulo State University, Jaboticabal, Sao Paulo, Brazil,* [2]*Faculdade de Medicina Veterinaria e Zootecnia/USP, Pirassununga, Sao Paulo, Brazil.*

Mulberry (*Morus* spp.) is the traditional feed for the silk worm, but its leaves have been widely used as feed for herbivorous animals in several countries, from the temperate areas through the tropics. An experiment was carried out to evaluate in vitro ruminal degradation and to chemically characterize fractions of mulberry leaves harvested at 30, 60, 90, and 120 d of regrowth. Four CHO fractions (A = nonstarch nonfiber CHO, B1 = nonfiber CHO minus sugar; B2 = available fiber and C = indigestible fiber) and 4 CP fractions (A = nonprotein N, B1+B2 = true rapidly and intermediate degraded protein, B3 = slowly degraded protein and C = unavailable protein) were evaluated according to their fermentation characteristics. Incubations were conducted in gas-tight bottles, and the gases accumulated were measured by a pressure transducer. Gas production was recorded from 2 to 124 h, every 2 h. Data were fitted to a modified dual pool logistic equation with a single pool using NLIN procedure of SAS. Polynomial contrasts were used to determine days of regrowth effects. Mulberry leaves had high crude protein (201 ± 5g/kg DM) and high potential of gas production (255 ± 20mL/g DM). Leaves B2(108 to 146 g/kg DM) and C (90 to 108 g/kg DM) carbohydrate fractions increased linearly ($P < 0.05$), and CP (224 to 191 g/kg DM) and degradation rate of non-structural carbohydrates (17 to 8%) decreased linearly ($P < 0.05$) as days of regrowth increased from 30 to 120 d. There was no effect of days of regrowth on leaves CHO fractions A (148 ± 10 g/kg DM) and B1 (280 ± 15 g/kg DM), and protein fractions B1+B2 (49 ± 4 g/kg DM), B3 (48 ± 3 g/kg DM) and C (22 ± 2 g/kg DM), in vitro organic matter digestibility (65 ± 3%) and total gas production ($P > 0.05$). A high proportion of protein fractions A and B1+B2 (up to 62%) relative to the total CP was observed. We concluded that mulberry is a good quality forager, and could be recommended as a protein supplement in ruminant diets based on poor quality forages.

Key Words: carbohydrate, in vitro gas production, protein

T108 Methane-generating potential of *Lotus subbiflorus* 'El Rincón' (LR) and *Lotus uliginosus var. Maku* (LM) harvested in spring. M. de J. Marichal*[1], R. Crespi[1], G. Arias[1], S. Furtado[1], M. H. Guerra[1], and L. Piaggio[2], [1]*Facultad de Agronomía, Universidad de la República, Montevideo, Uruguay,* [2]*Secretariado Uruguayo de la Lana, Montevideo, Uruguay.*

The objective of this study was to evaluate the methane generating potential of forage of *Lotus subbiflorus* 'El Rincón' (LR) and *Lotus uliginosus var. Maku* (LM). Three replicate plots (2 × 2 m) of each Lotus were seeded in August at the Experimental Research Center of the Secretariado Uruguayo de la Lana (S 33° 52·, W 55° 34·). In October, forages were first harvested (plant heights 20 ± 5cm) at ground level using a manual scissor, dried at 60°C (48 h), ground (2 mm screen) and analyzed for NDF, ADF and H_2SO_4 soluble lignin (Lig$_{sa}$). An in vitro gas production procedure was followed using rumen contents of 2 fistulated whethers fed alfalfa hay (17 and 45% CP and NDF, respectively). Rumen contents were collected 2 h after morning feed (alfalfa hay, 1.6 kg DM w^{1}d^1, twice daily), in preheated (39°C) bottles, pooled and blended (less than 1 min) and strained using 4 layers of gauze all maintained at 39°C under CO_2. Samples (500 mg, milled 2 mm) were weighed into 125 mL serum bottles, mixed with ruminal fluid (10mL), and buffer solution (40 mL) and reducing solution (2 mL) of Goering and Van Soest, at 39°C under CO_2. Three batches of 24 of bottles (in each batch 3 bottles by experimental forage and replicate, 3 with alfalfa as standard, and 3 blanks) were incubated (water bath, 39{oC, continuous stirring) for 24 h. Gas was collected at 8 h, and from 8 to 24 hs of incubation in separated bottles and methane in accumulated gas was measured by gas chromatography. Methane production at 8, 8 to 24 and overall 24 h and fiber fractions were analyzed in a complete randomized design (PROC GLM, SAS; Tukey test). Fiber fractions were similar ($P > 0.20$) for both species (47.8 and 44.4; 36.3 and 31.2, and 20.1 and 17.1% NDF, ADF and Lig$_{sa}$, respectively). In gas accumulated up to 8 h, methane production from LR was greater ($P = 0.01$) than for LM (9.2 and 7.6 mg CH4 g OM^1, respectively); however, no differences $P > 0.30$) were registered neither in gas accumulated from 8 to 24 h (10.8 and 10.9 mg CH4 g OM^1, respectively) nor in overall 24h (20.1 and 18.5 mg CH4 g OM^1, respectively) methane production. Both species seemed to be similar in their support of ruminal methane production.

Key Words: methane, *Lotus subbiflorus*, *Lotus uliginosus*

T109 Factors affecting in vitro undigested NDF as estimates of indigestible NDF. D. R. Mertens*[1], D. Taysom[2], and B. Steinlicht[2], [1]*Mertens Innovation & Research LLC, Belleville, WI,* [2]*Dairyland Laboratories Inc., Arcadia, WI.*

Objectives were to evaluate the effects of run (1 vs 2), time (120 vs 262h), single vs double inoculations, blank-correction (bc), ash-correction (om) and substrates on in vitro undigested NDF (uNDF) as estimates of indigestible NDF. Two sources of wheat straw (WS), corn silage (CS), alfalfa haylage (AH), grass hay (GH) and distiller's grains (DG) were fermented in flasks using the method of Goering and Van Soest (1970) with the modification that a composite inoculum containing strained ruminal fluid and blended ruminal solids from 3 steers was used. Donors were fed a TMR (12% CP, 43% aNDF and 18% starch - DM basis). The 262h fermentation was inoculated at 0h (262S), or 0 and 120h (262D), and the 120h fermentation was inoculated at 0h (120S). Two replicates (0.5g) were fermented in each of 2 in vitro runs that were 39d apart. Residues were extracted in neutral detergent with amylase and sulfite and were collected in crucibles with Whatman GF/C filters. Results were analyzed using mixed models with replicate-within-run as a random effect. Blanks were typically greater than zero, and differed by run, time and inoculation ($P < 0.01$). As a fraction of DM, uNDFbc at 262S varied from 0.034 for DG to 0.362 for WS. Blank corrections were large compared with the small uNDF residues of DG yielding erratic results. Results for WS, CS, AH and GH were pooled to evaluate factors affecting uNDF. All uNDF at 120h were larger than those measured at 262S or 262D ($P < 0.0002$). Both uNDF and uNDFom were larger for 262D compared with 262S ($P < 0.0001$). When blank-corrected, uNDFbc ($P = 0.34$) and uNDFombc ($P = 0.27$) were not different between 262D and 262S. Runs differed for all measures of uNDF ($P < 0.04$), while replicates within run did not ($P < 0.63$). Extending fermentation from 120 to 262h reduced uNDF by 5 to 15%; however double inoculation provided minimal reduction. The SEs of LSMeans were lower for 120S and for ash-corrected uNDF. We concluded that blank-correction was critical for the measurement of uNDF and that at least 3 blanks are needed per run. For robust results, uNDF should be replicated across rather than within runs.

Key Words: indigestible NDF, fiber, forage evaluation

T110 Intensive milk production on marandugrass pasture during the rainy season.

C. A. M. Gomide*[1], A. J. Anjos[2], K. G. Ribeiro[2], E. A. Salgado[1], M. J. F. Morenz[1], and D. S. C. Paciullo[1], *[1]Embrapa Dairy Cattle, Juiz de Fora, Minas Gerais, Brasil, [2]UFVJM, Diamantina, Minas Gerais, Brasil.*

The efficient exploitation of the potential forage production of tropical grasses can bring a great benefit to the producer. Besides the increase in production per area, it is possible to increase the area required to produce forage for the dry season. The objective of this study was to assess milk production, per cow and per hectare, in pasture of *Brachiaria brizantha* 'Marandu' managed under rotational stocking with a fixed rest period of 30 d or variable according to the light interception (LI) of 95% by the canopy. In both treatments, the grazing period was 3 d with 4 Holstein × Zebu cows per paddock. The average size of paddocks was 850 m^2. Assessments were made in summer-autumn period of 2010–2011, considering 5 grazing cycles. The experimental design was randomized blocks with 2 repetitions of the area. To evaluate the milk production each cow was considered as a repeat. Data were analyzed as repeated measures (grazing cycles) using the Mixed Procedure of SAS. Means were estimated using the "LSMEANS" command and comparisons made with Student *t*-test with a 10% significance level. The average milk production per cow did not differ between treatments with values of 15.3 and 14.6 L/day, respectively, for fixed and variable (LI) management. The average daily production decreased in response to grazing periods, from 15.8 to 13.8 respectively for the first and fifth cycle. The average rest period observed was 25.2 and 30 d for the treatment based on light interception and fixed interval, respectively. Consequently, the estimate of the stocking rate shows values of 5.1 and 4.1 cow/ha, representing an increase of 24% in favor of the management based on LI. Thus, the daily milk production per hectare has increased from 63.4 to 73.6 L in response to management that is based on pasture growth and not on pre-defined intervals. These results could be even better considering that in this year there was a long period without rain (38 d). Evaluations of the first year of study (2009–2010) showed an average rest period of 21 d for the management based on canopy light interception. Just as the production per cow, daily production per hectare decreased from 72.3 to 63.0 L in response to the grazing cycles. This reduction is due, in part, to the advancement of the growing season and reduced pasture growth factors. Support: FAPEMIG and CNPq.

Key Words: grazing cycles, light interception, rest period

T111 Nutrient digestibility of annual winter forages using different indigestible markers and fecal collection schedules in growing beef heifers.

C. A. Njombwa, D. D. Henry,* F. M. Ciriaco, V. R. G. Mercadante, K. M. Bischoff, G. H. L. Marquezini, M. Ruiz-Moreno, G. C. Lamb, and N. DiLorenzo, *University of Florida, North Florida Research and Education Center, Marianna.*

Twelve Angus and Angus-crossbred heifers (364 ± 52 kg of BW) were used to determine the effects of indigestible markers and fecal sample collection schedules on apparent total tract digestibility of nutrients in 3 annual winter forages. The study was conducted at the University of Florida Feed Efficiency Facility (FEF). Winter forages consisted of ryegrass, a blend of ryegrass and Trical 342 triticale, and a blend of oat and ryegrass planted in 0.7-Ha paddocks. On d 0 heifers were randomly assigned to their forage treatments and allowed to graze for 28 d. On d 29 heifers were moved to the FEF (2 heifers/pen) and from d 29 to 44 were offered daily fresh cuts of the same forages. Individual intake was monitored in the FEF using a GrowSafe system (GrowSafe Systems Ltd., Alberta, Canada). From d 29 to 44, heifers received 10 g/d of Cr_2O_3 and 10 g/d of TiO_2 via a gelatin capsule and a balling gun. Feed and fecal samples were collected from d 39 to 43 and 40 to 44, respectively. Fecal samples were collected by rectal grab at 0800, 1200 and 1600 h, and composited within heifer using 2 samples/d (2s; 0800 and 1600 h only) or 3 samples/d (3s; all samples). Data were analyzed as a split-split plot design with the whole plot testing forage treatment effect, the split plot testing the fecal collection schedule (2s vs. 3s) and the split-split plot testing the marker (Cr_2O_3 vs. TiO_2) using heifer as the experimental unit. No effect of treatment was found ($P > 0.05$) for DM, OM, NDF or ADF digestibility of winter forages. Across forage treatments, mean apparent nutrient digestibility in the total tract were 59 ± 5.9%, 62 ± 5.8%, 48 ± 9.9%, and 27 ± 14.7% for DM, OM, NDF, and ADF, respectively. No effect of marker, sampling schedule, or marker x sampling schedule interaction was found for nutrient digestibility ($P > 0.05$). In conclusion, collecting fecal samples at 0800 and 1600 h was sufficient for measuring digestibility in winter forages. Both Cr_2O_3 and TiO_2 may be used indistinctively to estimate digestibility of winter forages, however standard errors of the mean reported, especially for digestibility of fiber fractions may be of concern. The use of digestibility markers that associate more intimately with the forage (e.g., internal markers) should be tested in future studies.

Key Words: digestibility, winter forages, markers

T112 Estimating crude protein and fiber contents in Tifton-85 bermudagrass swards with a new portable chlorophyll meter.

R. Silva[1], R. Rossiello[2], É. Junior[2], M. Morenz[2], and J. Costa Junior*[3], *[1]UFBA, Salvador, Bahia, Brazil, [2]UFRRJ, Seropédica, Rio de Janeiro, Brazil, [3]UFRGS, Rio Grande do Sul, Brazil.*

Traditional methods for determining the nutritional value are costly and time consuming, so several indirect methods are under study. This study aimed to evaluate the performance of a new model of portable chlorophyll meter as a fast and inexpensive procedure for the assessment of nutritional attributes of Tifton 85 bermudagrass (*Cynodon* spp. 'Tifton 85'). Data were obtained from a field trial where treatments consisted of 3 levels of soil N availability: low (native soil N); medium (75 kg N/ha/cutting), and high (150 kg N/ha/cutting). Measurements were performed in 2 successive regrowth periods, with duration of 28 and 29 d, respectively, in the rainy season. Chlorophyll meter readings (FCI values - Falker chlorophyll index) were taken in the uppermost fully expanded leaf. Correlation analysis showed significant relationships between FCI values and acetone 80% extractable–total chlorophyll ($r = 0.83$; $P < 0.0001$); crude protein (CP) contents that oscillated between

100.2 and 183.5 g/kg DM also showed significant relationships (r = 0.85; $P < 0.0001$); neutral detergent fiber (NDF) and acid detergent fiber (ADF) contents whereas lignin contents did not showed consistent associations. Crude protein contents were determined from N-Kjeldahl analysis, and the NDF, ADF and lignins by the method of Van Soest et al. (1991), in dried and ground samples. The results obtained were first subjected to standard normal distribution tests and after processed for variance analysis (F test, $P \leq 0,05$). The averages were compared through SNK test (a = 0,05) for the N variables and cut period, respectively. The programs used for data analysis were SAEG v.9.1 (UFV, 2007) and Graph Prism 5.0. Taken together, these preliminary results showed the feasibility of using this new chlorophyll meter to predict CP and ADF contents in Tifton 85 bermudagrass. However, there is need of more research to validate the use of a chlorophyll meter with other fibrous fractions.

Key Words: *Cynodon* spp., total chlorophyll, fibrous fractions

T113 Mixed silage of potato residue and corn straw affects growth performance and blood biochemical parameters in mutton sheep.

D. Wang[1,2], J. Q. Wang*[1,2], D. P. Bu[2], Y. D. Zhang[2], P. Sun[2], and L. Y. Zhou[2], [1]*College of Animal Science and Technology, Heilongjiang Bayi Agricultural University, Daqing, Heilongjiang, China,* [2]*Institute of Animal Science, Chinese Academy of Agricultural Sciences, Beijing, China.*

This study was conducted to determine the effects of mixed silage with potato residue and corn straw on growth performance and blood biochemical parameters in mutton sheep. A total of 40 healthy White-Suffolk cross sheep within initial body weight (47.45 ± 6.38 kg) were randomly allocated into 4 treatments with 10 replicates per treatment and 1 sheep per replicate. The feeding trial lasted for 70 d. Four treatments included: 1) control group(Ctrl), 40% basal diet + 60% corn silage; 2) test group 1 (S25), 40% basal diet + 45% corn silage + 15% mixed silage; 3) test group 2 (S50), 40% basal diet + 30% corn silage + 30% mixed silage; 4) test group 3 (S75), 40% basal diet + 15% corn silage + 45% mixed silage. Data were analyzed using MIXED procedures of SAS (SAS Institute, 2001). The ADG of S75 group was increased by 14.29% compared with Ctrl group ($P < 0.05$). There was no difference in the dry matter intake (DMI) ($P > 0.05$). The ammonia-N content in S25, S50 and S75 groups was significantly lower than that in Ctrl group by 18.92% ($P < 0.01$), 30.17% ($P < 0.01$) and 33.03% ($P < 0.01$), respectively. No remarkable differences were observed in acetate content, propionate content, butyrate content, acetate percentage, propionate percentage, butyrate percentage, the ratio of acetate to propionate and the ratio of acetate to propionate and butyrate ($P > 0.05$). There was no significant difference in serum total protein ($P > 0.05$). On the sixtieth day of the trial, serum urea nitrogen content was greater in S25 and S75 groups than that in S50 and Ctrl group($P < 0.05$) and serum glucose contents of S75 group was improved compared with the other 3 groups ($P < 0.05$). In conclusion, the mixed silage with potato residue and corn straw can increase ADG, serum urea nitrogen content, serum glucose contents and decrease the ammonia-N content of mutton sheep. Therefore, the study suggests that the mixed silage with potato residue and corn straw can account for 75% of corn silage in the mutton sheep diet.

Key Words: potato residue, fermentation quality, blood biochemical parameters

T114 Effect of different fat protected sources on milk yield and composition in goats fed on corn silage as based diet in dairy goats.

C. Vázquez-Fontes*[1], R. Ayala[2], A. Z. M. Salem[2], N. Pescador-Salas[2], L. R. Bernal-Martínez[1], and M. Gonzalez Ronquillo[2], [1]*Universidad Autonoma del Estado de Mexico, Facultad de Ciencias Agrícolas,* [2]*Facultad de Medicina Veterinaria y Zootecnia, Toluca, Estado de Mexico, Mexico.*

High quality milk and dairy products are nutritious and healthy foods that are frequently consumed by people who desire healthy products. In ruminant, fats are the major source of CLA in the human food. Canola and Safflower oil has the highest source of polyunsaturated fatty acids (PUFA) than that found in any other type of vegetable oil (i.e., almost 79% PUFA). The available evidence suggested that increase the intake of 18:2n-6 in high-forage diets could be used as a nutritional strategy for enhancing the supply of *cis*-9,*trans*-11-CLA available for absorption. The objective of the present study was to determine the milk yield and milk composition in dairy goats, supplemented with different fat protected sources, Canola calcium soap (CS), Safflower calcium soap (SFS) or lactomilk (LM) rich in 16:0 fatty acid. Three lactating dairy French alpine goats (BW 54 ± 2 Kg) in 3 × 3 Latin square design were used. Goats were housed in an individual metabolic cages, and fed at 0800 and 1600 h, with free water access and milked daily at 0800 h. Diets (14% CP, 2.8 Mcal MEm) were formulated with corn maize silage ad libitum, supplemented with a concentrate based on corn grain (50%), barley hay (21%), soybean meal (20%) and minerals (3%) plus one fat protected source (6%). Each 20 d as experimental period consisted for 14 d for adaptation and ended with 6 d of samples collection. Individual intake and daily milk yield were recorded daily. Milk fat, true protein, SNF, was determined for infrared Milko-Scan 133B analyzer® (Foss Electric, Hillerød, Denmark). Data of each period was analyzed using proc GLM in SAS; LS means are reported in Table 1. Milk yield was higher ($P = 0.009$) in SFS versus with CS and LM, while fat content (g/d) was lower ($P = 0.001$) in CS versus SFS and LM; and true protein content (g/d) was also higher ($P = 0.003$) in SFS followed by LM and CS. Total solids and SNF (g/d) was higher ($P = 0.005$) in SFS compared with the other treatments. According to the present study SFS treatment increase milk yield and chemical composition versus CS and LM.

Table 1. Effect of different fat protected sources on milk yield (kg/d) and composition (g/d, %) in dairy goats

Item	CS	SFS	LM	SEM	*P*-value
Milk yield (kg/d)	0.949^a	1.105^b	0.883^a	0.87	0.009
Fat (g/d)	32.3^a	35.0^b	34.3^b	0.56	0.002

T115 Effect of oil palm (*Eleais guineensis*) effluent plus supplement in the feeding of pigs (Duroc x Pietrain) in the finishing phase during dry season. I. Espinoza,* R. Vivas, D. Zambrano, B. Montenegro, G. Muñoz, M. Romero, H. Medina, R. Soria, M. Medina, L. Godoy, and E. Torres, *Universidad Técnica Estatal de Quevedo, Quevedo, Los Ríos, Ecuador.*

This investigation was carried out at the "El Recuerdo" pig farm, located at one and a half mile at the Valencia - La Mana highway, province of Los Ríos, Ecuador. Its geographical location is 01° 6′ 20'' south latitude and 79° 29′ 23'' west longitude at 120 m above sea level and was conducted between August and October of 2010, lasting 56 d, including the period of adaptation. The effect of oil palm (*Eleaeis guineensis*) effluent (agro-industrial waste) plus supplement in the diet of pigs (Duroc × Pietrain) in the finishing stage during the dry season, along with the productivity indices (weight gain, feed intake, feed conversion, carcass yield and backfat) and cost/benefit ratio of the treatments under study were determined, assuming that with the implementation of one of the treatments under study production rates will be improved. Through an economic analysis of the treatments under study it was determined which of them improved the benefit / cost ratio. The treatments under study were 2 (T1: 2.5 kg of balanced feed plus 1 kg of oil palm effluent and T2: 2.5 kg of balanced feed plus 2 kg of oil palm effluent) compared with a control (2.5 kg of finishing phase balanced feed). A complete randomized block design was used in this study with 3 treatments and 6 replications. The highest feed intake in T2 ($P < 0.05$) and T1 in relation to the control, were because the pigs were influenced directly by the increased availability of food offered since the rations were larger in both cases. The total weight gains were similar ($P < 0.05$) in both treatments under study. However, there was a greater weight gain in the treatment supplemented with 1 kg of oil palm effluent surpassing the control with 3.67 kg. Besides a better feed conversion at 28 d in T1 ($P < 0.05$) was observed. In the variables carcass yield and backfat, no significant influences were observed when supplementing the diet of the pigs with oil palm effluent. The best cost / benefit ratio was achieved by T1 with 0.27.

Key Words: oil palm affluent, pig, supplement

T116 Planting date and crop harvest phenological stage effects on biomass and nutritive value of non-photosensitive forage soybean lines in Puerto Rico. A. Aponte, E. Valencia,* and J. Beaver, *University of Puerto Rico, Mayaguez, Mayaguez, PR.*

Forage soybean [*Glycine max* L. (Merr.)] has high potential for biomass production in the tropics, because, in a short period of time high quality hay can be produced for animal feed. However, in the tropics information on soybean for forage or grain is non-existent. Information of the effects of planting dates and crop harvest phenological stage (CHPS) on dry matter yield (DMY) of non-photosensitive soybeans are needed. This research assessed biomass production (Mg ha-1), crude protein (CP), neutral detergent fiber (NDF), and acid detergent fiber (ADF)] % of 10 non-photosensitive soybean lines at 2 CHPS and 2 planting dates on an Oxisol (Cotito series) at Isabela, Puerto Rico. The field design was a complete block with 4 replications in a split-plot arrangement of 10 forage soybean lines and 2 CHPS (R2 and R5.4); 100% flowering and 75% grain physiological filling, respectively. Planting dates were September 2010 and January 2011. For each planting date and CHPS, a 1.2 m^2 area was harvested from the main plot and fresh weight and a sub-sample (500g) taken. Subsamples were oven-air-dried to determine % dry matter (DM). Nitrogen % (Kjeldahl), NDF and ADF (Van Soest procedure) were determined in a commercial laboratory. The data was analyzed using the Statistical Package, INFOSTAT. Unlike planting date, CHPS had a significant effect ($P < 0.05$) on the DMY. Soybean forage DM produced on average between 5.4 and 6.5 Mg/ha when harvested at the R2 (8 weeks) and R5.4 (12 weeks) stages of development, respectively. Maximum biomass was obtained at the R5.4 harvest with an increase in DM of 1.0 Mg/ha in 28 d. There was an interaction ($P < 0.05$) between the lines x CHPS for CP ranging from 29.6% to 33.6% for R2 harvest, while samples for the R5.4 harvest ranged from 23.0 to 26.7%. NDF in R2 stage ranged from 33.3 to 34.6, and increased in the R5.4 stage from 38.1% to 44.8%, while ADF for R2 ranged from 21.0% to 25.6%, whereas ADF increased from 26.2% to 33.2% for the R5.4 stage. These results indicate that biomass for soybean lines did not differ ($P > 0.05$) between planting date, but there was a marked effect of CHPS on DM yield. Forage soybeans harvested at the R5.4 versus the R2 stage of development had 60% more biomass, and higher nutritional value. Fiber values were similar to alfalfa and can satisfy the nutritional requirement of ruminants in the tropics.

Key Words: forage soybeans, phenological stages, nutritive value

T117 Nutritional characterization of pastures used in Colombian dairies with emphasis on fatty acid profile. E. A. De La Vega,* J. E. Parales, C. A. Mendoza, M. M. Knowles, G. J. Díaz, M. L. Pabón, and J. E. Carulla, *Universidad Nacional de Colombia, Bogotá, Cundinamarca, Colombia.*

Fatty acid profile of different pastures used in Colombian dairy farms and their relationship with grazing management strategies and altitude (meters over sea level; mosl) were examined. Forage samples of pastures were taken from 115 dairy farms in 5 dairy regions. Pasture type and management were characterized for each farm. Samples were oven-dried and analyzed for DM, NDF, ADF, CP, total fat and ash. Fatty acid profiles of the samples were determined using GC. The data were subjected to multivariate statistical analysis using the 2-stage cluster procedure. To define homogeneous clusters, we followed the Bayesian Information Criterion Schwarz including continuous and discrete variables. None of the variables measures related to grazing management were included as main grouping criteria. Five clusters were identified which main grouping criteria were the altitude and type of pasture. Cluster 1: lowland ($\mu \pm SD$; 442 ± 99 mosl) native pastures; cluster 2: medium altitude ($\mu \pm SD$; 874 ± 444 mosl) pastures composed mainly of *Brachiaria* spp.; cluster 3: upland pastures ($\mu \pm SD$; 2711 ± 144 mosl) composed mainly of *Lolium* spp. pastures and mixed pastures of *Pennisetum clandestinum* with *Trifolium pratense*; cluster 4: upland grasslands ($\mu \pm SD$; 2597 ± 88 mosl) consisting of monocultures of *Pennisetum clandestinum* and cluster 5: upland pastures ($\mu \pm SD$; 2605 ± 83 mosl) composed of mixtures of *Pennisetum clandestinum* and *Lolium* spp. Lipids of low land and medium altitude pastures had lower content of linolenic acid ($\mu \pm SD$; 20.1 ± 7.5 vs 35.6 ± 9.4 g/100 g FA) and higher in saturated fatty acids ($\mu \pm SD$; 59.8 ± 8.2 vs 45.4 ± 8.4 g/100 g FA) than upland pastures ($P < 0.05$). Most variable fatty acids in forage lipids were linolenic and palmitic acid. Degree of saturation was mainly explained by an increase in palmitic acid and a reduction in linolenic acid ($r^2 = 0.73$; $P \leq 0.001$). Low land and medium altitude pastures had higher levels of DM (17.5 vs. 24.7 g/100 g DM), NDF (56.8 vs 67.7 g/100 g DM), ADF (26.6 vs 36.6 g/100 g DM) than high altitude pastures ($P \leq 0.05$). Differing pasture species combinations at various altitudes resulted in variable nutritional quality and lipid profiles for dairy pastures in Colombia.

Key Words: fatty acids, forages, linolenic acid

T118 Effect of sowing density and planting date on the establishment of *Pennisetum purpureum* 'CT-115' in a semiarid region of northern Mexico. E. Gutierrez Ornelas*[1,3], J. J. Nava Cabello[1], R. Herrera[2,3], H. Bernal Barragan[1,3], E. Treviño Ramirez[1], and E. Olivares Saenz[1], [1]*Universidad Autónoma de Nuevo León, San Nicolás de los Garza, Nuevo León, México,* [2]*Instituto de Ciencia Animal, San José de Las Lajas, Habana, Cuba,* [3]*Red Internacional de Nutición y Alimentación en Rumiantes, México.*

The objective of the experiment was to evaluate the effect of 2 sowing densities ((D1 = 17,850 and D2 = 11,350 plants/ha) and 4 planting dates of King Grass, *Pennisetum purpureum* cv. CT-115 according to a completely random block design with a 4 × 2 factorial arrangement of treatments, where each planting date (July, August, September, and October 2009) was done under an area of 900 m^2, including 2 replications per density. Seven plants were randomly sampled in each of the 16 experimental units to estimate the interest variables. Basic climatic factors affecting establishment of non irrigated forages were registered. Forage establishment variables were measured during May 2010. On January 2010 lowest temperatures were recorded (−6°C) during 2 consecutive days without affecting viability of plants after re-growing conditions were present on April 2010. Sowing density only affected ($P \leq 0.05$) the proportion of senescence material (D1 = 15.8 vs. D2 = 11.4%) and dry matter production (D1 = 6.1 vs. D2 = 4.3 ton/ha). Dry matter percentage was affected ($P \leq 0.05$) by the planting time, having lower content than those plants planting on July and August. Leaf proportion was higher ($P \leq 0.05$) in July and August (57.7 and 58.5%, respectively) compared with September and October (44.6 and 43.7%, respectively). Leaf/stem ratio and the number of stems/plant were higher ($P \leq 0.05$) in the 2 first months of planting. It can be concluded that the better sowing density was D1. The lowest temperatures registered during January 2010 did not affect the establishment of *Pennisetum purpureum* 'CT-115' planted from July to October at the region of Marin Nuevo León, México.

Key Words: *Pennisetum purpureum*, cultivar CT-115, sowing density

T119 Effect of plant density over the productive performance of gliricidia. E. N. Muniz*[1], J. H. A. Rangel[1], D. O. Santos[1], C. O. Sá[1], and J. L. Sá[2], [1]*Embrapa Tabuleiros Costeiros, Aracaju, Sergipe, Brazil,* [2]*Embrapa Semi* Árido, *Petrolina, Pernambuco, Brazil.*

Gliricidia sepium (Jacq.) Walp. is a forage tree species very well adapted to water stress conditions, with high protein content in its leaves make it a low cost strategy for ruminant diets during drought periods. In northeast Brazil, gliricídia has been used as cattle and sheep food in silvopastoral systems, and also as silage or hay providing good dry matter productivity of high quality and good acceptance by animals. The present work aimed to evaluate the effect of different plant densities over the biomass and dry matter productivity of gliricídia. The trial was carried out without irrigation in a randomized block design with 4 replications in the Pedro Arle Experimental Station belonging to Embrapa Tabuleiros Costeiros at Frei Paulo County, Sergipe, Brazil. The densities of 10,000; 20,000; 30,000; and 40,000 plants/ha were tested. Fresh biomass and dry matter productivity of 6 harvests were evaluated for the growth period between 05/22/2009 and 03/22/2011. Cuts were done at 09/02/2009, 03/16/2010, 05/26/2010, 08/24/2010, 12/09/2010 and 03/22/2011. Mean values of cuts for total biomass, stem biomass, leaves biomass, leaves percentage and total dry matter per cut were presented in Table 1. Values of biomass productivity increased with the increase of plant density after the density of 20,000 plant/ha. Based on the results, it is recommended the density of 40,000 plants/ha of gliricidia for that condition.

Table 1. Means of biomass productivity of gliricidia at different plant densities

Treatment	Total biomass/ cut (t)	Stem biomass/ cut (t)	Leaves biomass/ cut (t)	Leaves (%)	Leaves DM/ cut(t)	Total leaves DM (t) 6 cuts
10000	21.54^{b}	7.12^{b}	14.41^{b}	67.98^{a}	3.02^{b}	18.14^{b}
20000	20.72^{b}	6.56^{b}	14.16^{b}	68.49^{a}	2.92^{b}	17.53^{b}
30000	25.19^{ab}	8.05^{ab}	17.15^{ab}	69.05^{a}	3.46^{ab}	20.78^{ab}
40000	27.28^{a}	9.13^{a}	18.15^{a}	67.13^{a}	3.75^{a}	22.49^{a}

^{a,b}Means followed by the same letter in columns are not different by Tukey test ($P < 0.05$).

T120 Assessment of the socio-economic value of goods and services from Manitoba grasslands. S. Kulshreshtha[1], M. Undi*[2], J. Zhang[1], M. Ghorbani[1], K. M. Wittenberg[2], A. A. Stewart[3], E. Salvano[4], E. Kebreab[5], and K. H. Ominski[2], [1]*Dept of Bioresource Policy, Business and Economics, University of Saskatchewan, Saskatoon, SK, Canada,* [2]*Department of Animal Science & National Centre for Livestock and the Environment, University of Manitoba, Winnipeg, MB, Canada,* [3]*Shur-Gro Farm Services Ltd., Waskada, MB, Canada,* [4]*Manitoba Agriculture, Food, and Rural Initiatives, Winnipeg, MB, Canada,* [5]*Dept of Animal Science, University of California, Davis.*

Grasslands in Manitoba occupy 2.4 million ha and provide goods and services (G & S) that have direct and indirect monetary value. The objectives of this study were to a) provide a framework for comparing the value of G & S from grasslands by utilizing direct and indirect assessment, b) assess the value of Manitoba grasslands and the variables influencing value, and c) identify gaps in knowledge thereby improving estimates of grassland contribution to socio-economic well-being. Methods of valuation employed in the study were specific to the type of G & S examined. Market price was utilized to value grassland G & S where transactions occur in the marketplace while the benefit transfer method was used to infer non-market values of those G & S that are not typically sold through the marketplace. A total of 18 grassland G & S were identified for Manitoba grasslands, but only perennial forage production, carbon storage, nutrient cycling, water regulation, waste treatment, soil formation, erosion control, wildlife habitat, and recreation were included in the valuation. Genetic, medicinal, and ornamental resources, water supply (including filtration), nursery function, biological value, and many cultural services, while important, could not be assigned monetary value due to lack of data. The socio-economic value of grasslands in Manitoba was estimated to be \$936 million yr^{-1} (equivalent to \$390 ha^{-1} on average) with a range of \$702 million to \$2,518 million yr^{-1}. The 2 most highly valued G & S in Manitoba grasslands were carbon storage and forage production. More research will be required to further quantify carbon storage in Manitoba grasslands as well as assess the value of G & S not included in the above total value of grasslands.

Key Words: grassland, goods and services, socio-economic value

Growth and Development II

T121 Effect of residual feed intake on hypothalamic gene expression and meat quality in heat-stressed Angus-sired cattle.

C. N. Key,* S. D. Perkins, C. F. Garrett, C. D. Foradori, C. L. Bratcher, L. A. Kriese-Anderson, and T. D. Brandebourg, *Auburn University, Auburn, AL.*

Residual feed intake (RFI) is a heritable feed efficiency measure. The relationship between RFI, heat stress and meat quality is unknown. To address these issues, 48 Angus-sired steers were trained to the Calan Gate (Northwood, NH) system. Daily feed intake and RFI were assessed during a 70 d feeding trial conducted July through September. The test diet was 50% balage consisting of a winter annual mix, 50% grain (2.9 Mcal ME/kg DM). Feed intake was recorded daily while body weights and hip heights were recorded at 14 d intervals. Ultrasound measurements of rib eye area (REA) and backfat (BF) were recorded initially and before slaughter. RFI was calculated for each animal as the difference between actual dry matter intake and the expected intake to create 2 divergent cohorts consisting of High (H) and Low (L) RFI individuals. At slaughter, hypothalamic tissue samples were collected to facilitate gene studies into the mechanisms underlying variation in RFI. After chilling for 24 h post harvest, carcass characteristics were measured. Carcass and growth data were analyzed using a mixed model with RFI level (L, H) as the independent variable (SAS, 2002). Means were separated using lsmeans at a significance level of $P < 0.05$. The lsmeans for RFI were −1.2 and 0.99 respectively for the L and H cohorts ($P < 0.0001$) and were greater than 2 standard deviations apart. As expected dry matter intake was higher for the H individuals versus the L steers ($P < 0.0001$) while on-test gain was not different between groups. Marbling score was greater in L than H steers ($P < 0.05$). However there were no differences in objective color measures L*, a*, and b*, adjusted back fat, ribeye area or yield grade between L and H cohorts. Real-time PCR studies in the arcuate nucleus indicate that neuropeptide Y (NPY) and agouti related protein (AgRP) mRNA were expressed 2.8-fold and 1.85-fold greater while Pro-opiomelanocortin (POMC) mRNA was expressed 1.6-fold lesser in L than H animals. These data suggest there is no relationship between RFI and meat quality while surprisingly the mRNA expression of neuropeptides that stimulate feed intake were increased in efficient animals during heat-stressed conditions.

Key Words: RFI, meat quality, heat stress

T122 Effect of residual feed intake on meat quality and hypothalamic gene expression in Angus-sired cattle.

S. D. Perkins,* C. N. Key, C. F. Garrett, C. D. Foradori, C. L. Bratcher, L. A. Kriese-Anderson, and T. D. Brandebourg, *Auburn University, Auburn, AL.*

Residual feed intake (RFI) is a heritable feed efficiency measure. Mechanisms underlying RFI are poorly understood while the relationship between RFI and meat quality is unknown. To address these issues, 48 Angus-sired steers were trained to the Calan Gate (Northwood, NH) system. Daily feed intake and RFI were assessed during a 70 d feeding trial. The test diet was 50% sorghum-sudan silage, 50% grain (2.9 Mcal ME/kg DM). Feed intake was recorded daily while body weights and hip heights were recorded at 14 d intervals. Ultrasound measurements of rib eye area (REA) and backfat (BF) were recorded initially and before slaughter. RFI was calculated for each animal as the difference between actual dry matter intake and the expected intake to create 2 divergent cohorts consisting of High (H) and Low (L) RFI individuals. Steers were humanely harvested and hypothalamic tissue (HT) samples were collected to facilitate gene studies into the mechanisms underlying variation in RFI. After chilling for 24 h post harvest, carcass characteristics were measured. Carcass and growth data were analyzed using a mixed model with RFI level (L, H) as the independent variable (SAS, 2002). Means were separated using lsmeans at a significance level of $P < 0.05$. The lsmeans for RFI were −1.3 and 1.5 respectively for the L and H cohorts ($P < 0.001$) and were greater than 2 standard deviations apart. As expected dry matter intake was higher for the H individuals versus the L steers ($P < 0.001$) while on test gain was not different between the 2 groups. There were no differences in marbling score, objective color measures L*, a*, and b*, adjusted back fat, ribeye area or yield grade between L and H cohorts suggesting there is no relationship between RFI and meat quality. Initial targeted gene expression studies in the arcuate nucleus indicate that neuropeptide Y (NPY) mRNA is expressed 2.7-fold lower and pro-opiomelanocortin (POMC) mRNA is expressed 3.6-fold higher in L than H animals. This suggests differences in neuropeptide expression in part underlie differences in feed efficiency observed in growing cattle during conditions of thermoneutrality.

Key Words: RFI, meat quality, neuropeptide Y

T123 Serum IGFI and hepatic *IGFI* mRNA levels in feedlot cattle infected with bovine respiratory disease.

C. A. Gifford*[1], B. Wilson[1], C. Maxwell[1], D. M. Hallford[2], and C. R. Krehbiel[1], [1]*Oklahoma State University, Stillwater,* [2]*New Mexico State University, Las Cruces.*

Bovine respiratory disease (BRD) is a leading cause of feedlot morbidity and mortality. Calves treated for BRD exhibit decreased growth, but mechanisms responsible for BRD-induced impaired growth are still unknown. The objectives of these studies were to evaluate serum IGFI and hepatic *IGFI* mRNA levels in BRD-infected calves. In study 1, serum samples were collected from control calves (CONT1; n = 5) and calves receiving a single treatment for BRD (1TRT1; n = 5) at arrival, at time of treatment, and on d 33, and serum IGFI levels were quantified via RIA. Serum IGFI or relative fold change of *IGFI* mRNA was tested against treatment, day, and treatment × day using the GLM procedure of SAS and means were separated using PDIFF when appropriate. There was not a treatment x day interaction ($P > 0.10$), but overall means of IGFI were greater ($P < 0.05$) for CONT1 (100.1 ± 8.6 ng/mL) than 1TRT1 (55.6 ± 9.4 ng/mL). Serum IGFI was low at arrival (39.6 ± 3.4 ng/mL) and increased ($P < 0.05$) to 152.7 ± 12.4 ng/mL on d 33 for both groups. In study 2, serum and peripheral blood leukocytes (PBL) were collected from calves chronically infected with BRD (CHRON; n = 6) and controls (CONT2; n = 6). Serum IGFI levels decreased ($P < 0.05$) in CHRON (65.3 ± 46.0 ng/mL) compared with CONT2 (236.5 ± 46.0). In PBL, *IGFI* mRNA was present but similar ($P > 0.10$) in CHRON and CONT2. In study 3, hepatic mRNA was collected from controls (CONT3; n = 6), calves treated once for BRD (1TRT3; n = 6), calves treated twice (2TRT3; n = 5), and calves treated 3 times (3TRT3; n = 6). Relative abundance for *IGFI* mRNA was quantified, and, relative to CONT3, 1TRT3 exhibited similar ($P > 0.10$) *IGFI* mRNA levels. However, 2TRT3 and 3TRT3 *IGFI* levels were approximately 2.5-fold below CONT3 ($P < 0.05$). These results demonstrate that serum IGFI is reduced at time of arrival and in calves chronically infected with BRD. In calves treated once for BRD, reduced feed intake might account for a reduction in IGFI without affecting growth. However, calves treated multiple times for BRD exhibit alteration in hepatic synthesis of *IGFI* mRNA possibly leading to long-term growth suppression.

Key Words: bovine respiratory disease, IGFI, growth

T124 Relationship between carcass traits and tenderness with residual feed intake and residual average daily gain of Brahman steers. F. Rouquette Jr.*[1], R. Randel[1], J. Paschal[2], T. Machado[3], and C. Long[1], [1]*Texas AgriLife Research and Extension Center, Overton,* [2]*Texas AgriLife Extension Service, Corpus Christi,* [3]*Texas A&M University-Kingsville, Kingsville.*

Residual feed intake (RFI) and residual average daily gain (RADG) indices have been used to assess an efficiency rating to cattle. The objectives of this 3-year experiment were to determine the relationship between RFI and RADG groupings on carcass traits and tenderness. After weaning, yearling Brahman bulls were fed a growing ration via calan gates in drylot during 3 consecutive years, (2008, n = 56; 2009, n = 47; 2010, n = 34). Bulls were phenotyped for RFI and RADG and sorted into 4 efficiency groups: 1 = more than 0.5 standard deviation (SD) below the mean (most efficient); 2 = less than 0.5 SD below the mean; 3 = less than 0.5 SD above the mean; and 4 = more than 0.5 SD deviation above the mean (least efficient). Following the drylot period, bulls were stocked on bermudagrass pastures during the summer, castrated in the fall, and transported to a commercial feedlot for finishing to an approximate 1.0 cm backfat. After harvest, standard carcass traits were taken. Year was an independent variable and with an interaction for year and RFI and RADG, carcass trait relationships were assessed by year using Proc Mixed. Steers that were sorted into most efficient group had higher ($P < 0.05$) dressing % (2008, 2010), liveweight and hot carcass weights (2009), backfat (2010), and USDA Yield grade (2008, 2009, and 2010). Steers sorted into the least efficient group had higher ($P < 0.05$) marbling score (2009) and quality grade (2009). Steers harvested in 2010 were assessed for tenderness using Warner-Bratzler shear force. The shear force values for the 4 efficiency groupings were different when using either RFI ($P = 0.078$) or RADG ($P < 0.001$). For both efficiency rankings, the least efficient steers (group 4) had the highest scores (least tender) of 4.29 kg (RFI) and 4.33kg (RADG). These carcass traits indicated a general lack of relationship for either RFI or RADG groups. However, the most tender steaks were in Group 3 (RFI) and Group 2 (RADG).

Key Words: residual feed intake, residual average daily gain, carcass

T125 Adipocyte location and anabolic implant alter adipocyte transcriptome in steers. S. K. Duckett,* J. W. Long, M. D. Owens, S. E. Ellis, and S. L. Pratt, *Clemson University, Clemson, SC.*

The accumulation of excess fat results in economic loss in beef production. However, understanding how lipid is accumulated at different depots could lead to strategies reducing financial loss by targeting specific sites for lipid deposition. The objectives of this study were to: 1) determine if location of fat depot alters adipocyte gene expression and 2) evaluate the impact anabolic implants have on adipocyte's transcriptome in 2 separate adipose depots. Angus x Hereford steers (n = 24; BW = 488 kg) were randomly allotted to non-implant (CON) or implant (IMP) treatments. Steers were individually fed a high concentration diet for 72 d and IMP steers received a single Revalor-S (24 mg estradiol, 124 mg trenbolone acetate) at time of allotment. At slaughter, adipose tissue samples were collected from subcutaneous (SQ) and mesenteric (MS) depots, flash-frozen, and stored at −80°C for RNA extraction. Total cellular RNA was isolated using the mirVana miRNA Isolation Kit (Ambion, Austin, TX). The cleared homogenate was loaded on to the binding matrix by vacuum and the column washing and elution of bound tcRNA were performed per manufacturer's protocol. Four pools of tcRNA were generated for SQ-CON, SQ-IMP, MS-CON and MS-IMP. The samples were subjected to RNA sequencing (LC Sciences, Houston, TX) using the Illumina high-throughput sequencing technology. Data were analyzed by LC Sciences using Bowtie, Tophat, and Cufflinks statistical analysis software systems. The number of mappable reads ranged from 87,387,760 to 91,927,097 for all tissue-treatment combinations. This resulted in 32,493 to 35,030 predicted messenger RNA transcripts for all tissue-treatment combinations. Gene expression differences were compared between data sets of MS-CON vs MS-IMP, MS-CON vs SQ-CON, MS-IMP vs SQ-IMP, and SQ-CON vs SQ-IMP. Of differentially expressed genes identified, 95 were differentially expressed due to adipose depot ($P < 0.05$) and 36 were differentially expressed due to IMP ($P < 0.05$). Therefore, adipocyte gene expression is impacted by both location and anabolic steroid treatment, which suggests that strategies/treatments could be developed to adjust lipid accumulation based on location and exogenous hormonal treatment.

Key Words: beef, implants, gene expression

T126 Subcutaneous adipose tissue gene expression in bulls fed ergot alkaloid-containing fescue seed. T. A. Burns,* M. C. Miller, H. M. Stowe, S. M. Calcatera, S. L. Pratt, J. G. Andrae, and S. K. Duckett, *Clemson University, Clemson, SC.*

Grazing toxic endophyte-infected tall fescue (E+) is a common practice in the southeastern US and is associated with decreased performance and adipose tissue necrosis. The objective of this study was to determine the effects of E+ on male adipose tissue gene expression. In addition, isolation of adipose tissue is inherently difficult due to the abundance of lipid; therefore, a secondary objective of this work was to identify a RNA isolation method that efficiently isolated RNA of good quality. Eight beef bulls approximately 12 to 16 mo of age were stratified by breed, weight, and BCS and then assigned to 1 of 2 treatment groups receiving 4.2 g/kg of BW per day of E+ or endophyte-free fescue (E-) seed in a total mixed ration. After a feeding period of 126 d, bulls were slaughtered and tissues snap frozen for gene expression analysis. Four commercially available kits were used to isolate RNA according to manufacturer's instructions: mirVana miRNA Isolation Kit (Invitrogen; Grand Island, NY), Direct-zol RNA MiniPrep (Zymo Research; Irvine, CA), RNeasy Lipid Tissue Midi Kit (Qiagen; Valencia, CA), and PureYield RNA Midiprep System (Promega; Madison, WI). Data were analyzed using the Proc GLM procedure of SAS 9.2. Quality of RNA, assessed by 260/280 absorbance ratio, was acceptable for all isolation methods and was greatest ($P < 0.05$) for RNA isolated using Direct-zol, but only mirVana and RNeasy RNA had a consistently acceptable 18S/28S ribosomal band ratio. Efficiency of extraction (µg RNA/g tissue) was greatest ($P < 0.05$) for mirVana isolations. Therefore, real time PCR was performed on *stearoyl-CoA desaturase* (*SCD1*) and *cytochrome P450 subfamily 3A* (*CYP3A*) genes with reference gene *glyceraldehyde-3-phosphate dehydrogenase* from mirVana-isolated RNA. Subcutaneous adipose tissue of E+ bulls had downregulated expression ($P < 0.05$) of *SCD1* indicating a reduction in fatty acid desaturation compared with E-. Associated with animal metabolism of ergot alkaloids present in toxic fescue, *CYP3A* expression was not different ($P > 0.05$) in E+ compared with E- bulls. Therefore, expression of *SCD1* mRNA isolated from subcutaneous adipose tissue of bulls is affected by E+ fescue.

Key Words: bovine, fescue, RNA isolation

T127 Growth performance of Mahabadi goat kids fed different levels organic trivalent chromium. A. Emami, A. Zali, M. Ganjkhanlou,* A. Hojabri, and A. Akbari, *University of Tehran, Tehran, Iran.*

This study was carried out to determine the effects of supplementing chromium-methionine (Cr-Met) on performance in Mahabadi goat kids. Thirty-two male kids (average initial BW of 22 ± 2 kg, 4mo) were used in a completely randomized design with 4 treatments: 1) control (without Cr), 2) 0.5, 3) 1.0 and 4) 1.5 mg Cr as Cr-Met/animal/d. Diets were formulated to meet NRC requirements with forage (alfalfa and corn silage): concentrate ratio of 30:70 in TMR form. Diets were the same except for top-dress addition of Cr-Met and fed in 2 equal meals (0800 and 1600 h) and orts were collected before morning meal. Animals were kept in individual pens with self-mangers. Experimental period was 90 d. Animals were weighed at 21 d intervals. Feed conversion ratio (FCR) was calculated according to FCR = DMI (Dry matter intake) (kg)/Average daily gain (ADG) (kg). DMI, ADG and FCR data were analyzed using MIXED procedure of SAS 9.1. The Tukey test was used for comparison of treatment means. ADG was not affected by the Cr-Met ($P > 0.05$). Also DMI and FCR were not affected by the chromium supplementation ($P > 0.05$). These results indicated that dietary supplementation of Cr-Met failed to significantly affect growth performance of Mahabadi goat kids.

Table 1. DMI, ADG, and FCR of kids fed different levels of organic chromium

	Treatment (mg of Cr)				
Trait	Control	0.5	1.0	1.5	SEM
DMI(kg/d)	1.01	1.00	1.03	1.07	0.04
ADG	0.14	0.14	0.15	0.17	0.01
FCR	7.55	7.48	6.95	6.44	0.47

Key Words: feed intake, daily gain, feed conversion ratio

T128 Postweaning feed restriction effects on steer feedlot performance and carcass characteristics. R. L. Endecott*[1], B. L. Shipp[2], M. D. MacNeil[2], L. J. Alexander[2], and A. J. Roberts[2], [1]*Department of Animal and Range Sciences, Montana State University, Miles City,* [2]*USDA-ARS, Fort Keogh Livestock and Range Research Laboratory, Miles City, MT.*

The objective was to evaluate effects of 2 levels of supplemental feed provided to cows during late gestation and 2 levels of feed provided to their sons during postweaning development on subsequent feedlot performance and carcass characteristics. Bull calves (n = 56 in 2010; n = 51 in 2011) were born from dams receiving adequate (1.8 kg/d) or marginal (1.2 kg/d) winter supplementation. After weaning, bulls were developed on ad-libitum (Control) or 27% less feed (Restricted) for ~140 d. Bulls were then band-castrated and placed on an 80% corn finishing diet ad libitum. Individual intakes were measured with a GrowSafe system for the final 100–150 d of the finishing period. Cattle were harvested at a commercial packing plant and carcass data were collected. Dam winter supplementation effects were not detected ($P \geq 0.22$). Postweaning phase ADG exhibited a postweaning treatment × year interaction ($P < 0.01$). Restricted calves had similar ADG in both years (0.64 vs 0.68 ± 0.03 kg/d) and gained less than Control calves. Control calves had greater ADG in 2010 than in 2011 (1.16 vs 1.03 ± 0.03 kg/d). Postweaning treatment did not affect feed intake during the finishing phase ($P = 0.29$; 13.0 vs 12.8 ± 0.22 kg/d for Restricted vs Control; as-fed basis). During the finishing phase, ADG exhibited a postweaning treatment × year interaction ($P < 0.01$). Restricted steers had similar ADG in both years (1.25 vs 1.27 ± 0.05 kg/d) and gained more than Control steers. Control steer ADG was less in 2010 than in 2011 (0.92 vs 1.13 ± 0.05 kg/d). Compared with Control steers, Restricted steers had lower ($P \leq 0.08$) final BW (603 vs 623 ± 9 kg), HCW (357 vs 373 ± 6 kg), and yield grade (2.71 vs 2.89 ± 0.10). However, back fat thickness (1.09 vs 1.14 ± 0.05 cm), ribeye area (85.4 vs 85.8 ± 0.98 cm^2), and marbling score (5.59 vs 5.50 ± 0.12) were not different ($P \geq 0.34$). Calves restricted during postweaning development gained more efficiently, and when harvested on a common date, had lower carcass weights and yield grade, but similar fat thickness, ribeye area and quality grade compared with their ad libitum-fed counterparts.

Key Words: postweaning development, uterine programming, finishing

T129 Stearoyl-CoA desaturase (SCD1) localization and intensity in bovine adipose and muscle tissues from implanted and non-implanted steers. M. Wilder, S. Safayi, S. E. Ellis, and S. K. Duckett,* *Clemson University, Clemson, SC.*

Anabolic steroids are commonly used during the finishing phase to increase weight gain and feed efficiency. The objective of this study is to assess the localization and relative amount of stearoyl-CoA desaturase (SCD1) in mesenteric adipose tissues (MS), subcutaneous adipose tissue (SC), and longissimus muscle (LM) of implanted and non-implanted steers. Stearoyl-CoA desaturase is the rate-limiting enzyme involved in fatty acid metabolism, which converts saturated fatty acid to monounsaturated fatty acid. In this experiment, 12 steers (448kg) were implanted with Revalor-S (24 mg estradiol, 124 mg trenbolone acetate) and 12 steers were not implanted. All steers were fed a high concentrate diet for 72 d before slaughter. Fat and muscle samples were removed at slaughter, immediately flash-frozen, and stored at −80°C for subsequent cyrosectioning and immunofluorescent staining. Cryosections were stained with POPO-1 iodide, a high-affinity blue nucleic acid stain, and green fluorescent phalloidin, an F-actin stain. Cryosections were also incubated overnight with SCD-1 antibody (4 μg/mL) and stained with AlexaFluor 594 secondary antibody. Micrographs were collected with the Nuance Multispectral imaging system using a consistent exposure and illumination protocol. SCD1 staining intensity was most obvious in the perinuclear region, but was also visible through the cytoplasm. SCD1 staining was visible in adipocytes, muscle cells, endothelial cells and schwann cells. Discrete cell populations were manually traced in each micrograph to assess the recorded fluorescent staining intensity in regions and cells of interest. Average intensities in each group of cells were analyzed to estimate the relative abundance of SCD1 protein. There was a tissue by treatment interaction ($P < 0.05$). Adipose tissues from SC and MS had greater SCD1 intensity than LM, regardless of treatment. The SCD1 staining intensity was reduced in MS from implanted steers relative to MS of non-implanted and SC of both non-implanted and implanted. Using immunofluorescent staining, we were able to visualize SCD-1 localization in various adipose tissues and determine changes in SCD-1 relative amounts due to implant treatment.

Key Words: beef, adipose tissues, SCD

T130 Body′s growth curve and shape of grazing young bulls, receiving concentrate supplementation with different protein profiles. H. J. Fernandes*[1,2], A. G. da Silva[2], M. F. Paulino[2], S. A. Lopes[2], L. O. Tedeschi[4], J. A. G. Azevêdo[3,2], and A. Aguiar[5], [1]*State University of Mato Grosso do Sul, Aquidauana, MS, Brazil,* [2]*Federal University of Viçosa, Viçosa, MG, Brazil,* [3]*State University of Santa Cruz, Ilhéus, BA, Brazil,* [4]*Texas A&M University, College Station,* [5]*University of Florida, Gainesville.*

The objectives of this study were to analyze and compare full body weight (FBW) and body measurements (BM) growth of crossbred bulls grazing *Brachiaria decumbens* Stapf. pastures over 430 d. Twenty bulls with initial FBW of 129 ± 28.1 kg, were divided in 4 groups, receiving either mineral supplement *ad libtum* (control) or 0.5% of FBW of one of the concentrate supplementation rations (26.7% CP), identified as T1 (high urea level), T2 (low urea level), and T3 (no urea). The FBW and the BM were recorded every 28 d. The BM included hooks width (HW), pins width (PW), pelvic girdle length, rump height (HeR), abdomen width, body length (BL), height at withers (HeW), and rib depth (RiD). The first and the second canonical variables were estimated using all BM by PROC CANDISC of SAS. A growth multiphase model with 3 phases was adjusted using PROC NLIN of SAS. The phases of the model corresponded to a first rainy season, a dry season (the feed restriction season in the year to grazing animals) and a second rainy season. Growth models and their parameters were compared using a dummy variable. The main BM to describe the differences between animal body shape (explaining 73.1% of the differences) were RiD, PW, HeR, and HeW. Animals in control group tend to be shorter and wider. There were no differences ($P > 0.05$) in the growth curves of FBW between the concentrate supplemented treatments. The growth curves of FBW of the control and the supplemented animals differs in days in the experiment at which the animals respond to feed restriction in dry season (82 and 113.3 d, $P = 0.047$), in the growth rate during this phase (0.141 and 0.328 kg/d, $P = 0.006$), and in days in the experiment at which the animals respond to the end of this phase (314 and 292 d, $P = 0.006$). These parameters could explain the greater mature weight ($P = 0.003$) of the supplemented animals. The main differences ($P < 0.05$) between the supplemented and the control animals in the growth curves of BM were the greater mature HeW, HeR, RiD, and BL in the supplemented group. The protein patterns of the concentrate affected ($P < 0.05$) the growth of the HeW, RiD, and HW.

Key Words: biometrics, cattle, modeling

T131 Mathematical models to describe growth of grazing beef cattle.

H. J. Fernandes*[1], V. S. Siquiera[1], G. C. Z. N. de Oliveira Coelho[1], A. L. B. Netto[2], K. O. De Barros[1], A. Aguiar[3], L. M. Paiva[1], and J. C. de Souza[2], *[1]State University of Mato Grosso do Sul, Aquidauana, MS, Brazil, [2]Federal University of Mato Grosso do Sul, Aquidauana, MS, Brazil, [3]University of Florida, Gainesville.*

The objective of this study was to evaluate the use of different mathematical models to describe growth of grazing beef cattle. Ten Nellore castrated males and 10 females, with initial age and weight of 16 ± 1.27 mo and 224 ± 18.5 kg, respectively, were grazing *Brachiaria decumbens* Stapf. pasture and received mineral supplement ad libitum, for 16 mo. Every 28 d, animals were weighed and biometric measures (including hook width, pin width, pelvic girdle length, rump depth, rump height, abdomen width, body length, height at withers, rib depth, and girth circumference) were taken to develop growth curves of the animals. Six mathematical models were evaluated to describe animal growth: multiphase (with 3 phases), linear, quadratic, exponential, monomolecular, and Richards. Assessment of adequacy of the models was performed using coefficient of determination (R^2), simultaneous F-test for identity of parameters, concordance correlation coefficient (CCC), and partition of the mean square error of prediction (MSEP). The analysis of paired mean square error of prediction and delta information criterion of Akaike were used to compare the models for accuracy and precision. Based on the simultaneous F-test for identity of parameters, monomolecular and Richards models produced estimates different ($P < 0.05$) of the observed growth data. Linear and exponential models presented low R^2 (49.3 and 52.6%) and CCC <0.800. The quadratic model had R^2 = 70.0% and CCC = 0.826 and partitioning of the MSEP of this model showed more than 99% of deviations observed were attributed to the random errors. The best fit was the multiphase model (R^2 = 82.5% and CCC = 0.906), and it was the most ($P < 0.05$) accurate and precise model. Best performance of the multiphase model can be attributed to the fact that this model is able to separate animal growth in 3 phases, best describing the seasonal environmental changes that grazing animals are subject to during the year.

Key Words: modeling, Nellore, tropical environment

T132 Dietary fat content and fiber type influence adiposity, lipid oxidative genes and cecal volatile fatty acid concentrations in pigs.

H. Yan,* V. Almeida, H. Lu, T. Stewart, A. Schinckel, and K. Ajuwon, *Purdue University, West Lafayette, IN.*

The interactive effect of fat level and dietary fiber type on performance, backfat thickness and expression of key transcripts involved in energy metabolism was evaluated. Growing pigs (n = 32, initial BW = 10.2 ± 0.15 kg) were allocated randomly to 4 treatments with 2 dietary fat levels; low fat (LF, 3%) and high fat (HF, 17.5%) swine grease as fat source and 2 fiber types (inulin and solka floc, 4% inclusion) in a 2 X 2 factorial design. There were 2 replicates per treatment and 4 pigs per replicate. Pigs were fed ad libitum for 6 wks. At slaughter, liver and mesenteric adipose tissues were collected for gene expression quantification of peroxisome proliferator-activated receptorγ co-activator (PGC1α), peroxisome proliferator-activated receptor α (PPARα), acyl-coA oxidase (ACO) and carnitine palmitoyltransferase 1(CPT1α) via real time PCR. Fecal samples were analyzed for the concentration of key volatile fatty acids. Gene expression data are expressed as normalized values to 18s. There were no interactions between fat level and fiber type for final BW, ADG and G:F ($P > 0.05$). There was an increase in ADG and G:F and a trend ($P = 0.06$) toward increased final BW in HF- than LF-treated pigs. However, no effect of fiber type was found ($P > 0.05$). Pigs fed HF diet had greater ($P < 0.01$) backfat thickness than LF-treated pigs. Inulin reduced the subcutaneous fat deposit in the HF diet pigs ($P < 0.05$). High fat diet also resulted in lower ($P < 0.05$) concentrations of acetate, butyrate and propionate. Inulin tended ($P < 0.07$) to increase propionate concentration compared with cellulose. Expression of PGC1α and PPARα in liver was unaffected by fat level and fiber type ($P > 0.05$). In the liver, Inulin led to increased ($P = 0.04$) expression of ACO expression compared with solka floc (1.53 ± 0.22 vs. 1.10 ± 0.23, respectively). However, no effect of fat level was observed ($P > 0.05$). Pigs fed HF diet had greater ($P = 0.002$) expression of CPT1α in liver tissue than LF diet (1.65 ± 0.20 vs. 0.83 ± 0.18, respectively). High dietary fat level led to a tendency ($P = 0.07$) toward increased CPT1α mRNA abundance in mesenteric fat compared with LF-treated pigs (1.55 ± 0.25 vs. 1.03 ± 0.24, respectively), whereas no effect of fiber type was detected ($P > 0.05$). This study shows that dietary fatty acid and fiber type have a profound influence on adiposity and level of fermentation end products in the hind gut which may affect fatty acid oxidation in distant organs such as the liver.

Key Words: dietary fat, fiber, oxidation

T133 Factors affecting serum IGF-1 and triiodothyronine concentrations as related to fat deposition in feedlot lambs.

F. A. Rodriguez-Almeida*[1], D. M. Hallford[2], J. A. Grado-Ahuir[1], D. Briones[1], and E. Flores[1], *[1]Universidad Autónoma de Chihuahua, Chihuahua, México, [2]New Mexico State University, Las Cruces.*

To identify factors affecting serum IGF-1 and T3 concentrations after weaning and their relationship to fat deposition, 115 F_1 lambs (males and females) weaned at 90 d (BW = 17 ± 3.7 kg), sired by Charollais (CH), Dorper (DP), Hampshire (HM), Suffolk (SF) and Texel (TX) rams bred to estrus synchronized-Pelibuey (PB) and Blackbelly (BB) ewes, were utilized. Lambs were individually fed an ad libitum mixed ration in 80 pens (1.25 × 2.45 m) and 35 stalls (0.5 × 1.45 m) and weighed every 14 d until they reached a minimum BW of 42 kg for males and 40 kg for females. Serum concentrations of IGF-1 and T3 at d 14, 42, and 70 of the feeding trial were quantified by RIA. Log-transformed hormone concentrations were analyzed with PROC MIXED of SAS, fitting a linear model with fixed effects of breed of sire (SB), breed of dam (DB), sex, number weaned, management (pen *vs* stall), day of blood sampling, 2-way interactions, and BW at sampling as first and second order covariates. Sire within SB was fitted as a random effect and repeated measures within animal were assumed correlated with an ARH(1) covariance structure. There were management and sex by day and SB by DB interactions ($P < 0.05$) for IGF-1. IGF-1 concentrations were greater ($P < 0.05$) for lambs in pens than for lambs in stalls later on the trial and increased ($P < 0.05$) with time for males but not for females. Lambs from the CH × PB cross had the lowest ($P < 0.05$) IGF-1 concentrations. Pearson correlations ($P < 0.05$) for IGF-1 at d 14, 42, and 70 were −0.42, −0.47 and −0.42 with back fat; −0.54, −0.65 and −0.51 with kidney fat (KF); and −0.36, −0.43 and −0.26 with percent of total carcass fat (PTCF). There were day main effects and sex by management and sex by SB interactions effects ($P < 0.05$) for T3. Mean was greatest ($P < 0.05$) at d 70 and was greater ($P < 0.05$) in females than in males in stalls but not in pens. Also, T3 concentrations were greater ($P < 0.05$) in females than in males for the CH, DP and SF sired breeds, but not for HM and TX. Pearson correlations for T3 were important ($P < 0.05$) only at d 70 with KF (0.23) and at d 14 and 70 with PTCF (−0.40 and −0.21). Serum IGF-1 concentrations in lambs, more than T3, are related to fat deposition as affected by sex, breed, management and days on feed.

Key Words: IGF-1, triiodothyronine, sheep breeds

Lactation Biology II

T134 Effects of feed restriction and prolactin-release inhibition at drying-off on milk production, metabolism and mammary gland involution.

S. Ollier*[1], X. Zhao[2], and P. Lacasse[1], [1]*AAFC-Dairy and Swine Research and Development Centre, Sherbrooke, QC, Canada,* [2]*Department of Animal Science, McGill University, Sainte-Anne-de-Bellevue, QC, Canada.*

The risk of acquiring a new intramammary infection during the dry period increases with milk production at drying-off and decreases as mammary gland involution progresses. A method commonly used to reduce milk production is a drastic reduction in feed supply in the days that precede drying-off. Our recent work has shown that milk production can also be reduced by an inhibition of the lactogenic signal driven by prolactin (PRL). To compare these 2 drying-off procedures, 24 Holstein cows in late lactation were assigned to 3 treatments based on milk yield, SCC and parity. They were fed 1) a lactation diet until drying-off (Control), 2) only dry hay the last 5 d before drying-off (Hay), or 3) as Control cows, but received twice daily i.m. injection of quinagolide (4 mg per injection), a specific inhibitor of PRL-release, from 5 d before drying-off to 13 d after (Quin). Cows from Control and Hay treatments received water injections. Blood and mammary secretion samples were collected on the last 7 d before and 1, 3, 5, 7, 10, and 14 d after the last milking. Quinagolide induced a sharp decrease ($P < 0.001$) in basal serum PRL concentrations on all the injection days. Interestingly, PRL was also depressed in Hay cows before drying-off. Both Quin and Hay treatments induced a drop ($P < 0.001$) in milk production, which averaged 17.9 and 10.1 kg/d, respectively, at drying-off compared with 24.8 kg/d for Control cows. Feeding dry hay decreased blood concentrations of glucose ($P < 0.001$) and most aminoacids (12 / 19; $P < 0.05$), and increased blood concentrations of β-hydoxybutyrate and Nonesterified fatty acids significantly ($P < 0.001$), whereas quinagolide did not affect these metabolites. Mammary secretion SCC was greater at d 1 of the dry period in the Hay ($P < 0.001$) and at d 5 in the Quin ($P < 0.05$) than in the Control cows. The BSA concentration increased faster ($P < 0.05$) in the mammary secretion of both Hay and Quin than that of Control cows, whereas the citrate:lactoferrin ratio, another indicator of involution rate, decreased faster ($P < 0.001$). In conclusion, this experiment shows that PRL-release inhibition could be a new alternative to reduce milk production before the drying-off and to hasten mammary gland involution without disturbing the metabolism of the cow. This strategy may reduced the incidence of new intramammary infection at drying-off.

Key Words: quinagolide, dry period, prolactin

T135 Effects of recombinant bovine somatotropin on blood flow to the mammary gland in early lactating Holstein cows.

H. L. Sánchez-Rodríguez*[1], R. C. Youngblood[1], J. E. Curbelo[1], C. Steadman[1], R. C. Vann[2], E. Baravik-Munsell[3], S. T. Willard[1,5], and P. L. Ryan[1,4], [1]*Department of Animal and Dairy Sciences, Mississippi State University,* [2]*Brown Loam Branch Experimental Station, Mississippi State University, Raymond,* [3]*Department of Clinical Sciences, Mississippi State University,* [4]*Department of Pathobiology and Population Medicine, Mississippi State University,* [5]*Department of Biochemistry and Molecular Biology, Mississippi State University.*

Doppler and B-mode ultrasound were used to evaluate the effects of recombinant bovine somatotropin (rBST) administration on mammary gland (MG) blood flow volume (BFV), Resistance Index (RI) and vessel diameter in cycling, lactating Holstein cows. The rBST (n = 4; 500 mg) was administered once at 42 d postpartum, while Control cows (n = 4) received 1.75 mL of saline solution. Ultrasound and temperature recordings were taken at d −7, −5, −2, 0, 1, 2, 5, 7, 9, 12, 14, 16, and 19 and the periods before and after treatment (d 0) were compared. The MG perfusion was characterized by the BFV and RI of the left and right pudendoepigastric trunk arteries (PETA). Additionally, both PETA diameters, posterior skin temperatures (ST) of the MG, and rectal temperatures (RT) were recorded. No differences were observed between the right and left PETA ($P > 0.05$); therefore, both values were combined for further analysis. Administration of rBST increased BFV ($P < 0.001$; 2837.73 ± 99 and 3107 ± 73 mL/min before and after, respectively) and decreased RI ($P < 0.001$; 0.46 ± 0.02 and 0.40 ± 0.01 before and after, respectively). In Control cows, a general decrease in BFV ($P < 0.001$; 3032.47 ± 95 and 2660.60 ± 56 mL/min before and after, respectively) and increase in RI ($P < 0.001$; 0.44 ± 0.02 and 0.51 ± 0.01 before and after, respectively) were observed through the sampling period. The PETA diameters were greatest in rBST treated than in Control cows ($P < 0.01$; 20.29 ± 0.02 and 19.71 ± 0.02 mm, respectively). A positive correlation was observed between the PETA diameter and BFV in Control (r = 0.18; $P < 0.01$) and rBST (r = 0.29; $P < 0.001$) cows, respectively. The ST variability of the MG was increased ($P < 0.05$) by rBST administration. However, RT and milk yield were not affected ($P > 0.05$) by treatment. These preliminary findings suggest that Doppler ultrasound may represent a feasible technique for the study of the vascular perfusion changes in the MG associated with rBST administration. Further studies in later stages of lactation are required to clarify the trends observed in RT and milk yield.

Key Words: mammary gland blood flow, Doppler ultrasound, dairy cows

T136 Effects of colostrum versus formula feeding on hepatic glucocorticoid and α_1- and β_2-adrenergic receptors in neonatal calves.

D. Rohrbeck, J. Steinhoff-Wagner, E. Kanitz, and H. M. Hammon,* *Leibniz Institute for Farm Animal Biology (FBN), Dummerstorf, Germany.*

Colostrum feeding affects glucose metabolism and the endocrine status in neonatal calves. Cortisol and catecholamines stimulate glycogen degradation and gluconeogenic enzyme activities in liver via glucocorticoid receptors (GR) and α_1- and β_2-adrenergic receptors (AR). We have tested the hypothesis that the number of GR as well as α_1- and β_2-AR in neonatal calves depends on colostrum feeding. We used 14 male German Holstein calves, fed either colostrum or formula for 4 d (group C and F, respectively) twice daily. Nutrients in formula based on milk protein (lactalbumin, casein), lactose, and coconut fat in same amounts as in colostrum milking, but formula contained no biologically active substances such as hormones and growth factors. Amounts (per meal) fed were 4% of BW on d 1 and 5% of BW on d 2 to d 4. On d 4 blood samples were taken to measure plasma concentrations of glucose and cortisol and liver samples were harvested 2 h after feeding. For AR measurements, liver membrane suspensions (2 mg protein/ml) were prepared and saturation binding assays were performed with increasing concentrations of (^{3}H)-prazosin and (^{3}H)-CGP-12177 for determination of α_1- and β_2-AR, respectively. For GR measurements the cytosol fraction (8 mg protein /ml) was incubated with increasing concentrations of (^{3}H)-dexamethasone. Maximal binding capacity (B_{max}) and binding affinity (K_D) were calculated by computer program. Data were analyzed by General Linear Model of SAS with feeding as fixed effect. Plasma

glucose concentrations were higher ($P < 0.05$) in C than F, but plasma cortisol concentrations did not differ between groups. For GR, B_{max} was higher ($P < 0.05$) in C than F, whereas K_D indicated no differences. B_{max} of α_1-AR tended to be higher ($P < 0.1$) in C than F, but K_D of α_1-AR as well as B_{max} and K_D of β_2-AR were not affected by feeding in a significant manner. Results indicated dependence of GR and α_1-AR on milk feeding immediately after birth and pointed at possible involvement of GR and α_1-AR in regulation of neonatal glucose metabolism in calves. Supported by DFG, Germany.

Key Words: calves, colostrum feeding, glucocorticoid and adrenergic receptors

T137 Fitness of lactation curve functions to daily and monthly test-day milk data in an Ethiopian dairy cattle population. G. Gebreyohannes[1], S. Koonawootrittriron[1], M. A. Elzo*[2], and T. Suwanasopee[1], *[1]Kasetsart University, Bangkok, Thailand, [2]University of Florida, Gainesville.*

The objective of this research was to identify a lactation curve function that best fit daily (DD) and monthly test-day milk (MD) data in an Ethiopian dairy cattle population. Three functions were compared: an incomplete gamma (IG), a modified incomplete gamma (MIG; b = 1) and an inverse polynomial (IP). Analysis used 6,707 lactation milk records of 2,066 cows collected from 1979 to 2010 in the Bako, Holetta and Debre Zeit research centers. Breed groups were Horro (H), Boran (B), B-Friesian, H-Friesian, B-Simmental, H-Simmetal, B-Jersey and H-Jersey. The MIG and IG were first log-transformed to linear form before fitting. Goodness of fit of IG, MIG, and IP were compared using R-squared values. Factors affecting R-squared values were analyzed using a model that contained herd-year-season, parity, data type (DD and MD), breed group, lactation curve function and the interaction between data type and lactation curve function as fixed effects, and residual as a random effect. All factors in the model affected R-squared values ($P < 0.001$). Least squares means of R-squared values (LSMR2) were compared among subclasses of each factor. Milk data from cows in later parities (>4 parities; range 0.84 to 0.85) showed significantly higher LSMR2 ($P < 0.001$) than first parity cows (0.80 ± 0.002). The LSMR2 of functions fitted to MD data (0.88 ± 0.001) was higher ($P < 0.001$) than the one for DD data (0.79 ± 0.001). Horro cows had higher LSMR2 (0.86 ± 0.003) than other breed groups (0.77 to 0.85; $P < 0.001$). The MIG (0.90 ± 0.002) and IP (0.90 ± 0.002) functions had similar LSMR2, but both MIG and IP were significantly different from IG (0.71 ± 0.002; $P < 0.001$). The MIG function had the highest LSMR2 for DD data (0.88 ± 0.002), while the IP function had the highest LSMR2 for MD data (0.94 ± 0.002). The MIG and IP functions can be recommended for describing lactation patterns of Ethiopian dairy cattle using daily and test-day milk data, respectively.

Key Words: cattle, lactation curve function, test-day

T138 Effect of rearing intensity on growth performance and on mammary tissue in Holstein yearling heifers. V. Lollivier*[2,1], F. Dessauge[1,2], M. Boutinaud[1,2], and Y. le Cozler[2,1], *[1]INRA, UMR1348 Pegase, Saint-Gilles, France, [2]Agrocampus Ouest, UMR1348 Pegase, Rennes, France.*

Intensive growth during the first months of life influence the shaping animal's final body weight, but if excessive, it may alter the mammary gland development and subsequent milk yield, at least during lactation one. A long-term experiment aimed at studying the effect of growth intensity from birth to insemination in Holstein dairy heifers, combined to a targeted age at first calving of 22 or 24 mo, is being conducted and includes each year 60 to 70 heifers. Preliminary results indicate that the effect of intensive growth on lactation performance could be limited. Moreover, the effect on mammary development remains to be studied. In October 2011, 3 heifers which followed the routine rearing procedure (SP) and 4 heifers which were reared according to the intensive growth program (HP) were slaughtered at one year of age. Body composition and mammary gland weight were measured and mammary tissue morphology was investigated. Average daily gain from birth to slaughter was 874 and 968 g/d for SP and HP heifers, respectively. This corresponded to an average body weight of 358 and 389 kg at 360 and 355 d of age respectively. Mammary gland weight was not significantly affected by the treatment (2.22 vs 2.02 kg for SP and HP heifers, respectively). Impact of growth intensity on lobulo-alveolar mammogenesis was studied through histological analysis of mammary tissue. Results may have implications for understanding control mechanisms that regulate parenchymal development in Holstein heifers.

Key Words: mammogenesis, growth intensity, heifer

T139 Obesity and parity affect the mammary gland serotonin (5-HT) system. K. E. Merriman,* J. LaPorta, and L. L. Hernandez, *University of Wisconsin, Madison.*

5-Hydroxytryptamine (5-HT) is synthesized and secreted by the mammary gland as well as a homeostatic regulator. 5-HT was recently determined to be involved in the mammary gland's response to consumption of high-fat diet (HFD) in rats. The objective of our study was to determine the effects of HFD and a HFD plus vertical sleeve gastrectomy (HFD+VSG) on the mammary gland serotonergic system compared with low-fat diet animals (LFD). We conducted qPCR analysis for the following mRNA in the mammary gland: tryptophan hydroxylase 1 (TPH1), the rate-limiting enzyme in 5-HT synthesis, serotonin reuptake transporter (SERT), responsible for the 5-HT reuptake into the cell for degradation, and the 5-HT 7 receptor subtype (HTR7), responsible for regulating mammary gland involution. We determined that LFD primparous rats had similar expression for TPH1, SERT and HTR7 as nulliparous rats, while multiparous rats had significantly increased TPH1 (30-fold), SERT (700-fold) and HTR7 (6-fold) ($P < 0.05$) expression. In nulliparous HFD and HFD+VSG rats, there was a significant increase in mRNA expression for TPH1 (20, 60-fold, respectively), SERT (325, 75-fold, respectively) and HTR7 (6, 2-fold, respectively) compared with LFD rats ($P < 0.05$). In primparous HFD and HFD+VSG rats there was also a significant increase in mRNA expression for TPH1 (25, 255-fold, respectively), SERT (25, 990-fold, respectively) and HTR7 (70, 12-fold, respectively) compared with LFD rats ($P < 0.05$). There was no difference in the expression of TPH1, SERT and HTR7 compared with LFD rats ($P > 0.05$) in multiparous HFD and HFD+VSG. These results show that LFD rats have increased serotonergic components with increasing parity. Additionally, it is demonstrated that the serotonergic signaling system is over-stimulated in HFD and HFD+VSG rats that are nulliparous and primiparous relative to LFD. This suggests in normal weight animals, as parity increases there is an increase of 5-HT synthesis in the mammary gland that is necessary to maintain mammary gland homeostasis. In obese animals, there is an over-production of 5-HT and signaling within the mammary gland that could lead to issues with mammary gland homeostasis.

Key Words: 5-hydroxytryptamine, obesity, parity

T140 Cooling of heat-stressed cows during the dry period alters lymphocyte but not mammary gland gene expression. S. Tao*[1], E. E. Connor[2], J. W. Bubolz[1], I. M. Thompson[1], B. C. do Amaral[1], M. J. Hayen[1], and G. E. Dahl[1], [1]*University of Florida, Gainesville,* [2]*USDA-ARS, Beltsville, MD.*

Heat stress (HT) during the dry period compromises mammary gland development, decreases future milk production, and impairs immune status of dairy cows. Our objective was to evaluate the effects of cooling heat-stressed cows during the dry period on gene expression of the mammary gland and lymphocytes. Cows were dried off 46 d before their expected calving date and assigned to 2 treatments, HT or cooling (CL). Average temperature-humidity index during treatment was 76.6 for all cows. CL cows were cooled with sprinklers and fans that came on when ambient temperature exceeded 21.1°C, whereas HT cows were not. Rectal temperature (RT) was measured twice daily and respiration rates (RR) recorded thrice weekly during the dry period. After parturition, all cows were housed in a free-stall barn with cooling. Lymphocytes were isolated at dry-off, −20, 2, and 20 d relative to calving from a subset of cows (HT, n = 9; CL, n = 10) and mammary biopsies were taken at the same intervals (HT, n = 7; CL, n = 6) for RNA extraction. Gene expression was assessed using a custom multiplex expression assay based on traditional reverse transcription-PCR. Genes involved in prolactin (PRL) signaling (*PRLR-L*, *PRLR-S*, *SOCS2* and *3*, *IGFII*, *IGFBP5*, and *Cyclin D1*), fatty acid (FA) metabolism (*ACC* and *LPL*) and *IGFI* were evaluated in mammary tissue, and genes related to FA metabolism (*ACC*, *FASN*, and *LPL*), cytokine production (*IL6*, *IL8*, and *TNFα*) and *IGFI* were evaluated in lymphocytes. Data was analyzed by the PROC MIXED procedure of SAS. Compared with HT, CL cows had lower ($P < 0.01$) RT (39.4 vs. 39.0°C) and RR (78 vs. 46 breath/min) in the afternoon before calving. No differences ($P > 0.15$) were observed in PRL signaling or FA metabolism gene expression in the mammary gland. In lymphocytes, HT cows had higher ($P \leq 0.05$) *IGFI* and *TNFα* mRNA expression during the transition period relative to CL and upregulated ($P < 0.05$) *IL8* and downregulated ($P = 0.01$) *FASN* mRNA expression at 2 d relative to calving. We conclude that cooling HT cows during the dry period alters cytokine production and lipid metabolism in lymphocytes.

Key Words: heat stress, lymphocyte, mammary gland

T141 Identification and quantification of milk synthesis and secretion related proteins in bovine milk using a proteomics approach. J. Lu*[1,2], S. Boeren[2], J. Vervoort[2], H. van Valenberg[1], S. de Vries[2], J. van Arendonk[3], T. van Hooijdonk[1,4], and K. Hettinga[1], [1]*Dairy Science and Technology Group, Wageningen University, Wageningen, the Netherlands,* [2]*Laboratory of Biochemistry, Wageningen University, Wageningen, the Netherlands,* [3]*Animal Breeding and Genomics Centre, Wageningen University, Wageningen, the Netherlands,* [4]*FrieslandCampina, Amersfoort, the Netherlands.*

Lactation physiology is a process that is still partly understood. Proteomics techniques have shown to be useful to help advance the knowledge on lactation physiology in human and rodent species but is rarely used for dairy cows, except for mastitis. In fact, many aspects in bovine milk secretion still need to be investigated in detail and advanced proteomics techniques can help to improve this knowledge. Filter-aided sample preparation (FASP) and NanoLC-Orbitrap-MS/MS were applied to milk fat globule membrane and serum fractions, which were isolated from bovine tank milk samples (65 Holstein cows). This resulted in the identification of 246 proteins. Most proteins were low in abundance. Many of these low abundant proteins were for the first time found in bovine milk. The identified proteins in milk were similar to previous reports on the proteome of cells from mammary gland biopsies. The identified proteins were categorized according to their function description in Uniprot (www.uniprot.org). Sixty-three proteins were found to be directly related to milk component synthesis and secretion. These proteins are mainly enzymes and transporters. Thirteen enzymes which are part of the central metabolic pathway were identified. Eleven enzymes catalyze steps in lipid synthesis, including acetyl-CoA synthetase, fatty acid synthase, glycerol-3-phosphate acyltransferase. Forty-three transporters were identified. These transporters are involved in intracellular transport of lipids, proteins, minerals and vitamins, as well as secretion of these compounds. Butyrophlin, adipophilin, and XDH, which are essential proteins for lipid droplet secretion from epithelial cell, were all found in milk. Besides identification of proteins, dimethyl-labeling was tested to perform relative quantification of the proteins and was shown to give accurate results. The proteins identified to be involved in milk synthesis and secretion suggests that milk may be used rather than more intrusive tissue biopsies in the study of milk synthesis and secretion. These proteomic techniques can be used to solve different biological questions to increase our knowledge of lactation.

Key Words: proteomics, lactation physiology, milk synthesis and secretion

T142 Physiological state but not gestational photoperiod affects weights of liver and thymus in mice. P. A. Bentley* and T. B. McFadden, *University of Alberta, Edmonton, Alberta, Canada.*

Exposing dairy cows to short day photoperiod during gestation increased milk yield by 3 kg/d in the subsequent lactation. Although the mechanisms responsible for this effect are unknown, recent studies in other mammals have shown effects of altered photoperiod on peripheral tissues; such changes could influence milk yield. In this experiment, mice were used to investigate the effects of gestational photoperiod on lactation and development of mammary gland and other organs. We hypothesized that altering photoperiod during gestation would elicit physiological changes causing differences in milk production. Mice (n = 6/treatment x time) were exposed to long (16L:8D), normal (12L:12D) or short (8L:16D) day photoperiod treatment during gestation. Two groups of mice/treatment were sacrificed on d 17 and 19 of gestation. The remaining mice were allowed to pup and after parturition were placed on 12L:12D and litter size was standardized. For all mice, organ weights were determined immediately after sacrifice on d 17 and 19 of gestation and d 5 and 10 of lactation. For lactating mice, litter weight gain was measured daily to estimate milk yield. Data were analyzed for main effects and interaction of photoperiod and time using Proc GLM of SAS. There was no significant effect of photoperiod on litter weight gain during the first 10 d of lactation, nor on organ weights. However, litter weights of dams exposed to long or short day photoperiod were numerically greater after d 5 of lactation than those exposed to normal day length. Dam weight did not vary by photoperiod treatment and was used to normalize organ weights. Liver weights were greater ($P < 0.05$) on d 10 of lactation than during gestation, corresponding to the increased metabolic demand of lactation. Thymus weights decreased ($P < 0.01$) from d 17 to d 19 of gestation but increased ($P < 0.0001$) from d 5 to d 10 of lactation. Differences in thymus weight may reflect altered immune activity during the periparturient period. These data indicate some physiological adaptations to pregnancy and lactation in mice that may provide targets for studying molecular mechanisms involved in similar adaptations in dairy cows.

Key Words: photoperiod, gestation, metabolism

Meat Science and Muscle Biology II

T143 Pearson correlation coefficients of multiple methods for measuring water-holding capacity in two pork muscles. J. W. Rickard[1], Z. D. Callahan*[1], T. A. Wilmoth[2], C. S. Perkins[1], M. E. Wilson[2], and B. R. Wiegand[1], *[1]University of Missouri, Columbia, [2]West Virginia University, Morgantown.*

Water holding capacity is an economically important aspect of fresh and further processed pork. The ability to retain or take up added water contributes to consumer acceptance and the overall eating experience of pork products. The objective of this experiment was to estimate the relationship, via Pearson correlation coefficients, of multiple accepted methods of water holding capacity determination currently employed in academic and industry laboratories. Longissimus dorsi (LD) and lumbar lean (LL) were sampled using a 2.54 cm coring device on 24 h chilled carcasses from 40 individually fed market barrows of the same genetic line. Samples were subject to duplicate determination of water holding capacity using 24 h drip loss (DL), Carver Press method (CPM), vacuum package purge(VPP), and centrifugation (CENT)(1000 x g for 10 min). Additionally, we evaluated the relationship between LD muscle fiber type and diameter, pH 24hr, and various measures of water holding capacity of fresh muscle. Within LD muscle samples, a significant correlation existed for DL and CENT ($P = 0.003$, r = 0.454). Within LL muscle samples, a significant correlation existed for CENT and VPP ($P = 0.003$, r = 0.451). LD VPP was positively correlated to LD primary fiber number ($P = 0.008$, r = 0.523), but negatively correlated to LD secondary fiber number ($P = 0.014$, r = - 0.387). For LD and LL samples subject to CENT, there was a significant and negative correlation to pH 24hr ($P = 0.035$, r = - 0.337 and $P = 0.05$, r = - 0.312, respectively). Finally, in the current study, CPM measures of water holding capacity did not have a significant relationship to any other variable of interest ($P > 0.55$). These results indicate that muscle morphology is related to downstream water holding characteristics of fresh pork muscles. Additionally, the less invasive and less time consuming method of centrifugation (which requires approximately 15 min from sampling to result) might have merit in predicting water holding characteristics of LD and LL from pork carcasses.

Key Words: pork, water-holding capacity, Pearson correlations

T144 Carcass and muscle fiber characteristics of ractopamine fed market pigs with a genetic propensity to deposit significant subcutaneous carcass fat. C. S. Perkins*[1], T. A. Wilmoth[2], Z. E. Kerley[1], Z. D. Callahan[1], M. E. Wilson[2], and B. R. Wiegand[1], *[1]University of Missouri, Columbia, [2]West Virginia University, Morgantown.*

Ractopamine hydrochloride (Paylean) functions as a potent repartitioning agent in growing-finishing pigs with respect to muscle and fat deposition. The objective of this experiment was to assess the extent of fat and lean partitioning in pigs with a propensity to deposit high levels of subcutaneous carcass fat. Additionally, we investigated the change in primary and secondary muscle fiber size and number in this pig model when Paylean was fed at 7.4 ppm for the final 30 d of finishing. Following an approved animal care and use protocol, individually penned, growing (42 kg) barrows (n = 40) were fed a commercial corn-soy diet until they reached 91 kg body weight. Then, barrows were equally and randomly assigned to a diet containing 0 (CON) or 7.4 ppm Paylean (PAY) until they reached 121 kg final wt. Carcass measurements of hot carcass weight (HCW), loin muscle area (LMA), tenth rib fat (TRF), and last rib fat (LRF) were made. Longissimus dorsi (LD) and semitendonosus samples were removed after a 24hr carcass chill. Samples were fixed and used to determine diameter and number of primary and secondary fibers. As expected, PAY diets increased ($P < 0.005$) HCW (86.8 kg vs 94.5 kg) and increased ($P < 0.0001$) LMA (38.45 cm2 vs. 47.22 cm2). However, TRF and LRF were not changed with PAY inclusion ($P = 0.17$ and $P = 0.96$, respectively). Primary muscle fiber diameter was lower ($P = 0.03$) in the LD and tended to be lower ($P = 0.06$) in secondary muscle fibers of the LD for PAY fed pigs. Additionally, primary muscle cell number tended to be lower ($P = 0.63$), but did not differ ($P = 0.42$) for secondary muscle fiber number of the LD for PAY fed pigs. Measures of 24hr drip loss and pH in the LD did not differ ($P > 0.05$), because of treatment. These data indicate that a typical PAY feeding program (7.4 ppm for 30 d) increased muscle mass, but did not decrease subcutaneous fat depth at the tenth and last rib for a genetic line of pigs with a propensity to deposit greater than average subcutaneous carcass fat. Dietary PAY appears to alter some morphological aspects of muscle fiber types in the longissimus muscle.

Key Words: subcutaneous fat, ractopamine, muscle fiber

T145 Shelf stability and quality of fresh ground pork and pork sausage from pigs fed a combination of dried distillers grains with solubles, ractopamine hydrochloride, and conjugated linoleic acid. B. R. Wiegand,* H. L. Evans, Z. D. Callahan, and C. S. Perkins, *University of Missouri, Columbia.*

This experiment evaluated the effects of ractopamine (RAC), conjugated linoleic acid (CLA) and distillers dried grains with solubles (DDGS) on fatty quality and shelf stability of ground pork. Picnic shoulders (n = 72) were selected from pigs fed one of 8 dietary treatments, consisting of 2 levels of DDGS inclusion (0 or 20% DDGS), 2 levels of RAC (0 and 7.4 mg/kg), and 2 levels of CLA (0 and 0.6%). Picnic shoulder trim from each animal was divided into 3 sections and each was assigned to 1 of 3 processing treatments: A) ground pork, B) fresh pork sausage, or C) fresh pork sausage + rosemary extract. Samples were analyzed for fatty acid profiles, TBARS, and color during retail display. Higher IV were seen with DDGS ($P < 0.0001$) and RAC ($P = 0.004$) inclusion and lower IV with CLA ($P < 0.0001$). A significant interaction between RAC and CLA was observed for TBARS (mg malonaldehyde / kg sample) values ($P = 0.03$). In non-RAC fed pigs, CLA decreased TBARS when compared with non CLA fed pigs (0.654 vs. 0.831). Moreover, in non-CLA fed pigs, RAC decreased TBARS from 0.831 to 0.559, indicating that RAC was more effective at lowering TBARS than CLA, but no additive effect was seen on TBARS when both RAC and CLA were fed ($P > 0.05$). Within each processing treatment, RAC inclusion led to decreased ($P < 0.05$) TBARS. In non-RAC fed pigs, processing treatment B resulted in lower TBAR than A; however, processing treatment C had lower TBARS than both A and B. In RAC-fed pigs, no difference existed between process A and B or process B and C ($P > 0.05$); however, TBARS for ground pork (process A) were significantly higher than for pork sausage (process B). Dietary DDGS inclusion did not affect TBARS values ($P = 0.78$). Minolta L* (lightness) reflectance values were lower for DDGS-fed pigs over the entire display period (52.97 vs. 53.87; $P = 0.02$). Additionally, an interaction was observed between RAC and processing treatment for L* values ($P = 0.01$). Within processing treatments B and C, RAC inclusion led to lower L* reflectance values when compared with non-RAC fed pigs. Dietary fat source influences pork meat fatty acid profile and shelf-life can be extended with addition of rosemary as an antioxidant in pork sausage.

Key Words: pork, fat quality, shelf life

T146 Effects of genotype and dietary oil supplementation in pigs. 2. Pork quality and fatty acid composition.

T. M. Bertol*[1], R. M. L. de Campos[2], J. V. Ludke[1], N. N. Terra[3], E. A. P. de Figueiredo[1], V. L. Kawski[1], A. Coldebella[1], and N. M. Lehr[1], [1]*Embrapa Suínos e Aves, Concórdia, SC, Brazil,* [2]*Fundação Universidade Federal do Vale do São Francisco, Petrolina, PE, Brazil,* [3]*Universidade Federal de Santa Maria, Santa Maria, RS, Brazil.*

A 42 d study was carried out to evaluate the effect of genotype (GEN): terminal sire line Duroc × F1 (DC×F1); terminal sire line Embrapa MS115 × F1 (MS115×F1); and MS115 × Moura (MS115×MO) and 3 dietary oils (DIET): 3% soybean oil (SBO); 3% canola oil (CAN); and 1.5% canola oil + 1.5% flax oil (CAN+FLX), on pork quality and fatty acid composition. Ninety animals (45 barrows and 45 gilts) averaging 130.7 ± 3 d of age were utilized, 15 barrows and 15 gilts of each GEN per diet. The progeny of MS-115 sire line showed higher ($P < 0.05$) pH values at 45 min and 24 h post slaughter than DC×F1 pigs. The DCxF1 pigs had lower ($P < 0.05$) a* values and higher ($P < 0.05$) L* values than the other GEN. The highest ($P < 0.05$) content of intramuscular fat (IMF) was observed in DC×F1 pigs, followed by MS115×MO and MS115×F1 with the lowest values. Shear force was higher ($P < 0.01$) in MS115×F1 pigs, followed by DC×F1 and the lowest values observed in the MS115×MO. DIET did not affect meat quality, except marbling, which was higher ($P < 0.05$) in pigs fed CAN compared with CAN+FLX. DC×F1 pigs showed the highest values ($P < 0.01$) of C14:0, C16:0, C18:0, C16:1, and C18:1 fatty acids (FA), while MS115×F1 pigs had the highest ($P < 0.01$) content of C18:2, C18:3, C20:2, and C20:4 and the lowest ($P < 0.001$) content of C14:0, C16:0, and C18:1 in the loin. CAN or CAN+FLX oils provided higher ($P < 0.01$) content of C18:1 and lower ($P < 0.01$) content of C18:2 and C20:2. C18:3 was higher ($P < 0.01$) in the loin of pigs fed CAN+FLX and in the backfat of pigs fed CAN or CAN+FLX. The n-6/n-3 ratio was 14.61, 11.30, and 6.46 in the loin and 8.89, 6.68 and 3.77 in the backfat, for SBO, CAN and CAN+FLX oils, respectively. In conclusion, MS-115 sire line positively influenced meat color, but when crossed with F1 females reduced tenderness and IMF. Duroc sire line positively influenced the IMF. Moura breed positively influenced meat tenderness and IMF. Supplementing the diet with CAN or CAN+FLX oils provided higher monounsaturated and C18:3 and lower C18:2 FA, reducing the n-6/n-3 ratio, than supplementing SBO oil. CAN+FLX DIET provided the best n-6/n-3 ratio.

Key Words: canola oil, flax oil, soybean oil

T147 Effects of antibiotics on growth performance, plasma biochemical index and meat quality of growing-finishing pigs.

X. Wu, Y. Zhang, X. Liu, H. Yang, and Y. Yin,* *Key Laboratory of Agro-Ecological Processes in Subtropical Region, Institute of Subtropical Agriculture, Chinese Academy of Sciences, Changsha, China.*

To investigate the effects of antibiotics on growth performance, plasma biochemical index and meat quality of growing-finishing pigs, 1010 weaned piglets (average weight of 6.5 ± 1.5 kg) were chosen and grouped into 2 groups: control group (antibiotic-free group, 350 piglets) and antibiotics group (660 piglets), and fed with the same base diet. The diet in the antibiotics group supplemented with antibiotics (aureomycin 800 ppm, olaquindox 100 ppm and colistin 800 ppm) from d 28 to 120 (first stage), while the control group didn′t use any antibiotics. On d 120 and 180, 6 piglets from each treatment were selected randomly and slaughtered for tissue sampling, respectively. The results showed that mortality of pigs in the first stage was lower in the antibiotics group ($P < 0.05$), and the ADG and AIDF tended to be higher; however, ADFI and ADG tended to be lower in the second stage. Compared with the antibiotic-free diet, antibiotics tended to increase plasma IgG and IgM in the first stage, while decrease in the second stage; blood glucose had a similar change. Antibiotics decreased plasma urea in the first stage ($P < 0.05$), however, plasma urea tended to be higher in the second stage. Plasma cholesterol was lower in the control group in the second stage ($P < 0.05$). It is interesting that antibiotics resulted in a significant decrease in plasma Fe in the first stage ($P < 0.05$), and plasma Total Iron Binding in the antibiotic-free group was higher ($P < 0.05$). The result from the evaluation of meat quality showed that brightness of the meat from the antibiotic-free group had a decreasing trend, and red scale had an increasing trend. These data suggest that the use of antibiotics postweaning decreased feed efficiency in a extended period, and also decreased meat quality.

Key Words: antibiotics, meat quality, pig

T148 Effects of level of feeding and breed on fatty acid profile of meat from Brazilian native goats.

L. S. Lopes[1], M. L. Chizzotti*[2], M. M. Ladeira[2], K. C. Busato[2], J. R. R. Carvalho[2], R. T. S. Rodrigues[2], and D. P. D. Lana[3], [1]*State University of Santa Catarina, Chapecó, SC, Brazil,* [2]*Federal University of Lavras, Lavras, MG, Brazil,* [3]*University of São Paulo, Piracicaba, SP, Brazil.*

Goat meat is an important protein source for Brazilian semi-arid's population. The meat composition can be affected by breed, age, gender and nutrition. The aim of this study was to evaluate the effects of 3 breed groups (Canindé, Moxotó and F1 Boer × nondescript breed) and 3 feeding levels on fatty acid profile of goat meat, using a 3 × 3 factorial design. Forty-five goats (15 of each breed group), with average initial body weight of 15 kg were used. Five goats of each breed group were randomly allocated to one of the following treatments: ad libitum intake, restricted fed at 75% of the ad libitum intake and restricted fed at 50% of the ad libitum intake. The diet consisted of 40% of Elephant grass and 60% of concentrate. Animals were kept in individual stalls, partially shaded, in the middle of a native Caatinga area, to simulate the semi-arid environment. After 90 d on feed, all animal were slaughtered and the carcasses were dissected into meat and bone. The meat was then ground and sampled. The fatty acid profile was accessed by gas chromatography. There was no interaction between level of feeding and breed group ($P > 0.10$). The polyunsaturated fatty acid concentration was higher ($P < 0.05$) in Moxotó than in F1 Boer group. The n-3 content in F1 Boer was greater ($P < 0.05$) than in Moxotó. There were no differences ($P > 0.05$) among breeds for the other fatty acids. For the levels of consumption, the ad libitum treatment had higher ($P < 0.05$) concentration of oleic (C18:1 c9), conjugated linoleic acids (C18:2 c9t11), unsaturated and monounsaturated fatty acids and lower ($P < 0.05$) levels of saturated fatty acids than the restricted fed treatments. The n-3 concentration was higher ($P < 0.05$) in the treatment with 50% restriction. As a conclusion, breed has a small effect on meat fatty acid profile, but the level of consumption affects the fatty acid profile of goat meat. Funded by FAPEMIG and CNPq.

Key Words: CLA, fat, intake

T149 Effect of dietary organic chromium on meat quality of Mahabadi goat kids.

A. Emami, M. Ganjkhanlou,* A. Zali, A. Hojabri, and A. Akbari-Afjani, *University of Tehran, Tehran, Iran.*

The objective of this study was to evaluate the possible effect of different levels of dietary chromium from chromium-methionine (Cr-Met) on meat quality of Mahabadi goat kids. Thirty-two male kids (BW = 22 ± 2 kg, 4 Mo) were used in a completely randomized design with 4 treatments: 1) control (without Cr), 2) 0.5, 3) 1.0 and 4) 1.5 mg Cr as Cr-Met/animal/d. Diets were formulated for NRC requirements with forage (alfalfa and corn silage): concentrate ratio of 30:70 in TMR form. Diets were the same, except for top-dress addition of Cr-Met fed in 2 equal meals (0800 and 1600 h). Experimental period was 90 d. At the end of the trial, kids were weighed and slaughtered following 16-h fasting. Meat samples were taken from the longissimus dorsi muscle (LDM). Color (lightness (L*), redness (a*) and yellowness (b*)), and pH of LDM were measured at 24 h after slaughter. Some of the LDM were immediately stored at −20°C for assessing moisture, intramuscular fat and crude protein content. Cooking loss (CL) was determined by weighing the samples before and directly after cooking in a water bath at 70°C for 1 h. Percentage of CL was calculated. Data were analyzed by the GLM procedure of SAS 9.1 and Tukey test ($P \leq 0.05$). PH, lightness, moisture (%), intramuscular fat (%), crude protein content (%) and CL percentage were not affected by Cr supplementation ($P > 0.05$). However, chromium supplementation decreased redness ($P = 0.02$) and yellowness ($P = 0.01$) of LDM. These results suggest that supplementing diet with Cr-Met did not influence the meat quality but decreased redness and yellowness of LDM in Iranian Mahabadi goat kids.

Table 1. Meat quality of kids fed different levels of Cr-Met

	Treatment (mg of CR)				
Trait	Control	0.5	1.0	1.5	SEM
pH	5.74	5.83	5.74	5.84	0.06

T150 Influence of dietary zilpaterol hydrochloride on finishing performance, carcass characteristics and meat quality of castrated male goats.

A. Hatefi*[1], A. Towhidi[1], A. Zail[1], M. Ganjkhanlou[1], and A. Plascencia[2], [1]*Department of Animal Science, University of Tehran, Karaj, Alborz, Iran,* [2]*Instituto de Investigaciones en Ciencias Veterinarias, Universidad Autónoma de Baja, CaliforniaMexicali, Baja California, México.*

The effects of β-2 agonist zilpaterol hydrochloride (ZH) supplementing on growth performance, carcass characteristics, longissimus muscle (LM) composition and meat quality characteristics (cooking loss and Warner-Bratzler shear force (WBSF)) in male goats were investigated. Sixteen Mahabadi castrated male goats (6 mo old and 23 ± 4.4 kg live body weight) were fed with the finishing diet based on 2.35 Mcal ME and 15.23%CP for 93 d (feedlot period). The goats were assigned to 2 treatment (ZH and control) arrangements in a completely randomized design. After 60 d of feedlot period, 8 castrated goats were treated to 0.2 mg/kg live body weight ZH for 30 d with 3 d as the withdrawn period. Then, all the goats (n = 16) were harvested and, their carcasses were stored at 0–2°C for 48h. The meat composition and quality were determined by standard procedures of the AOAC (1990) and AMSA (1995), respectively. The data collected from dry matter intake, total live body weight, postmortem aging for WBSF and cooking loss were analyzed by MIXED procedure, and the data obtained from other studied parameters were analyzed by GLM procedure of SAS software. Results showed that ZH decreased ($P < 0.01$) dry matter intake and increased total live body weight in the end of feedlot period ($P = 0.02$). These parameters improved feed efficiency ($P < 0.01$) and average daily gain ($P = 0.02$). After slaughter, it was clearly observed that ZH increased ($P < 0.01$) hot carcass weight and LM area and decreased back fat thickness and improved carcass dressing yield ($P < 0.01$). ZH led to increased WBSF values, cooking loss percentage, protein and moisture contents ($P < 0.01$), whereas it decreased fat content in LM ($P = 0.02$). Likewise, the postmortem aging decreased WBSF value in the LM muscle of ZH and control ($P < 0.01$). These results indicate that ZH has positive effects on enhancing feedlot performance and carcass efficiency, and improves some chemical compounds in castrated male goat meat. However, supplementation of this β-2 agonist can adversely affect meat quality characteristics.

Key Words: zilpaterol hydrochloride, meat quality, carcass characteristics

T151 Effect of diet linseed supplementation in ewes during gestation and lactation on fatty acid profile of suckling lamb meat.

A. Nudda,* G. Battacone, M. Lovicu, N. Castanares, R. Boe, A. Fenu, and G. Pulina, *Dipartimento di Agraria, Sezione di Scienze Zootecniche, Università di Sassari, Sassari, Italy.*

The polyunsaturated n-3 fatty acids (PUFA n3) contained in the human diet are essential for regular growth and development. Thus the increase of PUFA n3 content in meat represents a primary task in applied animal science. In this work, the effect of α-linolenic acid (ALA) diet supplementation of dairy ewes during pregnancy and early lactation on ALA conversion into longer-chain PUFA (C20:5, EPA; C22:5, DPA; C22:6, DHA) in muscle of 28 suckling lambs was investigated. Twenty-eight Sarda dairy ewes were divided in 4 groups and fed one of the dietary treatment from approximately the last 8 weeks of gestation to the first 4 weeks of lactation. A control diet (CONT) and an ALA enriched diet by adding lineseed (LIN) were used. The 4 dietary treatments consisted of gestation/lactation feeding of ewes to give CONT/CONT, CONT/LIN, LIN/LIN or LIN/CONT lambs. Lambs were slaughtered at 4 weeks of age. After 24 h at 4°C, the longissimus dorsi muscle was dissected from each right half-carcass. Fatty acid composition of intramuscular fat was determined by gas-chromatography. The effect of ALA supplementation during gestation, lactation or both on PUFAn3 was tested by one way ANOVA using dietary treatment as the main effect. The LIN/LIN treatment resulted in a significantly higher content of ALA (almost 3-fold; $P < 0.01$) and EPA (2-fold; $P < 0.01$) compared with the CONT/CONT. The LIN supplementation only during gestation (LIN/CON) decrease the ALA and EPA concentration compared with LIN/LIN group. Feeding the LIN only during lactation determined lower values for EPA (−50%; $P < 0.01$) and ALA (−24%; $P = 0.07$) compared with LIN/LIN group. These results evidenced that a continuous linseed supplementation during gestation and lactation resulted in an increase in muscle ALA concentration and in a conversion to its longer-chain metabolite EPA but not in DHA. From a nutritional point of view, the lineseed supplementation during all experimental periods resulted in a increase of PUFA n3 in lamb meat of 74%. Research supported by Cargill - Animal Nutrition Division, Milan, Italy.

Key Words: lamb meat, PUFA n-3, maternal linseed diet

T152 The influences of intermittent feeding zilpaterol hydrochloride during two last week finishing period on growth performance in Japanese quails. A. Towhidi,* M. Mohammadi Arekhlo, H. Moravej, and A. Zare Shahneh, *Department of Animal Science, College of Agriculture and Natural Resources, University of Tehran, Karaj, Iran.*

Zilpaterol hydrochloride is a β-adrenergic agonist which has been shown to increase lean muscle and decrease fat deposition. The objective of this study was to determine the effect of intermittent feeding of zilpaterol hydrochloride (ZH) on growth performance of Japanese quails. 128 male quails at 33 d of age were divided into 4 treatments. Each treatment consisted of 4 replicates of 8 birds. Diets were based on corn and soybean meal during the finisher period (24% CP and 2.9 Mcal/kg of ME). The birds intermittently (2 d on, 2 d off) received different levels of ZH including 0, 0.2, 0.225, or 0.25 mg/kg of live weight. The treatment diets were fed until 47 d of age and then ZH was withdrawn 3 d before slaughter at d 50. Data were analyzed using the GLM procedure in SAS. Results showed that ZH supplementation improved weight gain ($P < 0.05$), and feed efficiency ($P < 0.01$) in treated groups compared with control diet, but did not affect feed intake. The highest feed efficiency belonged to the 0.225 mg/kg live weight treatment. Quails fed zilpaterol hydrochloride had lower abdominal and subcutaneous fat ($P < 0.05$) compared with the control. Dietary zilpaterol hydrochloride did not affect carcass, thigh, breast and liver weight. It was concluded that intermittent feeding of zilpaterol hydrochloride improved growth performance in Japanese quail.

Key Words: β2-agonist, body weight, Japanese quail

Nonruminant Nutrition: Feed Ingredients

T153 Dietary *Aspilia africana* leaf on nutrients digestibility and physio-chemical properties of intestinal segments in quails. O. O. K. Oko,* E. A. Agiang, and I. E. Iso, *University of Calabar, University of Calabar, Calabar, Cross River State, Nigeria.*

The prohibition of most synthetic growth promoters is steering increasing interest in phytobiotics as possible alternatives. Phytobiotics are heterogeneous groups of feed additives originating from fruits, herbs and spices. This study evaluated the effects of *Aspilia africana* leaf (AaL) products on nutrients digestibility and physio-chemical properties of intestinal segments in quails. A total of 420, 1-wk-old quails were assigned to 14 treatments; representing supplementation with 0% (control), 2.5, 5.0, 7.5 or 10% of either meal, aqueous or ethanolic extract of AaL, or 0.02 g/kg terramycin (antibiotic) to a corn and soybean meal based-diet for 42 d (n = 30 chicks per treatment). Each treatment had 3 pens of 10 chicks/pen. On d 36, a digestibility trial involving 12 quails per treatment was initiated. Feed and fecal samples were collected for 4 d and the apparent nutrient digestibility for crude protein, fat, fiber and ash were analyzed. On d 42, quails were euthanized and their intestinal tracts were excised and segmented. The weight, length and density of each segment were measured and 1 mL of digesta was obtained for pH determination. Data were subjected to a 2-way ANOVA. Results indicated that, compared with the control, 5 to 7.5% AaL and antibiotic improved ($P \geq 0.05$) nutrient digestibility in quails; values were higher in quails fed 5 to 7.5% AaL than those on the antibiotic for digestible protein (2.84% v 0.50%), fat (4.82% v 1.42%) and fiber (4.15% v 3.48%). Intestinal length and densities were not affected ($P \geq 0.05$) by dietary treatments. Intestinal weights were reduced ($P \leq 0.05$) by an average of 22.21% and 32.64% in quails fed AaL and terramycin diets, respectively. Also, the pH of contents from the cecum and jejunum were reduced ($P \leq 0.05$) by 0.88 and 0.50 units, respectively, in AaL-fed quails. Comparatively, the aqueous extract exerted higher phytogenic effects on the physio-chemical properties of the intestinal segments in quails than the meal or ethanolic extract. These findings indicate that dietary supplementation with 5 to 7.5% aqueous extract of *Aspilia africana* leaf could modulate the intestinal characteristics of quails, thus enhancing nutrient digestion.

Key Words: quail, phytobiotics, digestion enhancer

T154 Effects of egg by-product supplementation on the egg production, nutrient digestibility, egg quality, blood profiles, and fecal noxious gas emission in laying hens. L. Yan,* J. P. Wang, and I. H. Kim, *Department of Animal Resource & Science, Dankook University, Cheonan, Choongnam, South Korea.*

A total of 288 42-week-old ISA-brown laying hens were used in a 5-week feeding trial to investigate the effects of egg by-product supplementation on the egg production, nutrient digestibility, egg quality, blood profiles, and fecal noxious gas emission. Hens were randomly allotted into 4 treatments with 12 replications (6 layers per replication) per treatment according to their initial BW. Dietary treatments were: 1) CON (basal diet); 2) EP1 (basal diet + 1% egg by-product); 3) EP2 (basal diet + 2% egg by-product); 4) EP3 (basal diet + 3% egg by-product). Egg by-product used in this trial consisted of 44.01% DM and 15.86% CP (feed basis). All diets were formulated to meet or exceed the NRC (1994) requirements for laying hens. Hens were individually caged and provided with 16 h of light daily. All cages were equipped with nipple drinkers and common trough feeders, experimental feed and water were provided ad libitum throughout the experimental period. The hens were housed in a windowless laying house at approximately 21°C. All statistical analyses were conducted in accordance with a randomized complete block design, using the GLM procedures of SAS software package (1996). Overall, administration of egg by-product led to a higher ($P < 0.05$) egg production and egg weight compared with the CON group. However, the nutrient digestibility, blood profiles, and fecal noxious gas emission were not affected ($P > 0.05$) by dietary egg by-product supplementation throughout the experimental period. The inclusion of egg by-product increased ($P < 0.05$) yolk height, yolk color, and egg gravity compared with the CON group. Hens fed the egg by-product supplemented diets led to a higher ($P < 0.05$) eggshell thickness and egg shell strength compared with the CON group. No difference was observed ($P > 0.05$) in the haugh unit throughout the experiment. In conclusion, results indicated that egg by-product could be used as a good material in laying hens to improve egg production and egg quality.

Key Words: laying hen, egg by-product, egg quality

T155 Economic evaluation of increasing levels of acerola meal replacing corn in the diet of broilers. V. C. da Cruz*[1], L. H. Zanetti[1], G. do Valle Polycarpo[2], R. F. de Oliveira[1], A. L. C. Brichi[1], L. C. Carvalho[1], O. J. Sabbag[1], and C. C. do Valle Polycarpo[3], *[1]São Paulo State University, Dracena Campus, Dracena, São Paulo, Brazil, [2]University of São Paulo, Pirassunununga Campus, Pirassununga, São Paulo, Brazil, [3]São Paulo State University, São José do Rio Preto Campus, São José do Rio Preto, São Paulo, Brazil.*

The aim of this study was evaluate economically the different additions of acerola meal (AM) replacing corn (C) in diets of broilers from 1 to 42-d-old. Nine hundred eighty 1-d-old male Cobb chicks were allotted in a completely randomized design with 4 treatments: T0- basal diet - without addition of AM, T5- addition of 5% AM replacing C, T10- addition of 10% AM replacing C, T15- addition of 15% AM replacing C, and 7 replications with 35 birds per experimental unit. AM addition was performed in relation to the percentage of corn inclusion in diet. The nutritional composition of AM was: 89.15% (DM), 8.36% (CP), 4.57% (EE), 3.19% (MM), 46.27% (CF), 50.86% (NDF), and 41.33% (ADF). An increase in the cost of the rations was observed at levels above 5% inclusion of AM replacing C. Diet with inclusion of 5% of AM showed better cost of feed (US$912.61) with a value similar to the control diet (US$913.87). Diets with higher inclusion levels (10 and 15% replacing C) had higher costs (US$1,008.17 and US$1,014.46, respectively), probably by the greater inclusion of soybean oil to keep the diets isocaloric. Because it is an ingredient with low-energy (756 kcal/kg AMEn), the AM (US$ 0.598/kg) used in diets for broilers, must be accompanied by the addition of soybean oil, therefore not causing an effective reduction in the cost per kg of ration. It was observed better value for operating profit, profitability index and final cost/bird for the treatment with 10% inclusion of AM, possibly because this diet provided lower mortality in the experiment; thus, making it more viable economically. The use of AM in diets for broilers can be advantageous in off-season periods, when the price of corn and soybeans are high. The use of alternative ingredients is directly related to the price of traditional feedstock such as corn and soybean meal, as well as the cost of possible supplementation to maintain adequate nutritional levels to animal performance. Thus, the experimental diet with 5% inclusion of AM has lower total cost. However, observing operating profit and profitability index, better values are found in treatment with 10% inclusion of AM.

Key Words: poultry, economic viability, residue byproducts

T156 Effects of egg by-product supplementation on growth performance, nutrient digestibility, blood profiles, relative organ weights, and meat quality in broiler. H. Y. Baek,* Z. F. Zhang, and I. H. Kim, *Department of Animal Resource & Science, Dankook University, Cheonan, Choongnam, South Korea.*

A total of six hundred sixty 1-d-old ROSS 308 broilers (BW = 39.2 ± 0.1 g) were used in a 35-d experiment to evaluate the effect of egg by-product on growth performance, apparent total tract digestibility (ATTD), blood profiles, relative organ weight, and meat quality. Broilers were randomly assigned to 4 dietary treatments with 11 replicate pens per treatment and 15 broilers per pen. Treatments were: 1) CON, basal diet; 2) EP1, CON + 1% egg by-product; 3) EP2, CON + 2% egg by-product, and 4) EP3, CON + 3% egg by-product. During d 1–12, feed conversion rate (FCR) was lower ($P < 0.05$) in EP3 treatment than that in CON treatment, though BWG and FI were not affected ($P > 0.05$) by dietary treatments. During d 12–26, BWG and FCR were improved ($P < 0.05$) in EP3 treatment relative to CON and EP1 treatments. During d 26–36, no differences ($P > 0.05$) were noted in BWG, FI and FCR among treatments. Overall, BWG was higher ($P < 0.05$) in EP3 treatment than that in CON treatment, and FCR was lower ($P < 0.05$) in EP3 treatment than CON, EP1 and EP2 treatments. The ATTD of energy was higher ($P < 0.05$) in EP2 and EP3 treatments compared with CON treatment, but no differences ($P > 0.05$) were noted in the ATTD of DM and N among treatments. The concentration of leukocytes was higher ($P < 0.05$) in EP3 treatment than that in CON and EP2 treatments on d 35 of the experiment. Relative organ weight was not affected ($P > 0.05$) by supplementation of egg by-product. Drip loss was lower ($P < 0.05$) in EP2 and EP3 treatments than that in CON treatment. In conclusion, dietary supplementation with 3% egg by-product may improve growth performance, nutrient digestibility, and increase the concentration of leukocytes in broilers.

Key Words: egg by-product, growth performance, broilers

T157 A survey of free and conjugated deoxynivalenol in European feedstuffs. S.-T. Tran* and T. K. Smith, *Department of Animal and Poultry Science, University of Guelph, Guelph, ON, Canada.*

Deoxynivalenol (DON, vomitoxin), produced by many *Fusarium* species, is one of the most widely distributed mycotoxins globally and is found as a contaminant of cereal grains such as corn, wheat, barley and triticale. Recent studies have described the presence of conjugated forms of DON which are produced by the plant after invasion by the fungus. The aim of the current study was, therefore, to investigate the natural occurrence of free and conjugated DON in European feedstuffs. Free and conjugated DON were determined in 118 feed samples collected in 2011 from Denmark, France, the Netherlands and Russia. Free DON was absent in 26 samples. Levels of free DON ranged from 0.10 to 10.80 µg/g. The highest levels of free DON were found in French samples while Dutch and Russian samples were much less contaminated and French samples contained the highest average free DON concentrations. Conjugated DON was detected in 36%, 38%, 52% and 70% of contaminated samples from Denmark, France, the Netherlands and Russia, respectively. High levels of conjugated DON (>20%) were detected in the majority of Russian samples (17 of 21) and French samples (4 of 12) but no significant differences between concentrations of free DON and total DON content were observed within each country. Samples highly contaminated with DON did not necessarily show a high concentration of conjugated DON. The current survey of free and conjugated DON in European feedstuffs emphasizes the potential challenges in understanding the hazard posed by DON concentration. Although much research has been carried out since the original discovery of free and conjugated DON, the significance of these mycotoxins for animal health remains to be determined.

Key Words: deoxynivalenol, conjugated, feedstuffs

T158 Effects of sorghum particle size on growth performance and carcass characteristics in finishing pigs. C. B. Paulk,* J. D. Hancock, A. C. Fahrenholz, J. M. Wilson, L. J. McKinney, and K. C. Behnke, *Kansas State University, Manhattan.*

A total of 200 finishing pigs (PIC TR4 × 1050; initially 54 kg) were used in a 69-d growth assay to determine the effects of sorghum particle size on growth performance and carcass characteristics. Pigs were sorted by sex, ancestry, and BW with 5 pigs per pen and 10 pens per treatment. Treatments were a corn-soybean meal-based control with the corn milled to a target particle size of 600 µm and sorghum milled to target particle sizes of 800, 600, and 400 µm. Actual mean particle sizes were 555 µm for corn and 724, 573, and 319 µm for sorghum. Pigs were slaughtered (average final BW of 123 kg) at a commercial abattoir and hot carcass weight (HCW) was used as a covariate for analyses of backfat thickness, loin depth, and percentage fat free lean index (FFLI). Pigs fed the sorghum-based treatments were not different ($P > 0.12$) in growth performance, HCW, backfat thickness, loin depth, or FFLI compared with those fed the corn control; however, there was a tendency for pigs fed sorghum based treatments to have improved ($P < 0.07$) dressing percentage. As particle size of sorghum was reduced from 724 to 319 µm, ADG was not affected ($P > 0.39$) but G:F increased (linear effect, $P < 0.01$). Reducing particle size of sorghum had no effect ($P > 0.15$) on HCW, backfat thickness, loin depth, or FFLI, but dressing percentage tended to improve ($P < 0.06$). Regression analysis indicated that sorghum ground to 515 µm supported G:F equal to that of corn ground to 555 µm. In conclusion, linear improvements in G:F were demonstrated with reduction of sorghum particle size from 724 to 319 µm. Moreover, our data suggest that when ground 50 µm finer than corn, sorghum-based diets will support growth performance and carcass measurements equal to corn-based diets.

Table 1.

Item	Corn, 555 µm	Sorghum, 724 µm	Sorghum, 573 µm	Sorghum, 319 µm	SE
ADG, g	1,078	1,128	1,103	1,100	23
ADFI, kg	2.90	3.10	2.99	2.91	0.07
G:F, g/kg	372	365	369	379	4
HCW, kg	88.1	90.6	89.7	90.0	1.8
Dress, %	72.5	72.7	73.0	73.2	0.2
Backfat thickness, mm	22.7	22.1	22.1	22.4	0.9
Loin depth, mm	59.7	60.9	59.9	59.4	0.9
FFLI, %	49.2	49.7	49.5	49.3	0.6

T159 Chemical composition of canola meal, 00-rapeseed meal, and 00-rapeseed expellers. T. Maison* and H. H. Stein, *University of Illinois, Urbana.*

The objective of this work was to compare the chemical composition of canola meal, 00-rapeseed meal, and 00-rapeseed expellers. Eleven samples of canola meal were collected from crushing plants in North America, and 10 samples of 00-rapeseed meal and 5 samples of 00-rapeseed expellers were collected from crushing plants in Europe. All samples were analyzed for GE, DM, CP, AA, ash, acid hydrolyzed ether extract (AEE), crude fiber, ADF, NDF, ADL, glucose, fructose, maltose, sucrose, raffinose, stachyose, verbascose, starch, Ca, K, Mg, Na, P, S, Co, Cr, Cu, Fe, Mn, Mo, Se, Zn, phytic acid, and glucosinolates. Concentrations of these components in canola meals were compared with those in 00-rapeseed meals, and 00-rapeseed meals were compared with 00-rapeseed expellers. Results indicated that concentrations of sucrose, P, K, Zn, and glucosinolates are greater ($P < 0.05$) in 00-rapeseed meal than in canola meal. Concentrations of GE and AEE are greater ($P < 0.05$) in 00-rapeseed expellers than in 00-rapeseed meal, but concentrations of CP, Thr, ash, sucrose, crude fiber, NDF, ADL, Ca, K, Mg, P, S, and Mo, are greater ($P < 0.05$) in 00-rapeseed meal than in 00-rapeseed expellers. For canola meal, concentrations of CP, Ca, Fe, and Mn are greater than values published by NRC (1998), but concentrations of most other nutrients in canola meal are in good agreement with NRC (1998) values. In conclusion, the concentration of glucosinolates is much less in canola meal than in 00-rapeseed meal, and concentrations of AEE and GE are greater in 00-rapeseed expellers than in 00-rapeseed meal. However, concentrations of most other nutrients are greater in 00-rapeseed mal than in 00-rapeseed expellers.

Table 1. Composition of canola meal (CM), 00-rapeseed meal (RSM), and 00 rapeseed expellers (RSE), DM-basis

Item	CM	RSM	RSE
GE,[1] kcal/kg	4,708	4,734	5,143
CP,[2] %	41.4	40.7	38.8
Fat,[1] %	4.3	4.1	12.6
NDF,[2] %	33.6	33.8	27.0

T160 Comparison of growth performance of pigs fed cull chickpeas high in fiber.

J. M. Uriarte,* J. F. Obregon, H. R. Güemez, J. A. Romo, J. M. Romo, and A. Leon, *Universidad Autonoma de Sinaloa.*

The objective of this experiment was to determine the effect of substituting high-fiber (11.3% crude fiber, CF) cull chickpeas for soybean meal and corn on growth performance in pigs. Forty-eight pigs (BW = 32.158 ± 1.148 kg; Large White × Landrace × Large White × Pietrain) in groups of 4 were placed in 12 concrete floor pens (1.5 × 6 m). In a complete randomized experimental design, pigs received one of 3 diets: 1) diet with 17.8% CP, 3.27 Mcal of ME/kg, 0.99% Lys and CF 3.47%; containing 71.5% corn, 26% soybean meal and 2.5% premix (CONT); 2) diet with 17.8% CP and 3.23 Mcal of ME/kg, 1.01% Lys, 5.95% CF, with 47.2% corn, 35% cull chickpeas, 13% soybean meal, 2.3% vegetable oil and 2.5% premix (CHP35), and 3) diet with 17.5% CP and 3.20 Mcal of ME/kg, 1.03% Lys, 8.42% CF, with 22.5% corn, 70% cull chickpeas, 5.0% vegetable oil and 2.5% premix (CHP70). Pigs were weighed at d 0 and 42 of the experiment and feed intake was recorded daily. Average daily gain and feed intake/gain ratio were calculated from these data. Body weight at d 42 was reduced ($P = 0.01$) in pigs fed diets containing cull chickpeas, being 69.8, 58.5 and 47.1 kg for CONT, CHP35 and CHP70, respectively. Average daily gain (0.837 CONT, 0.623 CHP35, and 0.358 kg CHP70) was also reduced ($P = 0.01$) by treatments containing cull chickpeas. Feed intake (2.088, 1.656 and 1.154 kg) was reduced in pigs fed cull chickpeas ($P = 0.01$). Feed/gain ratios (2.687, 2.663 and 3.289) were similar ($P = 0.16$) across treatments. Thus, we concluded that high-fiber cull chickpeas fed at 35% or more of the diet negatively affects growth performance of growing pigs.

Key Words: chickpeas, growth performance, pigs

T161 Standardized ileal digestibility of Illinois bundleflower, low-oligosaccharide soybean meal and conventional soybean meal.

J. A. Jendza* and S. K. Baidoo, *University of Minnesota, Waseca.*

Twenty-four growing pigs were fitted with ileal T-cannula, housed in individual metabolism crates, and used to determine the standardized ieal digestibility (SID) of low-oligosaccharide soybean meal (LOSBM), conventional soybean meal (SBM) and Illinois bundleflower (IBF). The lower fiber content of LOSBM results in higher analyzed concentration of CP and amino acid when compared with SBM. The reduced fiber content in LOSBM was also expected to improve SID of protein and amino acids as compared with SBM. Illinois bundleflower is a relatively novel, high-protein feedstuff for which little nutritional data are available. Treatments consisted of 3 diets formulated to supply all protein from a single source and a fourth N-free diet made primarily from cornstarch and sucrose. Diet 1 contained 33.6% IBF, and supplied 12% CP and 3,600 kcal/kg of DE. Diet 2 contained 25.3% SBM, and supplied 12% CP and 3,725 kcal/kg of DE. Diet 3 contained 22.6% LOSBM, and supplied 12% CP and 3,770 kcal/kg of DE. Diet 4 contained no source of protein, supplied 3,791 kcal/kg of DE, and was used to calculated basal endogenous losses. Digestibility results were compared across treatments using a multiple comparison test, the Tukey adjustment, and with $\alpha = 0.05$. Generally, SID of amino acids were numerically greater for LOSBM than SBM (between 0.54 to 12.13 percentage points higher), but the differences were not significant. On the other hand, the SID of most amino acids in IBF were 20 to 40 percentage points lower than that of SBM ($P < 0.05$). The SID of lysine, methionine, and threonine for SBM were 91.9, 87.8, and 83.2%, respectively. The SID of lysine, methionine, and threonine for LOSBM were 92.4, 88.8, and 86.2%, respectively. The SID of lysine, methionine and threonine for IBF were 73.3, 58.1, and 49.2%, respectively. In conclusion, LOSBM is at least as good a source of SID amino acids as SBM, but the protein value of IBF is much lower.

Key Words: swine, standardized digestibility, ileal cannula

T162 Resistant starch content of cereal grains common utilized for pig nutrition.

G. Giuberti, A. Gallo, M. Rzepus, M. Moschini, and F. Masoero,* *Università Cattolica del Sacro Cuore, Piacenza, Italy.*

Resistant starch (RS) has been defined as the portion of starch that is not hydrolyzed by the enzymes in the small intestine. Therefore it passes to the large bowel, where can be principally fermented to short-chain fatty acids. In pigs, diets containing starch with a high level of RS were associated with a greater digesta mass that may benefit the diversity and population of gut bacteria and may improve the production of short-chain fatty acids, including butyrate. However, high-RS diets may affect digestion of nutrient, were associated with a lower in vivo starch digestibility and feed efficiency and can exacerbate the expression of swine dysentery. Currently, limited information is available about the RS content of single cereal grains commonly employed in pig nutrition. Consequently a set of 42 raw samples (6 maize, 6 dehulled barley, 6 triticale, 6 rice, 6 high moisture corn or HMC, 6 wheat and 6 sorghum) randomly collected from international feed companies was evaluated for the RS content with a 2-steps in vitro method simulating gastric and pancreatic phases. Following Englyst classification of starch fractions, RS was measured considering the starch not hydrolyzed after 120 min of enzymatic incubation. Data were subject to one-way ANOVA and significance were declared at $P < 0.05$. Minimum significant difference (MSD) was generated from Tukey′s test and was used as the basis of the multiple comparisons among means. Cereals were characterized by a wide range of RS content ($P < 0.05$) and the MSD was 53 g/kg DM. In particular, sorghum had the highest RS content (262 ± 31 g/kg DM; $P < 0.05$), whereas wheat the lowest (53 ± 27 g/kg DM; $P < 0.05$). Intermediate RS values were recorded for dehulled barley (133 ± 31 g/kg DM), triticale (138 ± 40 g/kg DM), HMC (142 ± 25 g/kg DM), rice (165 ± 29 g/kg DM) and corn (191 ± 22 g/kg DM) samples. A proper evaluation of the RS content of cereal grains could be important for a complete feed evaluation. However, more research is warranted to increase knowledge about the role of RS on metabolic and productive responses in pigs.

Key Words: resistant starch, in vitro method, pig

T163 Effects of molasses supplementation on the growth performance, nutrient digestibility, blood characteristics, fecal moisture, and fecal noxious gas emission in growing pigs.

J. Li*[1], X. Y. Guo[1], D. S. Nam[2], and I. H. Kim[1], [1]*Department of Animal Resource & Science, Dankook University, Cheonan, Choongnam, South Korea,* [2]*Nonghyup Feed Co. Ltd., Seoul, South Korea.*

A total of 120 growing pigs [(Landrace × Yorkshire) × Duroc, BW = 22.81 ± 1.21 kg] were used in a 5-week feeding trial to evaluate the effects of dietary administration of molasses on growth performance, apparent total tract digestibility (ATTD), blood characteristics, fecal moisture, and fecal noxious gas emission. Pigs were randomly distributed into 1 of 3 dietary treatments on the basis of BW. Each treatment had 10 replicate pens with 4 pigs per pen. Dietary treatments were: CON, basal diet; T1, CON + 2.5% molasses; T2, CON + 5.0% molasses. The cane molasses used in this trail contained 4.12% CP and 9.234 MJ/kg ME (feed basis). All diets were formulated to meet or exceed the NRC requirements for growing pigs. All pigs were housed in an environmentally controlled room with a full slatted plastic floor. Each pen was equipped with a one-sided, stainless steel self-feeder and a nipple drinker, pigs were allowed ad libitum access to feed and water. No differences ($P > 0.05$) were observed in ADG, ADFI, or G:F among dietary treatments. There were no differences ($P > 0.05$) in the ATTD of DM, N, and energy among dietary treatments. No effects ($P > 0.05$) were observed on the concentrations of RBC, WBC, and lymphocyte percentage. The fecal moisture was not affected ($P > 0.05$) by the supplementation of molasses. The fecal acetic acid emission in T2 treatment was lower ($P < 0.05$) than that in CON treatment on d 3, 5 and 7, but no difference ($P > 0.05$) was observed in the ammonia (NH_3) emission among treatments. This study indicated that the supplementation with 5% molasses in growing pig diets reduced the fecal acetic acid emission, without negative effects on the growth performance of growing pigs.

Key Words: growing pigs, growth performance, molasses

T164 Effects of fermented corn by *Bacillus subtilis* on the growth performance, nutrient digestibility, fecal microbial shedding, and fecal noxious gas emission in growing pigs.

J. H. Jung,* H. Y. Baek, and I. H. Kim, *Department of Animal Resource & Science, Dankook University, Cheonan, Choongnam, South Korea.*

A total of 160 growing pigs [(Landrace × Yorkshire) × Duroc, BW = 27.3 ± 0.47 kg] were used in a 6-week growth experiment to investigate the effects of fermented corn by *Bacillus subtilis* on growth performance, nutrient digestibility, fecal microbial shedding, and fecal noxious gas emission. Pigs were allotted to 1 of 5 dietary treatments (8 replicate pens per treatment with 4 pigs per pen) based on their initial BW using a randomized complete block design. All the pigs were housed in an environmentally controlled room with a slatted plastic floor. Each pen was equipped with a 1-sided self-feeder and a nipple drinker, pigs were allowed *ad libitum* access to feed and water throughout the experimental period. Dietary treatments were: 1) CON (basal diet); 2) FC3, CON + 3% fermented corn; 3) FC6, CON + 6% fermented corn; 4) FC9, CON + 9% fermented corn; 5) FC12, CON + 12% fermented corn. Common corn was fermented by *Bacillus subtilis* 2–19cx for 48 h (35–40°C). The counts of *Bacillus subtilis* in fermented corn are 10^9 cfu/gram. An adjustment period with same corn-soybean meal was provided 3 d before the experiment. Pigs fed the FC6 and FC9 diets led to a greater ($P < 0.05$) ADG than those fed the CON and FC3 diets. FC6 treatment significantly increased ($P < 0.05$) G:F compared with CON treatment. No difference ($P > 0.05$) was observed in the nutrient digestibility throughout the experiment. The inclusion of fermented corn did not affect ($P > 0.05$) the fecal *Lactobacillus* and *E. coli* population. No difference was noted in fecal ammonia, H_2S, total mercaptans, and acetic acid emission. In conclusion, fermented corn could be used as a good feed material for growing pigs, with its optimal supplementation level at 6%. The inclusion of fermented corn did not affect the fecal microbial shedding, and fecal noxious gas emission in the current study.

Key Words: *Bacillus subtilis*, fermented corn, growing pig

T165 Apparent dry matter digestibility and nitrogen balance in pigs fed high fiber diets.

A. Woldeghebriel,* S. Smith, T. Barios, and B. Pope, *North Carolina A&T State University, Greensboro.*

The current study was conducted to investigate the effects of feeding high fiber diet on apparent total tract dry matter digestibility and nitrogen balance in growing pigs. Sixteen barrows averaging 16.4 kg were randomly assigned to 1 of 4 diets after metabolic crate assignments with individual pig serving as experimental unit. Diets included a corn-soybean meal basal diet as the control (CON), and 3 antibiotic-free, high-fiber diets (D1, D2 and D3) each containing 5% sugar beet pulp plus one of the following: 1:2, 1:1, and 2:1 oat to barley ratios. Diets were formulated to contain similar amounts of protein (18% CP) and energy (3.415 Mcal DE/ kg) and were supplemented with minerals and vitamins to meet NRC nutrient recommendations. However, the fiber content of the CON diet was much lower than the average of the 3 high-fiber diets (8.38% vs. 22.40% NDF). Pigs had free access to water, but feed allowance was limited to 10% of average initial body weight and fed twice daily. The study period was divided into a 10 d adjustment period and a 5 d collection of urine and feces. Data were analyzed using SAS procedures where animals were considered random effects, and diet means were used to compare treatment effects. Results of the study indicated that DM and N intakes in pigs fed D2 and D3 were higher ($P < 0.05$) than CON or D1-fed pigs. However, there was no significant difference in DM and N intakes between D2 and D3, or between CON and D1-fed pigs. The lowest ($P < 0.05$) apparent dry matter digestibility coefficient determined was for D1-fed pigs, with no significant differences among the rest of the treatment groups. The averages for total and fecal N losses in pigs fed high-fiber diets were higher ($P < 0.05$) than CON-fed pigs. Relatively higher fecal and lower urinary N losses were observed as oat to barley ratios increased, but differences observed were not statistically significant. It seems therefore, N-excretion had shifted from urine to feces indicating that microbial mass in feces increases as the amount of fiber in the diet increases.

Key Words: dietary fiber, oats, nitrogen loss

T166 Effects of supplemental zinc amino acid complex on physiology and performance in heat-stressed growing pigs. M. V. Sanz-Fernandez*[1], S. C. Pearce[1], L. R. Long[1], N. K. Gabler[1], J. F. Patience[1], M. E. Wilson[2], M. T. Socha[2], R. P. Rhoads[3], and L. H. Baumgard[1], *[1]Iowa State University, Ames, [2]Zinpro Corporation, Eden Prairie, MN, [3]Virginia Polytechnic Institute and State University, Blacksburg.*

Heat stress (HS) reduces livestock productivity and this may in part be caused by leaky gut. We have recently demonstrated that supplementing Zn amino acid complex (ZnAA) improves intestinal barrier function in HS pigs (Sanz-Fernandez et al., 2012). Consequently, we hypothesized that ZnAA would improve pig performance during HS. Crossbred gilts (n = 59; 43 ± 6 kg BW) were subjected to 3 experimental periods (P). During P-1 (20 d), pigs were housed in groups in thermo-neutral (TN) conditions (19°C, 61% RH) and ad libitum fed 1 of 3 diets: 1) control (120 ppm of Zn from $ZnSO_4$; n = 29), 2) control + 100 ppm ZnAA from Availa Zn (Zinpro Corporation; Zn220; n = 14), and 3) control + 200 ppm ZnAA from Availa Zn (Zn320; n = 16). Pigs remained on their diets throughout the whole experiment. During P1 (5 d), pigs were moved into individual pens in TN conditions. During P2, half of the controls (n = 13), and all the Zn220 and Zn320-fed pigs were exposed to constant HS conditions (36°C, 50% RH) and fed ad libitum; the other half of the control pigs (n = 16) remained in TN conditions and were pair-fed (PF) with the HS pigs to eliminate the confounding effects of dissimilar feed intake (FI). Pigs were sacrificed at d 1 or 7. As expected, there were no treatment differences in rectal temperature (Tr) or respiration rates (RR) during P1. During P2, HS pigs had increased Tr ($P \leq 0.01$; 40.23 vs. 38.37°C) and RR (114 vs. 37 bpm) compared with PF pigs. Within the HS groups, Tr linearly increased ($P \leq 0.05$) with increasing levels of ZnAA (40.6 vs. 40.31°C). Heat stress markedly reduced FI ($P \leq 0.01$; 60%), and ZnAA did not ameliorate this decrease. There were no treatment differences in ADG during P-1, but during P1 there was a quadratic response ($P \leq 0.05$) as Zn220-fed pigs outgained (8.5%) controls and Zn320-fed pigs. On d 1 of P2, pigs in all treatments lost a similar amount of BW (3.24 kg). By d 7, the PF pigs tended ($P \leq 0.10$) to lose more BW than the HS pigs (3.63 vs. 0.02 kg), but feeding ZnAA did not improve BW loss. Data from this small experiment indicate that supplementing ZnAA did not prevent reduced performance during severe HS.

Key Words: heat stress, zinc amino acid complex, pig

T167 Evaluation of the antioxidative capacity of *Lactobacillus plantarum* in vitro and its antioxidative effect on weaned pigs. H. F. Ji,* J. Wang, L. Hou, S. X. Wang, D. Y. Zhang, H. Liu, and Y. M. Wang, *Institute of Animal Husbandry and Veterinary Medicine, Beijing Academy of Agriculture and Forestry Sciences, Beijing, China.*

This study was conducted to evaluate the antioxidative capacity of *Lactobacillus plantarum* and its effects on antioxidant enzyme levels in weaned pigs. The strain of *Lactobacillus plantarum* was originally isolated from the gastrointestinal tract of healthy weaned pigs in our laboratory and strains were identified by the China Center of Industrial Culture Collection. The antioxidant capacity of *Lactobacillus plantarum* was analyzed in vitro. Resistance of this strain to reactive oxygen species (ROS), such as hydrogen peroxide, superoxide anions, hydroxyl radicals, and DPPH (1,1-diphenyl-2-picrylhydraxyl) was determined. The result showed that over 90% of *Lactobacillus plantarum* cells were viable after 240 min of incubation in the presence of 1.0 mmol/L hydrogen peroxide. The free radical scavenging activity of *Lactobacillus plantarum* against superoxide anions, hydroxyl radicals, and DPPH increased along with the increase of *Lactobacillus plantarum* concentration. Subsequently, 48 piglets weaned at 28 d of age (8.02 ± 0.49 kg BW), were divided into 3 dietary treatments comprising of a basal diet or the basal diet supplemented with chlortetracycline at 50 mg/kg or 5.1×10^7 *Lactobacillus plantarum* cfu/g diet. The experiment lasted 4 weeks. Data were analyzed statistically by using ANOVA procedures of SAS (SAS 1996). The results showed that the supplementation of *Lactobacillus plantarum* had higher average daily gain compared with basal diet control (505 vs. 463 g/d; $P < 0.05$) and lower feed conversion ratio compared with basal diet and antibiotic control (1.62 vs. 1.78, 1.71; $P < 0.05$). Supplementation of *Lactobacillus plantarum* increased serum superoxide dismutase (127.6 U/ml; $P < 0.05$) and glutathione peroxidase (478.4 U/ml; $P < 0.05$), while malondialdehyde levels decreased (4.10 nmol/ml; $P < 0.01$) in serum of weaned pigs. In general, *Lactobacillus plantarum* had high antioxidant capacity and its supplementation improved the antioxidant status of weaned pigs, and it could be used to alleviate oxidative stress and increase growth performance of weaned pigs.

Key Words: *Lactobacillus plantarum*, antioxidative capacity, weaned pig

T168 Evaluation of Oleobiotec in the diet of broilers challenged with *Clostridium perfringens* compared with an antibiotic administered continuously in feed. V. Noirot, P. Etienne, M. Champagnac, and D. Eclache,* *Laboratoires Phodé, Terssac, France.*

The product Oleobiotec (Laboratoires Phodé, France), a formulation of plant active principles among which spices extracts and characterized essential oils, was tested on male broiler chickens challenged with *Clostridium perfringens* on a Canadian experimental farm. Three hundred 1-d-old Ross × Ross broiler chickens were divided into 2 groups of 6 replicate pens of 25 birds. They were slaughtered at 38 d at a minimum weight of 2.5 kg. The control group was fed basal diet supplemented with 55 ppm of bacitracin methylene disalicylate (BMD-110). The treated group received the same basal diet supplemented with Oleobiotec (200, 150 and 100 ppm in starter, grower and finisher feeds, respectively). Contamination of the litter was carried out by dispersing the litter of clostridia infected flocks. Microbial pressure was increased by high dose (× 40) of a live anticoccidial vaccine (Coccivac) at 9 d and by a diet rich in wheat. The chickens did not receive any in-feed anticoccidials. The chickens were weighed individually at 0, 7, 17, 30, and 38 d. Feed intake and feed conversion ratio were evaluated for each pen and group at weighing time. Dead birds were recorded daily. Contamination of the litters was checked by pen at 21 and 38 d using the most probable number (MPN) method using McGrady′s probability table and was not significantly different between treatments (J21: 39 vs. 195 MPN of spores/g; J38: 47 vs. 70 MPN of spores/g for control and Oleobiotec respectively, $P > 0.05$). Death rate was lower with Oleobiotec (3.4%) than with BMD (6.0%), but the difference was not significant ($P > 0.05$). Body weight at 30 d of age was reduced with Oleobiotec (1831 g vs. 1881 g for the control, $P < 0.05$). Oleobiotec produced similar results on average daily gain and feed conversion ratio to BMD ($P > 0.05$). In this study, Oleobiotec enabled us to obtain similar performances on broilers challenged with *Clostridium perfringens* to bacitracin zinc.

Key Words: plant extract, broiler chicken, *Clostridium perfringens*

T169 Ingestion of a novel galactoglucomannan oligosaccharide-arabinoxylan (GGMO-AX) complex affected growth performance and fermentative and immunological characteristics of broiler chicks challenged with *Salmonella typhimurium*. T. A. Faber*[1], R. N. Dilger[1], M. Iakiviak[1], A. C. Hopkins[2], N. P. Price[3], and G. C. Fahey Jr.[1], *[1]University of Illinois, Urbana, [2]Temple-Inland, Diboll, TX, [3]National Center for Agricultural Utilization Research (NCAUR), ARS-USDA, Peoria, IL.*

Fermentable carbohydrates may enhance the ability of the gastrointestinal tract to defend against a pathogenic infection. We hypothesized that a galactoglucomannan oligosaccharide-arabinoxylan (GGMO-AX) complex would positively affect immune status and prevent colonization and shedding in *Salmonella typhimurium* (ST)-infected chicks. Using a completely randomized design, one day old commercial broiler chicks (n = 240; 4 replications/treatment; 5 chicks/replication) were assigned to 1 of 6 dietary treatments differing in concentration of GGMO-AX (0, 1, 2, or 4%) or containing 2% Safmannan (Saf) or 2% short-chain fructooligosaccharides (scFOS). Cellulose was used to make diets iso-total dietary fiber (TDF). On d 10 post-hatch, an equal number of chicks on each diet were inoculated with either phosphate buffered saline (sham control) or ST (1×10^8 cfu). All birds were euthanized on d 10 post-inoculation (PI) for collection of intestinal contents and select tissues. Overall, body weight gain and feed intake of chicks was greater ($P < 0.05$) in infected chicks PI, except for weight gain on d 0–3 PI. Gain:feed was affected ($P < 0.05$) by diet, with Saf-fed chicks having the highest G:F. The GGMO-AX substrate demonstrated prebiotic-like effects as indicated by increased cecal short-chain fatty acid concentrations, decreased cecal pH, and increased populations of *Lactobacillus* spp. and *Bifidobacteria* spp. as dietary GGMO-AX concentration increased. Excreta ST populations on d 5 and 10 PI, and ileal and cecal ST populations, tended to be affected ($P < 0.10$) by diet. Messenger RNA expression of IFN-γ in the cecal tonsils was the only cytokine independently affected by infection and diet ($P < 0.01$). Chicks fed 2 and 4% GGMO-AX had similar expressions of IFN-γ and IL-1β, regardless of infection, suggesting that ST virulence was suppressed. Dietary supplementation with GGMO-AX resulted in prebiotic-like effects, but did not limit ST intestinal colonization or shedding, but possibly decreased the virulence of ST within the digestive tract.

Key Words: chick, galactoglucomannan oligosaccharide (GGMO), *Salmonella typhimurium*

T170 Effects of oligosaccharides in a soybean meal-based diet on fermentative and immune responses in broiler chicks challenged with *Eimeria acervulina*. T. A. Faber*[1], R. N. Dilger[1], A. C. Hopkins[2], N. P. Price[3], and G. C. Fahey Jr.[1], *[1]University of Illinois, Urbana, [2]Temple-Inland, Diboll, TX, [3]National Center for Agricultural Utilization Research (NCAUR), ARS-USDA, Peoria, IL.*

Fermentable oligosaccharides, particularly those found in soybean meal (SBM), may modulate fermentation in the ceca, thus affecting intestinal immune responses to intestinal pathogens. We hypothesized that fermentable oligosaccharides found in SBM would positively affect cecal fermentation and intestinal immune status in chicks challenged with an acute coccidiosis (*Eimeria acervulina*) infection and fed either a SBM-based diet or a semi-purified soy protein isolate- (SPI) based diet. Using a completely randomized design, day-old broiler chicks (n = 200; 5 replications/treatment; 5 chicks/replication) were assigned to one of 4 SBM- or SPI-based diets containing either dietary cellulose (4%) or a fermentable carbohydrate, galactoglucomannan oligosaccharide-arabinoxylan (GGMO-AX) complex (4%). On d 9 post-hatch, an equal number of chicks on each diet were inoculated with either distilled water (sham control) or *E. acervulina* ($1\text{x}10^6$ oocysts) and then euthanized on d 7 post-inoculation (PI). Overall, body weight gain and feed intake were greater ($P < 0.01$) for SBM-fed chicks, regardless of infection status. Gain:feed ratio was greater ($P \leq 0.05$) for SPI-fed chicks except during d 3–7 PI. Infection status, but not fiber source, affected propionate, isobutyrate, isovalerate, and total BCFA concentrations ($P \leq 0.02$). Soybean meal-based diets resulted in greater ($P \leq 0.04$) SCFA and BCFA concentrations than SPI-based diets. Messenger RNA fold changes of all duodenal cytokines were greater ($P \leq 0.01$) for infected chicks, and SBM-fed chicks had greater ($P < 0.01$) IFN-γ and IL-12β expression compared with SPI-fed chicks. Cecal tonsil cytokine expression was also affected ($P \leq 0.02$) by infection; however, protein source only affected ($P < 0.01$) IL-1β expression in this tissue. Overall, a SBM-based diet, compared with a semi-purified SPI-based diet, resulted in greater weight gain, feed intake, and SCFA production regardless of infection status, and also greater duodenal cytokine expression in *E. acervulina*- infected chicks, which is hypothesized to be related to the oligosaccharides found in SBM.

Key Words: chick, coccidiosis, galactoglucomannan oligosaccharide (GGMO)

T171 Effect of *Lactobacillus gasseri* from chicken origin on the production performance, intestinal flora, and immune function of broiler chickens. X.-H. Teng,* X. Li, and J. Li, *College of Animal Science and Technology, Northeast Agricultural University, Harbin, Heilongjiang, China.*

Many studies have shown that *Lactobacillus* dominates in normal animal intestinal tract and it is very important to maintain a healthy body. The objective of this research was to determine the effect of *L. gasseri*, which was separated, filtrated and prepared from chicken cecum in our laboratory, on production performance, intestinal flora and immune function of broiler chickens. A total of 150 AA broiler chickens at 1 d of age were randomly divided into 5 groups by sex and body weight, with 3 replicates per group and 10 chickens (5 female and 5 male) per replicate. The test data was analyzed by SPSS 16.0. A control group received the basal diet, while groups 1, 2, 3 and 4 received the basal diet supplemented with 1) 5mg/kg Flavomycin, 2) 1% lactobacillus of plant origin (as control group using a commodity product), 3) 0.73% *L. gasseri*, and 4) 0.73% *L. gasseri* plus 0.02% xylooligosaccharide, respectively. The results showed that average daily gain and average daily feed intake of 6-week-old broiler chickens in control group was lower ($P < 0.05$) than in groups of 1, 3 and 4. There was no difference ($P < 0.05$) in feed/gain ratio between control and treatment groups. For the intestinal flora, the number of *Lactobacillus* in the control group was lower ($P < 0.05$) than in groups of 2,3 and 4, but the number of *E. coli* in the control group was higher ($P < 0.05$) than in groups of 2, 3 and 4. Concentrations of IgA and IgG, weights of the thymus and bursa of Fabricius, and spleen index scores in the control group were lower ($P < 0.05$) than in groups of 3 and 4. Additionally, spleen index scores in group 1 was higher ($P < 0.05$) than in control group. There were no significant differences ($P > 0.05$) for other response variables in group of 1 compared with control group. The results suggested that addition of *L. gasseri* to diets could improve production performance and may alter intestinal flora and immune function of broiler chickens compared with a flavomycin-containing diet.

Key Words: *Lactobacillus gasseri*, production performance, immune function

T172 Effect of supplementing curcumin as feed additive on the performance, biochemical profile, immune response and carcass characteristics in broilers. M. Pavani[1], Y. Ramana-Reddy*[1], P. Gopal-Reddy[2], S. R. Sakunthala-Devi[1], T. Monika[1], M. Sudhakar-Reddy[1], and A. Gopal-Reddy[1], *[1]S.V. Veterinary University, Tirupati, Andhra Pradesh, India, [2]Tuskegee University, Tuskegee, AL.*

An experiment was designed to study the effect of curcumin at 0.0, 0.1, 0.2 and 0.3% level in the feed on the performance, serum biochemical profile, immune response and carcass characteristics in broilers. One hundred sixty broiler chicks (vencobb strain) were randomly divided into 4 equal groups having 8 replicates of 5 each and fed the experimental diets (starter 0–3 wk; finisher 4–6 wk) for 6 weeks with 0.0, 0.1, 0.2 and 0.3% curcumin. Sera samples were collected for biochemical profile on d 42. All the biochemical parameters studied were estimated by commercially available kits (M/S Qualigens India Ltd.). Cell medaited (PHA-P response) and humoral (SRBC titers) responses were observed by Corrier and Deloach, (1990) and Wegmann and Simthies, (1966) methods, respectively. Eight birds from each treatment were slaughtered at the end of the experiment for studying the carcass characteristics. The experimental data was analyzed by completely randomized design (CRD). The average daily gain (g), feed intake (g/d) and feed efficiency (kg/kg gain) in broilers were not affected by the curcumin levels in the diet. Serum glucose, total protein, albumin, triglycerides, creatinine, urea (mg/dl), SGOT, SGPT and alkaline phosphatase (IU/L) were also not influenced by the level of curcumin in the diet. However, cholesterol level (mg/dL) was significantly ($P < 0.01$) lower in broilers fed diets with different levels of curcumin compared with those fed control diet. Further, humoral and cell mediated responses were significantly ($P < 0.01$) higher in broilers fed diets with different levels of curcumin compared with control but the responses were not significantly different among the broilers fed diets with 0.1, 0.2 and 0.3% level curcumin. Dressing percentage and vital organs weight (g/kg carcass wt) such as liver, heart and gizzard were similar among the broilers fed experimental diets. Weights of the lymphoid organs (g/kg carcass wt), spleen, bursa and thymus was significantly ($P < 0.05$) higher in broilers fed curcumin supplemented diets but among the different levels of curcumin, the values were not significantly different.

Key Words: curcumin, broilers, performance

T173 Effect of a mixture of turmeric and capsicum oleoresins on performance and oocyst excretion of broilers challenged with coccidiosis. C. Oguey*[1], V. Brito[2], A. Casarin[3], and M. Forat[3], *[1]Pancosma, Geneva, Switzerland, [2]Euronutec, Queretaro, Mexico, [3]Instituto Internacional de Investigacion Animal, Queretaro, Mexico.*

Capsicum and turmeric are known to stimulate innate immunity. So combining these 2 plant extracts should improve performance of birds infected by *Eimeria*. The objective of this trial was to evaluate the effect of a mixture of capsicum and turmeric oleoresins (XT, XTRACT 6986, Pancosma) on performance and oocyst excretion of broilers challenged with coccidiosis. One day old male broilers were randomly allocated for 52 d to 1 the 2 following treatments (48 birds * 12 cages / treatment): PC = 50 ppm Roxarsone + 110 ppm Monensin + 7.5 ppm Avilamycine, and XT = 50 ppm Roxarsone + 110 ppm Monensin + 100 ppm XT. All birds were challenged to Eimeria spp. via litter spray at d14. FI, BW, BWG, FCR and oocyst excretion (expressed as log10) were recorded. Data were analyzed using GLM procedure of SAS. Before challenge, no oocysts were excreted and FI, BWG and FCR were similar between PC and XT ($P > 0.37$), showing the positive effect of XT on performance in the absence of infection. After challenge, final BW, BWG and FCR were also similar between PC and XT ($P > 0.25$). This demonstrated that the substitution of avilamycine with XT can maintain the performance of challenged birds. Oocyst excretions of E. acervulina and E. maxima were similar between the 2 treatments ($P > 0.32$). For E. tenella, birds in XT excreted the same amount of oocysts after 14 and 21 d of infection compared with PC (respectively 0.97 vs. 1.69 log after 14 d, $P = 0.25$ and 3.62 vs. 4.04 log after 21 d, $P = 0.12$) but excreted more oocysts 28 d after challenge (3.354 vs. 2.608 log, $P = 0.02$). This suggests that XT did not have the same effect as avilamycine on oocysts shedding. However, XT could be used to substitute this drug with no negative effect on performance of broilers challenged with coccidiosis.

Key Words: phytonutrients, poultry, coccidiosis

T174 Preventive supplementation with L-arginine and glutamine improved self-renewing of intestinal mucosa in LPS-injected rats. X. Wu[1,2], C. Zhang[1,2], Z. Ruan[2], Z. Deng[1], and Y. Yin*[1,2], *[1]State Key Laboratory of Food Science and Technology and College of Life Science and Food Engineering, Nanchang University, China, [2]Institute of Subtropical Agriculture, Chinese Academy of Sciences, China.*

To evaluate the effect of preventive supplementation with L-arginine and glutamine on self-renewing of intestinal mucosa in lipopolysaccharide (LPS)-injected rats, 40 Sprague Dawley rats (average weight of 185 ± 15 g) were randomly divided into 5 treatment groups: control groups A (CA) and B (CB), both receiving daily oral supplementation with 0.9% saline, 300 mg/kg per day arginine (Arg), 300 mg/kg per day glutamine (Gln), or 150 mg/kg per day each of Arg plus Glu (AG). At 10:00am on d 15, animals were injected with 4 mg/kg LPS (groups CB, Arg, Gln, and AG) or sterile saline (group CA) after oral supplementation. Four hours later, all animals were killed for blood and intestinal mucosa collection. Real-time PCR was used to detect mRNA abundance of β-catenin, proliferating cell nuclear antigen (PCNA), vascular endothelial growth factor (VEGF), and hepatocyte growth factor (HGF) in intestinal mucosa. Data were analyzed as a one-way ANOVA. The results showed that plasma amino acids in the AG group tended to be similar with the control group. The combination of Arg and Gln supplementation mitigated morphology impairment (lower villus height, $P < 0.05$) in jejunum induced by LPS. Overall, LPS administration resulted in a significant increase in VEGF and HGF mRNA abundance in jejunum ($P < 0.05$). The combination of Arg and Gln increased PCNA mRNA abundance in both jejunum and ileum ($P < 0.05$), while they also increased β-catenin and decreased VEGF in ileum ($P < 0.05$). There were no differences in mRNA expression of these genes between the Arg and Glu groups ($P > 0.05$). Arg only increased PCNA mRNA abundance in jejunum and Gln decreased VEGF mRNA in jejunum ($P < 0.05$). These results suggest combined oral supply of Arg and Gln has more favorable effects on proliferation and differentiation of stimulated intestinal epithelium cells in LPS-induced rats compared with Arg or Gln alone.

Key Words: arginine, glutamine, intestinal epithelium cells

T175 Effects of different levels of dihydromyricetin from *Ampelopsis grossedentata* in feed on growth performance, immune and antioxidantive activities in *Sarotherodon* sp. X. Shu[1], l. C. Cai[1,2], and Y. L. Yin*[1], *[1]Institute of Subtropical Agriculture, Chinese Academy of Sciences, Changsha, Hunan, China, [2]Institute of Biological Resources, Jiangxi Academy of Science, Jiangxi, Nanchang, China.*

The experiment was conducted to study effects of adding dihydromyricetin (DMY), natural herb extract from *Ampelopsis grossedentata* in feed on growth performance, immune and antioxidantive activities in fish. In this experiment, a total of 720 *Sarotherodon* sp. with average body weight of 13.57 g was randomly allocated to 24 glass tanks and assigned to 6 treatments: 5 levels of DMY (0.1%, 0.2%, 0.4%, 0.8% and 1.6%) and one control (basal diet). Feed was offered to the fish twice daily during the 8-week trial. Feed intake (FI) and survival rate were recorded daily, and live weight gain (WG), average daily gain (ADG) and feed efficiency were calculated. At 4 and 8 wk of age, 5 fish from each group were randomly selected to collect blood into sterile centrifuge tubes for further analysis. Data was analyzed as a complete randomized design by the one-way ANOVA using SPSS, and Duncan multiple range test was used to compare treatment means. The results suggested that treatment with 0.1%, 0.2%, 0.4% and 0.8% DMY were not different ($P > 0.05$) from the control, but 1.6% DMY enhanced ($P < 0.05$) body weight gain and decreased ($P < 0.05$) feed conversion. The serum content of total protein increased ($P < 0.05$) and the activities of serum lysozyme (LSZ), superoxide dismutase (SOD) and catalase (CAT) were improved ($P < 0.05$) in all treatments containing DMY. Fish survival rate was also improved with DMY addition compared with the control treatment, with survival being highest for the 0.4% DMY treatment. In conclusion, dietary supplementation of 0.1% to 1.6% DMY can improve *Sarotherodon* sp. performance, survival, and serum indices.

Key Words: fish, nutrition, growth

T176 Effects of mild heat stress on growth and carcass characteristics in broiler chickens. E. Sucu[1,2], M. V. Sanz-Fernandez[1], S. C. Pearce[1], A. Nayeri[1], G. P. Murugesan[1], R. R. Rhoads[3], M. E. Persia[1], and L. H. Baumgard*[1], *[1]Department of Animal Science, Iowa State University, Ames, [2]Department of Animal Science, Uludag University, Bursa, Turkey, [3]Department of Animal Science, Virginia Polytechnic Institute and State University, Blacksburg.*

Heat stress (HS) markedly alters bioenergetics in a variety of farm animals but how HS affects growth, carcass characteristics, and metabolic responses in broiler chickens has not been thoroughly evaluated. Thirty-six Ross male chickens, 28 d of age (1120 ± 20 g BW) were housed in climate chambers at the Iowa State University Zumwalt Station and exposed to one of 2 environmental conditions: 1) thermal neutral (TN) conditions (constant 25°C) with ad libitum water and feed intake (n = 15) or 2) mild HS conditions (constant 35°C) and ad libitum water and feed intake (n = 21). A blood sample was collected via cardiac puncture, and liver, abdominal fat pad and breast muscle were immediately weighed following sacrifice at 24 h, 3 d or 7 d of environmental exposure. All animals were feed restricted for 6 h before sacrifice. All data were analyzed using the PROC MIXED procedure of SAS (SAS Inst. Inc. Cary NC). The statistical analysis included the effects of environmental treatment, day of sacrifice and their interaction. Overall, HS birds had an increased rectal temperature compared with TN birds ($P < 0.05$, 41.7 ± 0.07 vs. 41.2 ± 0.08°C) and this temperature difference tended ($P = 0.13$) to become less pronounced with time. There was a treatment by time interaction ($P < 0.05$) on body weight gain as ADG was decreased by 77, 40 and 22% in HS compared with TN birds at d 1, 3 and 7, respectively. The temperature and ADG data indicate the birds were acclimating to the mild heat strain. Overall, compared with TN birds, actual liver weight and liver weight as a percentage of BW were decreased ($P < 0.05$) in HS birds (15 and 9%, respectively), but liver lipid content (4.22%) and liver dry matter (25.5%) did not differ between environmental treatments. The abdominal fat pad (22.6 g), breast muscle (137.5 g) and plasma insulin (1.3 ng/ml) levels did not differ between environments. Results of this study indicate that a mild but constant heat strain markedly reduces productivity and alters liver weight in broiler chickens. Reasons why HS affected liver weight are unknown but are of bioenergetic interest.

Key Words: heat stress, broiler chicken, metabolism

T177 Effect of season on copper concentration in blood serum from goats in different reproductive status. R. Rojo, B. Albarrán-Portillo, A. García-Martínez, J. Cedillo-Monroy, and J. F. Vázquez-Armijo,* *Centro Universitario UAEM Temascaltepec, Universidad Autónoma del Estado de México, Temascaltepec, México, Mexico.*

The effect of season (rainy: RS, and dry: DS) on copper (Cu) concentration in blood serum of crossbred goats were studied. Blood samples from 40 crossbred goats were taken each season. The goats were clustered into 5 different groups considering their reproductive status, as follows: pubertal goats, anestrous adult goats, cyclic adult goats, pregnant goats, and kidded goats. Concentration of Cu in blood serum (mg/L) were assayed using atomic absorption. Data were analyzed for a completely randomized design with a factorial arrangement with 8 replicates. Blood serum concentration of Cu were 1.15, and were affected by reproductive status, season, and their interaction. Blood serum concentration of Cu were lower in RS (0.92) than DS (1.37) ($P < 0.05$). Overall, kidded goats had the highest ($P < 0.01$) Cu concentration (RS: 0.98 ± 0.07; DS: 1.95 ± 0.06) than other animals in both seasons. Adult goats showed a deficiency of Cu concentration in blood serum, especially during RS (0.88 ± 0.09). However, the lowest value obtained was to Pubertal goats in RS (0.69 ± 0.07). The results reflect the different requirements imposed by reproductive status and season interaction on goats.

Key Words: copper, blood serum, goats

T178 Effects of the beta-2 adrenergic agonist zilpaterol hydrochloride in castrated male goats: Plasma insulin, cortisol, thyroids, triglyceride, and glucose concentrations. A. Hatefi*[1], A. Towhidi[1], A. Zail[1], M. Ganjkhanlou[1], and A. Plascencia[2], *[1]Department of Animal Science, University of Tehran, Karaj, Alborz, Islamic Republic of Iran, [2]Instituto de Investigaciones en Ciencias Veterinarias, Universidad Autónoma de Baja, California Mexicali, Baja California, México.*

To evaluate the influence of zilpaterol hydrochloride (Zilmax, Intervet, South Africa) supplementation on blood insulin, cortisol, T3 and T4 (as thyroid hormones) and the metabolites glucose and triglyceride, 16 Mahabadi castrated male goats were individually fed a dry-rolled barley-based finishing diet with or without zilpaterol hydrochloride supplementation dosed at 0.20 mg/kg BW/d for finishing 30 d of 90 d feedlot period. Blood samples were taken at first and end of supplementing period and plasma was stored at –20°C until analysis. These samples were quantified by spectrophotometry procedure for glucose and triglyceride, by RIA for insulin and cortisol and triiodothyronine (T3) and thyroxin (T4) were determined according to standard ELISA methods. Obtained data were analyzed MIXED procedure of SAS software according to a completely randomized design. A P-value < 0.05 was considered statistically significant. Results showed that ZH supplementing has significant effect on metabolic hormones at d 90; as caused to increase insulin (108.02 vs. 100.56 ng/mL and $P < 0.01$), T3 (0.75 vs. 0.65 ng/mL and $P < 0.01$), T4 (25.41 vs. 21.99 ng/mL and $P < 0.01$) and decrease cortisol (20.78 vs. 28.55 ng/mL and $P < 0.01$) concentrations compare with control and d 60. Following to expressed hormonal changes at d 90, this β-agonist significantly influenced on blood metabolites as caused to decrease glucose (104.55 vs. 119.43 mg/dL and $P < 0.01$) and triglyceride (43.25 vs. 49.42 43mg/dL and $P = 0.02$) than control and d 60. Our study indicated zilpaterol hydrochloride supplementation of 0.20 mg/kg BW/d on castrated male goats at end of feedlot period has significant effects on blood metabolic hormones and metabolites at end of supplementing period.

Key Words: zilpaterol hydrochloride, metabolic hormones, castrated male goat

T179 Effect of water deprivation on the thermoregulatory system of desert goats (*Capra hircus*). A. Al-Haidary* and E. Samara, *King Saud University, Riyadh, Saudi Arabia.*

This study was conducted during summer season to investigate the effect of water deprivation under heat stress conditions on the thermophysiology of desert goat. The experiment was conducted on 4 stages (euhydration, dehydration, rehydration, d 10 of rehydration). The first 3 stages were lasted for 72 h each, while the last stage lasted for 24 h. A telemetry system was used for continuous measurement of goat's core body temperature. Results revealed that desert goat had showed a distinguished circadian rhythm of core body temperature during euhydration. The rhythm minimum and maximum were attained early in the morning and at the end of the day, respectively with 0.79°C oscillation range. Water deprivation that coincided with high ambient temperature of summer season has affected goat's core body temperature. The range of oscillation of core body temperature increased during dehydration stage to 1.78°C, then decreased to 88°C during rehydration stage, and further decreased to 0.72°C at d 10 of rehydration. The observed increase in core body temperature due to water deprivation indicates thermo-labile characteristics of desert goat. Goat's body heat storage was significantly ($P < 0.05$) increased during dehydration stage. Furthermore, dehydration had significantly ($P < 0.05$) increased daily averages of respiration rate, heart rate, skin, coat, and rectal temperatures of desert goat. Dehydration had also significantly ($P < 0.05$) decreased overall means of daily feed intake, dry matter intake, feces water content, and body weight. Ten days of rehydration has been approved sufficient for all measured thermo-physiological parameters to recover from the effect of water deprivation. These results demonstrate the capability of desert goat to ameliorate the stressful effects of water deprivation under heat stress conditions.

Key Words: core body temperature, gaot, dehydration

T180 Comparison of the morphological characters of ovulated follicular waves during synchronized and normal estrous cycle in dairy cattle. M. Poorhamdollah*[1], H. Kohram[1,2], A. Z. Shahneh[1], and A. Sadeghi-Sefidmazgi[3], *[1]University of Tehran, Karaj, Tehran, Iran, [2]Shahid Chamran University, Ahvaz, Iran, [3]Isfahan University of Technology, Isfahan, Iran.*

The objective of this study was to compare the morphological characteristics of follicular waves during a synchronized estrous cycle to those of a normal estrous cycle in dairy cattle. A total of 10 Holstein dairy cows were selected and divided into 2 groups (n1 = n2 = 5). In group 1, the estrous cycles were synchronized by 2 successive injections of $PGF_{2\alpha}$ (Vetglan, cloprostenol, Aburaihan, Iran), 14 d apart; and the characteristics of ovulated follicular waves were evaluated. In group 2, the ovulated waves during a natural estrous cycle for each cow were served as controls. Ovaries of all cows were examined daily by transrectal ultrasound (B mode; Pie medical, Falco 100, 8 MHz). *t*-test was used to assess the significance of difference between morphological characteristics of follicular waves in synchronized and normal estrous cycles. The results showed that there were no significant differences ($P > 0.05$) between morphological characteristics in terms of the maximum size of the largest follicle (F1); (15.60 ± 1.12 vs 13.60 ± 0.42; mm), maximum size of the second largest follicle (F2); (10.20 ± 1.01 vs 8.72 ± 0.59; mm), mean large size of subordinate follicles (6.04 ± 1.06 vs 6.03 ± 0.34; mm), mean size of F1 at deviation (8.80 ± 1.15 vs 7.64 ± 0.46; mm), mean days of emergence to deviation of F1 (4.00 ± 0.70 vs 3.48 ± 0.32), mean number of emergent follicles (11.00 ± 1.57 vs 7.44 ± 0.46) and mean size of F1 at growth and static phase (3.85 ± 0.63 vs 4.16 ± 0.67 and 2.72 ± 0.40 vs 2.44 ± 0.50; mm, respectively) as well as daily growth rates of F1 (1.04 ± 0.15 vs 1.38 ± 0.04) of follicular waves in synchronized estrous cycle versus normal estrous cycle in dairy cattle, respectively. In conclusion, there were no significant differences between morphological characters of follicular waves in synchronized estrous cycle and normal estrous cycle in dairy cattle.

Key Words: cattle, follicular wave, $PGF_{2\alpha}$

T181 Effect of methionine supplementation during postpartum period in dairy cows. II: Embryo quality. A. H. Souza*[1], P. D. Carvalho[1], A. R. Dresch[1], L. M. Vieira[1,2], K. S. Hackbart[1], D. Luchini[3], S. Bertics[1], N. Betzold[4], M. C. Wiltbank[1], and R. D. Shaver[1], *[1]University of Wisconsin-Madison, Madsion, [2]University of Sao Paulo-VRA, Brazil, [3]Adisseo, Alpharetta, GA, [4]U.S. Dairy Forage Research Farm, Prairie du Sac, WI.*

Objectives of this study were to evaluate the effects of supplementing methionine in the postpartum period on embryo quality in dairy cows. Holstein cows (n = 72), receiving same basic TMR (NRC 2001), were milked twice a day and were kept in tie-stalls. Animals were blocked by parity and calving date and randomly assigned to 2 treatments differing in level of dietary methionine: 1) Methionine (MET); diet composed of (%DM) corn silage (39.7), alfalfa silage (21.8), HMSC (17.2), roasted soybeans (8.6), grass hay (4.6), canola meal (4.0), mineral-vitamin mix (2.7) and ProVAAl Ultra (w/Smartamine, 1.4), formulated to deliver 2875 g MP with 6.8 Lys %MP and 2.43 Met %MP; 2) Control (CON); cows fed the same basal diet but replacing ProVAAl Ultra by ProVAAL Advantage (no added Smartamine), formulated to deliver 2875 gr MP with 6.8 Lys %MP and 1.89 Met %MP. Data was analyzed with the proc GLIMMIX of SAS and cows treated as a random experimental unit. Cows were superovulated with a modified 5d-Double Ovsynch with 4 d of decreasing FSH (Folltropin, 400mg/cow) doses and flushed 6 d after synchronized ovulations. A single batch of FSH and frozen semen (single ejaculates 15x106 sptz/straw) of 2 sires were used. In addition, a single treatment-blinded technician graded all embryos. There were no differences between groups in CL number, fertilization, or embryo quality. Surprisingly, % of structures recovered/CL was greater for MET than CON. Thus, most ova/embryo properties did not differ between groups; however, potential effects of MET on embryo development after the first week of pregnancy need to be investigated. Supported by Adisseo, Accelerated Genetics, USDA Grant 2010–85122–20612.

Table 1.

	MET	CON

Key Words: methionine, embryo quality, dairy cow

T182 Lactation and physiological performance in Holstein dairy cows managed under summer heat stress conditions in northwest Mexico. P. Luna-Nevarez*[1], C. Leyva-Corona[1], F. Rivera-Acuña[1], J. F. Medrano[2], G. Rincon[2], G. A. Silver[3], D. M. Hallford[3], R. L. Ashley[3], and M. G. Thomas[4], *[1]Instituto Tecnologico de Sonora, Ciudad Obregon, Sonora, Mexico, [2]University of California, Davis, [3]New Mexico State University, Las Cruces, [4]Colorado State University, Fort Collins.*

Milk production is challenging for Holstein dairy cows managed under severe high temperature and humidity weather conditions common to northwest Mexico during summer, such that a cooling system is recommended to alleviate heat stress. Thus, the objective of this study was to evaluate the effect of a low-pressure cooling system on milk production and physiological responses indicative of heat stress during summer in dairy cows milked in Sonora. Twenty-eight multiparous Holstein cows with ~150 d in milk, that received bovine somatropin every 14 d during lactation, were randomly assigned in 2 groups, cooling (CL, n = 14) and heat stress (HS, n = 14), from May 7 to July 23, 2011. All cows were maintained in shaded holding pens. Cows in the CL group received a cooling program in the waiting parlor, which included 4 series of shower (5 min) alternated with forced ventilation (10 min) 6 times per day (0700, 0900, 1100, 1300, 1500 and 1700). Heat-stressed cows were cooled only before milking (0700 and 1700). Milk production was recorded daily using an electronic system. Blood samples were collected once per week to measure serum levels of prolactin and IGF1. Rectal temperature and respiratory frequency were measured twice the day before bleeding. Ambient temperature and humidity values were collected from a nearby climatic station. Data were analyzed in SAS (2009) using a mixed model procedure with repeated measures. Cows in the CL group had higher ($P < 0.05$) milk production (22.6 vs. 21.6 ± 0.5 kg/day) and serum concentrations of prolactin (35.1 vs. 29.4 ± 1.2 ng/mL) and IGF1 (295.8 vs. 269.6 ± 15.7 ng/mL) relative to HS cows. Conversely, relative to CL cows, HS cows had a higher ($P < 0.05$) rectal temperature (38.4 vs. 38.2 ± 0.1°C) and respiratory frequency (70.5 vs. 66.6 ± 1.2 breath/min). We conclude that reduced serum levels of prolactin and IGF1 in dairy cows during summer are a consequence of heat stress, which is remedied by cooling to maintain an acceptable level of lactional performance in Holstein dairy cows.

Key Words: cooling, heat stress, prolactin

T183 Relative quantification of mRNA abundance for LH receptor, angiogenin and p450scc, and determination of hormone levels in dominant follicles and follicular cysts from dairy cows.

R. M. Villaseñor-González, J. A. Grado-Ahuir,* E. Burrola-Barraza, P. Hernández-Briano, L. E. Escobedo-Morales, and S. A. Quintana-Quintana, *Facultad de Zootecnia y Ecología, Universidad Autónoma de Chihuahua, Chihuahua, Chihuahua, México.*

Follicular cysts are nonovulatory structures that contribute to prolong the calving interval in dairy cattle. The objective was to compare the expression of mRNA encoding LH receptor (LHCGR), angiogenin (Ang) and cytochrome P450 side-chain cleavage enzyme (CYP11A1) in granulose cells and the hormonal level in dominant follicles (DF) and follicular cysts (FC). We obtained follicular structures (DF, n = 16; and FC, n = 16) from dairy cows slaughtered at a local abattoir. The follicular fluid was subjected to ELISA to determine estradiol 17β (E2), progesterone (P4) and IGF-1 (intraassay coefficient of variation was 5.58, 7.02, and 10.30% for E2, P4, and IGF-1, respectively). Abundance of target genes mRNA relative to GAPDH was quantified by real-time PCR. The experiment was conducted using a completely randomized design, with the fixed effect of type (DF or FC). Correlation among gene expression and hormones levels were also calculated. There were no difference ($P > 0.05$) between DF and FC for the expression (fold change) of LHCGR (8.18 ± 0.54 vs 7.16 ± 0.28), Ang (1.79 ± 0.20 vs 1.78 ± 0.21), CYP11A1 (3.50 ± 0.24 vs 3.42 ± 0.24) and the concentrations of E2 and P4 (1384.64 ± 1.82 vs 1142.11 ± 1.82, and 13.10 ± 1.41 vs 18.63 ± 1.41 ng/ml, respectively). The concentrations of IGF-1 in FC was higher ($P < 0.05$) than in DF (132.78 ± 1.18 and 78.21 ± 1.18 ng/ml, respectively). Positive correlations ($P < 0.05$) between LHCGR with CYP11A1 (r = 0.74), LHCGR with E2 (r = 0.95), and CYP11A1 with E2 (r = 0.69) were detected in DF. In FC there was a positive correlation ($P < 0.05$) between LHCGR with E2 (r = 0.82), and a negative correlation between CYP11A1 with IGF-1 (r = −0.70) and follicular diameter (r = −0.59). The results provide evidence for IGF-1 to be involved in the growth and extended lifespan of follicular cysts

Key Words: follicular cysts, gene expression, IGF-1

T184 Hormonal regulation of the hedgehog system in ovarian granulosa and theca cells of cattle.

L. J. Spicer,* P. Y. Aad, and N. B. Schreiber, *Oklahoma State University, Stillwater.*

Although expression of Indian and Desert hedgehog (Hh) proteins, as well as their receptor Patched 1, dramatically decrease during follicular atresia in rodents, little is known about the hormonal regulation of these Hh system proteins in cattle. Therefore, in vitro experiments were conducted to study the effects of gonadotropins, steroids, transforming growth factor-β superfamily proteins, wingless-type MMTV integration site family member 3A (WNT3A), and IGF1 on components of the Hh system. Gene expression of Indian hedgehog (*IHH*), Desert hedgehog (*DHH*) and its type 1 receptor, Patched 1 (*PTCH1*), were quantified by real-time RT-PCR in cultured bovine granulosa (GC) of small (1–5 mm) follicles or theca (TC) cells of large (5–20 mm) follicles collected from bovine ovaries. In cultured GC, 24-h treatment with 300 ng/mL of E2 increased ($P < 0.05$) *IHH* mRNA abundance in the presence of FSH as well as in the presence of 30 ng/mL of IGF1 ($P < 0.05$). Alone IGF1 suppressed GC IHH mRNA abundance by 78% ($P < 0.05$). In IGF1-treated GC, cortisol (300 ng/mL) and WNT3A (300 ng/mL) increased ($P < 0.05$) GC *IHH* mRNA by 1.9- and 5.5-fold, respectively, whereas 300 ng/mL of prostaglandin E2 (PGE2) or angiogenin had no effect ($P > 0.10$). Relative expression of *DHH* mRNA was 20-fold less than that of *IHH* mRNA in small follicle GC treated with WNT3A. In cultured TC, 24-h treatment with 30 ng/mL of IGF1 and LH decreased ($P < 0.05$) *PTCH1* mRNA expression by 50% and 40%, respectively. The combined treatment of IGF1 and LH was less inhibitory (i.e., 20% suppression) on *PTCH1* expression than either treatment alone. Treatment of TC with bone morphogenetic protein 4 (BMP4; 30 ng/mL) reduced ($P < 0.05$) *PTCH1* mRNA abundance by 50%, whereas treatment with growth differentiation factor 9 (GDF9; 250 ng/mL) or activin (25 ng/mL) was without effect ($P > 0.10$). We conclude that the ovarian Hh system in cattle is controlled by several hormones including IGF1 and FSH, and that these effects are regulated by estradiol and other intra-ovarian factors such as WNT3A and BMP4. We hypothesize that as follicles grow and develop, increased free IGF1 may suppress production of IHH by GC and PTCH1 by TC.

Key Words: hedgehog proteins, granulosa, theca

T185 Pregnancy per AI of conventional versus sex sorted semen in dairy heifers subjected to a modified CIDR-PGF2α-GnRH timed-AI protocol.

J. Howard*[1,2], C. Autran[1], J. Branen[2], K. Carnahan[1], R. Kasimanickam[3], G. Sasser[2], and A. Ahmadzadeh[1], [1]*University of Idaho, Moscow,* [2]*BioTracking LLC, Moscow, ID,* [3]*Washington State University, Pullman.*

The 5-d CIDR-CoSynch is an effective timed-AI protocol in heifers. Sexed sSorted (SS) yields lower fertility than conventional semen (CS), and thus, there is less room for technical error when SS semen is used in timed-AI protocols. The objectives of this study were to evaluate the effect of GnRH at CIDR insertion on pregnancy per AI (P/AI) in a 5-d CIDR-CoSynch protocol and to compare the P/AI of CS versus SS in dairy heifers subjected to timed-AI. In a 2 × 2 factorial design, 477 Holstein replacement heifers, received a CIDR insert on d 0 (start of treatment). Subsequently, heifers were paired by age and assigned randomly to receive either 100 μg of GnRH (GnRH-CIDR, n = 241) or no GnRH treatment (CIDR5, n = 236). On d 5, the CIDR was removed and all heifers received 25 mg PGF2α. Seventy-two hours after CIDR removal all heifers received GnRH (100 μg, i.m.) and were randomly assigned to be inseminated with CS (n = 234) or SS semen (n = 243). Estrus activity was monitored using tail chalk methods from d 5 to d 8. Pregnancy status was determined via ultrasound and by PSPB analysis (bioPRYN) on d 32 and 45 after AI. P/AI data were analyzed by logistical regression. P/AI was marginally ($P = 0.06$) different between treatments (GnRH-CIDR 45.8% vs. CIDR5 50.2%). P/AI was greater ($P < 0.01$) for CS compared with SS semen (59.5% vs. 37.0%), however there was no treatment by semen effect. Regardless of semen type and across both treatments, P/AI was greater ($P < 0.01$) in heifers detected in heat then not observed in heat (54.5% vs. 32.1%). Pregnancy detection did not differ between ultrasound and bioPRYN. The results of this experiment indicate that GnRH administration at CIDR insertion does not improve P/AI in heifers subjected to 5-d CIDR-CoSynch protocol, and the use of sex-sorted semen should be limited to use in heifers detected in estrus.

Key Words: dairy heifers, timed AI, sex-sorted semen

T186 Insulin action on hepatic gene expression in dairy cows with different fat mobilization during early lactation.

H. M. Hammon*[1], U. Kautzsch[1], C. Weber[1], B. Kuhla[1], M. Röntgen[1], and R. M. Bruckmaier[2], [1]*Leibniz Institute for Farm Animal Biology (FBN), Dummerstorf, Germany,* [2]*Veterinary Physiology, Vetsuisse Faculty, Bern, Switzerland.*

Changes in insulin action around calving contribute to metabolic adaptation in dairy cows during the transition from pregnancy to lactation. Insulin action may be affected by the physiological status and body fat mobilization. The objective of this study was to investigate insulin effects on hepatic gene expression of factors involved in energy metabolism in cows with variable liver fat concentration (LFC) after calving. German Holstein cows (>10,000 kg milk/305 d; ≥ 2nd lactation) were classified by LFC postpartum (pp) in low (L; < 240 mg fat/g DM; n = 9) and high (H; > 240 mg fat/g DM; n = 10). Euglycemic-hyperinsulinemic clamps (6 mU/kg BW × min insulin for 6 h) were performed in wk 5 ante partum (ap) and wk 3 pp and liver biopsies were taken before and at the end of the clamp to measure LFC and mRNA concentrations of pyruvate carboxylase (PC), cytosolic and mitochondrial phosphoenolpyruvate carboxykinase (PEPCKc, PEPCKm), propionyl-CoA-carboxylase (PCCA), carnitine palmitoyl-transferase 1A (CPT1A), glucose transporter GLUT2 and GLUT4, IGF-I, and glucocorticoid, growth hormone, and insulin receptors (GR, GHR1A, InsR). Phosphoglycerate kinase 1 was usesd as reference gene and data were analyzed by Mixed Model of SAS with LFC, time, and insulin as fixed effects. LFC differed between cows ($P < 0.01$) (H: 306 ± 0.2 mg/g; L: 195 ± 0.1 mg/g). PC mRNA concentrations increased ($P < 0.05$), but mRNA of GLUT2, GLUT4, IGF1, GHR1A and GR decreased ($P < 0.05$) from ap to pp. Insulin decreased ($P < 0.05$) mRNA concentrations of PC, PEPCKc, PEPCKm, PCCA, CPT1, and InsR, but increased mRNA of IGF-I and GLUT4 ap and pp. Insulin increased GHR1A mRNA only pp and PEPCKc mRNA decreased from ap to pp only without insulin (time × insulin: $P < 0.05$, respectively). PEPCKc mRNA tended to be lower ($P = 0.1$), but expression of GLUT4 and GR were higher ($P < 0.05$) in L than in H. Hepatic gene expression depended partly on time, but was less affected by LFC. Insulin strongly inhibited enzymes involved in hepatic glucose production and fat oxidation, but stimulated parameters of the somatotropic axis and GLUT4. Supported by DFG, Germany.

Key Words: dairy cow, insulin action, hepatic gene expression

T187 Modulation of the metabolic response to an endotoxin challenge in Brahman heifers through OmniGen-AF supplementation.

N. C. Burdick*[1], J. A. Carroll[1], J. D. Chapman[2], T. H. Welsh Jr.[3], R. C. Vann[4], and R. D. Randel[5], [1]*USDA-ARS, Livestock Issues Research Unit, Lubbock, TX,* [2]*Prince Agri Products Inc., Quincy, IL,* [3]*Texas AgriLife Research, Texas A&M System, College Station,* [4]*MAFES, Mississippi State University, Raymond,* [5]*Texas AgriLife Research, Texas A&M System, Overton.*

This study examined the effect of feeding OmniGen-AF (OG; Prince Agri Products) on the metabolic response of newly-weaned heifers to an endotoxin (lipopolysaccharide; LPS) challenge. Brahman heifers (n = 24; 183 ± 5 kg) from the Texas AgriLife Research Center in Overton, TX were separated into 2 treatment groups at weaning: 1) Control (C; n = 12) and 2) OG (n = 12; fed at 4 g per 45.4 kg BW) and fed for 69 d. On d 39, heifers were transported from Overton to New Deal, TX. On d 40, heifers were fitted with indwelling jugular catheters and moved into a barn with individual stalls. On d 41 heifers were challenged with LPS (0.25 μg/kg BW i.v.) and blood samples were collected at 0.5 h intervals from −2 to 8 h and again at 24 h relative to LPS challenge (0 h). Serum was isolated and stored at −80°C until analyzed for glucose, insulin, nonesterified fatty acids (NEFA), and blood urea nitrogen (BUN). Heifer weight was also recorded at various intervals throughout the study. Heifer BW increased throughout the study ($P < 0.01$) and was not affected by treatment ($P > 0.21$). Pre-LPS glucose concentration was greater in OG (255.7 ± 6.6 mg/dL) than C heifers (227.8 ± 6.6 mg/dL; $P < 0.01$). Glucose concentration increased post LPS ($P < 0.01$), but was not affected by treatment with OG ($P = 0.36$). Insulin concentration pre- and post-LPS was not affected by treatment with OG ($P = 0.84$ and 0.89). Post-LPS insulin concentration increased ($P < 0.01$) and peaked at 2 h post LPS. Pre- and post-LPS NEFA concentration was greater in C (0.19 ± 0.01 and 0.39 ± 0.01 mmol/L) than OG heifers (0.16 ± 0.01 and 0.31 ± 0.01 mmol/L; $P < 0.05$), with NEFA concentration increasing post LPS ($P < 0.01$). Pre- and post-LPS BUN concentration was also greater in C (10.2 ± 0.2 and 10.5 ± 0.1 mg/dL) than OG heifers (8.5 ± 0.3 and 9.3 ± 0.1 mg/dL; $P < 0.03$), with BUN concentration increasing post LPS ($P < 0.01$). These data suggest that supplementing heifers with OG altered their metabolic response by increasing available glucose before the LPS challenge and reducing the need for OG heifers to mobilize energy through lipolysis and proteolysis, which may have allowed for a more acute response to the challenge.

Key Words: cattle, metabolism, OmniGen-AF

T188 Ultrasound body composition traits response to an endotoxin challenge in Brahman heifers supplemented with OmniGen-AF.

R. C. Vann*[1], N. C. Burdick[2], J. A. Carroll[2], J. D. Chapman[3], T. H. Welsh Jr.[4], and R. D. Randel[5], [1]*MAFES-Brown Loam Experiment Station, Raymond, MS,* [2]*USDA-ARS, Livestock Issues Research Unit, Lubbock, TX,* [3]*Prince Agri Products Inc., Quincy, IL,* [4]*Texas AgriLife Research, Texas A&M University, College Station,* [5]*Texas AgriLife Research, Texas A&M University, Overton.*

This study examined the effect of feeding OmniGen-AF (OG; Prince Agri Products) on body composition response of newly weaned heifers to an endotoxin (lipopolysaccharide; LPS) challenge. OmniGen-AF is a yeast-based product and our hypothesis was that this yeast based product would provide a level of stress/immunological protection that would allow for nutrient sparing during times of stress. Brahman heifers (n = 24; 183 ± 5 kg) from the Texas AgriLife Research Center in Overton, TX were separated into 2 treatment groups at weaning: 1) Control (C; n = 12) and 2) OG (n = 12; fed at 4 g per 45.4 kg BW) and fed for 69 d. On d 39, heifers were transported from Overton to New Deal, Texas.

On d 40, heifers were fitted with indwelling jugular catheters and moved into a barn with individual stalls. On d 41, heifers were challenged with LPS (0.25 µg/kg BW i.v.) and blood samples were collected at 0.5 h intervals from −2 to 8 h and again at 24 h relative to LPS challenge (0 h). Ultrasound body composition traits for longissimus muscle area, rib fat, percent intramuscular fat and rump fat were collected at weaning (d 0), d 39, 44 and 69. Data were analyzed using the PROC Mixed procedure of SAS specific for repeated measures. Heifer BW increased throughout the study ($P < 0.001$) and was not affected by treatment ($P > 0.68$). Ultrasound body composition traits for longissimus muscle area, percent intramuscular fat, rib fat and rump fat increased ($P < 0.0001$) throughout the study. However, there were no effects ($P > 0.20$) of feeding treatment on ultrasound body composition traits throughout the study. There were tendencies ($P < 0.09$) for the OG group to have more stable rib fat and percent intramuscular fat measurements after transport and an endotoxin challenge. While no significant differences between treatments were observed in this study, the data suggest that OG supplementation before transport and LPS challenge may have preserved energy stores in Brahman heifers.

Key Words: cattle, ultrasound, OmniGen-AF

T189 Hepatic expression of mitochondrial respiratory complex genes of pure and crossbred beef cows grazing different herbage allowances of native pastures. M. Veyga, A. L. Astessiano, A. Kaitazoff, V. Bassaizteguy, A. I. Trujillo, and M. Carriquiry,* *School of Agronomy, UdelaR, Montevideo, Uruguay.*

Hepatic expression of genes encoding proteins of the mitochondrial respiratory complexes has been related to mitochondrial function and feed efficiency, which in turn may depend on nutritional plane and animal genotype. Adult cows (n = 24) in a factorial arrangement of herbage allowances throughout the year (2.5 vs. 4 kgDM/kgBW; LO vs. HI) and cow genotype (purebred: Angus and Hereford vs. F1 crossbred; PB vs. CB) were used in a complete randomized block design to evaluate hepatic expression of 9 genes encoding proteins of the mitochondrial respiratory complexes. Cows were maintained in the herbage allowance treatment since May 2007 and gestated and lactated one calf every year from 2007 to 2009. At the end of the third year, cows were slaughter at 190 ± 15 d postpartum and liver mass was recorded and samples were collected to measure gene expression by SYBR-Green real time PCR using HPRT and β-actin as endogenous control genes (which expression did not differ among cow groups by microarray analysis). Data were analyzed using a mixed model and means were considered to differ when $P < 0.05$. Liver mass did not differ between HI than LO cows but was less in PB than CB cows (45.9 vs. 49.6 ± 1.26 g/kgPV0.75). Expression of SDHA and SDHD (complex II), UQCRC1 (complex III) mRNA did not differ due to herbage allowances or cow genotype. However, hepatic expression of NDFUS4 (complex I, 0.90 vs. 1.51 ± 0.24), CYC1 (complex III, 0.68 vs. 1.05 ± 0.13), and ATP5B and ATP5O (complex V, 0.72 vs. 1.08 ± 0.16 and 0.56 vs. 1.02 ± 0.16, respectively) mRNA tended ($P \leq 0.094$) to be less in HI than LO cows. Hepatic expression of ATP5B and ATP5O and CYC1 and COX5B (complex IV) mRNA were greater in PB than CB cows (1.10 vs. 0.7 ± 0.17; 1.08 vs. 0.5 ± 0.16; 1.04 vs. 0.69 ± 0.13 and 1.28 vs. 0.97 ± 0.13, respectively). However, ATP50 mRNA tended ($P = 0.066$) to be affected by the interaction between herbage allowance and cow genotype as its expression was greater in LO-PB cows than the other groups. Results suggest that increased mitochondrial gene expression may compensate reduced liver size in PB than CB cows and could indicate a higher feed efficiency of cows grazing low vs. high herbage allowance of native pastures.

Key Words: liver, respiratory chain, mRNA

T190 Expression of adipokines and their receptors in adipose tissue of pure and crossbred beef cows grazing different herbage allowances of native pastures. A. Kaitazoff,* A. Casal, A. L. Astessiano, M. Veyga, A. I. Trujillo, and M. Carriquiry, *Facultad de Agronomía, UdelaR, Montevideo, Uruguay.*

Adipose tissue metabolism plays an important role during periods of negative energy balance or feed restriction and adipokines secreted by adipose tissue participated in regulating energy homeostasis. Pure and crossbred adult beef cows (n = 10) were used in a complete randomized block design to evaluate the effects of herbage allowances throughout the year (2.5 vs. 4 kgDM/kgBW; LO vs. HI) on adipokines and their receptors mRNA expression in mesenteric adipose tissue. Cows were maintained in the same herbage allowance treatment since May 2007 and gestated and lactated one calf every year from 2007 to 2009. At the end of the third year, cows were slaughter at 190 ± 15 d postpartum, mesenteric adipose tissue was dissected and weighed and samples were collected to measure gene expression by SYBR-Green real time PCR using HPRT and Î^{2}-actin as endogenous control genes. Data were analyzed using a mixed model and means were considered to differ when $P \leq 0.05$. Cow BW at slaughter did not differ between HI and LO cows (436 ± 16 kg). However, mesenteric adipose tissue mass was less for HI than LO cows (25.1 vs. 28.3 ± 2.6 g/kgPM). Adipose adiponectin (ADIPO) and its receptor-1 (ADIPOR1) mRNA expression were not affected by herbage allowance but ADIPOR2 mRNA tended ($P = 0.13$) to be greater for HI than LO cows (1.04 vs.0.57 ± 0.23). Expression of leptin and its receptor-b (LEPRb) mRNA, as well as insulin receptor (INSR) mRNA in adipose tissue did not differ between herbage allowances but LEPR-a was less in HI than LO cows (0.90 vs. 2.23 ± 0.69). Adipose angiopoietin-like protein 4 (ANGLP4) mRNA was greater in HI than LO cows (1.19 vs. 0.09 ± 0.65). Expression of adipokine receptors (ADIPOR2 and LEPR-a) as well as ANGPL4 mRNA in mesenteric adipose tissue could be mediating differences in energy metabolism in rangeland beef cows grazing different herbage allowances.

Key Words: beef cattle, grazing, adipokines

T191 Hepatokines in periparturient dairy cows with different extent of body fat mobilization. C. Schäff, T. Laeger, H. M. Hammon, M. Röntgen, and B. Kuhla,* *Nutritional Physiology "Oskar Kellner," Leibniz Institute for Farm Animal Biology (FBN), Dummerstorf, Germany.*

Adropin and the fibroblast growth factor-21 (FGF21) are 2 hepatokines linking feed intake with energy homeostasis and lipid metabolism. While adropin acts to reduce feed intake and hepatic fat synthesis, FGF21 increases hepatic ketogenesis and feed intake/kg BW in rodents. Thus we investigated whether adropin and FGF21 are regulated during the periparturient period of dairy cows and if their expression/secretion is associated with the postpartum (pp) liver fat content (LFC). German Holstein cows (>10,000 kg milk/305 d; >2nd lactation) were grouped retrospectively according to the mean LFC pp in low (L; <24% total fat/DM; n = 9) and high (H; LFC > 24.4% total fat /DM; n = 10). Cows were fed TMR ad libitum and frequent blood samples were withdrawn to analyze the concentration of FGF21, nonesterified fatty acids (NEFA) and β-hydroxybutyrate (BHBA). Liver biopsies were taken at d −34, −17, 3, 18, 30 relative to parturition and at slaughter (d 40 pp) to measure LFC and mRNA concentrations of the hepatokines and the non-regulated house-keeping gene phosphoglycerate kinase 1 (PGK1) via real-time RT-PCR. Data were evaluated by Mixed Model of SAS with LFC and time as fixed effects and pairwise comparisons (multiple *t*-test). Daily dry matter intake (DMI) varied with time ($P < 0.001$) with a continuous rise after calving in both groups. The DMI/kg BW increased also with time

($P < 0.001$) and was lower in H than in L cows ($P < 0.01$). LFC peaked at d 18 pp and was higher in H than in L cows (H: 41.3%; L: 24.5%; $P < 0.001$). Pairwise comparison revealed that at d 30 pp, mRNA expression of adropin was higher in H than in L cows ($P < 0.05$). Expression of FGF21 was not different between groups. Plasma concentrations of FGF21 decreased from ante partum by d 3 pp and re-increased thereafter ($P < 0.01$) whereas NEFA and BHBA (each $P < 0.001$) were higher in H than in L cows pp. Higher expression of adropin in H cows after the LFC peak pp may contribute to the depletion of liver fat but also to the lower feed intake pp in H as compared with L cows. Hepatic FGF21 mRNA expression is not paralleled by FGF21 plasma concentration. Supported by DFG, Germany.

Key Words: dairy cow, adropin, FGF21

T192 Glucose and epinephrine tolerance tests in steers categorized as residual feed intake efficient versus inefficient.

M. H. Ramos*[1], D. H. Keisler[2], and M. S. Kerley[2], [1]*Research Instituto Flavio Guarani - Rehagro, Belo Horizonte, Minas Gerais, Brazil,* [2]*University of Missouri, Columbia.*

Two experiments were performed to examine peripheral glucose and insulin dynamics in feedlot steers classified as residual feed intake efficient (–RFI) vs. inefficient (+RFI). Crossbred Angus steers were used in experiment one (n = 72; initial weight 333 ± 8.5 kg) and 2 (n = 60; initial weight 355 ± 7.3 kg). All steers were fed for a total of 70 d and had access to the same diet (87% corn, 8% corn distiller's grains, 1% blood meal, 1.6% feather meal, and 2.5% mineral and vitamins). Residual feed intake was calculated based on the regression of dry matter intake (DMI) onto metabolic body weight (BW0.75) and average daily gain (ADG). In experiment one, 2 –RFI and 2 +RFI steers were selected for a glucose tolerance test (GTT1) and in experiment 2, 4 –RFI and 4 +RFI steers were selected for a glucose tolerance test (GTT2) and an epinephrine tolerance test (ETT). Therefore, as planned, body weight and ADG did not differ ($P > 0.05$) between treatments for all tolerance tests, yet DMI and RFI differed ($P < 0.05$) between treatments for all tolerance tests, which allowed us to have 2 distinct groups of animals to perform our experiments. For GTT1, each steer was injected with 150 mg/kg BW of glucose via jugular catheter and 20 min later given 30 mU/kg BW of insulin. For GTT2, each steer was injected with 150 mg/kg BW of glucose via jugular catheter, but no insulin followed. For ETT, each steer was injected with 1 ug/kg BW of epinephrine via jugular catheter. Frequent blood samples were collected before and after injection of glucose for all tests. Serum was assayed for glucose and insulin. Basal, peak, area under the curve, clearance rate (%/min) and half-life's of glucose and insulin did not differ between treatments for GTT1 and GTT2. In addition, results for ETT did not show any difference ($P > 0,05$) for basal, peak, area under the curve, clearance rate (%/min) and half-life's of glucose and insulin. We conclude that peripheral glucose and insulin dynamics do not differ according to RFI classification of feedlot steers.

Key Words: RFI, glucose, epinephrine

T193 Insertion of used CIDRs on day 3 to 5 post-insemination in heifers to improve pregnancy rate.

C. E. Ferguson*[1], B. Pousson[1], H. Nordberg[1], J. Veillon[1], W. Storer[1], and D. J. Kesler[2], [1]*McNeese State University, Lake Charles, LA,* [2]*University of Illinois, Champaign-Urbana.*

Increasing progesterone (P_4) concentrations from d 3 to 5 of the estrous cycle improves pregnancy rates in repeat-breeder beef cattle. This study was designed to determine if increasing P_4 on d 3 to 5 post-insemination improves pregnancy rates in beef heifers. A total of 92 beef heifers were used in 2 replicates during this experiment. All heifers were synchronized using the Co-Synch + CIDR protocol and were timed AI (TAI) at 56 h following $PGF_{2\alpha}$ administration and CIDR removal. They were administered 100 µg of GnRH at TAI and on d 3 to 5 post-GnRH all treated heifers received a used CIDR from the prior synchronization and control heifers received insertion of the empty CIDR gun. Jugular blood samples were collected from all heifers in replicate 2 (n = 60). Plasma P_4 concentrations were determined via radioimmunoassay, and ~30 post-TAI heifers were tested for pregnancy using ultrasonography. Statistical analysis was performed in SAS using a proc glm with a tukey's chi-squared and proc glimmix with lsmeans post-hoc tests. In replicate one, significantly more ($P < 0.05$) treated heifers were pregnant (12/16, 75%) compared with control heifers (5/16, 31%). In replicate 2, there was no difference in pregnancy rates for treated (12/30, 40%) and control (12/30, 40%) heifers. The mean pregnancy rates between replicates were different ($P < 0.05$); therefore, they were not combined. In replicate 2, all heifers in the control group with plasma P_4 below 1 ng/ml (on consecutive blood samples from d 3 to 5) were removed from further P_4 analysis. Plasma P_4 was significantly higher in pregnant vs. control heifers on d 4 (1.25 ± 0.09 ng/ml vs. 0.85 ± 0.21) and d 5 (1.89 ± 0.18 ng/ml vs. 1.40 ± 0.11). The pregnancy rate among the heifers, with >1ng/ml of P_4, was 12/21 (57%). Use of used CIDRs on d 3 to 5 produced variable pregnancy rates due possibly to differences in P_4 remaining within the CIDR. However, supplementing P_4 at this time may improve pregnancy rates as pregnant heifers had significantly higher P_4 concentrations during this time compared with open heifers.

Key Words: progesterone, heifer, supplementation

T194 Effect of phase of estrous cycle and fixed-timed insemination on fertility of Criollo cows after a norgestomet or progesterone based treatment.

A. Quezada-Casasola*[1,2], L. Avendaño-Reyes[1], J. A. Ramírez-Godínez[3], J. R. Núñez-Cuesta[2], F. J. Carlos-Pérez[2], G. Mena-Ortíz[2], and K. Siqueiros[2], [1]*Instituto de Ciencias Agrícolas, Universidad Autónoma de Baja California, Mexicali, B. C., México,* [2]*Universidad Autónoma de Ciudad Juárez, Cd. Juárez, Chihuahua, México,* [3]*Universidad Autónoma de Chihuahua, Chihuahua, Chihuahua, México.*

Phase of estrous cycle and time of insemination were examined for their influence on fertility of 86 cycling mature Criollo (Corriente) cows after a 9-d norgestomet (Crestar; n = 28) or a 7-d progesterone (CIDR; n = 58) synchronization. Cyclicity was assumed if serum progesterone (P4) concentrations were ≥ 1 ng/mL in either one of 2 samples taken 8 d apart, being the second sample taken the same day of onset of synchronization treatment for phase of estrous cycle determination as well (follicular = P4 ≥ 1 ng / mL in first sample and < 1 ng/mL in second sample, and luteal P4 <1 ng/mL in first sample and ≥1 ng/mL in second sample). Cows were randomly inseminated at 48 or 60 h after the progestin or progesterone device withdrawal along with an injection of 100 µg of GnRH analog. Fertility (pregnancy rate as dependent variable and norgestomet or progesterone, phase of cycle and time of insemination as well as their interactions as independent variables) was analyzed using Proc Logistic of SAS. Synchronization method (Crestar and CIDR) had no effect on pregnancy rate (39.2% and 34.4%, respectively; $P > 0.1$). Also, cows with ovaries in follicular phase had similar pregnancy rate to those with ovaries in luteal phase (34.1% and 37.7%, respectively: $P > 0.1$). Pregnancy rate was higher in cows inseminated at 60 h than those at 48 h after progestin or progesterone removal (53.1% and 15.3%, respectively; $P < 0.01$). Follicular or luteal phase of estrous cycle at start of treatment did not have an effect on pregnancy of Criollo cows after insemination. Furthermore, the higher pregnancy rate of cows inseminated 60 h after the end of progestin or progesterone treatment might indicate that, in Criollo cows, ovulation may occur at a longer time interval after synchronization treatment than other cattle breeds and/or that the dominant follicle and its oocyte present after synchronization require specific conditions that may include a longer period of time to be successfully ovulated.

Key Words: Criollo cattle, ovulation, artificial insemination

T195 Injection site does not alter effectiveness of beef cattle synchronization. C. L. Pickworth*[1,2], D. H. Poole[2], and W. Greene[1], *[1]The Ohio State University, Wooster, [2]North Carolina State University, Raleigh.*

Quality assurance programs are valuable assets to the beef cattle industry for improving meat product quality and consumer acceptance. A key area in beef quality assurance programs is to reduce injection site blemishes in valuable meat cuts by administering all intramuscular injections in the neck. A common belief among cattle producers utilizing estrus synchronization is that the drugs are more effective when administered in the rump compared with the neck. The objective of this study was to compare the effectiveness of injection site of prostaglandin (PGF2α) on first service conception rates following estrus synchronization. One hundred and 5 beef cows and heifers were blocked by breed and stratified by parity before being randomly assigned to 1 of 2 treatments. The 2 treatments were: intramuscular PGF2α administration in the neck or in the rump. Cows and heifers were synchronized using a combination of a 7 d intravaginal progesterone implant (CIDR) and PGF2α injection followed by estrus detection and breeding either on observed heats or timed insemination. Days pregnant was determined by a veterinarian using ultrasonography approximately 70 d post-insemination. Data were analyzed as a randomized complete block design in Proc Mixed with animal as the experimental unit. Differences are declared significant at $P < 0.05$ and means are reported as LS means. Site of PGF2α injection did not affect ($P > 0.05$) overall conception rates in response to artificial insemination at 57.5 and 55.6% conception after first service for cattle receiving injections in the neck and rump, respectively. Nor did injection site affect ($P > 0.05$) whether cattle were bred based on estrus detection or timed insemination. Parity and breed of cattle did not affect ($P > 0.05$) pregnancy rates, nor were there any interactions ($P > 0.05$) with site of injection. Overall conception rate at the end of the breeding season was 86.6%. Administering PGF2α intramuscularly in the neck does not alter conception rates or effectiveness of the synchronization protocols as is misconceived by producers. Therefore, all producers should follow beef quality assurance protocols when administering intramuscular injections during estrus synchronization.

Key Words: beef production, estrus synchronization, quality assurance

T196 Presynchronizing $PGF_{2α}$ injection before a fixed time artificial insemination (TAI) CO-Synch + CIDR program. S. L. Hill*[1], S. L. Pulley[1], H. I. Mellieon Jr.[1], K. C. Olson[1], J. R. Jaeger[1], R. M. Breiner[1], G. A. Perry[2], G. C. Lamb[3], and J. S. Stevenson[1], *[1]Kansas State University, Manhattan, [2]South Dakota State University, Brookings, [3]University of Florida, Marianna.*

We hypothesized that follicular wave synchronization may be improved by inducing luteal regression before initiating a TAI program. The objective of the current study was to determine if injecting $PGF_{2α}$ (PG) 3 d before initiating CO-Synch + CIDR program would: 1) increase uniformity of follicles; and 2) improve pregnancy outcomes. Suckled beef cows at 9 locations (n = 1,537) were assigned randomly to 2 treatments after stratification of cows based on breed, parity, and days postpartum: 1) PG-CO-Synch + CIDR: PG (25 mg i.m.) on d −-13, GnRH-1 (100 μg i.m.) and insertion of a CIDR insert on d −10, PG (25 mg i.m.) and CIDR insert removal on d −-3; or 2) control: same as PG-CO-Synch + CIDR without the initial PG injection. All cows were inseminated at 72 h after CIDR removal and GnRH-2 (100 μg i.m.) was administered after TAI. Blood was collected on d −23, −13, −10, −3, and 0 for later progesterone analyses. Cows treated with PG on d −13 were more likely ($P < 0.05$) to have luteolysis after d −13 than control cows (83 vs. 29%) and reduced ($P < 0.05$) serum progesterone (0.55 vs. 1.40 ng/mL) on d −10. PG-CO-Synch + CIDR cows had larger ($P < 0.05$) follicles (12.5 vs. 10.8 ± 0.4 mm) on d −10 and more ($P < 0.05$) ovulated after GnRH-1 than controls (60.6 vs. 36.5%); however, follicle diameters on d 0 were not more uniform in PG-CO-Synch + CIDR cows. Multiparous cows treated with PG on d −13 had a greater ($P < 0.05$) incidence of estrus between d −13 and −10 than multiparous controls and all treated and control primiparous cows (32.3 vs. 15.4, 16.8 and 16.2%, respectively). Incidence of estrus between d −3 and 0 after PG on d −3 was likewise greater ($P < 0.05$) for treated multiparous cows vs. other treatment-parity groups (74.1 vs. 64.3, 58.6, and 59.1%, respectively). Pregnancy rates at d 35 did not differ between treatments but were greater ($P < 0.001$) at d 35 (60.0 vs. 47.7%) and at the end of the breeding season (96.2 vs. 92.3%) for multiparous vs. primiparous cows, respectively. In summary, more multiparous cows in the PG-CO-Synch + CIDR treatment exhibited estrus and had greater pregnancy outcomes than primiparous cows, but no overall treatment advantage was detected compared with the control.

Key Words: timed AI, luteolysis, follicle diameter

T197 Effects of pregnancy on endometrial gene expression related to amino acid, fatty acid and glucose metabolism in dairy cattle. R. L. A. Cerri*[1,2], I. M. Thompson[1], I. H. Kim[3], A. D. Ealy[1], P. J. Hansen[1], C. R. Staples[1], J. L. Li[1], and W. W. Thatcher[1], *[1]University of Florida, Gainesville, [2]University of British Columbia, Vancouver, BC, Canada, [3]Chungbuk National University, South Korea.*

Objectives were to determine effects of pregnancy on endometrial gene expression related to amino acid, fatty acid and glucose metabolism on d 17 of the estrous cycle and pregnancy. Heifers (n = 33) were assigned randomly after parturition to lactating (L, n = 17) or nonlactating (NL, n = 16) groups. Cows were subjected to an ovulation synchronization program for a timed artificial insemination (TAI); 10 cows in L and 12 in NL were inseminated. Slaughter occurred 17 d after the day equivalent to TAI, and conceptus and intercaruncular endometrial tissues collected. Only pregnant (L, n = 8; NL, n = 6) and non-inseminated cyclic (L, n = 7; NL, n = 4) cows were analyzed. Microarray analysis used the bovine Affymetrix platform. Data were analyzed using Bioconductor GCRMA and Limma methods. Differentially expressed genes were selected with P-value <0.01 and fold differences >1.5. Analyses detected 697 genes differentially expressed for pregnancy (406 downregulated and 291 upregulated). Gene ontology (GO) analyses of downregulated genes during pregnancy revealed several terms related to amino acid, fatty acid or glucose metabolism. Genes upregulated in pregnant cows were associated with 89 GO terms, among them terms related to amino acid metabolism (amino acid and derivative metabolic processes, GO:0006519; translation, GO:0006412), fatty acid metabolism (monocarboxylic acid metabolic processes, GO:0032787), and glucose metabolism (carboxylic acid metabolic process, GO:0019752). Several genes such as ASL, ARG2, SLC27A5, CRAT, FBP1, PCK2, SLC2A1 were upregulated in pregnancy and are candidate targets for interventions aiming for improvement in fertility of dairy cows. New insights into changes that occur in the endometrium during the period of corpus luteum maintenance identify several upregulated metabolic genes that may contribute to countering sub-fertility observed in lactating dairy cows.

Key Words: endometrium, gene expression, pregnancy

T198 Use of bovine pregnancy-associated glycoproteins (bPAGs) to diagnose pregnancy in postpartum Nelore beef cows.

K. G. Pohler*[1], M. F. Smith[1], T. Martins[2], R. F. G. Peres[3], and J. L. M. Vasconcelos[2], [1]*Division of Animal Sciences, University of Missouri, Columbia,* [2]*FMVZ – UNESP, Botucatu, SP, Brazil,* [3]*Agropecuária Fazenda Brasil, Barra do Garças, MT, Brazil.*

Although accurate pregnancy diagnosis is a critical factor affecting reproductive management success, relatively few beef operations utilize the technology. Binucleate trophoblast cells constitute 15 to 20% of the ruminant placenta trophoblast population, appear around d 19 to 20 of gestation in cattle and secrete bPAG. Bovine PAG are commonly used to diagnose pregnancy success in *Bos taurus* breeds and are a marker of placental function; however, much less is known about the efficacy of bPAG for pregnancy diagnosis in *Bos indicus* breeds. The objective was to measure serum concentrations of bPAG to detect the presence of an embryo/fetus on d 30 after artificial insemination (AI; d 0) in *Bos indicus* (Nelore) beef cows. In experiment 1, postpartum Nelore beef cows (n = 56) were AIed at a fixed time following synchronization of ovulation. Serum samples were collected on d 0, d 21, d 24, d 27, and d 30. Real-time ultrasonography for diagnosis of pregnancy was performed on d 30 with 39% confirmed pregnant (n = 22). The first increase ($P < 0.0001$) in serum bPAG occurred on d 24 and there was no relationship ($P = 0.44$) between ovulatory follicle diameter and bPAG concentrations at d 30; which is similar to *Bos taurus* breeds. In experiment 2, ovulation was synchronized in postpartum Nelore beef cows (n = 720). Pregnancy diagnosis and blood sample collection occurred between d 29 and 33 post insemination. Pregnancy rate at d 30 was 54% (n = 386) and average serum concentration of bPAG was 15.11 ± 9.92 ng/mL (mean ± SD). Serum concentrations of bPAG accurately detected pregnancy in 97% of all cows compared with real-time ultrasonography and none of the nonpregnant cows had a serum bPAG concentration that exceeded the threshold level for pregnancy detection. Serum concentrations of bPAG were higher ($P < 0.03$) in primiparous cows (n = 55; 20.45 ng/mL ± 1.80 ng/mL; mean ± SEM) compared with multiparous cows (n = 331; 14.23 ng/mL ± 0.49 ng/mL; mean ± SEM). In summary, bPAG first increased in Nelore beef cows on d 24 following insemination and a single serum sample on d 29–33 post-insemination was 97% accurate in diagnosing pregnancy.

Key Words: cattle, pregnancy, placenta

T199 Fetal to maternal transplacental DNA transfer in female beef cattle.

D. R. Eborn,* T. G. McDaneld, R. M. Thallman, and S. E. Echternkamp, *USDA, ARS, U.S. Meat Animal Research Center, Clay Center, NE.*

Exchange of DNA between mother and fetus has been well documented in humans but only limited reports exist for beef cattle. Our objective was to determine if we could detect male fetal DNA in the maternal blood after parturition. Whole blood was collected within 48 h after parturition from multiparous (n = 48) and primiparous (n = 54) bovine females having single (n = 75) or twin (n = 27) births. Real-time PCR analysis was performed on genomic DNA, extracted from the blood sample, using male-specific primers that target the Y chromosome. Male genomic DNA isolated from whole blood was also included in each assay as a positive control. No dams (n = 30) giving birth to only female offspring were positive for the Y PCR test. However, of the dams that gave birth to a male calf (n = 72), a total of 9 were positive for the Y PCR test. Common characteristics of those 9 females included 8 primiparous and 1 multiparous (second parturition) dams that birthed either a single male calf (n = 4) or twins (n = 5) that included at least 1 male. In addition, 3 of the 4 single male births experienced dystocia requiring assistance with a calf jack, and the positive multiparous dam gave birth to a set of twins (1 male, 1 female) that were dead at birth due to dystocia. Samples that were positive for the Y PCR test were reassayed with the same primers as well as with additional Y-specific primers obtained from a bovine SNP beadchip assay to confirm results. Six of the 9 females that were positive for the original Y-PCR test were also positive for the additional Y SNP PCR tests. Results indicate that DNA can be transferred from the fetus to the dam and that it may be more likely to occur in younger females experiencing trauma at calving such as dystocia or birth of twins. USDA is an equal opportunity provider and employer.

Key Words: Y chromosome, parturition, transplacental DNA transfer

T200 Nutrient restriction during early pregnancy alters cotyledon arterial vascular reactivity in response to bradykinin in beef cows.

A. Reyaz*[1], F. Yao[2], M. S. Sane[2], L. E. Camacho[1], C. O. Lemley[1], K. C. Swanson[1], S. T. O'Rourke[2], and K. A. Vonnahme[1], [1]*Center for Nutrition and Pregnancy, Department of Animal Sciences, Fargo,* [2]*Department of Pharmaceutical Sciences, North Dakota State University, Fargo.*

It is hypothesized that altered uterine or umbilical blood flows in nutrient restricted cows would be due to changes in placental arterial sensitivity to bradykinin (BK). To examine the effects of maternal nutrient restriction on cotyledonary (COT) artery vasoactivity during early gestation, multiparous beef cows were randomly assigned to either 100% (CON; n = 6) or 60% NRC requirements (RES; n = 4) on d 30 of gestation. At d 85 of gestation cows were slaughtered and arteries that terminated into the fetal portion of the placentome (COT artery) were dissected to be used for in vitro vasoreactivity assays using wire myography. Arterial rings were placed into organ chambers of a wire myograph filled with 5 mL of physiological saline aerated with a mixture of 95% O_2 and 5% CO_2. The arterial rings were normalized by progressive stretching. The presence or absence of endothelium in the arterial rings was verified by testing the ability of BK (10–7 M) to produce endothelium-dependent relaxation in arteries pre-contracted with U46619 (10–6 M). Endothelium-intact rings were contracted with U46619 (10–6 M) and the dose response curve (DRC) to BK was obtained. In addition, a BK DRC was obtained for rings which were incubated for 30 min with inhibitors to: 1) BK2 receptor, HOE 140 (10–6); 2) Ca^{2+}-activated K+ channels, iberiotoxin (IBTx;10–7 M); and 3) endogenous nitric oxide synthase; N(omega)-L-arginine (NLA 10–5). Cotyledonary arteries from RES cows were more sensitive ($P < 0.01$) to a BK induced relaxation compared with CON cows. There was a treatment by dose interaction ($P = 0.02$) when arteries were incubated with HOE140, with COT arteries from CON cows contracting, and no change in vasoactivity observed in COT arteries from RES cows. CON cows were more sensitive ($P < 0.01$) to BK induced relaxation in the presence of IBTx compared with RES cows. There was no effect ($P = 0.56$) of maternal diet in the response to BK when COT arteries were in the presence of NLA, which blocked relaxation.

Alterations in placental vasoactivity may affect uterine-umbilical blood flows and nutrient availability to the developing calf.

Key Words: bradykinin, cow, placenta

T201 Assessment of serum IGF-1 and β-hydroxybutyrate concentrations on reproductive performance prior to calving and breeding in young beef cows grazing native range.

J. T. Mulliniks*[1], A. J. Roberts[2], R. C. Waterman[2], T. W. Geary[2], E. J. Scholljegerdes[1], and M. K. Petersen[2], [1]*New Mexico State University, Las Cruces,* [2]*USDA-ARS, Fort Keogh Livestock and Range Research Laboratory, Miles City, MT.*

Metabolites involved in the metabolic adaptation to negative energy balance may potentially contribute to regulation of reproductive success. Therefore, the objective of this 4-yr study was to determine the association of serum metabolites, cow BW, BCS, and calf performance on conception date in spring calving 2- and 3-yr-old beef cows (n = 381) grazing native range at the Fort Keogh Livestock and Range Research Laboratory. Cows were classified by subsequent calving date in a 55 ± 2 d breeding season as either conceiving early (EC; conceived in first 15 d of breeding) or late (LC; conceived during the remaining breeding season). Blood samples were collected in 2 periods 30 ± 1 d before calving and 14 ± 1 d before breeding to determine circulating concentrations of IGF-1 and β-hydroxybutyrate (BHB). Assignment to conception group resulted in a mean conception date that was 33 d earlier ($P < 0.01$) in EC than LC cows. Cow age × sample period × conception date interaction ($P < 0.01$) occurred for serum BHB concentrations. Serum BHB concentrations were similar ($P > 0.10$) for 2-yr-old cows regardless of their conception date classification and sampling period. However, pre-calving serum BHB concentrations were greater ($P < 0.01$) for LC than EC in 3-yr-old cows with no difference ($P = 0.86$) at pre-breeding. Serum IGF-1 concentrations were greater ($P < 0.01$) for EC cows relative to LC cows at pre-calving and pre-breeding sampling periods. Cow BW and BCS were not different ($P \geq 0.43$) at pre-calving or pre-breeding between EC and LC cows. Calf BW at birth was not different ($P = 0.25$) between EC and LC cows, but EC cows weaned lighter (205-d BW; $P < 0.01$) calves, suggesting more energy may have been diverted from milk production toward reproduction in EC cows. This study indicates that pre-calving serum concentrations of BHB and IGF-1 may be indicative of their capacity for subsequent rebreeding. Chute-side measurements of these factors may provide producers opportunity to manage cows differently to improve overall reproductive efficiency.

Key Words: beef cows, conception date, serum metabolites

T202 Sex comparison of white Fulani cattle blood profile in southwestern Nigeria.

A. O. Ladokun*[1], O. A. Oyebode[1], and T. O. Ososanya[2], [1]*University of Agriculture, Abeokuta, Ogun, Nigeria,* [2]*University of Ibadan, Ibadan, Oyo, Nigeria.*

Sexual dimorphism has been established in the brain regions of farm animals and poultry, but for their blood, reports do not agree as to differences at the same age. While some reports show no differences except for pregnant and lactating females, others indicate otherwise. This study was carried out to investigate the blood of white fulani breed of cattle in southwestern Nigeria if there would differences at same matured age (4 yr). A total of 100 cattle was used consisting of 50 bulls and 50 cows. Full hematology was investigated using the Vet Auto hemoanalyser machine. Some serum metabolites were also investigated including Total Protein, Albumin and total cholesterol. Data obtained were subjected to one-way ANOVA (ANOVA). The results show that white blood cell count (WBC) was significantly ($P \leq 0.05$) higher in females (17.23 ± 1.08) than in males (12.25 ± 0.77). Mean corpuscular hemoglobin concentration (MCHC) also showed sex differences with females having higher and significant ($P \leq 0.05$) average value (33.8 ± 0.19) than males (32.6 ± 0.24). The results from Serum analysis show that bulls (with 37.8 ± 0.54) have higher and significant ($P \leq 0.05$) Albumin values than cows (34.9 ± 0.29). Though the results obtained in this study fall within normal ranges for this species, it however does not indicate any specific sex effect for this breed.

Key Words: cattle, blood, sex

T203 Maternal diet restriction effects on fetal organ weights in beef cows during early pregnancy.

L. E. Camacho,* C. O. Lemley, T. J. Swanson, K. C. Swanson, and K. A. Vonnahme, *Department of Animal Sciences, North Dakota State University, Fargo.*

The objectives were to examine the effects of maternal nutrient restriction on fetal organ weights during early gestation. On d 30 of pregnancy, multiparous beef cows were randomly assigned to either 100% (CON; n = 6) or 60% NRC requirements (RES; n = 6). Cows were individually fed once daily in a Calan gate system at 1000 h. At d 85 of gestation cows were slaughtered and fetal organ tissues were collected and weighed. Fetal eviscerated weight (g) was greater ($P = 0.05$) in RES vs. CON. Absolute fetal organ or tissue weights (g) and fetal organ or tissue weights relative to fetal weight (g/kg) were not different ($P \geq 0.09$) between dietary treatmens for adrenals, kidneys, perirenal fat, spleen, or stomach complex. Fetal brain weight was not different ($P = 0.5$) between treatments, while brain weight relative to fetal weight was decreased ($P = 0.02$) in RES vs. CON. Fetal lung weight was not different ($P = 0.67$) between treatments, while lung weight relative to fetal weight was decreased ($P = 0.04$) in RES vs. CON. Heart weight was increased ($P = 0.001$) in RES vs. CON fetuses, while heart weight relative to fetal weight was not different ($P = 0.33$) between treatments. Fetal pancreas weight was increased ($P = 0.06$) in RES vs. CON, while pancreas weight relative to fetal weight was not different ($P = 0.17$) between treatments. Fetal omental and mesenteric fat weight and omental and mesenteric fat relative to fetal weight were increased ($P \leq 0.06$) in RES vs. CON. Maternal diet restriction during early pregnancy alters fetal organ weights. Interestingly, compensatory fetal intra-abdominal visceral fat deposition appears to occur when beef cows are nutrient restricted during early gestation.

Key Words: beef cows, fetal organs, nutrient restriction

T204 Maternal feed efficiency during gestation is correlated with offspring birth weight and girth in nutrient restricted and control-fed ewes.

A. M. Meyer*[1], K. A. Vonnahme[2], D. A. Redmer[2], L. P. Reynolds[2], and J. S. Caton[2], [1]*Department of Animal Science, University of Wyoming, Laramie,* [2]*Center for Nutrition and Pregnancy, Department of Animal Sciences, North Dakota State University, Fargo.*

We hypothesized that some of the variation in offspring fetal and neonatal growth observed within a given gestational nutritional treatment (e.g., nutrient restriction) in developmental programming studies is related to differences in maternal metabolic efficiency and nutrient utilization. Thus, our objective was to investigate the relationship of maternal feed efficiency (G:F) during gestation with offspring birth and neonatal responses. Data from 2 studies with similar designs and dietary treatments were utilized. In both studies, primiparous ewes with singleton pregnancies received a pelleted diet providing either 100% (control; n = 24) or 60% (nutrient restricted; n = 24) of NRC recommendations for

gestation. Nutritional plane treatments began on d 40 to 50 of gestation and lasted until parturition. Ewes were fed individually, and G:F was calculated as ADG (g/d) divided by DMI (g/d). At birth, lambs were immediately removed from their dams for artificial rearing. Data were analyzed using the CORR procedure of SAS to determine the relationship of ewe G:F during gestation with lamb measures within each nutritional plane. For nutrient restricted ewes, gestational G:F (range: −0.12 to 0.10) was positively correlated with birth weight (r = 0.50; $P = 0.01$), curved crown rump length (CCR; r = 0.46; $P = 0.02$), and heart girth (r = 0.60; $P = 0.002$), as well as BW at 7 d (r = 0.46; $P = 0.03$) and 21 d (r = 0.42; $P = 0.04$). Despite this, G:F of nutrient restricted ewes was not correlated ($P = 0.59$) with lamb ADG from birth to 21 d. For control ewes, gestational G:F (range: 0.08 to 0.21) also was positively correlated with birth weight (r = 0.39; $P = 0.06$) and heart girth (r = 0.54; $P = 0.006$), but was not correlated ($P > 0.16$) with CCR, 7- or 21-d BW, or ADG to 21 d. These data indicate that ewe metabolic efficiency and nutrient utilization, as measured by G:F, are related to lamb weight and size at birth. This relationship is stronger in a nutrient restriction model, suggesting that more efficient dams are able to partition more nutrients for fetal growth when nutrients are limiting.

Key Words: developmental programming, feed efficiency, fetal growth

T205 Nutrient intake during lactation affects performance of beef cows and calf growth. K. J. McLean,* B. H. Boehmer, L. J. Spicer, and R. P. Wettemann, *Oklahoma Agricultural Experiment Station, Stillwater.*

Fall calving cows grazing native grass pasture were used during 3 consecutive years (n = 44, n = 51 and n = 58, respectively) to evaluate the effects of nutritional supplementation during breeding and the first trimester of gestation on cow performance, plasma IGF-1, and subsequent postnatal growth of calves. Cows calved in Sept-Oct and were assigned to control (C, 1.82 kg/d of 38% CP supplement, approximately 100% of NRC requirements) or low (L, 0.2 kg/d of 8% CP supplement) from November 17 to March 20; supplement was individually fed in a stall barn. Cows were maintained on the same pasture and exposed to bulls for 60 d commencing Dec. 1. During lactation half of the cows on the C and L prenatal treatments were assigned to the C treatment the other half was assigned to the L treatment. The GLM procedure (SAS) was used to analyze BW, BCS and plasma IGF-1 of cows, and calf BW, as a 2X2 factorial ANOVA. Control cows lost less BW from Nov. to Jan. compared with L cows (37.8 ± 3.1 and 59.2 ± 3.1 kg, respectively, $P < 0.001$). Control cows were also heavier in May compared with L cows (566 ± 10 and 538 ± 10 kg, respectively, $P = 0.05$). However, BCS was not influenced ($P > 0.11$) by treatments. At breeding in Dec., C cows tended ($P = 0.06$) to have greater plasma concentrations of IGF-1 compared with L cows (26 ± 3 and 17 ± 3 ng/mL, respectively). Birth weight and postnatal growth of calves was not influenced ($P = 0.63$) by prenatal treatment. Calves on postnatal C cows had greater ADG from birth to Jan. compared with L calves (0.81 ± 0.03 and 0.74 ± 0.02 kg/d, $P = 0.05$). Weaning weight (205 d) was greater for calves on postnatal C versus L cows (188 ± 5 and 173 ± 4 kg, respectively, $P = 0.02$). Protein supplementation of beef cows during early gestation that caused greater BW loss, less BW gain of suckling calves, and reduced plasma concentrations of IGF-1, did not alter birth weight or postnatal growth of prenatally exposed calves.

Key Words: beef cows, gestation, nutrition

T206 Mineral supplementation associated with Megalac E and/or citrus pulp during timed AI synchronization programs in postpartum Nellore cows. M. V. Biehl*[1], A. V. Pires[2,1], I. Susin[2], D. D. Nepomuceno[2], J. R. S. Goncalves[3], R. Sartori[2], F. M. da Rocha[1], L. H. Cruppe[4], J. L. M. Vasconcelos[5], and M. L. Day[4], *[1]University of Sao Paulo, Pirassununga, SP, Brazil, [2]University of Sao Paulo, Piracicaba, SP, Brazil, [3]Experimental Station Hildegard Georgina Von Pritzelwitz, Londrina, PR, Brazil, [4]The Ohio State University, Columbus, [5]Sao Paulo State University, Botucatu, SP, Brazil.*

The objective of this study was to compare reproductive performance of Nellore cows (n = 215), synchronized with a 7 or 9-d CIDR + estradiol benzoate (EB) and 3 supplementation programs. Cows were blocked according to BW (428 ± 3.43), BCS (2.77 ± 0.03, scale 1–5) and DPP (81.9 ± 1.16) in a 2 × 3 factorial arrangement. The supplements were: mineral mixture (MM); MM + MegalacE + citrus pulp (CP) (MEG); MM + Kaolim + CP (KAO). Supplementation began 30 d before CIDR insertion and were terminated 30 d after timed AI. Blood samples for P4 analysis were collected 10 d before and at CIDR insertion to determine reproductive status. The CIDR was inserted with 2 mg of EB and it was removed either 7 or 9 d later. All cows received 25 mg PGF (Lutalyse) 48 h before CIDR removal, 300 IU eCG (Novormon) and 0.6 mg estradiol cipionate (ECP) at CIDR removal. Treatments were: 7dMM (n = 35; e.g., 7d CIDR and MM supplementation), 7dKAO (n = 34), 7dMEG (n = 36), 9dMM (n = 36), 9dKAO (n = 36), and 9dMEG (n = 38). Estrus was detected for 48 h and timed AI performed 50 h after CIDR withdrawal. Rebreeding with bulls 10 d after AI for period of 30 d. Pregnancy diagnosis was performed 30 and 60 d after AI. At CIDR insertion, 73.8% (158/215) of cows were anestrus. Estrus was detected in 77.7% (167/215) of the cows and time to estrus (41.2 ± 0.5 h) did not differ among CIDR and supplementation treatments. Timed AI pregnancy rates neither differed between the length of CIDR treatments nor among the supplementation programs (7dMM, 51.4%; 7dKAO, 50%; 7dMEG, 27.8%; 9dMM, 36.1%; 9dKAO, 38.9% and 9dMEG, 36.8%). Natural mating rebreeding pregnancy rate also did not differ between the length of CIDR treatments and among the supplementation programs. Final pregnancy rate was greater ($P < 0.05$) for the supplement KAO compared with the MEG (84.3 and 67.6%, respectively), and the MM group did not differ from any of the treatments. In conclusion, supplementation with Kaolim + CP or Megalac E + CP did not improve reproductive performance. In addition, timed AI pregnancy rates did not differ between 7-d and 9-d CIDR+EB programs.

Key Words: Megalac E, beef cows, timed AI

T207 Different luteolytic doses of PGF$_{2\alpha}$ in Nellore cows on days 5 and 7 of the estrous cycle. M. V. C. Ferraz Junior[1], A. V. Pires[2], R. Sartori[2], M. V. Biehl*[1], D. D. Nepomuceno[2], I. Susin[2], E. M. Ferreira[2], F. M. Rocha[1], J. R. S. Goncalves[3], L. H. Cruppe[4], and M. L. Day[4], *[1]University of Sao Paulo, Pirassununga, SP, Brazil, [2]University of Sao Paulo, Piracicaba, SP, Brazil, [3]Experimental Station Hildegard Georgina Von Pritzelwitz, Londrina, PR, Brazil, [4]The Ohio State University, Columbus.*

The aim of this study was to evaluate the luteolytic competence of different PGF2α (PGF) doses on d 5 and 7 of the estrous cycle. Nonlactating Nellore cows in random stages of the estrous cycle were treated with 25 mg PGF (Lutalyse) for synchronization purpose. Three hundred and 39 cows detected in estrus after PGF injection were divided into 2 groups to be treated on d 5 or d 7 of the subsequent estrous cycle. Treatments consisted of 3 different PGF doses (12.5, 25 and 50 mg) within target d of the cycle (d 5 and d 7). Treatments were defined as follow: 5d12.5PGF (n = 57); 5d25PGF (n = 58); 5d50PGF (n = 58); 7d12.5PGF (n = 56); 7d25PGF (n = 55) and 7d50PGF (n = 55). Blood samples for progesterone (P4) analysis were collected at 0, 24 and 48 h after PGF treatments to assess the incidence of luteal regression. The presence of a CL was defined as P4 concentration ≥1 ng/ml at the time of PGF and its regression defined as attainment of concentrations of P4 ≤ 1 ng/ml by 48 h after PGF. Detection of estrus was performed twice daily with the aid of teaser bull for 5 d after PGF. Serum P4 concentrations were quantified using a chemiluminescent immunoassay (Immulite 1000, Siemens Healthcare Diagnostics, Deerfield, IL, USA). Data were analyzed using the GLIMMIX and MIXED procedures of SAS. Estrus detection rate was greater ($P < 0.05$) in animals treated on d 7 compared with d 5 of the estrous cycle (48.8% and 32.4%, respectively). Furthermore, as dosage of PGF increased, the estrus detection rate increased ($P < 0.05$; 24.8%, 41.6% and 54.9% for the 12.5, 25 and 50 mg doses, respectively). Interactions of d of the estrous cycle and PGF dose were not detected for estrus detection rate. Incidence of luteolysis was greater ($P < 0.05$) on d 7 compared with d 5 of the estrous cycle (75.9% and 40.5%, respectively) and increased with dose of PGF (41.6%, 56.6% and 75.2% for 12.5, 25 and 50mg, respectively), with no day x dose interaction. In conclusion, in Nellore cows, the capacity of PGF to induce luteal regression increases between d 5 and 7 of the estrous cycle and as dose of PGF increases from 12.5 to 50 mg/dose.

Key Words: luteolysis, estrous cycle, beef cows

T208 Relationship of body condition with serum prolactin, antral follicle count, and calving rate of beef cows.

M. L. Looper*[1], J. D. Patterson[1], B. C. Williamson[1], D. M. Hallford[2], and C. F. Rosenkrans Jr.[1], [1]*University of Arkansas, Fayetteville,* [2]*New Mexico State University, Las Cruces.*

Multiparous (mean age = 7.6 ± 2.1 yr; range 4 to 11 yr), Brahman-influenced beef cows were managed to achieve thin (BCS = 4.3 ± 0.6; BW = 462 ± 51 kg; n = 43) or good (BCS = 6.4 ± 0.8; BW = 582 ± 81 kg; n = 54) body condition (BC) beginning 164 d before breeding to determine the relationship of BC on serum prolactin, total antral follicle count, and calving rate. Cows grazed replicated (n = 4) common bermudagrass during a 60-d breeding season. Blood samples were collected at d 0, 30, and 60 of the breeding season, and serum concentrations of prolactin (PRL) were quantified; serum progesterone was determined on d −10 and 0 of the breeding season to determine luteal status at the beginning of breeding. Antral follicle count (AFC; total number of follicles >3 mm in diameter on both ovaries) was determined via ultrasonography at d 0 and 60 of the breeding season. Ovarian pairs were classified as low (<16 antral follicles), intermediate (16 to 24 antral follicles), or high (>24 antral follicles) AFC. Body weight and BCS were recorded during the breeding season (d 0, 30, and 60). Data were analyzed with ANOVA (model included BC, luteal status, and their interaction; pasture was used as a random effect), and CORR and chi-squared analyses of SAS. Seventy percent of cows were cyclic at the start of breeding. Thin cows gained more ($P < 0.001$) BW (76 ± 4 kg) and BC (1.0 ± 0.1 BCS units) than good-BC cows (51 ± 5 kg; 0.2 ± 0.1 BCS units) during the breeding season. Concentrations of serum PRL tended ($P < 0.12$) to be greater in cyclic cows (n = 68) than anestrous cows (n = 29) on d 30 and 60 of the breeding season. Cyclic cows had a decreased ($P < 0.02$) actual AFC on d 0 of the breeding season compared with anestrous cows (15.8 ± 1.4 vs. 21.7 ± 2.2 antral follicles, respectively). A luteal status × BC interaction tended ($P < 0.10$) to influence actual AFC on d 60 of the breeding season; anestrous, thin cows (21.3 ± 1.8 antral follicles) had increased actual AFC compared with all other groups (mean = 14.6 ± 2.1 antral follicles). More ($P < 0.05$) cyclic cows were classified as low AFC on d 0 than anestrous cows. Similarly, a greater ($P < 0.05$) number of cyclic cows than anestrous cows were classified as low or intermediate AFC on d 60. Body condition score on d 0 ($r = -0.29$; $P < 0.005$) and 60 ($r = -0.31$; $P < 0.003$) of the breeding season was inversely correlated with actual AFC on d 0. Calving rate was reduced ($P < 0.0001$) in thin cows (46%) compared with good-BC cows (87%). Calving rate of cows was similar ($P > 0.10$) among classifications of AFC at d 0 and 60 and averaged 76%. Luteal status tended to affect serum PRL during the breeding season. Further, presence of serum progesterone indicative of luteal activity as well as good BC appeared to negatively influence AFC in Brahman-influenced cows.

Key Words: antral follicle count, beef cow, prolactin

T209 Serum progesterone concentrations in Holstein and Nelore cows after the insertion of two different progesterone devices.

A. B. Nascimento*[1], P. L. J. Monteiro Jr.[1], F. L. M. Silva[1], M. M. Guardieiro[1], A. B. Prata[1], G. P. Nogueira[2], G. B. Mourão[1], M. C. Wiltbank[3], A. V. Pires[1], and R. Sartori[1], [1]*University of São Paulo, Piracicaba, SP, Brazil,* [2]*São Paulo State University, Araçatuba, SP, Brazil,* [3]*University of Wisconsin-Madison, Madison.*

The objective of this study was to compare the circulating progesterone (P4) profile for 2 different commercial devices for delivery of P4, CIDR (1.9 g, Pfizer) and Sincrogest (1.0 g, Ourofino) in Holstein and in Nelore cows. We hypothesized that independent of the P4 device inserted, the P4 concentrations would be lower in Holstein than in Nelore cows, possibly due to greater P4 metabolism in dairy than in beef cattle. Also, we hypothesized the lower content of P4 present in Sincrogest (1.0 g) would produce lower circulating P4 than CIDR (1.9g) in either Holstein or Nelore cows. Nonlactating, non-pregnant cows (n = 10 Holstein and n = 10 Nelore) were randomly assigned to 1 of 2 groups: CIDR or Sincrogest devices. Blood samples were taken from all cows at hour 0, 1, 6, 12, 24, and 48 after insertion of the devices to analyze P4 concentration by radioimmunoassay. Cows were fed a maintenance diet 14 h before device insertion and at 12, 24, and 48 h after device insertion (following blood sampling). Data were analyzed using generalized linear models, considering the heterogeneous first-order autoregressive covariance matrix, due to repeated measures on the same cow at different times. There was a significant effect of breed (1.18 vs. 2.24 ng/mL, Holstein vs. Nelore, $P = 0.0004$), type of P4 device (1.99 vs. 1.43, CIDR vs. Sincrogest, $P = 0.03$), time ($P < 0.05$), and an interaction of breed by time ($P = 0.0004$). Progesterone concentrations were different ($P < 0.01$) among Holstein and Nelore at hour 0, 1, 6, 12, 24, and 48. Circulating P4 differed or tended to differ for CIDR vs. Sincrogest at hour 1 ($P = 0.09$), 6 ($P = 0.07$), 12 ($P = 0.09$), 24 ($P = 0.05$), and 48 ($P = 0.01$) but not at hour 0 ($P = 0.83$). Thus, independent of the brand of P4 device utilized, P4 concentrations were about 90% greater in Nelore than in Holstein cows, probably due the higher P4 metabolism in Holsteins. Interestingly, the Sincrogest device with 47% less P4 than the CIDR device, produced circulating P4 that was only 28% lower than CIDR. Supported by FAPESP, CAPES and CNPq of Brazil.

Production, Management and the Environment: Beef, Swine, Sheep

T210 Management and facility factors that affect mortality in grow-finishing pigs. P. S. Agostini*[1,2], A. G. Fahey[2], E. G. Manzanilla[1], J. V. O'Doherty[2], C. de Blas[3], and J. Gasa[1], *[1]Universitat Autònoma de Barcelona, Bellaterra, Spain, [2]University College Dublin, Belfield, Dublin, Ireland, [3]Universidad Politécnica de Madrid, Madrid, Spain.*

The objective of this study was to investigate the effect of some on-farm production and management factors on the mortality rate of grow-finishing pigs. In total 316 batches from 246 growing-finishing farms, including 459,148 pigs, using a Pietrain male finisher and belonging to 8 Spanish companies were used. All data were collected by survey during 2008 and 2009. Survey information included season of placement, sex segregation by pens, number of pig origins, frequency of antibiotic treatments, water source in the farm, initial and final body weight (IBW and FBW), percentage of the barn utilized, floor, feeder, ventilation and number of animals placed. A multivariate linear mixed regression model was used including factors that had a P-value <0.25 in a univariate regression model. These factors were then included in the multivariate model and the final model was determined using a stepwise selection method. The company was considered as a random factor but it was not significant ($P > 0.05$) and thus not included in the final model. The average rate of mortality was 4.13 ± 2.65%. There was a significant increase in mortality when: a) batches were placed between October and March ($P < 0.01$), b) pigs were obtained from multiple origins versus a unique origin ($P < 0.05$), c) pigs were treated ≥3 times with antibiotics versus those treated <3 times ($P < 0.01$), d) fed in a multi-space feeder compared with single-space ($P < 0.01$) and finally e) in farms with more than 800 pigs placed ($P < 0.05$). Moreover, a quadratic effect of IBW ($P < 0.05$) was observed showing that pigs with lower and higher IBW had higher mortality. An interaction between IBW and type of feeder was found ($P < 0.01$) and it showed that pigs fed through multi-space feeder and with IBW lower and higher than 21 kg presented higher and lower mortality, respectively, compared with single-space and single-space with drinker. Total variability of mortality explained by the model was 26%. This study indicates that farms may reduce mortality by improving some farm facilities and/or modifying some management practices.

Key Words: grow-finishing pigs, factors, mortality

T211 Housing and management factors that affect feed conversion ratio in grow-finishing pigs. P. S. Agostini*[1,2], A. G. Fahey[2], E. G. Manzanilla[1], J. V. O'Doherty[2], C. de Blas[3], and J. Gasa[1], *[1]Universitat Autònoma de Barcelona, Bellaterra, Spain, [2]University College Dublin, Belfield, Dublin, Ireland, [3]Universidad Politécnica de Madrid, Madrid, Spain.*

The objective of this study was to investigate the effect of some on-farm production and management factors on the feed conversion ratio (FCR) of grow-finishing pigs. In total 316 batches from 246 growing-finishing farms, including 459,148 pigs, using a Pietrain male finisher and belonging to 8 Spanish companies were used. All data were collected by surveys during 2008 and 2009. Survey information included: season of placement, sex segregation by pens, number of pig origins, frequency of antibiotic treatments, water source in the farm, initial and final body weight (IBW and FBW), percentage of the barn utilized, floor, feeder, ventilation and number of animals placed. A multivariate linear mixed regression model was used that included factors that had a P-value <0.25 in a univariate model and then selected by stepwise procedure in the multivariate model. Company was considered as a random factor but it was not significant ($P > 0.05$) and thus not included in the final model. The mean FCR was 2.71 ± 0.15. Averages of FCR were lower when batches: a) were placed between April and September ($P < 0.01$), b) pigs were segregated by sex in pens (entire male versus female) ($P < 0.01$), c) the proportion of the floor covered by slats was reduced to less than 50% ($P < 0.05$), d) were fed in a single space feeder with an incorporated drinker ($P < 0.01$), e) treated 3 or more times with antibiotics than those treated less than 3 times ($P < 0.01$), f) pigs had a lower FBW at slaughtering ($P < 0.01$) and finally g) had a higher percentage of the barn utilized ($P < 0.01$). Moreover, a quadratic effect of IBW ($P < 0.01$) was observed showing that pigs with lower and higher IBW had higher FCR. An interaction between IBW and trimester of placement was also found ($P < 0.01$) and it showed that pigs placed between July and September and with IBW lower and higher than 19 kg had higher and lower FCR, respectively, compared with pigs placed in other months. Total variability of FCR explained by the model was 31%. This study indicates that farms may reduce FCR by improving some farm facilities and/or modifying some management practices.

Key Words: grow-finishing pigs, factors, feed conversion ratio

T212 Management and facility factors that affect the variability of average daily gain in grow-finishing pigs. P. S. Agostini*[1,2], A. G. Fahey[2], E. G. Manzanilla[1], J. V. O'Doherty[2], C. de Blas[3], and J. Gasa[1], *[1]Universitat Autònoma de Barcelona, Bellaterra, Spain, [2]University College Dublin, Belfield, Dublin, Ireland, [3]Universidad Politécnica de Madrid, Madrid, Spain.*

The objective of this study was to investigate the effect of some on-farm production and management factors on the average daily gain (ADG) of grow-finishing pigs and explain the variability found between companies. Information from 275,936 pigs from Pietrain male finisher, distributed in 190 batches belonging to 5 Spanish companies (ranging from 19 to 59 batches for each company), was collected by survey during 2008 and 2009. ADG was defined as the total average weight gain per pig (kg) divided by the length of the grow-finishing period (days). A multivariate linear mixed regression model was used and factors were considered to have a significant effect when $P < 0.05$. The company was considered as a random factor and batch and herd effects as the residual factor. The mean ADG was 0.632 ± 0.048 kg. Animals placed from July to December had higher ADG than batches placed in other months ($P < 0.01$). Pigs fed in a single-space feeder with incorporated drinker had higher ADG than single and multi-space without drinker ($P < 0.05$). Small batches (less than 800 pigs placed) had higher ADG ($P < 0.01$) and pigs raised a higher final body weight (FBW) at slaughtering also had higher ADG ($P < 0.01$). An interaction between FBW and feeder was found ($P < 0.05$) showing that pigs fed through single-space feeder with drinker and with FBW lower and higher than 102 kg had lower and higher ADG respectively compared with other feeders. When no fixed effects were included in the model (null model), about 33% of the variability was registered between companies, meanwhile when fixed effects were included (full model), companies only explained 8% of the variance. The total variance explained by the full model was 26%. Companies may have important specific factors affecting the ADG which have not been considered in this study; among them some approaches of health status, biosecurity conditions or nutrition programs should be included in future studies.

Key Words: grow-finishing pigs, factors, average daily gain

T213 Effects of herb supplementation on growth performance, litter performance, and diarrhea occurrence in lactating sows and piglets.

J. H. Jung,* J. P. Lee, and I. H. Kim, *Department of Animal Resource and Science, Dankook University, Cheonan, Choongnam, South Korea.*

This study was conducted to evaluate the effects of herb supplementation on growth performance, litter performance, and diarrhea occurrence in lactating sows and piglets. A total of 30 sows (Landrace × Yorkshire) and their litters were employed in this study. Sows were allocated to 1 of 3 treatment groups. Dietary treatments included: 1) CON, basal diet, 2) A, basal diet + 0.01% (*Scutellaria baicalensis* + *Astragalus membranaceus*), and 3) B, basal diet +0.01% (*Codonopsis pilosula* + *Angelica gigas*). The experiment started 7 d before farrowing and lasted for 28 d. Within 24 h after parturition, numbers of piglets were adjusted equally per sow. Backfat thickness was evaluated at 3-d before farrowing and weaning day (21d). No differences ($P > 0.05$) were observed in ADFI and backfat thickness throughout the experimental period. However, backfat loss was lower ($P < 0.05$) in CON treatment than that in A and B treatments. No significant difference ($P > 0.05$) was found in the estrus interval and fecal moisture content among dietary treatments. No significant difference ($P > 0.05$) was observed in the birth BW, 14 d BW, and 21 d BW (weaning weight) of piglets among treatments. No difference ($P > 0.05$) was observed in diarrhea occurrence of sucking piglets by dietary supplementation with herb. No significant difference ($P > 0.05$) was noted in total number of piglets born, number of weaned piglets, and mortality of piglets. In conclusion, no effect of herbs was observed on the performance of lactating sows and diarrhea occurrence in piglets. Further studies should be conducted to confirm the positive effect of dietary supplementation with herbs in lactating sows.

Key Words: herb, piglet, sow

T214 Wood to feed: Diversifying income opportunities by increasing the livestock feeding value of woody plant species.

T. R. Whitney*[1], J. W. Walker[1], W. C. Stewart[1], R. J. Ansley[2], B. D. Lambert[3], A. F. Cibils[4], C. B. Scott[5], J. L. Johnson[6], T. Bader[7], W. Winters[8], L. O. Tedeschi[9], G. E. Carstens[9], and J. P. Muir[3], *[1]Texas AgriLife Research, San Angelo, [2]Texas AgriLife Research, Vernon, [3]Texas AgriLife Research, Stephenville, [4]New Mexico State University, Las Cruces, [5]Angelo State University, San Angelo, TX, [6]Texas AgriLife Extension, Stephenville, [7]Cedar Beetle, Concan, TX, [8]Novas Wood Group, Houston, TX, [9]Texas A&M University, College Station.*

The primary goal of this project is to develop the technology and knowledge base necessary to convert invasive woody biomass material into a viable ruminant feed ingredient. Woody species such as *Juniperus* and *Prosopis* occur on millions of acres of rangelands in the US and continue to increase at rapid rates, reducing forage productivity, water resources, wildlife habitat, and ecosystem health. Treatments to manage these woody species are generally not cost-effective. However, increasing the value of woody biomass through conversion to animal feed or biofuels will provide cost-effective management options, while concurrently increasing grass production and ecosystem health. Although not unique to the livestock industry, current drought and escalating fuel and fertilizer prices have drastically increased feed costs and interest in using nontraditional feeds. Use of woody biomass as feed is not a novel idea, with research conducted in the early 1920s and late 1950s evaluated the feeding value of sawdust and mesquite wood in cattle diets. Limited adoption of mesquite as livestock feed probably occurred because of the relative costs of traditional feed ingredients was not great enough to justify the risk of using a novel feed and conversion of wood to feed was not very efficient. However, both of these conditions have changed. Thus, Texas AgriLife Research faculty, colleagues, and industry collaborators have renewed "wood to feed" efforts and have been successfully incorporating ground woody material into ruminant livestock diets. A recent study from our laboratory showed that ground juniper can replace ground oat hay in lamb feedlot diets without negatively affecting DMI, ADG, or G:F ($P > 0.05$). Even though a renewed interest in "wood to feed" has surfaced, livestock producers are reluctant to move forward because many questions still remain about how to integrate individual systems components into a profitable and sustainable operation. Therefore, to increase the adoption of technologies to cost-effectively harvest and utilize woody biomass as ruminant feeds, we are creating a web-based "Wood to Feed" Center where multidisciplinary scientists work directly with ranchers, landowners, and industry representatives to integrate expertise and novel ideas.

Key Words: woody plants, roughage, natural resources

T215 Effect of body size on feed intake and methane emissions from ewes offered fresh ryegrass.

M. D. Fraser, H. Fleming, V. J. Theobald, and J. M. Moorby,* *Institute of Biological, Environmental and Rural Sciences, Aberystwyth University, Aberystwyth, UK.*

Sheep production in the UK is stratified into systems that utilize smaller, hardier breeds in the hills, their crossbreds in the uplands, and heavier, more productive breeds and their crossbreds in the lowlands. This experiment tested the hypothesis that body mass and associated allometric relationships, rather than breed type, determines enteric methane production in sheep. Methane emission measurements were made on mature, barren ewes of 4 different breed types: Welsh Mountain (WMO), Scottish Blackface (SBF), Welsh Mule (WMU), and Texel (TEX) (n = 8 per breed). The mean live weights for the different breeds were 46 (±2.9), 62 (±6.2), 71 (±4.4) and 78 (±3.8) kg, respectively. Following a 3-week adaptation period, the ewes were housed in methane chambers and zero-grazed on herbage cut from an intensively managed perennial ryegrass sward. They were fed on an ad libitum basis, with 2 equal portions offered at 0900 and 1600 h. Data were collected for 3 consecutive days for each animal. There was a significant treatment effect of breed type on voluntary intake, with mean DM intake recorded as 1.08, 1.02, 1.30 and 1.55 for WMO, SBF, WMU, and TEX respectively (SED = 0.111 kg; $P < 0.001$). However, there was a relatively poor relationship between metabolic body weight (BW) and DM intake ($R^2 = 0.30$); consequently body mass was a poor indicator of methane emissions ($R^2 = 0.17$). There was a stronger correlation between DM intake (g/d) and methane emitted ($R^2 = 0.57$). In conclusion, BW was a relatively poor indicator of DM intake and therefore a poor predictor of methane emissions from sheep of different breed sizes when offered fresh ryegrass.

Key Words: breed size, methane, sheep

T216 Fifty years of the Wyoming ram test: How have sheep changed?

D. J. Burton,* P. A. Ludden, R. H. Stobart, and B. M. Alexander, *University of Wyoming, Laramie.*

Production characteristics of white-faced rams have been systematically evaluated over a 140 d test for gain and wool characteristics in the

Wyoming white-faced ram test since 1961. Records from this test are predominantly from Rambouillet rams but records from other breeds such as Columbia and Targhee are included. Individual production traits from test records (n = 3941) from 1961 through 2010 were analyzed to determine how sheep have changed over the last 50 years. Although age of rams on test has remained stable at 354 ± 0.6 d, both weight-on and -off test have increased linearly ($P < 0.001$) since 1961 with weight-off test increasing 22.7 kg over this time frame. This larger body size likely contributed to a linear increase ($P < 0.001$) in clean fleece weight. Rate of gain also increased linearly ($P < 0.001$) with rams gaining approximately 0.23 ± 0.01 kg/d in the early years to a current rate of gain of 0.39 ± 0.01 kg/d. Although wool characteristics remain an important component to the test index, spinning count, a measure of wool diameter, did not change in a linear manner ($P > 0.05$), and has remained stable at a 62 spinning count. Market forces may influence breed characteristics over time, and thus correlates to market prices were determined with a 0, 2 and 5 yr time lag. Average daily gain was strongly correlated (r >0.6) with feeder lamb price, and had the strongest correlation with a 2 year (r = 0.76) time lag. Sheep inventory negatively correlated (r = 0.87) with average daily gain but correlated similarly with a 0, 2 or 5 year time lag. Wool price did not correlate (r <0.1; $P \geq 0.5$) with spinning count at any of the time lags. Rambouillet rams have increased in size over the last 50 years with an increase in efficiency of production. Although clean fleece weight has increased proportionally to ram size, fiber diameter has remained largely unchanged and did not correlate to market wool price. This suggests that market influences on white-faced ram selection have largely affected growth traits while avoiding any negative effect on wool quality.

Key Words: ram, production, wool

T217 The environmental and economic impact of removing growth-enhancing technologies from United States beef production. J. L. Capper[1] and D. J. Hayes*[2], [1]*Washington State University, Pullman,* [2]*Iowa State University, Ames.*

This study quantified the environmental and economic impact of withdrawing growth-enhancing technologies (GET) from the US beef production system. A deterministic model based on the metabolism and nutrient requirements of the beef population was used to quantify resource inputs and waste outputs per 454 × 10^6 kg of beef. System boundaries extended from manufacture of cropping inputs to delivery of live animals at the slaughterhouse. Two production systems were compared – one using GET (steroid implants, in-feed ionophores, in-feed hormones and β-adrenergic agonists) where approved by the FDA at current adoption rates; the other without GET use. Both systems were modeled using characteristic management practices, population dynamics and production data from US beef systems. The economic impact and global trade and carbon implications of GET withdrawal were calculated based on feed savings from the environmental model. Withdrawing GET from US beef production reduced productivity (growth rate and slaughter weight) and increased the population size required to produce 454 × 10^6 kg beef by 385 × 10^3 animals. Feedstuff and land use were increased by 2,830 × 10^3 t and 265 × 10^3 ha respectively by GET withdrawal, with 20,139 × 10^6 more liters of water being required to maintain beef production. Manure output increased by 1,799 × 10^3 t as a result of GET withdrawal, with an increase in carbon emissions of 714,515 t per 454 × 10^6 kg beef. The projected increased costs of US beef produced without GET resulted in the effective implementation of an 8.2% tax on beef production, leading to reduced global trade and competitiveness. To compensate for the increase in US beef prices and maintain worldwide beef supply it would be necessary to increase beef production in other regions, with a projected cumulative increase in global carbon emissions of 3,147 × 10^6 t of CO2-equivalent from 2009 to 2023. It is clear that withdrawing GET from US beef production would reduce both the economic and environmental sustainability of the industry.

Key Words: productivity, carbon footprint, growth-enhancing technology

T218 Drought management: Replacing hay with a field pea/co-product supplement fed daily or on alternate days. D. G. Landblom*[1] and S. Senturklu[2], [1]*North Dakota State University-Dickinson Research Extension Center, Dickinson,* [2]*Canakkale Onsekiz Mart Universitesi, BMYO, Canakkale, Turkey.*

One hundred seven, 3- to 10-yr-old, third trimester to early-lactation cows were randomized to treatment and weight blocks, in a 110.5 d study to evaluate a 25% hay reduction and a blended RDP-RUP supplement replacement for hay fed either daily (C) or on alternated days (Alt-D) as a drought management strategy. Cows were fed an all mixed hay control diet (Alfalfa-Bromegrass; 10.2% CP) (C) or a mixed hay and wheat straw (4.7% CP) diet in which the amount of hay fed per cow was reduced 25% and replaced with a field pea/co-product supplement (22.8% CP) that was fed either daily (D) at 0.25% of initial BW or 0.50% of initial BW on alternate days (Alt-D). The 0.635 cm pelleted supplement contained a blend of RDP and RUP from field peas (70.0% RDP), distillers dried grains with solubles (65.0% RUP), and barley malt sprouts (64.0% RDP). Data were analyzed using MIXED procedures of SAS. Unsupplemented C cows were fed an average 16.5 kg of mixed hay daily compared with supplemented cows that were fed 9.57 kg of hay, 1.5 kg wheat straw, and 1.52 kg of the pea/co-product supplement totaling 12.66 kg daily (as-fed). Using the blended RDP-RUP supplement as a replacement for hay, fed either D or on Alt-D, did not affect ending cow weight ($P = 0.89$), body condition score ($P = 0.19$), 12th rib fat depth ($P = 0.19$), or pre-breeding estrous cyclicity ($P = 0.68$). Subsequently, hay conserving strategies did not affect fall calf weaning weight ($P = 0.63$), gain ($P = 0.62$), or ADG ($P = 0.64$). Daily cost per cow was $1.13, $1.19, and $1.185 for the C, D and Alt-D methods, respectively. The data suggest that blending the selected RDP and RUP ingredient sources supplied sufficient ammonia nitrogen to the rumen on the non-supplementation day and appeared to provide adequate nutrient flow when fed on alternate days; and proved to be an effective drought management strategy. Conversely, when hay is plentiful the conservation strategy would be a cost effective method for stockpiling hay as a hedge against drought or to make hay available as a cash crop.

Key Words: beef cattle, field pea, RDP-RUP

T219 Effect of grazing stockpiled perennial forages on beef cow performance, nutrient intake and soil nutrients. H. A. Lardner*[1,2] and D. Damiran[1,2], [1]*Western Beef Development Centre, Humboldt, Saskatchewan, Canada,* [2]*Department of Animal and Poultry Science, University of Saskatchewan, Saskatoon, Saskatchewan, Canada.*

An experiment was conducted to evaluate the effects of grazing stockpiled perennial forages in field paddocks or round bale hay fed in drylot pens on beef cow performance, estimated dry matter intake (DMI), nutrient intake and soil nutrient levels. Winter feeding systems were (i) field grazing [meadow bromegrass (*B. riparius*)-alfalfa (*M. sativa*)] stockpiled perennial forage (SPF) (TDN = 55.4%; CP = 11.6%) and (ii) similar grass-legume round bale hay fed in drylot pens (DL) (TDN = 56.9%; CP = 11.7%). Dry, pregnant Black Angus cows (n = 60; mean

BW = 620 ± 1.1 kg) were randomly allocated to one of 2 replicated (n = 3) winter feeding systems. In SPF, cows were allocated swathed forage in field paddocks on a 3 d basis and supplemented (rolled barley grain+ wheat dried distillers grains with solubles; TDN = 84.0%, CP = 18.4%) at 0.2% of BW. Soil nutrient levels were determined on each treatment site following winter grazing. The DMI was measured for each treatment using the herbage weight disappearance method. Cow BW, body condition score, and rib and rump fat were measured at start and end of the experiment. Statistical analysis was conducted as a one way ANOVA using the Proc Mixed Model procedure of SAS. Measured forage biomass was not different ($P > 0.05$) between DL and SPF systems, 4341 and 4910 ± 200 kg/ha, respectively. Forage utilization was lower ($P < 0.05$) in SPF than in DL (57.8% vs. 93.0%) system. Cows on SPF consumed less ($P < 0.05$) DM (8.8 vs. 12.5 kg/d), CP (1.04 vs. 1.47 kg/d), and ME (17.7 vs. 25.7 Mcal/d) from stockpiled forages than cows fed hay in DL. However, total DMI (forage + supplement) and corresponding nutrients were not different ($P > 0.05$) between systems. Cow BW (634.9 and 634.7 ± 1.5 kg), rib fat (3.3 and 3.4 ± 0.4 mm), rump fat (3.7 and 3.5 ± 0.4 mm) and calf birth weight (40.1 and 39.9 ± 0.9 kg) were similar ($P > 0.05$) between DL and SPF systems, respectively. Soil nutrient levels at the 0–60 cm depth were similar ($P > 0.05$) on the feeding sites, except SO_4 which tended to be lower ($P = 0.06$) on SPF (35.9 kg/ha) compared with DL sites (422.3 kg/ha). These results suggest it is possible to manage beef cows grazing stockpiled perennial forages during winter in western Canada.

Key Words: stockpiled forage, winter grazing, beef cow

T220 The environmental, economic and social implications of improving yield and average daily gain in beef production.

R. R. White* and J. L. Capper, *Washington State University, Pullman.*

A deterministic model of the US beef industry was developed to quantify changes in environmental impact (EI), profitability and social acceptability resulting from either increasing average daily gain (ADG) by 15% or increasing yield per animal by 15%, with the goal of producing 1 billion kg of beef. Both treatments were compared with a baseline scenario representative of the average growth rate (0.69 - 0.8 kg/d for stockers and 1.22–1.37 kg/d for finishers) and finishing weight (544 kg for heifers and 635 kg for steers) in the US beef industry. Metrics for EI included land, water and feedstuff use, as well as greenhouse gas (GHG) emissions and manure production with system boundaries extending from cropping inputs to animal slaughter. Profitability was calculated by enterprise budgets for current cattle and feed prices sourced from the National Agricultural Statistics Service. The consumer perception of the value (price-dependent) received from purchasing beef was the metric of social acceptability. When ADG increased, land, water and feed use per billion kg of beef were reduced by 2%, 13% and 4%, respectively and GHG emissions and manure production per billion kg of beef were reduced by 7% and 4%. Increased ADG increased whole-industry profitability by 7% which subsequently led to a 5% improvement in consumer's perceived value of purchased beef. Increased yield also reduced EI: land, water and feed use per billion kg of beef were reduced by 3%, 16% and 9%, respectively compared with controls, and GHG emissions and manure production per billion kg of beef were reduced by 10% and 8%. Industry profitability increased by 13.5%, resulting in a 15.8% improvement in consumer's perceived value of beef purchased. Given that sustainability is an environmental, economic and social construct, these conclusions suggest that the sustainability of beef production can be achieved by either increasing yield or increasing ADG. This research supports the assertion that, within the beef industry, management practices centered on improving efficiency will also improve sustainability.

Key Words: beef, sustainability, environmental impact

T221 Body development and endocrine relations at puberty in crossbred heifers.

J. O. J. Barcellos*[1], C. McManus[1], L. C. Canellas[1], E. R. Prates[1], S. R. Menegassi[1], J. Braccini Neto[1], and R. P. Oaigen[2], [1]*Federal University of Rio Grande do Sul, Porto Alegre, RS, Brazil,* [2]*Federal University of Para, Belém, PA, Brazil.*

The objective of this study was to determine the age and liveweight at puberty of crossbreed heifers from various Nelore (N)-Hereford (H) genetic groups (GG) (25%N-75%H; 37.5%N-63.5%H; 43.7%N-56.3H%; 50%N-50%H; 75%N-25%H) submitted to 4 average daily gains (ADG; kg/d) from weaning to puberty: 0.5 (L; n = 32), 0.75 (M; n = 32), 1.00 (H; n = 29) and 1.25 (VH; n = 27). Puberty was defined as estrus followed by formation of a corpus luteum. Backfat thickness (BF = mm) at the start and at the end of the experimental period was determined by ultrasound. Mean age and liveweight at puberty (LWP) were 388.0 ± 1.9 d and 331.4 ± 1.3 kg, respectively. Heifers with higher post weaning average daily gain were heavier at first estrous and had a lower age at puberty ($P = 0.028$). However, there was an interaction ($P = 0.012$) between growth rates and breed composition. The 75% Nelore were heavier, older and taller at puberty than 25%, 37.5%, and 43.5% N heifers ($P = 0.034$). The phenotypic correlation between body condition score, backfat thickness and puberty age were −0.37 and −0.58, respectively ($P = 0.041$). A linear effect ($P = 0.011$) was observed between the ratio weight:height at 11 mo of age (WH11) and age at puberty (AP). Heifers submitted to higher ADG showed the greater follicle diameter at 10 mo age ($P = 0.031$) and were younger at puberty ($P = 0.033$). The IGF-I blood serum levels were 206, 234, 308 and 312 ng/ml at puberty for L, M, H, and VH ADG, respectively. The IGF-I levels were associated ($P = 0.019$) with AP in heifers because they influenced follicular growth (FG) at 10 mo of the age. There was no multicollinearity among the variables evaluated in the model. A multiple regression analysis found a linear model ($P = 0.017$) to estimate puberty: AP = 437.96 - FG10 × 1.66 + GG × 0.46 + LWP × 0.71-WH11 × 42.67 -BF × 9.95-ADG × 47.59-LW11 × 0.35 ($r^2 = 0.87$). Variables related to body development were better than endocrine predictors of puberty in beef heifers.

Key Words: puberty, beef heifers, follicular growth

T222 Effects of prepartum grouping strategy on health, reproductive, and productive parameters of dairy cows.

P. R. B. Silva*[1,2], J. G. N. Moraes[1,2], L. G. D. Mendonça[1], A. A. Scanavez[1], G. Nakagawa[1], M. I. Endres[2], J. Fetrow[1], and R. C. Chebel[1], [1]*Department of Veterinary Population Medicine, University of Minnesota, St Paul,* [2]*Department of Animal Science, University of Minnesota, St Paul.*

Objectives were to evaluate the effect of an "all-in-all-out" (AIAO) prepartum grouping strategy on health, productive, and reproductive parameters of Jersey cows. Cows (254 ± 7 d of gestation) were paired by gestation length and assigned randomly to AIAO or control treatments. In the AIAO (n = 259) treatment groups of 44 cows were moved into a pen where they remained for 5 wk, whereas in the control treatment (n = 308) approximately 10 cows were moved into a pen weekly to maintain stocking density (44 cows/48 headlocks). Pens were identical in size and design and each of the pens received each treatment a total of 3 times, totaling 6 replicates. Cows were examined at enrollment, calving (d0), d28, and d56 for lameness and on d 1, 4, 7, 10, and 14 for retained fetal membranes (RFM) and metritis. Cows were observed daily for displacement of abomasum (DA) and mastitis until d60. Cows were examined by ultrasound for detection of corpus luteum (CL) on d 39 and 56. Cows were observed daily for estrus starting on d 50 and pregnancy exam was conducted 38 and 66 d after AI. Milk production and components were measured monthly and energy corrected milk yield was calculated for the first 3 tests. Data were analyzed by MIXED procedure and the fixed effect was treatment (AIAO vs control) and the random effect was treatment within pen and replicate. Treatment had no effect on incidence of lameness on d 0 ($P = 0.75$), 28 ($P = 0.45$), and 56 ($P = 0.35$). Similarly, treatment had no effect on incidence of RFM ($P = 0.84$), metritis ($P = 0.35$), acute metritis ($P = 0.54$), DA ($P = 0.92$), and mastitis ($P = 0.47$). Percentage of cows with a CL on d 39 ($P = 0.17$) and 56 ($P = 0.96$) were not affected by treatment. Similarly, percentage of cows inseminated in estrus ($P = 0.52$) and percentage of cows pregnant after first AI ($P = 0.47$) were not affected by treatment. Finally, treatment had no effect on milk ($P = 0.82$) or energy-corrected milk ($P = 0.66$) yield and on linear somatic cell score ($P = 0.28$). In conclusion, AIAO grouping strategy did not reduce incidence of peripartum diseases and did not improve reproductive and productive performance.

Key Words: prepartum cow, grouping strategy, performance

T223 Effects of prepartum grouping strategy on body condition score and metabolic parameters of peripartum dairy cows.

P. R. B. Silva*[1,2], J. G. N. Moraes[1,2], L. G. D. Mendonça[1], A. A. Scanavez[1], G. Nakagawa[1], M. I. Endres[2], and R. C. Chebel[1], [1]*Department of Veterinary Population Medicine, University of Minnesota, St Paul,* [2]*Department of Animal Science, University of Minnesota, St Paul.*

Objectives were to evaluate the effect of an "all-in-all-out" (AIAO) prepartum grouping strategy on body condition score (BCS) and metabolic parameters of peripartum Jersey cows. Cows (254 ± 7 d of gestation) were paired by gestation length and assigned randomly to AIAO or control treatments. In the AIAO treatment (n = 259) groups of 44 cows were moved into a pen where they remained for 5 wk, whereas in the control treatment (n = 308) groups of approximately 10 cows were moved into a pen weekly to maintain stocking density (44 cows/48 headlocks). Pens were identical in size and design and each of the pens received each treatment a total of 3 times, totaling 6 replicates. Cows received a BCS at enrollment, calving (d0), d28, and d56. Blood samples were collected from all cows on d −21, −14, −7, 0, 7, 14, and 21 for determination of nonesterified fatty acid (NEFA) concentration. Blood was sampled weekly from d-14 to d 14 from a subgroup of cows (n = 34/treatment) to determine concentration of glucose. Cows were classified according to NEFA concentration as above or below 0.10 mmol/L on wk 3 and as above or below 0.18 mmol/L on the week preceding calving, because, based on the data from the current study, these were the criteria that predicted occurrence of displacement of abomasum with the best sensitivity and specificity. Data were analyzed by MIXED procedure and the fixed effect was treatment (AIAO vs control) and the random effect was treatment within pen and replicate. Treatment did not affect BCS on d −21 ($P = 0.67$), 0 ($P = 0.64$), 28 ($P = 0.59$), and 56 ($P = 0.90$). Glucose concentration was not affected by treatment ($P = 0.28$) or by the interaction between treatment and day ($P = 0.11$). Similarly, treatment ($P = 0.17$) and the interaction between treatment and day ($P = 0.11$) did not affect NEFA concentration. Percentage of cows with NEFA >0.10 mmol/l on wk 3 before calving ($P = 0.19$) and percentage of cows with NEFA >0.18 mmol/l on wk 1 before calving ($P = 0.99$) were not affected by treatment. In conclusion, AIAO prepartum grouping strategy did not improve metabolic parameters of peripartum dairy cows compared with a conventional grouping strategy.

Key Words: prepartum dairy cow, grouping strategy, metabolic parameter

T224 Heterosis of productivity rates in the breeding cycle of pure and crossbred Hereford and Angus cattle grazing native pastures at low and high allowances.

A. C. Espasandin*[1,3], M. do Carmo[1], C. R. López-Mazz[1,2], M. Carriquiry[1], and P. Soca[1,3], [1]*Udelar School of Agronomy, Departament of Animal and Grass Production, School of Agronomy, Udelar, Uruguay,* [2]*Estación Experimental Bernardo Rosengurtt, Cerro Largo, Uruguay,* [3]*Estación Experimental, Paysandú, Uruguay.*

Uruguayan extensive cow-calf systems are based in native pastures with low offers of dry matter (DM), especially in the winter. Hereford cows represent 70% of the genetic resources of Uruguayan herds. Productivity of the breeding cycle in these systems is extremely dependent on weather conditions, reaching about 70 kg of calf weaning weight per breeding female per year. The objective of this experiment was to study the productivity of heterosis of crossed (F1; reciprocal F1) and purebred (PB) Hereford and Angus cattle, for 3 breeding cycles (2007 to 2009) in native pastures offered high (H) and low (L) forage allowances (2.5 and 4 kg DM/kg BW, respectively). Animals (n = 120-year) were located in 2 blocks with 4 plots each one (treatments): F1 cows in High allowance (HF1) or Low allowance (LF1), and Pure breed in High (HPB) and low (LPB) allowance. Productivity rate (PR) was estimated as the weight (kg) of a 4th month old weaned calf weaned per breeding female per year (WW) x weaning rate (WR; number of calves weaned/female exposed in the breeding season). Mixed models with cow nested in treatment were used to analyze WW and WR. Weaning rate was higher ($P < 0.05$) in F1 than PB cows (individual heterosis). Weaning weight was greater ($P < 0.05$) for calves of F1-H cows with 128 ± 3.4 kg, whereas F1-L, and PB-H and -L did not differ significantly (112, 115 and 107 ± 3.5 kg, respectively). Consequently, PR was superior in F1-H and inferior in PB-L treatments, weaning 111 kg and 81 kg of calf per breeding cow per year, respectively. The PR did not differ between PB-H and F1-L with 93 kg and 92 kg, respectively, per breeding cow per year. The management of forage allowance and genetic resources can lead to improved productivity of cow-calf systems based on grazing of native pastures.

Key Words: forage allowance, heterosis, productivity

T225 Effects of dried distillers grains fed for programmed rate of body weight gain in beef heifers grazing native rangelands prior to breeding on growth and reproductive performance.

N. P. Miller,* R. C. Dunlap, S. H. Cox, M. M. Marricle, D. M. Hallford, and E. J. Scholljegerdes, *New Mexico State University, Las Cruces.*

The objective of this study was to evaluate effects of dried distillers grains plus solubles (DDGS) on growth and reproductive performance of beef heifers fed at a programmed rate of BW gain. Eighty-two beef heifers (initial BW = 249 ± 3.2 kg) grazing native range (2 pastures per treatment; 4% CP, 42% NDF, DM basis) were used in a completely randomize designed experiment and assigned to 1 of 3 treatments 49 d before breeding. Treatments were: 1) high level of DDGS (1.81 kg/heifer daily) to provide gain at (0.36 kg/d) for 28 d and then fed (0.68 kg/heifer daily) to achieve a low rate of gain (0.18 kg/d) up to breeding (HL); 2) a low rate of gain for the first 28 d and the high rate of gain up to breeding (LH); 3) moderate rate of gain (0.27 kg/d) throughout the feeding period by feeding (1.13 kg/heifer daily) (MOD). Heifers were weighed every 14 d, at which time blood was collected via coccygeal venipuncture and serum progesterone concentrations were determined. Heifers were synchronized at the end of the feeding period using the CO-Synch + CIDR (progesterone insert) with fixed-time AI. Heifers received an injection of GnRH (100 µg, i.m.) and a CIDR was inserted at d −7 relative to timed AI. At d 0, CIDR was removed and heifers received 25 mg of PGF $_{2\alpha}$. Heifers were observed for estrus and bred 12 h after observation of estrus. All heifers not bred by 54 h after CIDR removal were given GnRH (100 µg, i.m.) and AI. Heifers were joined with bulls for 60 d. No difference ($P = 0.11$) in ADG was noted in the first 28 d of supplementation, however, ADG was greater ($P = 0.01$) for HL and MOD groups during the second period of the experiment. Days to reach puberty tended to be less ($P = 0.08$) for the LH treatment compared with the MOD and HL treatment. The LH treatment also tended to have a greater ($P = 0.06$) percentage of pubertal heifers at breeding compared with MOD. Treatment did not affect ($P = 0.35$) overall pregnancy rates. Despite the fact that HL and MOD treatments had greater ADG, the LH growth program increased the percentage of heifers that were pubertal at breeding.

Key Words: heifers, puberty, reproduction

T226 Beef heifer growth and reproductive performance responses to stockpiled fall forage allowances.

B. L. Bailey,* K. M. Krause, and T. C. Griggs, *West Virginia University, Morgantown.*

The objective of this study was to compare heifer growth and reproductive performance following 2 patterns of gain during the fall grazing season. Three 5-ha fields were selected as blocks in a randomized complete block design for application of grazing treatments. All fields had been in long-term hay and/or pasture and contained cool-season grass-legume mixtures. Spring born heifers (year 1, n = 71; year 2, n = 64) of primarily Angus background and 248 kg mean BW were allocated to 2 grazing treatments each replicated 3 times per year (11 hd/replicate of a treatment) for 193 and 188 d in years 1 and 2, respectively. The fall grazing treatment consisted of daily herbage dry matter (DM) allocation of 3.5 (LOW) or 7.0 (HIGH) % of BW. During the winter feeding period haylage (6.5 kg DM/hd/d, yr 1; 5.4 kg DM/hd/d, yr 2) and soybean hulls (1.7 kg DM/hd/d, yr 1; 1.5 kg DM/hd/d, yr 2) were fed. Heifers were grazed continuously (as one group) throughout the spring during both years. Individual BW and blood samples were collected. In both years, heifers were synchronized and artificially inseminated (AI) utilizing a single sire. A cleanup bull was used for 35 d. Mean ADG was greater for HIGH heifers (0.45 kg/d) than LOW heifers (0.16 kg/d) during the fall grazing period ($P < 0.05$). During the winter feeding period, ADG were 0.03 kg/d and 0.36 kg/d ($P < 0.05$) for LOW vs HIGH heifers. During the spring grazing period, ADG were 1.6 kg/d and 1.5 kg/d ($P = 0.05$) for LOW vs HIGH heifers. Proportion of heifers that reached puberty at the onset of the breeding season did not differ (42% and 44%, $P = 0.81$ for LOW vs HIGH), although LOW heifers had lower BW at the time of breeding (345 kg vs 362 kg, $P < 0.05$ for LOW vs HIGH). No treatment differences occurred for overall pregnancy rates by AI (28% vs 37%, $P = 0.34$), bull (42% vs 38%, $P = 0.70$), or overall (70% vs 75%, $P = 0.56$) for LOW vs HIGH heifers. We interpret these results to indicate that delaying the majority of weight gain until late in heifer development may decrease costs of winter feeding without detrimental effects on reproductive performance.

Key Words: beef heifers, grazing, reproductive performance

T227 Effects of climate and moon illumination on grazing activity of weaned beef calves during early summer.

S. Gadberry*[1], W. Whitworth[2], G. Montgomery[2], and K. Simon[1], [1]*University of Arkansas, Little Rock,* [2]*University of Arkansas, Monticello.*

How environmental conditions influence day and nighttime grazing behavior may be beneficial to intensive grazing management and understanding the dynamics of foraging behavior. The objective of this study was to examine the effects of climate and moon illumination on the grazing activity of weaned beef calves during early summer. Seven calves were equipped with 3-axis accelerometer dataloggers. Logger activity was recorded for 35d beginning June 13, 2011. Logger x, y, and z tilt positions differed by activity (Wilks $P < 0.001$). Activity (grazing, lying, and standing/walking) was predicted using linear discriminant analysis based on 2, 3h observation periods. A random sample representing 50% of observed activity was used for model training. Prediction based on a single model among calves did not differ from predictions based on within calf models ($P = 0.50$). Model sensitivity and specificity was 0.79 and 0.94, respectively. Hourly climate measurements [temperature (T), relative humidity, rainfall, and solar radiation] were recorded from a weather station located on the research facility. Relative humidity was calculated at T above 26.7 C. Moon illumination data (MOON) was downloaded from the US Naval Observatory. Grazing activity was separated into periods of day (DG) and night (NG) as determined by weather station solar measurements. Days (n = 3) with rainfall exceeding 1 cm over multiple h was removed. Dependent variables examined included the proportion of NG to DG, the number of grazing events during DG and NG, mean event duration, and NG:DG ratio for events and durations. NG was estimated at 37.9% (SE 0.01%). Proportion NG was correlated with average daytime T (0.57, $P < 0.01$) and heat index (0.42, $P < 0.01$) but not solar radiation (0.006, $P = 0.93$). NG was also correlated with MOON (0.23, $P < 0.01$). Number of NG events was not correlated with daytime T (−0.02, $P = 0.72$). However, mean duration per NG event was correlated (0.25, $P < 0.001$). Ratios of NG to DG duration >1 were associated with lower daytime T [30.8 vs 32.3 (SE 0.27); $P = 0.02$] but 6.7% (SE 2.8%) greater humidity ($P = 0.02$) and no difference in moon illumination ($P = 0.24$). These results suggest weather may be more of a determinant of NG activity than moon illumination.

Key Words: beef cattle, grazing activity, weather

T228 Riparian management practices in the Manitoba landscape: Off-stream watering systems for beef cattle.

A. A. Rawluk*[1], G. H. Crow[1], D. M. Veira[2], P. Bullock[1], L. A. Gonzalez[3], and K. H. Ominski[1], [1]*University of Manitoba, Winnipeg, Manitoba, Canada,* [2]*Agriculture & Agri-Food Canada, Agassiz, British Columbia, Canada,* [3]*Commonwealth Scientific and Industrial Research Organisation, Townsville, Queensland, Australia.*

Livestock are attracted to riparian areas as they offer shade, forage, and water. However, their presence can be detrimental to these sensitive ecosystems. This study aims to determine the impact of off-stream waterers and natural barriers on animal performance and distribution. The study was replicated at 2 experimental locations in Manitoba, Killarney and Souris, with each site being replicated in 2 grazing seasons. At each location the pasture was divided into 3 treatments: no off-stream waterer or barriers (CON), off-stream waterer with barriers along the river band to deter cattle from watering at the river (BAR), and off-stream waterer without barriers (NOBAR). Cows and calves (25 pairs/treatment) were weighed on the first and last day of each 28-d period. Visual observations were recorded at 5 min intervals from dawn until dusk for 4-d of each period to determine the preferred drinking location of cows in BAR and NOBAR. Treatment had no significant effect (*P*

> 0.05) on cow and calf weights averaged over the summer periods, with the exception of calf weights in Souris in 2010 ($P < 0.0001$). The average weight of cows in Souris was 612.3 ± 26.7kg and the average weight of calves is 131.4 ± 6.0kg, considering both years. Likewise the average weight of cows at the Killarney location was 509.5 ± 22.3kg and the average weight of calves is 122.7 ± 5.6kg, again considering both years. From visual observations in Killarney, the recorded usage of off-stream waterer varied between 100% in Period 1, 93% in Period 2, and 100% in Period 3 in BAR, and from 50% in Period 1, 38% in Period 2, and 40% in Period 3 in NOBAR. In Souris, the recorded usage of off-stream waterer varied between 85% in Period 1, 31% in Period 2, and 7% in Period 3 in BAR, and from 44% in Period 1, 33% in Period 2, and 0% in Period 3 in NOBAR. These results indicate that the presence of off-stream waterers do not create significant differences in weights among cows and calves. Furthermore, cattle did not drink exclusively from the off-stream waterers, however, they will use when available, possibly attracting them away from the riparian area.

Key Words: riparian areas, off-stream waterer, animal performance

T229 Effects of injectable trace minerals on the humoral immune response to porcine red blood cell challenge and fertility in beef heifers. P. Moriel[1], P. G. M. A. Martins*[1], G. C. Lamb[2], L. J. Havenga[3], and J. D. Arthington[1], [1]*University of Florida, Range Cattle Research and Education Center, Ona,* [2]*University of Florida, North Florida Research and Education Center, Marianna,* [3]*MultiMin USA Inc., Fort Collins, CO.*

Our objective was to evaluate the effects of injectable trace minerals (ITM; MultiMin 90, MultiMin USA Inc., Fort Collins, CO) on mineral status, humoral immune response, and measures of performance in Brahman × British beef heifers (n = 33; age = 296 ± 22 d) grazing established limpograss pastures. Heifers were randomly allotted to 1 of 2 treatments; (1) ITM (n = 17); 3.0 mL s.c., containing 90, 10, 15, and 5 mg/mL of Zn, Mn, Cu, and Se, on d 0, 51, 83, and 127, and (2) Control (n = 16); 3.0 mL of sterile saline s.c. on the same days. Heifer shrunk BW was determined on the beginning (d 0) and end of the study (d 177). Plasma P4 concentrations were assessed monthly in blood samples collected on a 10 d interval for determination of puberty. All heifers received an i.m. injection of a 25% porcine red blood cell (PRBC) solution on d 51 and neutralizing antibody titers were measured in blood samples collected on d 0, 3, 7, 14, and 21, relative to PRBC injection. Liver biopsy samples were collected on d 177 from 24 heifers (12/treatment) for determination of trace mineral status. Throughout the study, heifers remained in a single group, were provided free-choice access to salt with no supplemental minerals and were exposed to a single Angus bull from d 83 to 177. Heifer BW did not differ at the beginning (208 ± 8.0 kg) and end of the study (259 ± 8.4 kg), but ADG was greater ($P < 0.06$) for ITM compared with saline-injected heifers (0.31 vs. 0.26 kg, respectively; SEM = 0.018). Heifers receiving ITM had greater ($P < 0.06$) PRBC neutralizing antibody titers on d 7, 14, and 21 following challenge, compared with saline-injected heifers. Liver concentrations of Se were greater ($P < 0.01$) in ITM heifers vs. saline-injected heifers at the end of the study (d 177; 0.88 vs. 0.48; SEM = 0.06). Liver concentrations of Cu, Zn, and Mn were adequate for all heifers and did not differ between treatments ($P > 0.25$). There were no differences in age at puberty or overall pregnancy rate (average = 427 ± 49 d and 57.6%, respectively). These results demonstrate that ITM may increase BW gain, humoral immune responses, and Se status in growing heifers reared on pastures without access to supplemental trace minerals.

Key Words: heifer, immunity, trace minerals

T230 Effect of propionate salt inclusion in postpartum supplementation on young cow reproductive performance. J. A. Walker,* G. A. Perry, and K. C. Olson, *South Dakota State University, Brookings.*

Two-year-old cows were supplemented with propionate salt to evaluate animal and reproductive performance. Sixty cows were allocated to one of 3 treatments at calving. Propionate salt was incorporated in a protein supplement (30% CP, 73% TDN) at rates of 0, 80 or 160 g/d of propionate salt (Ca-propionate). Cows were individually supplemented twice weekly at 1.14 kg/d. Cows had access to a native range pasture (121.4 ha). Blood was collected weekly to determine postpartum anestrous interval based on serum progesterone (≥1 ng /ml). Body weight and BCS were determined at calving, end of supplementation, start of breeding season, and weaning. No differences in cow BW ($P = 0.28$) and BCS ($P = 0.77$) were found between treatments. Cow BW changed throughout the study ($P < 0.01$; 379 ± 5.2, 361 ± 5.2, 397 ± 5.2 and 444 ± 5.2 kg for calving, end of supplementation, start of breeding season and weaning, respectively). Cow ADG differed by period ($P < 0.01$): cows lost weight from calving to end of supplementation (−0.32 ± 0.14 kg/d), and gained from end of supplementation to breeding (5.11 ± 0.14 kg/d) and breeding to weaning (0.38 ± 0.14 kg/d). Cow BCS changed throughout the study ($P < 0.01$; 3.94 ± 0.06, 4.11 ± 0.06, 4.10 ± 0.06, and 4.66 ± 0.06 for calving, end of supplementation, start of breeding season and weaning, respectively). Calf BW was not different ($P = 0.98$) between treatments. Calf BW increased throughout the study ($P < 0.01$; 35.6 ± 2.2, 91.8 ± 2.2, and 197.9 ± 2.2 kg at birth, start of breeding season, and weaning, respectively). Postpartum anestrous interval ($P = 0.70$), percentage of cows initiating estrous cycles before the breeding season ($P = 0.54$), conception rate to AI ($P = 0.68$), and season long pregnancy rates ($P = 0.87$) were not different between treatments. Propionate salt did not influence cow BW, cow BCS, calf BW, or cow reproductive performance.

Key Words: propionate salt, young beef cows

T231 Metabolizable protein supply alters pregnancy and subsequent retention rate during heifer development while grazing dormant winter forage. J. T. Mulliniks*[1], D. E. Hawkins[2], K. K. Kane[1], S. H. Cox[1], L. A. Torell[1], E. J. Scholljegerdes[1], and M. K. Petersen[3], [1]*New Mexico State University, Las ,* [2]*West Texas A&M University, Canyon,* [3]*USDA-ARS, Fort Keogh Livestock and Range Research Laboratory, Miles City, MT.*

Type of heifer development system can have major effect on the future productivity and retention rate of the cowherd. Therefore, the objective of this experiment was to determine growth, reproductive performance, retention rate, and economic efficiency of heifer's developed in a range raised (with 2 CP treatments) or high input (feedlot developed) heifer development system. Spring-born, crossbred heifers (n = 191) were stratified to 1 of 3 treatments at weaning: (1) 0.9 kg/d of a 36% CP supplement containing 64% RDP (CSM), (2) 0.9 kg/d of a 36% CP supplement containing 50% RDP (RUP), or (3) a concentrate diet fed in dry lot (CONC) to gain 0.68 kg/d. Supplementation was initiated in February and terminated at the onset of a 45-d breeding season in May. Heifer BW and hip height (HH) were taken monthly from initiation of supplementation until breeding and again at weaning. Females were removed from the herd for failure to reproduce or wean a calf. Percent of heifers becoming pregnant and remaining in the herd at start of each breeding season was recorded to determine retention rate throughout their 3rd calf crop. Breeding BW was greater ($P < 0.01$) for the CONC than CSM or RUP developed heifers. Hip height at breeding was greater ($P < 0.01$) in RUP and CSM relative to CONC heifers. However, palpation BW and HH was similar ($P \geq 0.24$) for all heifer development treatments. At breeding, RUP and CSM heifers reached 51% of mature BW ($P < 0.01$) compared with CONC heifers at 58% of mature BW. Pregnancy rates were 94, 88, and 84% for RUP, CSM and CONC heifers ($P = 0.10$). Net return was $99.71 and $87.18 per developed heifer greater for RUP and CSM heifers, respectively compared with CONC heifers due to differences in pregnancy and development costs. Retention rate at age 4 was greatest ($P < 0.01$) for RUP heifers. This study indicates that range developed heifers can be as reproductively successful as heifers developed in a dry lot, while improving future productivity. Furthermore, metabolizable protein supply improves reproduction in heifers developed on dormant native range.

Key Words: beef heifers, heifer development, retention rate

T232 Winter growing rate of gain on subsequent growth of beef steers grazing a subtropical pasture in summer. J. I. Arroquy*[1,3], A. E. Fumagalli[1], D. Kuckseva[2], and P. Vispo[2], *[1]INTA EEA Santiago del Estero, Santiago del Estero, Argentina, [2]INTA EEA Colonia Benitez, Resistencia, Chaco, Argentina, [3]CONICET, Santiago del Estero, Argentina, [4]FAyA-UNSE, Santiago del Estero, Argentina.*

Eighty Braford steers (initial BW: 149.5 ± 3.0 kg; initial hip-height: 110.5 ± 0.3cm; 6 mo old) were allotted by BW to one of 4 growing-phase diets (4 pens/treatment) to evaluate the effect of winter animal performance on summer growing rate grazing Guineagrass. Diets were: 1) ad libitum access to low-quality Guineagrass hay plus protein supplementation (GHPS); 2) same as treatment 1 plus energy supplementation (GHPG); 3) limit fed high concentrate diet to achieve a gain of 0.7 kg/d (LFHC); and 4) ad libitum corn-silage diet (CS). Immediately after winter phase (130 d), steers grazed Guineagrass pasture for 123 d. Winter feeding treatments and grazing summer steers were evaluated by average daily gain (ADG), hip-height (cm), 12th-rib fat (mm) and ribeye area (cm2; ultrasonic evaluations). In winter growing phase, ADG was significantly greater in CS diet than the others ($P < 0.01$), LFHC had greater ADG than GHPS and GHPG ($P < 0.05$), and GHPS and GHPG did not differ. ADG for winter growing phase were: 257, 298, 438, and 647 g/d for GHPS, GHPG, LFHG and CS, respectively. ADG in summer did not differ among treatments (494, 568, 600, and 496 g/d for GHPS, GHPG, LFHG and CS, respectively). Hip-height had similar response to feeding treatment as ADG. CS fed steers were taller than other treatments ($P < 0.05$). Final summer BW was higher in CS and LFHC than GHPS and GHPG ($P < 0.05$). Final fat thickness for winter growth was superior in LFHC and CS (2.05 and 2.15 mm, respectively) compared with GHPS and GHPG ($P < 0.05$; 1.66 and 1.70, respectively), whereas fat thickness at the end of summer period did not differ among treatments (2.33 ± 0.13 mm). Ribeye area was larger for CS and LFHC than the others ($P < 0.05$) at the end of winter and summer period. In conclusion, even though compensatory growth in summer reduced differences among winter feeding treatments, moderate winter ADG increased final summer liveweight, hip-height as well as ribeye area.

Key Words: winter growing phase, guineagrass, summer growing phase

T233 Effects of weaning age and winter development environment on heifer performance. N. L. Hojer*[1], M. B. Hubert[2], P. S. Johnson[2], M. H. Price[3], and K. C. Olson[2], *[1]South Dakota State University, Brookings, [2]South Dakota State University, Rapid City, [3]South Dakota School of Mines & Technology, Rapid City.*

Our objective was to determine if early weaning (about 125 d) versus normal weaning (about 250 d) and wintering replacement heifers in drylot versus rangeland affected heifer growth and reproductive performance. Heifer calves from the 2009 and 2010 calf crops (n = 104 and 73, respectively) were allocated to the 2 weaning treatments and then stratified by age into the 2 winter development treatments forming a 2 by 2 factorial of treatments. Heifers wintered in drylot received mixed grass and alfalfa hay (yr 1: 11.6% CP, 52.5% TDN; yr 2: 12.3% CP, 53.4% TDN) plus 1.8 kg of a dried distiller's grain (DDGS)-based supplement/hd/d (yr 1: 22.7% CP, 75.8% TDN; yr 2: 25.4% CP, 76.7% TDN). Heifers wintered on rangeland also received 1.8 kg/hd/d of the same supplement. Over the winter, each treatment was allocated to a separate pen or pasture. After estrus synchronization and timed AI, all heifers were placed on rangeland to graze through the summer. During the summer of yr 1 heifers were allocated by winter treatment to 2 pastures, and in yr 2 all 4 treatment combinations were allocated to separate pastures. Responses measured were BW, ADG, puberty at initiation of estrus synchronization, and pregnancy detection. Pubertal status was indicated by serum progesterone ≥1 ng/ml. A winter by weaning treatment interaction affected ($P < 0.001$) BW and ADG both years. During the winter months, range heifers were lighter and grew slower than drylot, but BW did not differ due to winter treatments by the end of the summer. However, early weaned heifers remained lighter than normal weaned heifers at the end of the summer. Weaning treatment affected ($P = 0.03$) fall pregnancy rate (93.2% ± 4.0 and 74.7% ± 7.98 for early- and normal-weaning, respectively) in yr 2. In yr 1, there was a difference ($P = 0.006$) between drylot and range heifers (92.7% ± 3.52 and 72.8% ± 6.47, respectively) in the proportion that obtained puberty before estrus synchronization. In conclusion, a producer needs to consider important interactions between weaning and winter management practices when establishing a replacement heifer development program that best fits the goals of their operation.

Key Words: beef heifer development, weaning, heifer performance

T234 Blended byproduct feeds in finishing rations on performance, carcass, and fecal characteristics of yearling heifers. B. T. Johnson,* C. L. Maxwell, B. K. Wilson, J. J. Wagner, S. L. Roberts, B. W. Woolfolk, C. J. Richards, and C. R. Krehbiel, *Oklahoma State University, Department of Animal Science, Stillwater.*

This study compared inclusion levels of a 1:1 blend of Sweet Bran (SB) and dried distiller′s grains (DDGS) byproducts in a dry-rolled corn feedlot ration on performance, carcass merit, and fecal characteristics. Heifers (n = 108; initial BW = 324 ± 13.6 kg) were blocked by BW, randomized to treatment, and fed for 142 d. Treatments were control (CONT, 8% DDGS), intermediate with 22% SB and 22% DDGS (INTER), and all byproduct with 44% SB and 44% DDGS (ALL). During d 28 to 55, a time of severe environmental heat with an average Temperature Humidity Index (THI) value of 80, ALL increased ADG and G:F ($P < 0.02$) by 12.2% and 16%, respectively. Average daily gains were similar for all other periods. There was a trend ($P = 0.09$) for increased overall G:F with ALL using live final BW, and increased ($P < 0.01$) G:F on a carcass adjusted final BW basis. Heifers fed ALL had a 1.81% increase ($P < 0.05$) in dressing percentage. There was a trend ($P = 0.08$) for increases in HCW for the INTER (3.5%) and ALL (2.5%) compared with CONT, with no other differences in carcass characteristics. These data indicate that replacing dry-rolled corn in a finishing diet with a 1:1 blend of SB and DDGS increases feed efficiency and HCW without altering ADG. Rectal fecal samples were taken every weigh period for pH, fecal scoring, and DM content. Further analysis by treatment was compared by taking concrete bunk pad samples at every weigh period and determining sample DM and density. Fecal pH and scores increased ($P < 0.05$) throughout the study for ALL, indicating a more viscous structure. A linear decrease in fecal DM was noted as level of byproduct inclusion increased ($P < 0.05$) for each sampling period. Pad sample DM decreased linearly ($P \leq 0.05$) on d 56, 112, and 142. Data indicate replacing corn with a 1:1 blend of SB and DDGS also increases fecal pH, fecal score and decreases fecal DM and DM of the pad (more water in manure on the pad/pens). During high temperatures, the ALL diet may have additional performance benefits.

Key Words: byproduct, performance, fecal characteristics

T235 Transit effects on fecal *E. coli* O157:H7 prevalence and coliform concentrations in feedlot cattle.

C. C. Aperce,* C. A. Alvarado, C. L. Van Bibber, K. A. Miller, and J. S. Drouillard, *Kansas State University, Animal Sciences and Industry, Manhattan.*

Our objective was to evaluate effects of transportation on fecal shedding of *E. coli* 4 and 24 h after hauling. The study was a randomized complete block with 20 steers per block (10/treatment), 3 blocks (days), and 2 treatments: a non-transported group, and transported steers that were placed in a trailer, hauled for 1 h, and subsequently allowed to rest. Fecal samples were taken pre-transport, and at 5 and 29 h post-transport. Fecal samples were collected from both groups at h 0, 5, and 29 from freshly voided fecal pats. One gram of feces was transferred to a PBS tube, serially diluted, and plated on Petrifilm for enumeration of total coliforms, and another sample (1 g) was added to gram-negative broth with cefixime, cefsulodin, and vancomycin, and subjected to immunomagnetic separation. Resulting beads were plated onto MacConkey agar with sorbitol, cefixime, and tellurite. Non-sorbitol fermenting colonies were picked and tested for indole production and O157 antigen agglutination. Results were confirmed by API 20E kit. Prevalence of *E. coli* O157 was transient across replications ($P = 0.002$). *E. coli* O157 occurrence in the transported group was constant across the 3 sampling times (10, 3.3, and 16.7%, for h 0, 5, and 29, respectively; $P = 0.43$); however, a significant increase in its prevalence was observed in the control group at h 5 (33%) compared with h 0 (17%, $P = 0.06$) and 29 (13%, $P < 0.02$). Numbers of coliforms remained constant across sampling day ($P > 0.1$). There were no significant correlations between prevalence of *E. coli* O157 and coliform concentrations. Coliform concentrations of control steers remained stable from 0 to 29 h post-transit. Transported animals had lower coliform concentrations at hour 5 (3.2 log cfu/gram; $P < 0.02$), but returned to pre-transport levels of 4.5 log cfu at h 29. Results suggest that shedding patterns are influenced by transportation, and that shedding can vary greatly within a period of 29 h. Additional post-transit sampling times may be useful to determine more precisely the pathogen shedding patterns associated with transportation.

Key Words: *E. coli* O157:H7, hauling

T236 Cattle anthelmintic resistance testing and training in North Carolina.

N. C. Whitley[1], M. L. Alley[2], R. M. Kaplan[3], S. Howell[3], K. Moulton[1], R. A. Franco*[1], and A. E. Cooper[1], [1]*North Carolina A&T State University, Greensboro,* [2]*North Carolina State University, Raleigh,* [3]*University of Georgia, Athens.*

The objective was to investigate the presence of anthelmintic resistance in gastrointestinal nematodes (GIN) on cattle farms while providing parasite management training to agricultural professionals. Fecal egg count reduction testing was used as a training tool on 3 beef cattle farms using no treatment (CON) or labeled doses of moxidectin (Cydectin; pour on—CPO, 3 farms; injectable—CI, 1 farm), fenbendazole (Safeguard; SAFE; 3 farms), CPO and SAFE combined (CS; 1 farm) or levamisole (Prohibit; P; 1 farm) with a total of 346 calves used at weaning. Fecal samples were collected from calves 1 to 2 weeks before the start of the study, on d0 (d of treatment) and d14. A Modified McMasters technique was used to determine fecal egg counts (FEC; eggs per gram, epg) with a sensitivity of 4 or 8 epg. Fecal co—proculture for GIN speciation was conducted on d14 fecal samples collected randomly from calves in each treatment group. Animals were assigned to treatment groups for similar mean preliminary BW and FEC. Percentage reduction (RED) of FEC was calculated as: [1 – (mean d-14 treatment FEC/mean d-14 CON FEC)] × 100%. Only calves with a minimum d0 FEC of 40 epg were used in RED calculations (17/trt for Farm 1; 28 to 30/trt for Farm 2; 25 to 32/trt for Farm 3). Statistical means and standard errors were calculated using SAS Proc Means. Mean d0 FEC for Farm 1, 2 and 3 were 62 ± 7, 204 ± 12 and 222 ± 13 epg, respectively. Farm 1 RED were 84.9% for CPO and 99.3% for SAFE. Farm 2 RED for CPO, SAFE, CS and P were 91.4, 96.9, 99.8 and 95.8%, respectively. Farm 3 RED for CPO, CI and SAFE were 16.5, 39.6 and 99.8%, respectively. Larvae from CON fecal cultures on all farms were primarily *Cooperia* with *Ostertagia ostertagi* also present at 40% for Farm 1 and Hemonchus in very low numbers on all 3 farms. For those treatments not considered effective, *Cooperia oncophora* and *Cooperia* spp. were the predominant GIN, except for P (*O. ostertagi*). These findings indicate that anthelmintic resistance in GIN of cattle is present in NC; 10 professionals were trained and the awareness of more NC agents and producers to this potential problem has increased.

Key Words: anthelmintic, cattle, resistance

T237 Effects of temperament on physiological responses, feedlot performance, and carcass characteristics of Nelore steers.

C. L. Francisco[1,4], A. M. Jorge*[1], F. D. Rezende[2], A. Schmidek[2], J. M. B. Benatti[3], M. H. Faria[2], E. Oba[1], and R. F. Cooke[4], [1]*Universidade Estadual Paulista - FMVZ, Botucatu, SP, Brazil,* [2]*APTA, Colina, SP, Brazil,* [3]*Universidade Estadual Paulista - FCAV, Jaboticabal, SP, Brazil,* [4]*Oregon State University, EOARC, Burns.*

The objective of this experiment was to evaluate the effect of temperament on plasma hormones, performance, and carcass traits of Nelore (*Bos indicus*) feedlot steers. Forty-four steers were evaluated for BW and temperament at feedlot entry (d 0). Temperament was assessed by chute score and exit velocity. Further, individual exit score was calculated by dividing exit velocity results into quintiles and assigning steers with a score from 1 to 5 (exit score: 1 = slowest steers; 5 = fastest steers). Temperament scores were calculated by averaging chute score and exit score. Steers were also classified for temperament type according to temperament score [≤3 = adequate temperament (ADQ) or >3 = aggressive temperament (AGR)]. Shrunk BW was recorded on d 0 and 109, whereas blood samples were collected on d 0, 67, and 109 for analysis of plasma cortisol and insulin. Total DMI was recorded daily (d 0 to 109). Steers were slaughtered on d 109, and carcasses were evaluated for backfat thickness, LM area, carcass pH, and incidence of hematomas. Samples from the LM were collected and analyzed for Warner-Bratzler shear force. Plasma cortisol was greater ($P = 0.04$) whereas plasma insulin tended to be reduced ($P = 0.06$) in AGR vs. ADQ steers (19.6 vs. 16.7 ng/mL of cortisol, and 12.7 vs. 19.4 IU/mL of insulin). Feedlot BW gain was reduced ($P = 0.02$) in AGR vs. ADQ steers (1.05 vs. 1.30 kg/d). Total DMI tended to be reduced ($P = 0.14$) whereas G:F was reduced ($P = 0.03$) in AGR vs. ADQ steers (8.8 vs. 9.4 kg/d of DMI, and 119 vs. 138 g/kg of G:F). Carcasses from AGR steers had greater ($P = 0.05$) incidence of hematomas compared with ADQ carcasses (1.3 vs. 0.6 hematomas/carcass). No differences between ADQ and AGR steers were detected for the remaining carcass traits. In conclusion, aggressive steers had greater plasma cortisol during handling, decreased feedlot performance, and impaired carcass quality compared with cohorts with adequate temperament.

Key Words: Nelore steers, feedlot performance, temperament

T238 Skin temperature differentials in relation to residual feed intake in beef cattle using infrared thermography. L. S. Martello*[1], P. R. Leme[1], S. da Luz e Silva[1], R. da Costa Gomes[2], C. A. Zotti[1], C. L. Oliveira[1], and T. F. Canata[1], [1]*Faculdade de Zootecnia e Engenharia de Alimentos, Universidade de São Paulo, Pirassununga, SP, Brazil,* [2]*Faculdade de Zootecnia, Universidade Estadual de Londrina, Londrina, PR, Brazil.*

Infrared thermography (IRT) has been studied as an alternative for indirect measuring of the residual feed intake (RFI) because of its association with body heat dissipation and consequently with skin temperature. Moreover, different areas of the body have distinct relationships with heat dissipation and should be considered for analyses. Therefore the aim of this study was to evaluate the skin temperature measured by IRT on different body areas, in low and high RFI cattle under feedlot conditions. Residual feed intake of Nellore steers (n = 40) and bulls (n = 40) fed high concentrate diets (85% of concentrate) was determined after 70d feeding. Nine calves classified as high and 9 as low RFI were then allotted to individual pens with free access to shadow and sunlight and had the IRT determined for 10 consecutive days. The IRT of 8 body regions were measured at 7h, 12h and 16h with the infrared camera Fluke® TI 20. The evaluated regions were 2 spots on frontal head (FH1 and FH2), eye, cheek, flank, ribs, rump and front feet. The rectal temperature (RT) was also measured. The effect of efficiency group on IRT was evaluated by ANOVA using SAS software. The mean air temperature (AT) during the trial was 24.4°C ranging from 14.4°C to 30.7°C indicating a stressful environmental for cattle during hottest hours. The IRT temperatures showed a linear association ($P < 0.01$) with AT whereas RT showed a quadratic effect ($P < 0.05$) on AT. The IRT temperatures measured at eye, cheek, flank, ribs, rump and front feet were not affected by RFI group. However, IRT on FH1 and FH2 for high RFI cattle (31.4°C and 30.3°C, respectively) were lower ($P < 0.01$) than for low RFI cattle (31.8°C and 30.7°C, respectively). Conversely, lower RT was observed for low RFI (38.3°C) than for high RFI group (38.4°C; $P < 0.01$). The higher skin temperature, measured by IRT, for calves of low RFI group may be related with an improved efficiency of thermoregulatory mechanisms, because the RT remained lower in the Low RFI group. The IRT of frontal head (FH1 and FH2) is a promising body location for studies related to RFI in beef cattle

Key Words: infrared image, skin temperature, cattle

Ruminant Nutrition: Beef: Co-products

T239 Microbial community shifts during anaerobic digestion of finishing cattle manure with and without distillers grains in the diet. S. C. Fernando, A. K. Watson, Y. A. Wanniarachchi, T. J. Klopfenstein, G. E. Erickson, J. L. Harding, A. L. Shreck,* C. J. Johnson, and M. M. Klosterman, *University of Nebraska, Lincoln.*

Two diets were fed to finishing cattle and the manure was used to monitor methane production and microbial communities associated with anaerobic digestion of feedlot manure. Diet 1 contained 82.5% dry rolled corn (CONT) and diet 2 contained 40% wet distillers grains plus solubles (DM basis) replacing dry rolled corn (WDGS). Manure (feces and urine) was collected and frozen until used in anaerobic digesters. Continuously stirred anaerobic digesters (n = 7, 1 L capacity) were maintained for 5 mo to reach steady-state. Upon reaching steady-state, 50 mL of effluent was removed and replaced with 50 mL of manure/water slurry (9% DM) collected from CONT (n = 4) or WDGS (n = 3) fed animals on a daily basis. After a 35 d adaptation, samples were collected at 3-d intervals for microbial community analysis. The concentration of methane was measured under constant flow of N2 gas and was 0.116 and 0.137 L/g OM fed into the digester ($P = 0.05$) from CONT and WDGS respectively. The microbial communities (Eubacterial and Archaeal) were identified using 454-pyrosequencing. An average of 10,000 and 3,000 sequences were generated from each sample to evaluate the Eubacteria and Archaea communities respectively. Community level analysis revealed structuring of microbial communities based on diet ($P < 0.001$). Bacteria belonging to the phylum *Chloroflexi* (65.7%) and *Bacteroidetes* (19.2%) dominated the microbial community in digesters receiving WDGS manure. Within phylum *Chloroflexi*, genus *Longilinea* (35.7%) and unclassified *Anaerolineaceae* (64.3%) accounted for most the sequences. In contrast, digesters receiving CONT manure was dominated by phylum *Bacteroidetes* (68.2%) and *Chloroflexi* (24.5%). Within phylum *Bacteroidetes*, genus *Proteniphilum* (50.6%) and unclassified *Porphyromonadaceae* (45.5%) accounted for a most of the sequences. These results suggest the microbial food chain that contributes toward methane production is greatly influenced by the diet fed to cattle, suggesting that dietary manipulation may provide opportunities to reduce (or increase if desirable) methane production from cattle manure.

Key Words: anaerobic digester, methane, microbial

T240 Effects of crude glycerin on in vitro gas production and VFA profiles in Nellore feedlot steers. E. H. C. B. van Cleef*[1,2], J. M. B. Ezequiel[2], A. P. D'Aurea[1,2], A. C. Homem Junior[1,3], F. B. O. Scarpino[1,4], R. M. P. Pardo[5], and E. M. Ferreira[6], *[1]São Paulo State University, Jaboticabal, São Paulo, Brazil, [2]FAPESP, [3]CAPES, [4]CNPq, [5]Sucre University, Sincelejo, Colombia, [6]University of São Paulo, Piracicaba, São Paulo, Brazil.*

Two studies were conducted to evaluate the effects of crude glycerin on in vitro gas production and VFA profiles in feedlot Nellore steers. Ruminal fluid was collected from 5 rumen-cannulated steers fed finishing diets (70% concentrate) composed by corn silage, corn grain, soybean hulls, sunflower meal, mineral supplement and one of 5 concentrations (0, 7.5, 15, 22.5, or 30%) of crude glycerin (84% glycerol). Samples of 125 mL of ruminal fluid were placed into 250-mL flasks equipped with pipe collectors coupled to gasometers made with PET bottles. Total mixed rations were added at 1.7 g DM/flask, and consisted of the same ingredient mixture fed to each donor steer. Gas production (CH_4 and CO_2) were determined after 12 h of incubation at 39°C and repeated for 5 d (periods). Study 2 used the same treatments and donor animals. To determine VFA profiles 25 mL were collected 1 h before feeding, 1, 2, 4, 6, and 8 h after feeding. Samples of 1.6 mL were centrifuged with 0.4 mL meta-phosphoric acid and formic acid solution, and 0.2 mL of 2-ethyl-butyric acid 100 mM. After centrifugation, 1.2 mL was analyzed for concentrations of VFA using a gas chromatograph. The statistical design used was a Latin square (5 × 5) and data were analyzed using the MIXED procedure of SAS, in which contrasts were used to determine linear and quadratic effects of crude glycerin, and control treatment vs. crude glycerin treatment. Adding crude glycerin decreased in vitro production of CH_4 ($P \leq 0.01$) and CO_2 ($P \leq 0.05$). VFA profiles were highly affected by addition of crude glycerin. Propionate, valerate and butyrate were increased ($P \leq 0.01$) and acetate concentration was decreased ($P \leq 0.01$) as well as acetate:propionate ratio ($P \leq 0.05$). These results suggest that the crude glycerin causes significant changes in VFA profile decreasing waste of energy by the animals, evidenced by the decrease in methane production.

Key Words: biodiesel, co-products, methane

T241 Effect of lipid sources addition on nutrient intake of steers finished at feedlot. G. Fiorentini*[1,2], I. P. C. Carvalho[1,2], J. F. Lage[1,2], R. C. Canesin[1,2], C. S. Ribeiro Junior[1,2], and T. T. Berchielli[1,3], *[1]Universidade Estadual Paulista (UNESP) - FCAV, Jaboticabal, SP, Brasil, [2]Fundaçao de Amparo à Pesquisa do Estado de Sao Paulo (FAPESP), Sao Paulo, SP, Brazil, [3]Instituto Nacional de Ciência e Tecnologia em Ciência Animal (INCT-CA), Brasília, DF, Brazil.*

The objective of this study was to evaluate the effect of different lipid sources on nutrient intake of steers finished at feedlot. Forty-five Nellore steers (initial average body weight of 423kg, with 16 mo age) were feed on 60% maize silage and 40% concentrate, with 7% of ether extract on total diet. The fat sources were soybean grain (SG), protected fat (Lactoplus®) (PF), linseed oil (LO) and palm oil (PO) plus a control (CO) treatment, without additional fat. The supplements were based in corn and soybean meal. The animals were housed on individual stalls, for 90 d (divided in 3 periods of 30 d). The leftovers were removed and weighed every day. The feed and leftovers were analyzed for nutrient composition dry matter (DM), neutral detergent fiber (NDF) and crude protein (CP). The animals were assigned to a completely randomized design, with 5 treatments and 9 replications. The effect of diet type, period and its interaction were analyzed by ANOVA. When significant, differences were analyzed by the Tukey test. The results showed that the lipid source affected significantly ($P < 0.001$) the nutrient intake, evaluated as dry matter (DMI), neutral detergent fiber (NDFI) and crude protein (CPI), expressed in kg/animal/d. The period also affected significantly ($P < 0.01$) the DMI and CPI. There was no significant interaction between diet and period. Generally, in first and second period animals that received CO and PF showed greater intake of DM (8.7, 8.1, 7.6 and 7.6), NDF (3.1, 2.8, 2.8 and 2.7) and CP (1.4, 1.3, 1.2 and 1.2), respectively, while animals that received PO had the lowest intake of nutrients (3.8 and 4.2 kg DM, 1.9 and 1.94 kg NDF and 0.5 and 0.6 kg CP), respectively to first and second period. However, in third period the diets CO, PF and SG had greater DMI and CPI than PO while NDFI did not differ among diets. These results suggest that the addition of lipid sources at the level of 7% in diet influences the nutrients intake of feedlot steers. Diets with

PF and SG or CO provides a greater nutrient intake while the presence PO in the diet decreases the voluntary intake due to low acceptability.

Key Words: beef cattle, palm oil, protected fat

T242 Feeding distillers grains as an energy source to gestating and lactating beef heifers: Impact on steer progeny longissimus muscle fatty acid profile. P. J. Gunn*[1], G. A. Bridges[2], R. P. Lemenager[1], and J. P. Schoonmaker[1], [1]*Department of Animal Sciences, Purdue University, Lafayette, IN,* [2]*North Central Research and Outreach Center, University of Minnesota, Grand Rapids.*

Angus-cross beef heifers pregnant to a single sire (n = 80) were used to assess the effects of feeding dried distillers grains with solubles (DDGS) as an energy source during late gestation and early lactation on LM fatty acid profile of the male progeny. From 192 d of gestation through 118 ± 0.2 d of lactation, dams were fed either a control diet of corn silage and haylage (CON; 10% CP prepartum; 11.8% CP postpartum) or corn stover and DDGS (DG; DDGS at 1.2% BW per d; 15.7% CP) diet. Due to bunk design, progeny access to diets was unable to be restricted. Male progeny (n = 36) were weaned, commingled, and started on a step-up diet at 186 ± 0.2 d of age. At 210 ± 0.2 d of age, steers were placed in individual pens and fed a finishing diet devoid of DDGS (12.7% CP, 1.36 kcal/kg NEg on DM basis), once daily for ad libitum consumption. Steers were harvested at a common 12th rib fat depth of 1.41 ± 0.22 cm. A LM sample from the 12–13th rib interface of the carcass was collected, ground, and extracted for analysis of fatty acid methyl esters. Data were analyzed using the MIXED procedures of SAS. Concentrations of myristoleic (14:1) and palmitoleic (16:1) acids tended to be greater ($P = 0.06$) in CON than DG progeny. Conversely, DG progeny had greater stearic (18:0; $P = 0.01$; 17.3 vs. 15.9 g/100 g) and eicosenoic acid (20:1 n-9; $P = 0.004$; 0.105 vs. 0.094 g/100 g) concentrations than CON progeny. All other fatty acids and classes of fatty acids (short chain, medium chain, long chain, saturated, monounsaturated, and polyunsaturated), as well as the proportion of omega 3 and omega 6 fatty acids did not differ due to maternal treatment ($P \geq 0.17$). In summary, feeding DDGS at 1.2% of BW per day to first-parity heifers marginally affected LM fatty acid profile in steer progeny.

Key Words: DDGS, developmental programming, steer

T243 Effect of distillers grain supplementation on fescue intake and utilization. C. A. Schaeffer,* E. S. Vanzant, J. W. Lehmkuler, and K. R. McLeod, *University of Kentucky, Lexington.*

This experiment was conducted to determine effects of increasing level of supplemented dried corn ethanol distillers grains with solubles (EDG; 29% CP, 5% EE, DM basis) on intake and utilization of moderate quality tall fescue hay (12% CP; DM basis). Ruminally cannulated steers (n = 18, initial BW = 247 ± 6 kg) were used in a randomized complete block design. EDG was fed daily at 0, 0.25, 0.5, 0.75, 1.0, or 1.25% BW (DM basis). Hay was offered at 125% of the previous 5-d mean intake. Steers were adapted to diets for 14d before 2 sequential 7-d periods for intake and digestion measurement and 2d for determining ruminal fermentation and kinetic responses. Forage OM intake (FOMI, %BW), responded quadratically to treatment ($P = 0.05$) with little change in FOMI up to 0.75% BW EDG and decreasing FOMI thereafter. Total and digestible OM intakes (%BW) responded quadratically ($P = 0.05$), increasing from 0 to 0.75% BW EDG and plateauing between 0.75% and 1.25% EDG. OM digestibility responded cubically ($P = 0.07$) and was maximal at 0.5% BW EDG. NDF digestibility decreased linearly ($P = 0.06$) with increasing EDG. All ruminal fermentation variables demonstrated time x treatment interactions ($P \leq 0.10$). Ammonia concentration peaked 3 h post feeding, was lowest at 9 h post feeding and generally increased linearly ($P < 0.10$) with increasing EDG. Pre-feeding ruminal pH increased linearly ($P < 0.01$) with increasing level of EDG. At all other sampling times, pH decreased linearly ($P \leq 0.02$) with increasing EDG. Increasing level of EDG had little impact ($P > 0.14$) on total VFA concentrations. Ratio of acetate to propionate responded cubically ($P \leq 0.07$) to treatment at most time points. However, the linear portion of the response explained most (≥78%) of the variation in A:P at all sampling times except 0h, when A:P decreased as EDG increased. Liquid dilution rate was not affected by treatment ($P \geq 0.24$) nor was rumen content of OM (%BW) either just before ($P \geq 0.26$) or 4 h post ($P \geq 0.15$) feeding. Results suggest that, with growing cattle grazing fescue, increased growth would be expected as EDG supplementation increased to about 0.75% BW, with higher levels of EDG having little effect on gain.

Key Words: distillers grains, forage, intake

T244 Effect of soybean hull level on diet digestibility and growth performance of beef calves. J. R. Russell,* M. S. Kerley, and W. J. Sexten, *University of Missouri, Columbia.*

The objective was to determine a breakpoint where the fiber:starch may benefit from exogenous methods to improve fiber digestion. Fiber digestibility should be greatest at a DM WSC intake of 0.4% BW (diet 80) and should decrease as fiber:starch changes. Five diets with increasing soybean hull (SH) to whole shelled corn (WSC) ratios (20, 60, 80, 90, and 100% SH) were fed to beef cattle to determine the effect of increasing fiber inclusion on digestibility of DM (DMd), NDF (NDFd), and ADF (ADFd) as well as DMI, ADG, and G:F. Cattle were blocked by sex and stratified by BW. The diets were distributed across 40 steers (347 ± 29 kg BW) and 50 heifers (374 ± 24 kg BW) and fed for 70 d. Titanium dioxide was included in the diet for the final 14 d with fecal samples collected on d 70. Diets were balanced for RDP and post-ruminal AA based on available ME. Individual DMI was measured using the Growsafe Feed Intake System. Means comparison was used to identify significance. Diet 20 and 80 did not differ ($P > 0.05$) in DMd, however 20 was greater ($P < 0.05$) than 60, 90, and 100. The DMd was not different ($P > 0.05$) between the 60, 80, 90, and 100 diets. Diet 80 had a tendency to be greater than 20 for NDFd ($P < 0.08$) and ADFd ($P < 0.06$), though neither 80 nor 20 differed ($P > 0.05$) from the other 3 diets. Diet 80 was greater ($P < 0.05$) for DMI than 60, 90, and 100 but did not differ ($P > 0.05$) from 20. There was no difference ($P > 0.05$) in DMI between 20, 60, 90, 100. Diet 20 was greatest ($P < 0.05$) for ADG. The ADG of diets 60 and 80 did not differ ($P > 0.05$) but 80 was greater ($P < 0.05$) than 90 and 100. Diets 60, 90, and 100 did not differ ($P > 0.05$) for ADG. Diet 20 had the greatest ($P < 0.05$) G:F while the other diets did not differ ($P > 0.05$). In this experiment SH had approximately 70% energy equivalence to WSC. Intake of WSC at 0.4% BW increased ADG but did not improve G:F. Methods are needed to improve fiber digestibility of SH to make animal performance on SH-based diets comparable to starch-based diets.

Key Words: digestibility, fiber, soybean hulls

T245 Ruminal fermentation and blood metabolites of Holstein steers fed diets differing in wheat processing and fat source. K. Erjaei, A. Zali, M. Ganjkhanlou,* and M. Dehghan-Banadaky, *University of Tehran, Tehran, Iran.*

To evaluate the effects of wheat processing and dietary fat source on ruminal fermentation and blood metabolites, Holstein steers (n = 28) averaging 296 ± 56 kg were randomly allotted in 4 treatment (7 steers each). An experiment was conducted in a 2 × 2 factorial arrangement (2 methods of wheat processing: steam flake and treatment with formaldehyde and fat source: roasted soybean and Rumifat) with completely randomized design. On the last days of experiment, from each steer, blood samples were collected from the coccygeal vein and samples of ruminal fluid were collected by stomach tube. There were no significantly differences among diets for ruminal pH, total volatile fatty acids (VFA) and ammonia nitrogen (NH_3-N) concentrations. Concentration of propionate was greater, in steers fed steam flake wheat ($P < 0.01$). Other VFA concentrations were not affected significantly by dietary treatments. Plasma cholesterol and triglyceride concentrations were significantly lower and higher respectively in steers fed roasted soybean ($P < 0.01$ and $P < 0.01$). Plasma glucose concentration was higher ($P < 0.01$) in steers fed wheat treatment with formaldehyde. Steers fed roasted soybean had lower blood urea nitrogen ($P < 0.01$). Plasma NEFA and total protein concentrations were unaffected by dietary treatments. Results of this study show that wheat treatment with formaldehyde might be expected to protect starch from rumen degradation. Also blood metabolites indicate that roasting of soybean may protect ether extract and protein from rumen degradation.

Key Words: wheat processing, roasted soybean, ruminal fermentation

T246 Feedlot performance and fatty acid composition of muscles from Holstein steers fed diets differing in wheat processing and fat source.

K. Erjaei, A. Zali, M. Ganjkhanlou,* and M. Dehghan-Banadaky, *University of Tehran, Tehran, Iran.*

To evaluate the effects of wheat processing and dietary fat source on performance and fatty acid composition of muscles, Holstein steers (n = 28) averaging 296 ± 56kg were randomly allocated in 4 treatment (7 steers each). An experiment was conducted in a 2 × 2 factorial arrangement (2 methods of wheat processing: steam flake and treatment with formaldehyde and fat source: roasted soybean (RSB) and Rumifat) with completely randomized design. The study lasted 98 d (14d adaption). Dry mater intake (DMI) and average daily gain (ADG) of calves were measured daily and monthly respectively. Following the final weighing at 85d, To measure the traits related with carcass characteristics 3 steers per treatment were slaughter. No significantly differences were detected for DMI, ADG and feed efficiency. Carcass traits were not affected by dietary treatments. The amount of C18:2, C18:3, C24:0 and polyunsaturated fatty acids were greater ($P < 0.01$) in muscles from steers fed RSB. Also the amount of C18:0 and conjugated linoleic acid were greater ($P < 0.02$) in muscles from steers fed RSB. In contrast the amount of C: 16 and saturated fatty acid were greater ($P < 0.01$ and $P < 0.05$, respectively) in muscles from steers fed Rumifat. It was concluded that no difference were detected in performance of steers by fed diets differing in wheat processing and fat source but the use of RSB in the diet improved the fatty acid composition of muscles in terms of human health.

Key Words: roasted soybean, fatty acids, Holstein steers

T247 Evaluation of the ruminal bacterial diversity of cattle fed diets containing citrus pulp pellets (CP) using bacterial tag-encoded FLX amplicon pyrosequencing (bTEFAP).

P. R. Broadway*[1], T. R. Callaway[2], J. A. Carroll[3], N. C. Burdick[3], J. R. Donaldson[4], R. J. Rathmann[1], B. J. Johnson[1], J. T. Cribbs[1], L. M. Durso[5], D. N. Miller[5], D. J. Nisbet[2], and T. B. Schmidt[6], *[1]Department of Animal and Food Sciences, Texas Tech University, Lubbock, [2]Food and Feed Safety Research Unit, Southern Plains Agricultural Research Center, USDA-Agricultural Research Service, College Station, TX, [3]Livestock Issues Research Unit, USDA, Agricultural Research Service, Lubbock, TX, [4]Department of Biological Sciences, Mississippi State University, Mississippi State, [5]Agroecosystem Management Research Unit, USDA-Agricultural Research Service, Lincoln, NE, [6]Department of Animal and Dairy Sciences, Mississippi State University, Mississippi State.*

The rumen microbial ecosystem has been extensively studied, but remains a mystery from a quantitative perspective. Dietary components and changes cause shifts in the ruminal microflora that can affect animal health and productivity, but the majority of these changes remain unknown. The objective of this study was to analyze the diversity of bacterial populations in the rumen of cattle fed various amounts of citrus pulp (CPP). Heifers (n = 18; 298.7 ± 5.1 kg) were fed a basal feedlot diet and randomly assigned to 1 of 3 diets (n = 6/diet). Diets containing CPP (0, 10, or 20%) were formulated to be exchanged with steam flaked corn on a 1:1 basis. Using bacterial tag-encoded FLX amplicon pyrosequencing (bTEFAP), the normal ruminal microbiota was examined to understand how different concentrations of a common by-product feedstuff affect ruminal microbial ecology. Bacteria in the genera of *Prevotella* and *Eubacterium* were found to be the predominate bacteria that populated the rumen comprising 34% and 6%, respectively, of the bacterial population. The Firmicutes:Bacteroidetes ratio tended to increase ($P = 0.07$) in animals fed CPP when compared with controls. Also, *Butyrivibrio* and *Carnobacterium* populations increased in number with increasing amounts of CPP in the feed ration. In contrast, a decline ($P = 0.009$) in the population of *Dialister*and *Catonella* occurred with increasing CPP. An increase ($P = 0.04$) in the proportion of Bacilli bacteria in the ruminal microflora was associated with increases in dietary CPP. Overall, there were relatively few changes observed in ruminal microbial populations highlighting the functional flexibility of the rumen and demonstrating that feeding CPP at rates up to 20% does not adversely affect ruminal microbial ecology. The lack of major changes in ruminal microflora may possibly be due to a lack of essential oils in the CPP which may play a greater role in the alteration of ruminal microbial populations and may also explain the lack of apparent effect seen in other studies.

Key Words: bacterial diversity, citrus pulp

T248 Rumen dynamics of neutral detergent fiber in grazing steers supplemented with lipid sources.

I. P. C. Carvalho*[1,4], T. T. Berchielli[1,3], G. Fiorentini[1,4], E. Detmann[2], L. G. Rossi[1], J. F. Lage[1,4], Y. T. G. Salcedo[1], and C. S. Ribeiro Junior[1,4], *[1]Universidade Estadual Paulista Julio de Mesquita Filho, Jaboticabal, Brazil, [2]Universidade Federal de Viçosa, Viçosa, [3]INCT/CA member, Brazil, [4]FAPESP, Sao Paulo, Brazil.*

This study was carried out to evaluate the effects of lipid sources in supplements on the flow kinetics of fibrous particles and neutral detergent fiber (NDF) degradation profile using Nellore steers on *Brachiaria brizantha* 'Xaraes' pasture. Ten fistulated Nellore steers with average live weight of 350 ± 9.5 kg were randomly assigned to a double 5 × 5 Latin square design. Different lipid sources (linseed oil, palm oil, soybean grain and calcium salts (Lactoplus) was added to the supplements (100 g/kg DM) and offered at 1.0% body weight. The control treatment was composed of a corn and soybean meal supplement with no additional fat. The transit kinetics of fibrous particles was done through a pulse dose of ytterbium mordant fiber. Fecal samples were collected at 0, 3, 6, 9, 12, 24, 36, 48, 72, 96 and 120 h after marker administration. In situ fiber incubation was carried out to estimate the rumen degradation parameters of NDF, with the incubation times corresponding to the fecal sampling. The transit kinetics parameters were estimated through adjustment of a gamma-2 time-dependent model to the ytterbium excretion profiles. All adjustments of non-linear models were performed according to the Gauss-Newton iterative algorithm. The effectively degraded fraction of potentially degradable NDF (EDF), discrete lag (LAG) and mean retention time in the rumen (MRTR) are secondary parameters, derived from the rumen flow of fibrous particles (γ) and common rate of lag and degradation (λ), therefore, not subject to statistical analyses. The potentially degradable and undegradable fraction of pasture NDF were 52.83 and 47.17g/Kg, respectively. The time of intestinal transit (τ) was not affect ($P > 0.05$) by lipid supplementation. Animals fed palm oil had a reduction on γ and λ ($P < 0.05$). EDF and LAG were also lower on palm oil diet. This results indicates that the inclusion of palm oil in the supplement of gazing animals impair fibrous substrates utilization.

Table 1. Estimated parameters of fibrous particles kinetics and neutral detergent fiber degradation profile according to lipid source supplementation

Treatment	γ (h−1)	λ (h−1)	τ (h)	EDF (%)	LAG (h)	MRTR (h)
Control	0.0319	0.060	5.75	72.19	4.70	62.70
Palm	0.0185	0.021	6.95	54.73	13.42	108.11
Linseed	0.0318	0.054	5.90	70.12	5.22	62.89
C. Salts	0.0234	0.056	6.74	79.93	5.03	85.47
Soybean G.	0.0330	0.058	6.47	67.73	4.86	60.61
P-value	<0.0001	<0.0001	0.8746	-	-	-

Key Words: beef cattle, degradation rate, oil

T249 Effects of supplementation with a pressed dried distillers grain block on beef cow performance and hay intake during late gestation.

C. L. Marshall*[1], J. D. C. Molle[1], J. M. Kern[1], R. A. Vraspir[1], A. N. Scheaffer[2], S. L. Lake[1], and A. M. Meyer[1], [1]*Department of Animal Science, University of Wyoming, Laramie,* [2]*SweetPro LLC, Walhalla, ND.*

Multiparous crossbred beef cows (n = 72; BW = 600.2 ± 6.2 kg, BCS = 4.3 ± 0.4, age = 6.9 ± 0.1 yr) in late gestation were blocked by expected calving date and randomly allocated by BW to 1 of 3 treatments: ad libitum chopped grass hay (CON; 6.5% CP and 56.8% NDF, DM basis), CON hay with ad libitum access to a pressed dried distillers grain block (BLOCK; SweetPro 16; 16.0% CP and 5.0% fat), and CON hay with 0.57 kg/cow per day of a positive control supplement (POS; 57% corn and 43% DDGS; 16.0% CP and 6.0% fat). Each treatment had 6 replicates (n = 4/pen), and the trial consisted of 2 periods (period 1: d 1 to 41; period 2: d 42 to 70). Hay was weighed and fed twice daily and refusals weighed once weekly to determine pen hay intake. All CON and POS cows had ad libitum access to a trace mineralized salt, whereas macro and trace minerals were provided by the BLOCK supplement. Data were analyzed with treatment, block, and treatment x block as fixed effects in the model for performance measures. Week and week x treatment were also fixed effects in the model for hay intake. Means were separated using LSD and considered significant when $P \leq 0.10$ or tendencies when $P < 0.15$. Hay intake was affected ($P = 0.06$) by treatment, where cows receiving the BLOCK treatment consumed less ($P = 0.02$) hay than CON (15.07, 15.43, 15.26 ± 0.11 kg for BLOCK, CON, and POS, respectively). Although BW change was not affected ($P = 0.29$) by treatment during period 1, BLOCK and POS had greater BW change during period 2 ($P \leq 0.07$) and for the overall trial ($P = 0.005$). During period 1, cow BCS change tended to be affected ($P = 0.11$) by treatment, where BLOCK and POS had greater ($P \leq 0.09$) BCS change than CON. Body condition score change during period 2 and overall was unaffected ($P \geq 0.46$) by treatment. Additionally, treatment did not affect ($P \geq 0.35$) ultrasonic backfat thickness, LM depth, or marbling score. These data suggest that the ad libitum pressed dried distillers grain block used was not only able to improve cow performance in a similar manner to supplement fed daily, but also reduced hay intake compared with control.

Key Words: beef cows, gestation, supplementation

T250 Supplementing urea in beef finishing diets containing 25% modified distillers grains has no influence on cattle performance, but does decrease marbling in yearling steers.

L. J. Garbel* and B. P. Holland, *South Dakota State University, Brookings.*

Finishing diets containing elevated levels of distillers grains may contain excessive concentrations of CP, yet still be deficient in degradable intake protein (DIP). To address this situation, finishing diets containing 25% modified distillers grains (MDGS), 40% dry rolled corn, 20% high moisture corn, 12% corn silage, and 3% dry supplement (DM basis) were supplemented with 0 (CON), 0.36 (Low-U), or 0.72% (High-U) urea. Diets contained 13.3 and 6.6, 14.2 and 7.6, and 15.2 and 8.5% CP and DIP for CON, Low-U, and High-U, respectively. Two hundred 51, predominately Angus yearling steers were blocked by source and randomly allotted to 24 pens. Steers in block 1 (n = 71; BW = 388 ± 41 kg) were housed in 9 partially roofed concrete-surfaced pens. Block 2 cattle (n = 180; BW = 375 ± 24 kg) were housed in 15 soil-surfaced dry lot pens. Cattle were fed for 98 and 144 d for blocks 1 and 2, respectively, before harvest at a commercial abattoir. Preplanned contrasts evaluated CON v supplemental urea, and Low-U v High-U, respectively. Calculated DIP requirements for microbial needs were 68 g/d deficient for CON, but in excess 33.7 and 132.6 g/d for Low-U and High-U ($P < 0.001$). Body weights, ADG, and G:F were not different between treatments ($P \geq 0.08$). Marbling score was increased ($P = 0.04$) in CON (524) steers compared with Low-U (495) and High-U (491). This resulted in 60.0% of carcasses in upper 2/3 Choice and Prime grades for CON compared with 40.6% for Low-U and 46.5% for High-U ($P = 0.05$). No other carcass trait differences were observed ($P \geq 0.28$). Results suggest that urea supplementation to finishing diets containing 25% MDGS does not improve feedlot performance, but can decrease quality grade yearling steers.

Key Words: feedlot, distillers grains, metabolizable protein

T251 Effects of alternate day feeding of dried distillers grains plus solubles on ruminal ammonia concentration, blood urea nitrogen, nonesterified fatty acids, and insulin-like growth factor I in forage-fed steers.

S. I. Klein*[1], A. M. Meyer[2], Q. P. Larson[1], J. S. Caton[1], and C. R. Dahlen[1], [1]*Department of Animal Sciences, North Dakota State University, Fargo,* [2]*Department of Animal Sciences, University of Wyoming, Laramie.*

Our objective was to examine the effects of feeding dried distiller′s grains plus solubles (DG) or grass hay on alternate days on ruminal ammonia (NH$_4$), blood urea nitrogen (BUN), nonesterified fatty acids (NEFA), and IGF$_1$ in forage-fed steers. Four ruminally, duodenally, and ileally cannulated Holstein steers (448.8 ± 7.3 kg BW) received each of 4 dietary treatments (TRT) in a 4 × 4 Latin square: 1) ad libitum hay only (CON); 2) hay and 0.4% BW DG daily (DG7); 3) hay daily and 0.8% BW DG on alternate days (DG3); and 4) hay only or 0.8% DG only on alternate days (DGA). Treatment periods consisted of 13 d of adaptation and 8 d of blood and ruminal sample collection. Supplemented days (SUP) and non-supplemented days (NSUP) were defined as days when DG3 and DGA did or did not receive DG, respectively. Ruminal ammonia was similar ($P > 0.10$) for all treatments at feeding on SUP.

Four h post-feeding on SUP, DG7 had greater (TRT × time; $P = 0.002$) NH_4 compared with CON and DGA whereas DG3 was intermediate. At feeding and 6 h post-feeding on NSUP DGA had increased (TRT × time; $P < 0.001$) NH_4 compared with all other treatments. At 4 and 6 h post-feeding on NSUP DGA had increased (TRT × time; $P < 0.001$) NH_4 compared with CON, DG7, and DG3. Steers fed DGA had less ($P < 0.01$) BUN on SUP compared with all other treatments (5.5, 7.9, 8.3, and 7.8 ± 0.4 for DGA, CON, DG7, and DG3, respectively). Similarly, BUN was greater ($P < 0.01$) for DGA on NSUP compared with CON, DG7, and DG3 (11.8, 8.1, 8.6, 8.9 ± 0.5 mmol/L for DGA, CON, DG7, and DG3, respectively). There were no differences ($P > 0.10$) in NEFA among treatments on SUP however, on NSUP DGA (209.5 ± 12.7 mmol/L) steers had increased ($P < 0.01$) NEFA compared with all other treatments (84.4, 88.0, and 77.7 ± 12.7 mmol/L for CON, DG7, and DG3, respectively). All treatments had similar ($P > 0.10$) concentrations of IGF_1 throughout the collection period (114.0, 126.3, 128.8, 128.9 ± 6.6 ng/mL for CON, DG7, DG3, and DGA, respectively). The feeding strategy DGA altered NH_4, BUN, and NEFA, but did not influence IGF_1.

Key Words: distillers grains, metabolism, supplementation frequency

T252 Carcass traits of steers finished in feedlot fed crude glycerin. J. F. Lage,* T. T. Berchielli, E. San Vito, A. F. Ribeiro, R. A. Silva, E. E. Dallantonia, L. M. Delevatti, B. O. Felipe, M. Machado, P. M. França, and R. A. Reis, *Universidade Estadual Paulista "Júlio de Mesquita Filho," Jaboticabal, São Paulo, Brazil.*

This trial aimed to evaluate the effects of feeding crude glycerin (CG) - 80% of glycerol - included on 10% of diet dry matter, replacing corn or soybean hulls in different concentrate levels (60:40 or 40:60) on carcass traits of steers finished in feedlot. Sixty intact male (Nellore), with 18 mo of age and 373.73 ± 24.67 initial body weight, were randomly assigned to 6 treatments, with 10 replicates in factorial arrangement (2 levels of concentrate x 3 feeding regimens). The diets were: control diet, without inclusion CG, containing corn in the concentrate (CN); diets with inclusion CG with high level of starch, containing corn in the concentrate (CGC) and diets with inclusion CG with low level of starch, containing soybean hulls in the concentrate (CGS). The diets were isonitrogenous and formulated to meet the requirements for maintenance and gain of the animals according to Brazilian recommendations. After 94 d on feed, the shrunk body weight (SBW) was recorded and the animals were slaughtered. The carcasses were weighed for obtained the hot carcass weight (HCW) and dressing percentage (DP). The carcass were refrigerated for 24 h at 0°C and then rib fat thickness (RFT) and ribeye area (REA) were measured in the region between 12 and 13 th rib. Data were analyzed using the GLM procedure of SAS and the effects of treatments were considered significant at $P < 0.05$. The interaction between concentrate levels and feeding regimens was not significant ($P > 0.05$). Differences were detected ($P < 0.05$) in the DP among the feeding regimens. The animals fed with the diet CGC had higher mean values for DP (57,23%) than the animals fed the diets CN (56,34%) and CGS (55,92%). No difference were detected ($P > 0.05$) for SBW, HCW, RFT and REA among the treatments, with mean values 498.36 kg, 281.57 kg, 5.13 mm and 76.11 cm^2, respectively. The variables evaluate were not altered ($P > 0.05$) by the concentrate allowance levels assessed (60:40 or 40:60). The inclusion of 10% of crude glycerin in diets with high starch increase the dressing percent, however, does not affect the shrunk body weight, hot carcass weight, ribeye area and rib fat thickness.

Key Words: beef cattle, glycerol, rib fat thickness

T253 Performance of Nellore steers receiving protected linseed oil during different periods of feedlot. W. Henrique*[1], V. G. Carvalho[2], T. M. Pivaro[2], J. L. V. Coutinho Filho[1], A. A. M. Sampaio[2], E. A. Oliveira[2,3], and B. L. Rosa[2], *[1]Sao Paulo Agency for Agribusiness Tecnhology, Sao Jose Rio Preto, Sao Paulo, Brazil, [2]FCAV/Sao Paulo State University, Jaboticabal, Sao Paulo, Brazil, [3]FAPESP Post-doctorate fellowship, Sao Paulo, Sao Paulo, Brazil.*

The objective was to assess the use of linseed oil protected from ruminal degradation during different periods of confinement or linseed oil, as ingredients of the diet, for 35 Nellore steers. The animals were housed in individual pens for 105 d at the Sao Paulo Agency for Agribusiness Technology, in Sao Jose do Rio Preto, Brazil. In addition to the control diet and with linseed oil during all the feedlot, it was evaluated the addition of protected linseed oil during the last 35 d, the last 70 d or during all the feedlot. The roughage used was corn silage exclusively, in the proportion of 40% in dry matter diet. All diets were isonitrogenous and those with the addition of oil were also isoenergetic. The proportion of protected linseed oil was 4.0% and linseed oil 3.4% in dry matter diet. The feedstuffs and the leftovers were analyzed and the animals were weighed at the beginning and at the end of the experiment, preceded by total fasting for 15 h. The experimental design was a randomized block one, balanced by animal weight, and means were compared by Student's *t*-test at 5% of probability. There were no differences for initial (392.94 kg) and final body weight (522.72 kg), average daily gain (1.236 $kg.day^{-1}$), dry matter intake, per day (9.392 kg) or related to the body weight (2.05%), and feed efficiency (0.131 kg gain.kg DM $intake^{-1}$). The addition of protected linseed oil during different periods of confinement or linseed oil did not bring additional benefits for the performance of fattening cattle in feedlot.

Key Words: cattle, fattening, weight gain

T254 Performance of crossbred heifers and steers fed increasing linseed oil levels. W. Henrique*[1], B. L. Rosa[2], E. A. Oliveira[2,3], A. A. M. Sampaio[2], T. M. Pivaro[2], A. T. Andrade[2], and V. G. Carvalho[2], *[1]Sao Paulo Agency for Agribusiness Technology, Sao Jose Rio Preto, Sao Paulo, Brazil, [2]FCAV/Sao Paulo State University, Jaboticabal, Sao Paulo, Brazil, [3]FAPESP Post-doctorate fellowship, Sao Paulo, Sao Paulo, Brazil.*

The objective was to assess the increasing linseed oil supplementation (1, 3.8 and 5.2% in DM diet) fed to crossbred cattle Nellore × Canchim and its influence on the average daily gain (ADG), slaughter weight (SW), feed efficiency (FE) and dry matter intake per day (DMI) and as a percentage of body weight (DMI%BW). Fifteen steers (427.80 ± 42.01 kg and 24 ± 2 mo old) and 14 heifers (400.57 ± 33.79 kg and 24 ± 2 mo old) were housed in individual pens at Jaboticabal, campus of Sao Paulo State University and fed diets with 80% concentrate in DM and sugarcane IAC 86–2480 as exclusive roughage source. The experiment was a randomized block design one, arranged in a 3 × 2 factorial scheme (oil ratios x sexual condition) and means were compared by Student's *t*-test at 5% of probability. After fattening period, the animals were slaughtered in a staggered way by blocks. There were no interactions ($P > 0.05$) between sexual conditions and oil levels for all variables. Steers showed higher ($P < 0.05$) SW (535.07 and 494.79 kg), ADG (0.982 and 0.857 kg/d) and DMI (9.098 and 8.070 kg/d) when compared with heifers, respectively. The FE and DM%BW did not showed difference ($P > 0.05$) for sexual condition. No difference ($P > 0.05$) was observed to ADG among diets (0.92 kg/d). Diets containing 1 and 3.8% presented higher values ($P < 0.05$) for DMI than 5.2% of oil (9.046, 8.764 and 8.040 kg/d, respectively). Similar results ($P < 0.05$) were observed for DMI%BW (1.93, 1.88 and 1.74%, respectively). Animals fed diets with 1 and 3.8% of oil were less efficient ($P < 0.05$) than animals fed diets with 5.2% of oil (0.094, 0.104 and 0.123 kg of ADG/kg of DMI, respectively). Increasing linseed oil in diets to crossbred beef cattle can improve feed efficiency by decreasing the dry matter intake and keeping the daily gain.

Key Words: feed efficiency, Nellore × Canchim, weight gain

T255 Performance of growing Nellore steers on pasture in the dry season fed crude glycerin. E. San Vito,* T. T. Berchielli, J. F. Lage, R. C. Canesin, R. A. Reis, C. S. R. Junior, L. M. Delevatti, M. Machado, E. E. Dallantonia, A. F. Ribeiro, and R. A. Silva, *Universidade Estadual Paulista "Julio de Mesquita Filho," Jaboticabal, São Paulo, Brazil.*

The aim of this work was to evaluate the effect of crude glycerin (CG) inclusion as a substitute to corn grain in the average daily gain (ADG) and shrunk body weight final of growing Nellore steers on pasture, supplemented in the dry season. The CG used was derived from soybean biodiesel production (80% glycerol). Fifty Nellore steers with initial shrunk body weight of 279.52 ± 16.31 kg were randomly assigned to 5 treatments, with 10 replicates. The animals were distributed in 10 paddocks, with 1.8 ha each (2 paddocks per treatment), of *Brachiaria brizantha* 'Xaraés'. Treatments were constituted by 5 levels of CG inclusion in the supplement: (0, 7, 14, 21 and 28% of CG based on dry matter) as a substitute to the corn grain. The animals were supplemented daily in a proportion of 0.7% of body weight, and it contained 40% of crude protein based on dry matter. The supplement was constituted of corn grain, soybean meal, urea, gluten meal and mineralized salt. The experiment was executed in 136 d, and the animals were weighed in the beginning and in the end of the experiment, after 14 h of solids and liquids shrunk to evaluate the average daily gain. Data was analyzed using the GLM procedure of SAS program and the effects of treatments (linear and quadratic) were considered significant at $P < 0.05$. There was an increased linear effect of glycerin levels ($P < 0.05$) on the final live weight ($r^2 = 0.73$) and daily average gain ($r^2 = 0.35$), and the following equations were adjusted: FW = 374.38 + 0.72 x % of CG in the supplement and ADG = 0.65 + 0.041 x % of CG in the supplement. Final shrunk body weight of animals was 375.4, 377.4, 381.8, 389.9 and 398.1 kg and the average daily gain was 0.704, 0.719, 0.752, 0.812 e 0.871 kg to the inclusion of 0, 7, 14, 21 and 28% of CG in the supplement, respectively. It is possible to conclude that an increase in crude glycerin levels (up to 28%) in the supplements of growing steers on pasture in the dry season can increase the average daily gain and final body weight of the animals.

Key Words: biodiesel, by-product, forage

T256 Palatability of post-extraction algal residue as a protein supplement for cattle. M. L. Drewery,* J. E. Sawyer, and T. A. Wickersham, *Texas A&M University, College Station.*

Market value of post-extraction algal residue (PEAR) is driven by its ability to compete with commonly fed protein sources; for example cottonseed meal (CSM) and dried distillers' grains (DDG). An initial step in evaluating PEAR (20% CP, 59% OM) is to determine palatability when fed as a protein supplement. Accordingly, we evaluated the palatability of PEAR-containing supplements in cattle consuming a basal diet of Bermudagrass (13% CP, 76% NDF). Twelve steers were used in a 12 × 12 Latin square experiment consisting of 12 4-d periods. Each period included 3-d where steers were fed a test supplement and a 1-d washout where steers were fed DDG. Supplements were formulated with different carrier ingredients (DDG, CSM, or liquid supplement, LS) and different levels of PEAR inclusion (0, 20, 40, and 60% for DDG and CSM and 0, 33, 66, and 100% for LS). Intake and time required for consumption were recorded daily. A significant ($P < 0.05$) treatment × day interaction for g consumed per min (GPM) was observed. This interaction resulted from changing rates of consumption as cattle adapted to supplements. Supplements containing DDG had the greatest rates of consumption (177 – 187 GPM), followed by CSM supplements (148 – 166 GPM). Blends including PEAR and LS had slower rates of consumption (58 – 93 GPM). Supplement formulation significantly ($P < 0.05$) affected the amount of supplement consumed and time required for complete consumption. Supplements which contained DDG or CSM were consumed in less than 11 min; complete consumption was observed 92 – 100% of the time. Treatments containing LS required more time for complete consumption (21 – 33 min) and were finished 77 – 96% of the time. Our results suggest PEAR can be blended (up to 60%) with existing ingredients utilized in beef rations to create suitable protein supplements. However, PEAR is not palatable when offered alone (complete consumption of 100% PEAR occurred 77.5% of the time and required 31.5 min) or incorporated into LS. Additional research is necessary to determine the impact of PEAR on nutrient utilization in cattle.

Key Words: supplementation, post-extraction algal residue, dried distillers grains

T257 Protein sources and nitrogen associated with the residual biodiesel glycerin supplements to fattening cattle during the rainy season: performance productive. A. J. Neto[1], J. T. Zervoudakis[1], L. da Silva Cabral[1], L. K. H. Zervoudakis*[1], R. L. Galati[1], P. V. R. Paulino[2], L. C. R. P. Silva[1], R. P. da Silva[1], J. Q. Soares[1], and T. de Paulo Trindade[1], *[1]Universidade Federal de Mato Grosso, Cuiabá, Mato Grosso, Brazil, [2]Universidade Federal de Viçosa, Viçosa, Minas Gerais, Brazil.*

The objective was to evaluate the effect of protein sources and nitrogen associated with the residual biodiesel glycerin in the diet of beef cattle grazing in the rainy season on performance. Twenty Nelore steers age and initial body weight average of 25 months and 422 kg were used, during the experimental period of 84 days. The area consisted of 4 paddocks of 1.6 ha each formed with *Brachiaria brizantha* 'Marandu', with a mass of forage and potentially digestible dry matter of 1552.71 and 1146.01 kg/ha, respectively. The experiment was structured in a completely randomized design to evaluate the following supplements: control (only mineral); GU – glycerin with urea; GFS - glycerin with soybean meal and GFA - glycerin with cottonseed meal as a function of the variables: gain total weight and average daily gain. The supplementation was provided daily at 10 a.m., with supply of 2.0 kg of supplement/animal. The productive performance of animals was 0.992; 1.095; 0.997 and 1.010 kg/animal/day for the supplements: MM, GU, GFA, and GFS. There was no difference ($P = 0.60$) between the levels of supplementation and the control group on average daily gain of animals. The combination of glycerin with protein sources and nitrogen promotes good animal performance under grazing.

Key Words: glycerol, pasture, weight gain

Ruminant Nutrition: Dairy II

T258 Oocyte and embryo quality of dairy cows fed omega 3 and 6 fatty acids sources in the transition period and early lactation. J. R. Gandra,* R. D. Mingoti, L. C. Verdurico, R. V. Barletta, J. E. Freitas Jr., C. S. Takiya, T. H. A. Vendramine, R. Gardinal, and F. P. Rennó, *1University of Sao Paulo, Sao Paulo, Brazil.*

The objective of this study was to evaluate the supplemental sources of omega 3 and 6 fatty acids and the effects in oocyte and embryo quality of dairy cows fed during the transition period and early lactation. Forty-eight Holstein cows were divided into 4 experimental groups in randomized design. The animals were randomly assigned to receive one of 4 treatments: 1) control (C; n = 12), without fat sources in the pre and postpartum, 2) flaxseed (FS; n = 12), in which cows were fed 60 and 80 g/kg of DM of flaxseed in the pre and postpartum, respectively; 3) whole raw soybeans (WS; n = 12), in which cows were fed 120 and 160 g/kg of DM of whole raw soybeans in the pre and postpartum; 4) calcium salts of unsaturated fatty acid (CSFA; n = 12; Megalac-E), in which cows were fed 24 and 32 g/kg of DM of calcium salts of unsaturated fatty acid in pre and postpartum. The experimental diets were fed from 35 d before the estimate calving, and provided until 84 d of lactation, formulated to meet the nutritional requirements of each period (pre and postpartum). The procedure for follicular aspiration (FA) was performed in 2 periods: 35 ± 7 d of lactation (FA1) and 60 ± 7 d of lactation (FA2). After FA the oocytes were classified grade I, II, III, atretic and degenerate. Only submitted in vitro fertilization (IVF) oocytes with grade I, II and III. Data were analyzed using PROC MIXED of SAS 9.1, with the effect of diet, aspiration (FA) and interaction as fixed effects, and animal has random effect. The data were analyzed by orthogonal contrasts (C vs. WS+CSFA+FS; WS vs. CSFA; and FS vs WS+CSFA. FA effect ($P < 0.05$) was observed for the number of degenerate and viable oocytes (3.00 vs 1.82) and (4.65 vs 8.70), respectively to FA1 and FA2. There was interaction ($P < 0.05$) between the fatty acids sources and FA in the number of viable embryos. Effect ($P < 0.05$) were observed for the contrast FS vs WS+CSFA, when analyzing the number of viable embryos (1.27 vs. 0.73), respectively. The oocyte and embryo quality of dairy cows fed omega 3 and 6 fatty acids sources in the transition period and early lactation influenced the oocyte and embryo quality in post-partum period.

Key Words: fat sources, follicular aspiration, transition period

T259 Effects of different PUFAs supplementation during the postpartum periods of early lactating dairy cows. I: Milk production and composition. E. Dirandeh[1], A. Towhidi*[1], M. Ganjkhanlou[1], S. Zeinoaldini[1], Z. Ansari Pirsaraei[2], and A. R. Zarenezhad[3], *[1]Department of Animal Science, Faculty of Agricultural Science and engineering, University College of Agriculture and Natural Resources, University of Tehran, Karaj, Tehran, Iran, [2]Department of Animal Science, Faculty of Animal Science and Fishery, Sari University of Agricultural and Natural Resources, Sari, Mazandaran, Iran, [3]Mahdasht Dairy Farm, Sari, Mazandaran, Iran.*

The objectives were to determine the effect of diet enriched in α-linolenic acid (n-3), or linolenic acid (n-6) on milk production and composition in lactating dairy cows. Ninety high-yielding multiparous Holstein dairy cows with no over clinical illnesses were blocked according to calving date and parity. Cows were assigned randomly to be fed either 1-soybean whole roast (S, n = 30), or 2-linseed (L, n = 30), or 3-palm oil as a source of saturated fatty acid (C, n = 30) from calving until first heat after d 40 postpartum (dpp) and then half of the cows in each treatment group were switched to receive either linseed (L) or saturated fatty acid (C) from first heat after d 40 to 120 dpp. There was no difference between groups (mean ± SEM) in parity (3.0 ± 1.90) or BCS at calving (3.2 ± 0.07). Milk yield were recorded daily throughout the experiment. Milk samples were taken weekly (Monday and Thursday mornings) and analyzed for fat, protein and lactose contents by infrared analysis at the National Milk Records Laboratory, Sari, Iran, using AOAC reference method No. 972.16 (AOAC 1990). Data were analyzed with PROC MIXED of SAS. Result showed milk yield was not affected by diet ($P = 0.36$). Milk yield increased over time ($P < 0.001$), while no treatment × day interaction was detected ($P = 0.35$). Milk composition was similar among diets, except milk fat percentage that was lower in LL group than other groups ($P = 0.01$). Concentration and yield of milk fat did not change from wk 0 to 4 in cows fed linseed and soybean whole roast, whereas milk fat concentration declined from 3.54 to 3.20% ($P < 0.05$) and from 1.25 to 1.14 kg/d ($P < 0.05$), respectively, from wk 0 to 4 in cows fed palm oil. Milk protein percentage and yield did not differ between the dietary groups in our study. There was no difference in lactose, total solid and SNF in the milks.

Key Words: dairy cow, n-3 fatty acid, n-6 fatty acid

T260 Effects of lipid and propionic acid infusions on feed intake of lactating dairy cows. S. E. Stocks* and M. S. Allen, *Michigan State University, East Lansing.*

Propionic acid is more hypophagic when hepatic acetyl CoA concentration is elevated during early lactation. The objective of this experiment was to evaluate effects of intravenous lipid infusion and intraruminal propionic acid infusion on feed intake of lactating cows. Eight multiparous, ruminally cannulated, Holstein dairy cows (81 – 252 d in milk) were used in a replicated 4x4 Latin square experiment with a 2x2 factorial arrangement of treatments. One cow was removed because of an adverse reaction to the lipid infusion. Treatments were propionic acid (PR) infused intraruminally at 0.5 mol/h for 18 h starting 6 h before feeding or sham control (CO), and intravenous jugular infusion of lipid (TG, Intralipid 20%) or saline (SA, 0.9% NaCl) infused at 0.5 L/h for 24 h starting 12 h before feeding. Changes in plasma concentrations of metabolites and hormones and hepatic concentration of acetyl CoA from before infusion until the end of infusion were evaluated. No interactions of treatments were observed for DMI or changes in concentration for metabolites or hormones. Infusion of PR decreased DMI 15% (16.1 vs. 19.0 kg/12 h, $P = 0.02$) compared with CO but lipid infusion did not affect DMI over the 12 h infusion period. Infusion of PR tended to decrease hepatic acetyl CoA concentration (−5.7 vs. −2.4 nmol/g wet tissue, $P = 0.09$) compared with CO, consistent with PR decreasing DMI by stimulating oxidation of acetyl CoA. Contrary to our expectations, TG did not increase concentrations of NEFA ($P = 0.75$) or BHBA ($P = 0.48$) in plasma, or acetyl CoA in liver ($P = 0.65$), and did not increase milk fat yield ($P = 0.67$), suggesting that the infused TG was stored or oxidized by extrahepatic tissues. As a result, there was no interaction between PR and TG for DMI. While the effect of PR on DMI was consistent with our previous results, this model was not useful to evaluate the interaction between PR and TG related to control of feed intake by hepatic oxidation.

Key Words: hepatic oxidation, control of feed intake, propionate metabolism

T261 Relationships between ruminal volatile fatty acid concentrations, milk production, digestibility, and milk fatty acid composition in dairy cows. A. N. Hristov*[1], K. J. Shingfield[2], P. Huhtanen[3], J. L. Firkins[4], and K. Harvatine[1], [1]*The Pennsylvania State University, University Park,* [2]*MTT Agrifood Research Finland, Jokioinen, Finland,* [3]*Swedish University of Agricultural Sciences, Umeå, Sweden,* [4]*The Ohio State University, Columbus.*

The objective of this meta-analysis was to investigate the relationships between ruminal volatile fatty acids (VFA) concentrations (acetate, Ac; propionate, Pr, valerate, Va), their molar proportions, mol/100 mol (p), Ac:Pr ratio (AcPr), milk production, digestibility, and milk fatty acid (FA) composition in dairy cows as a potential on-farm tool for monitoring rumen function. The data set used in the analysis contained 496 individual cow data from 27 experiments conducted at 4 locations. Data were analyzed using the CORR and MIXED (with study as random effect) procedures of SAS. Average DMI and milk yield of the cows were: 22 (SD = 4.7) and 32 kg/d (SD = 10.3), respectively. The greatest correlation (all $P < 0.001$) for DMI was with Va and pVa (r = 0.38 and 0.34) and Pr (0.22). The greatest correlation for milk yield was with AcPr (−0.44), Pr and pPr (0.43 and 0.42), and Va (0.36). Best fit (based on the Akaike Information Criterion) models for milk yield and DMI included Pr and pVa and total VFA, respectively. Correlations of milk fat and protein contents with rumen VFA were weaker: −0.18 (Pr and pPr), 0.16 (AcPr), and 0.15 (pAc) and −0.11(Pr), respectively. Milk fat yield correlated with Va and pVa (0.19 and 0.16) and milk protein yield with AcPr (−0.40), Ac (−0.35), and Pr and pPr (0.37). Digestibility of NDF correlated with Va and pVa (−0.43 and −0.45), Ac (0.42), and Pr and pPr (−0.33 and −0.38). The greatest correlations between rumen VFA and milk FA were: for Ac with 18:1 (c11–18:1, −0.50; c16–18:1, 0.49; and c13–18:1, −0.46) and 22:4n-3 (−0.40); for pAc with 22:4n-3 (−0.67), t6–8-18:1 (−0.48), c9–10:1 (0.48), and t13–18:1 and 22:6n-3 (−0.47); for Pr with c9–10:1 (−0.42), c9–17:1 (0.42), and 22:6n-3 (0.39); for pPr with c11–18:1 (0.50), 22:4n3 (0.49), and c9–10:1 (−0.47); and for Va with c9-t1218:2 (0.59), total c18:2 (0.52), t9–14:1 (0.50), and c16–18:1 (−0.43). This analysis indicated that milk yield in dairy cows correlated positively with Pr and inversely with AcPr. The greatest correlations of VFA and milk FA were for Ac with c11–18:1 and for Va with c9-t1218:2.

Key Words: dairy cow, milk fatty acid, volatile fatty acid

T262 Occurrence and concentration of mycotoxins, molds and yeasts in total mixed rations from South Dakota and Minnesota dairy farms. F. Diaz-Royon*[1], A. Garcia[1], K. F. Kalscheur[1], K. A. Rosentrater[2], J. S. Jennings[3], and K. Mjoun[3], [1]*Dairy Science Department, South Dakota State University, Brookings,* [2]*Department of Agricultural and Biosystems Engineering, Iowa State University, Ames,* [3]*Alltech South Dakota, Brookings.*

Because of mycotoxin degradation in the rumen, dairy cattle can resist better than other livestock the adverse health effects associated with their exposure. At the same time though, dairy cattle are subjected to greater production stress which may increase their susceptibility to mycotoxins. Total mixed rations (TMR) from twenty-seven large dairy farms in eastern SD and western MN were collected during the summer and fall of 2011. Samples were screened for mycotoxins, molds, and yeasts to provide an overview of their prevalence in dairy diets. Ten subsamples of 0.5 kg each were taken from the feed bunk of high-production dairy cow pens. Subsamples were composited and later split in two 0.8-1.0 kg samples. After vacuum sealing, one sample was stored at −20°C for mycotoxin analyses and the second sample was stored at 4°C for mold and yeast analyses. Samples were quantitative analyzed for 18 different mycotoxins through high performance liquid chromatography (HPLC) and gas chromatography-mass spectrometry (GC-MS). Detection limit was 0.5 ppm except for fumonisin B1 and aflatoxin B1, which were 1.0 and 0.05 ppm, respectively. Molds and yeasts were counted by direct plate dilution. In addition, mold isolates were identified using the conventional microscopic tape method in samples with mold growth equal to or higher than 1,000 cfu/g. There were 26 TMR samples (96.3%) positive for vomitoxin, with a maximum concentration of 0.8 ppm. These samples contained fumonisin concentrations lower than U. S. Food and Drug Administration maximum acceptable limits for use in animal feeds. Other mycotoxins were not detected. Mold growth was lower than 1,000 cfu/g in 15 TMR samples (55.5% of the samples) and higher than 10,000 cfu/g in 7 samples (25.9%). *Aspergillus* and *Mucor* were the fungi genera most isolated. On average yeast content in TMR was 1.9×10^6 cfu/g with only one sample (3.7%) showing yeast counts below 1,000 cfu/g. In spite of vomitoxin being detected in 96.3% of the TMR samples analyzed during the summer and fall of 2011, its concentration was always below that considered a health hazard by the FDA.

Key Words: mycotoxins, dairy cows, total mixed ration

T263 Feed restriction, but not L-carnitine infusion, affects the liver transcriptome with an evident induction of gluconeogenesis and inhibition of energy production and sterol synthesis in mid-lactating dairy cows. H. Akbar,* M. Bionaz, D. B. Carlson, S. L. Rodriguez-Zas, R. E. Everts, H. A. Lewin, J. K. Drackley, and J. J. Loor, *University of Illinois, Urbana.*

Abomasal carnitine infusion during acute feed restriction has been shown to increase hepatic fatty acid oxidation and decrease liver lipid accumulation in dairy cows. Using mid-lactating dairy cows we studied the effects of abomasal L-carnitine (20 g/d) in combination with restricted dry matter intake (DMI; 50% of previous 5-d average) on the hepatic transcriptome. Eight lactating Holstein cows were used in a replicated 4 × 4 Latin square design with 14-d periods. A 2 × 2 factorial arrangement was used to determine the effects of water infusion + ad libitum DMI, water infusion + restricted DMI, carnitine infusion + ad libitum DMI, or carnitine infusion + restricted DMI. Liver biopsies were obtained to extract RNA for transcriptome profiling using a bovine microarray consisting of 7,872 cDNA. Analysis of variance (false discovery rate $P \leq 0.15$ for overall treatments effect; equivalent to uncorrected $P \leq 0.05$) identified significant changes in transcriptomics only for feed restricted cows without any carnitine effect, resulting in 312 (155 downregulated, 157 upregulated) differentially expressed genes. Quantitative PCR (qPCR) was performed to confirm array data and measure expression of additional genes not present on the array. The qPCR data confirmed the effect of feed-restriction but not of carnitine treatment. Feed restriction increased expression of GPX3, involved in the detoxification of hydrogen peroxide, and of genes associated with gluconeogenesis (PC, PDK4), inflammation (SAA3), and signaling (ADIPOR2); whereas, it downregulated BBOX, key for L-carnitine biosynthesis, and the transcription factor HNF4A. Functional analysis of microarray data was carried out using Ingenuity Pathway Analysis, DAVID, and the novel dynamic impact approach (DIA). The functional analysis of DEG by feed restriction uncovered as the most relevant and inhibited functions biosynthesis of cholesterol and energy generation by mitochondrial respiration. Associated with the decrease of energy production the data also indicated a decrease in glucose catabolism, particularly through the glycolysis/pyruvate/TCA cycle and pentose phosphate pathways. Data indicated a decrease in fatty acid oxidation and ketone body production by feed restriction. Microarray and qPCR results revealed that in mid-lactating cows feed restriction but not L-carnitine affects the liver transcriptome with an evident inhibition of cholesterol synthesis and energy production. In contrast, gluconeogenesis increased and glucose catabolism decreased. We interpreted those results as a likely response of liver to spare energy for the lactating mammary gland. This study provides new and unexpected insights on the effect of negative energy balance on liver transcriptome in mid-lactating cows.

Key Words: bioinformatics, microarray, negative energy balance

T264 A comparison of methods to analyze physical effective factor and physically effective NDF in TMR and orts. S. D. Ranathunga,* K. F. Kalscheur, and D. P. Casper, *Dairy Science Department, South Dakota State University, Brookings.*

The objectives were to compare available methods to measure physical effective factor (pef) and physically effective NDF (peNDF) in TMR and orts while using different forage and dried distillers grains with solubles (DG) concentrations. Four Holstein cows were assigned to a 4 × 4 Latin square in a 2 × 2 factorial arrangement of treatments. Diets contained either low forage (LF; 41% of diet DM) or high forage (HF; 60% of diet DM) with DG at 0 or 18% of diet DM. The pef and peNDF of TMR and orts were measured using 3 methods: 1) Dry sieving method using 12 screens (DS), 2) Penn State shaker box using top 3 screens (PS), and 3) Z-box (Z). Average pef and peNDF for all TMRs differed ($P < 0.05$) between the 3 methods (55.5, 79.7, and 52.6% and 16.0, 22.9, and 15.2%, for DS, PS, and Z, respectively). Average pef and peNDF of the orts were greater ($P < 0.05$) for PS (65.4, 82.4, and 63.6% and 22.2, 27.8, and 21.6%) compared with other methods. There was a forage × DG effect on pef of TMR and pef and peNDF of orts irrespective of the method. The peNDF of TMR was affected by forage and DG concentrations irrespective of the method. The results suggest that PS method overestimates pef and peNDF of TMR and orts and interpretation of data are different compared with the DS method. Estimates pef and peNDF values of TMR and orts by the Z method are closer and interpretation of data similar to that of the DS method.

T265 Effect of post-ruminal supplementation of phytonutrients on bacterial diversity in feces of dairy cows. J. Oh*[1], A. N. Hristov[1], C. Lee[1], K. Heyler[1], T. Cassidy[1], S. Dowd[2], and D. Bravo[3], [1]*The Pennsylvania State University, University Park,* [2]*MR DNA Molecular, Shallowater, TX,* [3]*Pancosma, Geneva, Switzerland.*

The objective of this experiment was to investigate the effect of post-ruminal supplementation of phytonutrients on bacterial diversity in feces of lactating dairy cows. Eight ruminally cannulated Holstein cows (232 ± 34.1 DIM) were used in a replicated 4 × 4 Latin square design trial with 23-d periods. Treatments were control (CON) and 2 g/d of curcuma oleoresin (CU), garlic extract (GE), or capsicum oleoresin (CA). Treatments were dissolved in ethanol solution and pulse-dosed into the abomasum of the cows once daily, 2 h after feeding for 9 d during each experimental period. Fecal samples (8) were collected from the rectum on d 6 and 7 of phytonutrient supplementation and analyzed for bacterial diversity using 16S rDNA bacterial tag-encoded FLX amplicon pyrosequencing (bTEFAP). Predominant genera bacteria were *Clostridium*, *Eubacterium*, *Ruminococcus*, *Bacteroides*, *Oscillospira*, and *Odoribacter* (8 to 10% of the total population) and were not affected ($P > 0.11$) by treatment. Predominant species were *Eubacterium siraeum*, *Oscillospira guilliermondii*, and *Fecalibacterium prausnitzii* (7 to 10%) and were also not affected ($P > 0.11$) by treatment. Compared with CON, GE increased ($P < 0.04$) the proportion of bacteria of the genera *Thiococcus* (0.06 and 0.12%), *Borrelia* (0.01 and 0.06%), and *Lactococcus* (0.01 and 0.08%) and CU, GE, and CA decreased *Flexithrix* (0.05 vs. 0.02, 0.02, and 0.01%). Compared with CON, GE increased ($P < 0.03$) the proportion of *B. garinii* (0.01 and 0.06%) and *L. lactis* (0.01 and 0.07%). Relative to CON, CU and CA decreased ($P < 0.05$) *Prevotella multiformis* (0.06, 0.02, and 0.003%) and CU decreased ($P < 0.05$) *Clostridium stercorarium* (0.06 and 0.02%). The proportion of *F. dorotheae* was lower ($P < 0.04$) for CU, GE, and CA (0.02, 0.02, and 0.01 vs. 0.05% for CON). In conclusion, post-ruminal supplementation of phytonutrients did not alter the major bacterial species in feces of dairy cows, although some bacteria such as *Thiococcus*, *Borrelia*, and *Lactococcus* were enhanced by GE and species such as *Prevotella multiformis* and *F. dorotheae* were inhibited by the phytonutrients.

Key Words: phytonutrients, fecal bacteria, dairy cow

T266 Applicability of the plasma free amino acid dose response approach for determining lysine bioavailability of ruminally protected lysine products. N. L. Whitehouse*[1], E. S. Fletcher[1], A. F. Brito[1], and C. G. Schwab[2], [1]*University of New Hampshire, Durham,* [2]*Schwab Consulting LLC, Boscobel, WI.*

It has been long recognized that lysine (Lys) is a limiting AA for lactating dairy cows. As a result, several ruminally-protected Lys (RP-Lys) supplements are now available for increasing Lys concentrations in metabolizable protein (MP). However, there is no universally accepted procedure for obtaining estimates of efficacy of these products. To evaluate 4 different RP-Lys supplements, we examined the dose-response relationships between plasma free Lys concentrations and intestinally (Trial 1) or abomasally (Trials 2–4) infused Lys in lactating dairy cows. Four Latin square trials were conducted; 2 with basal diets formulated to have low concentrations of Lys in MP and 2 with high concentrations (according to NRC, 2001). At the start of the trials, DIM of cows were: 63–123 (Trial 1), 60–70 (Trial 2), 175–245 (Trial 3), and 90–130 (Trial 4). Blood samples collected from the tail vein were centrifuged, deproteinized, and composited by cow/d with plasma stored at −80°C until AA analysis. Our data (see table below) showed a linear response between plasma Lys concentrations and infused Lys, corroborating results from previous research. We also observed that expressing plasma Lys concentrations either as µg/mL or as µM, before expression as a percentage of total AA, resulted in relatively similar regression equation parameters as well as similar variation and bias estimations. It is concluded that the plasma free AA response approach can be utilized for determining Lys bioavailability of RP-Lys supplements.

Table 1. Regression parameters for incremental levels of infused lysine

Trial	MPLys, %	Infused Lys, g/d	Slope	Intercept	r^2	SE	RMSE
Lys, % Total AA (μ/mL)

T267 Physiological variables associated with reproductive success in dairy cows with different prepartum feeding strategies. F. C. Cardoso,* N. V. L. Serão, and J. K. Drackley, *University of Illinois, Urbana.*

To investigate the association between physiological factors and reproductive performance (days to conception; DTC) in dairy cows fed different prepartal dietary energy regimens, cow-level data from 408 cows from 7 different experiments by our group from 1993 to 2010 were analyzed. Treatments were classified as controlled energy (CE; median NE_L intake = 13.7 Mcal/d) or high energy (HE; median NE_L intake = 22.1 Mcal/d) diets fed during far-off (FO) or close-up (CU) dry periods. Principal component (PC) analysis was conducted on 8 variables: glucose wk 3 (GLU3), glucose wk 4 (GLU4), β-hydroxybutyrate wk 1 (BHBA1), insulin wk 2 (INS2), nonesterified fatty acids wk −1 (NEFA-1), energy-corrected milk wk 4 (ECM4), fat corrected milk wk 4 (FCM4), and milk urea nitrogen wk 4 (MUN4). Prior to analyses, the multinormality of the variables was assessed. The effect of PCs was investigated using linear and logistic (LR) regressions. For LR analysis, animals were classified in 2 groups as high (>131) or low (<121) DTC. All analyses were carried out using SAS 9.2 (SAS Institute, Inc.). PCs with eigenvalues (λ) greater than 0.9 were extracted, and only loadings greater than 0.4 were discussed. PC scores (PCS) were generated for each extracted PC. Four PCs were extracted from the analysis, accounting for 80.1% of total variability. The PC loadings indicated that, for PC1, increased ECM4 and FCM4 were associated with decreased INS2, GLU3, and GLU4. PC2 represented animals with higher NEFA-1 and BHBA1. PC3 had higher values for ECM4, FCM4, GLU3, and GLU4, whereas PC4 had higher values for MUN4 and INS2. Regressing PCS of PC2 on PC1 indicated that the relation between these PCs differed between diets ($P < 0.01$). For increased values of PC1, HE cows had increased values of PC2, whereas those fed CE showed decreased values of PC2. Inclusion of PCs in a logistic model revealed that high values of PC2 result in increased DTC (OR = 1.604, $P = 0.09$). In conclusion, PCs explained and predicted reproductive success in dairy cows. These 8 variables might be used to predict reproductive success.

Key Words: principal component, transition period, reproductive performance

T268 Plasma responses to intra-ruminal or post-ruminal administration of 2-hydroxy-4-methylthio-butanoic acid and its isopropyl ester in dairy cattle to evaluate rumen escape. G. I. Zanton,* S. E. Bettis, and M. Vazquez-Anon, *Novus International, Inc., St. Charles, MO.*

Two experiments were conducted to evaluate the rumen escape of methionine precursors. In experiment 1, 4 rumen cannulated, Holstein steers (718 ± 16 kg) were bolus dosed intra-ruminally (R) or post-ruminally via the omasal canal (O) with 80 mg of DL 2-hydroxy-4-methylthio-butanoic acid (HMTBa as MFP)/kg BW at the time of normal feed distribution. Treatments were administered during 2, 7 d periods according to a crossover design. Plasma samples were prepared from blood taken from the coxygeal vein at 0, 1.5, 3, 6, 9, 12, 18, 24, 30, 36, and 48 h after treatment administration. Plasma was analyzed for concentration of DL HMTBa. In experiment 2, the model developed in experiment 1 was used to compare the rumen escape of HMTBa provided as MFP to the isopropyl ester of HMTBa (HMBi). Eight rumen cannulated Holstein steers (548 ± 27 kg) were blocked by weight and randomly assigned to 4 treatment sequences according to a replicated 4 × 4 Latin square design. Treatment administration, sampling, and analysis were conducted as in experiment 1. Mean responses in area under the curve (AUC) were analyzed in the mixed procedure of SAS with significance declared at $P < 0.05$. In experiment 1, steers consumed 12.5 kg of DM or 1.7% of BW. Plasma HMTBa AUC was greater for O than for R (151 vs 73 ± 6 mg/L). By comparing the plasma HMTBa AUC for R relative to O, it was determined that MFP had a rumen escape of 49%. For experiment 2, DMI was 12.5 kg/d and 2.3% of BW and not affected by treatment or site of administration. Plasma HMTBa AUC was higher for HMBi (O: 169, R: 99 mg/L) than MFP (O: 135, R: 54 mg/L) at both sites; there was no interaction. By comparing the plasma HMTBa AUC for R relative to O for both sources, it was determined that HMBi had a rumen escape of 60% and MFP had a rumen escape of 41%.

Key Words: dairy, HMTBa, methionine

T269 Casein and fatty acid fractions in milk are affected by parity and nutritional regulated body condition score at the beginning of the transition period in dairy cows under grazing conditions. V. Artegoitia*[1,2], A. Meikle[2], L. Olazabal[3], J. P. Damian[2], M. L. Adrien[1], D. A. Mattiauda[1], J. Bermudez[1], A. Torre[3], and M. Carriquiry[1], *[1]Facultad de Agronomía, Universidad de la República Oriental del Uruguay, Montevideo, Uruguay, [2]Facultad de Veterinaria, Universidad de la República Oriental del Uruguay, Montevideo, Uruguay, [3]Laboratorio Tecnológico del Uruguay, Montevideo, Uruguay.*

The study objective was to evaluate the effect of BCS [high (H) vs. low (L)] at 30 d before calving (−30 d) on milk casein and fatty acid (FA) fractions in primiparous (P; PH, n = 13; PL, n = 9) and multiparous (M; MH, n = 9; ML, n = 8) Holstein cows fed under grazing conditions. Cows were offered different planes of nutrition of long-term pastures from −100 to −30 d pre-calving, to generate 0.5 BCS unit differences between groups at the end of the period. Milk samples were collected at wk 2 and 8 of lactation (WOL). Means were considered to differ when $P \leq 0.05$. Milk, protein, and fat yields and somatic cell counts (SCC) were greater in M than P cows, and milk protein and fat yields decreased from WOL 2 to 8 in all cows. Casein content was greater in M than P cows, decreased from WOL 2 to 8, and it was greater for MH cows than the other groups at WOL 2. Milk β-casein was less and κ-casein was greater in M than P cows, which could be due to a greater degradation of β-casein by plasmin activity associated to greater SCC in M cows' milk. The κ-casein was greater in PL than in PH cows, consistent with higher insulin concentrations in the former cows at the end of the treatment.

The de novo (4:0 to 15:1) and mixed origin (16:0 to 16:1) FA in milk fat increased, whereas preformed FA (≥17:0) decreased from WOL 2 to 8, associated with the early (WOL 2) lipid mobilization for milk synthesis. Mixed origin FA tended to be affected by BCS ($P = 0.10$), as they were greater for ML than MH cows. Saturated FA tended to be greater ($P = 0.06$) and MUFA were less in milk fat of M than P cows. Milk PUFA, particularly n-3 FA, were greater in H than L cows at WOL 2 for M cows and WOL 8 for P cows suggesting a greater dry matter intake in these cows. Milk CLA was greater in H than L cows and decreased from WOL 2 to 8 only in PL cows. Results indicate that casein and fatty acid fractions in milk are affected by parity and by BCS at the beginning of the transition period in dairy cows on grazing conditions.

Key Words: body reserves, milk composition

T270 Arterial amino acid concentrations drives milk yield in postpartum transition dairy cows.

M. Larsen* and N. B. Kristensen, *Department of Animal Science, Aarhus University, Foulum, Tjele, Denmark.*

Previous studies based on splanchnic amino acid fluxes and milk protein output showed that dairy cows mobilize close to 5 kg of essential amino acids in the first month postpartum. The present study aimed at investigating the effects of alleviating the protein deficiency in postpartum transition dairy cows on mammary uptake of amino acids. Eight Holstein cows (second lactation) were used in a complete randomized design with repeated measurements at 4, 15, and 29 d in milk (DIM). At the calving day, cows were assigned to either continuous abomasal infusion of casein (CAS) or water (CTRL). All cows were fed the same diet. Abomasal casein infusion was profiled as 360 g/d at 1 DIM, 720 g/d at 2 DIM, followed by daily reductions of 19.5 g/d ending at 194 g/d at 29 DIM. Arterial and mammary venous blood sample sets were obtained bihourly at sampling days. Data was analyzed using PROC MIXED in SAS with treatment, DIM, and the interaction as fixed effects. Cow was considered as random effect, and DIM within cow as repeated measurement. Dry matter intake was unaffected ($P = 0.36$) by treatment. Milk yield increased more rapidly after calving with CAS ($P < 0.01$) and averaged 43.8 ± 1.0 kg/d with CAS and 36.6 ± 1.0 kg/d with CTRL. Milk protein yield with CAS was 1,664 ± 39 g/d at 4 DIM compared with 1,212 ± 86 g/d for CTRL, whereas milk protein yield did not differ at 29 DIM (1383 ± 48 g/d; interaction: $P = 0.02$). The calculated utilization of infused casein to milk protein was 64% at 4 DIM and 60% at 29 DIM. Arterial concentrations and mammary venous—arterial concentration differences for essential amino acids (EAA) were higher at 4 DIM with CAS as compared with CTRL, but did not differ at 29 DIM (interactions: $P = 0.02$ and $P = 0.03$, respectively). Mammary extraction rate of EAA was unaffected by CAS ($P = 0.37$) and DIM ($P = 0.58$). Circulating levels of insulin and IGF-1 were unaffected by CAS ($P = 72$ and $P = 36$, respectively). In conclusion, these results suggest that mammary uptake of amino acid is driven by arterial supply during initiation of lactation, thus, extra metabolizable amino acids supplied to postpartum transition cows are efficiently used for milk protein production.

Key Words: transition dairy cows, protein requirement, amino acids

T271 Productive performance of dairy cows fed with omega 3 and 6 fatty acids sources in the transition period and early lactation.

J. R. Gandra,* L. C. Verdurico, R. D. Mingoti, R. V. Barletta, J. E. Freitas Jr., C. E. Araújo, K. A. Koyama, G. D. Calomeni, E. Ferreira de Jesus, and F. P. Rennó, *University of Sao Paulo, Sao Paulo, Brazil.*

The objective of this study was to evaluate the supplemental sources of omega 3 and 6 fatty acids and the effects in the milk yield and composition of dairy cows fed during the transition period and early lactation. Forty 8 Holstein cows were divided into 4 experimental groups in randomized design. The animals were randomly assigned to receive one of 4 treatments: 1) Control (C; n = 12), without fat sources in the pre and postpartum, 2) Flaxseed (FS; n = 12), in which cows were fed 60 and 80g/kg of DM of flaxseed in the pre and postpartum, respectively; 3) Whole raw soybeans (WS; n = 12), in which cows were fed 120 and 160g/kg of DM of whole raw soybeans in the pre and postpartum ; 4) Calcium salts of unsaturated fatty acid (CSFA; n = 12, Megalac-E), in which cows were fed 24 and 32g/kg of DM of calcium salts of unsaturated fatty acid in pre and postpartum. The experimental diets were fed since 35 d before the estimate calving, and provided until 84 d of lactation, formulated to meet the nutritional requirements of each period (pre and postpartum). Milk yield was measured daily and samples for milk composition were collected weekly from the first to the 12th week of lactation. Data were analyzed using PROC MIXED of SAS 9.1, with the effect of diet, time and interaction has fixed effects, and animal has random effect. The data were analyzed by orthogonal contrasts (C vs. WS+CSFA+FS; WS vs. CSFA; and FS vs WS+CSFA). There was no effect of the fatty acids sources on the milk yield, FCM, protein and lactose (kg/d and %). The average milk yield was 32.27 kg/d, where diets C, FA, WS and CSFA were (31.80, 31.43, 31.81 and 33.57 kg / d), respectively. There was effect of lipid sources for milk fat (kg /d and %) and in the contrast WS vs CSFA (3.52% vs. 2.88%); (1.09 kg/d vs 0.92 kg/d) respectively. The productive performance of dairy cows fed with omega 3 and 6 fatty acids sources in the transition period and early lactation was only affected in the milk fat yield and percent.

Key Words: fat sources, productive performance, transition period

T272 Effects of 18-carbon fatty acids on triacylglycerol accumulation in bovine mammary epithelial cells in vitro.

R. L. Cui, J. Q. Wang,* H. Y. Wei, D. P. Bu, X. M. Nan, H. Hu, P. Sun, and L. Y. Zhou, *State Key Laboratory of Animal Nutrition, Institute of Animal Science, Chinese Academy of Agricultural Sciences, Beijing, China.*

The objective of this study was to investigate the effects of concentration and ratio change of stearic acid, oleic acid, linoleic acid and linolenic acid on triacylglycerol (TG) accumulation in bovine mammary epithelial cells, and to reveal their contribution to TG accumulation when the four 18-carbon fatty acids (18-C FA) existed in medium simultaneously. Bovine mammary epithelial cells from a 3-year old lactating (ca. 100 DIM) Chinese Holstein dairy cow were incubated at 38°C in DMEM/F12 medium containing 1 g/L fatty acid-free bovine serum albumin (BSA), 5 mg/L prolactin, 5 mg/mL insulin, 5 mg/mL Holo-transferrin, 5 mg/mL progesterone, 10^{-7} mol/L hydrocortisone, 10 ng/mL bovine epithelial growth factor and 5 mg/mL bovine estradiol. An orthogonal L_{16} (4^5) test was performed in this experiment, and the concentrations of 18-C FAs were all 25, 50, 75 and 100 μM. TG contents in cells and medium were tested by Triglyceride Quantitation Kit after different combination performed for 24 h. In addition, every treatment had 3 replicates in this experiment, and ANOVA of SAS was used to analyze the experimental data. The results showed that stearic acid was the most important determinant of TG accumulation when the four 18-C FAs existed in medium simultaneously, and TG accumulation tended to increase as stearic acid concentration increased. The combination of 100 μM stearic acid, 100 μM oleic acid, 50 μM linoleic acid, 75 μM linolenic acid was the the optimal combination for increasing TG accumulation in our experiment. In conclusion, stearic acid was the most important determinant of TG accumulation when the four 18-C FAs were all available.

Key Words: bovine mammary epithelial cells, 18-carbon fatty acids, triacylglycerol

T273 Effects of 18-carbon fatty acids on cell proliferation and triacylglycerol accumulation in bovine mammary epithelial cells in vitro. R. L. Cui, J. Q. Wang,* H. Y. Wei, D. P. Bu, X. M. Nan, H. Hu, P. Sun, and L. Y. Zhou, *State Key Laboratory of Animal Nutrition, Institute of Animal Science, Chinese Academy of Agricultural Sciences, Beijing, China.*

The objective of this study was to investigate the effects of 18-carbon fatty acids (18-C FAs) on cell proliferation and triacylglycerol (TG) accumulation in bovine mammary epithelial cells in vitro. Bovine mammary epithelial cells from a 3-year old lactating (ca. 100 DIM) Chinese Holstein dairy cow were incubated at 38°C in DMEM/F12 medium containing 1g/L fatty acid-free bovine serum albumin (BSA), 5mg/L prolactin, 5 mg/mL insulin, 5 mg/mL holo-transferrin, 5 mg/mL progesterone, 10^{-7} mol/L hydrocortisone, 10 ng/mL bovine epithelial growth factor and 5 mg/mL bovine estradiol. Epithelial cells were cultured with different concentration of stearic acid, oleic acid, linoleic acid and linolenic acid for 24 h, separately, and the cells cultured without any fatty acids served as control. Then the MTT experiment was performed and the TG contents in medium were detected by Triglyceride Quantitation Kit. In addition, every treatment had 3 replicates in this experiment, and ANOVA of SAS was used to analyze the experimental data. In MTT experiment, the concentrations of 4 18-C FAs were all 0, 0.78, 1.56, 3.125, 6.25, 12.5, 25, 50, 100, 200, 400 μmol/L, and the results showed that the cell proliferation was inhibited significantly when the cell cultured with 200 or 400 μmol/L stearic acid, oleic acid, linoleic acid or linolenic acid ($P < 0.05$). According to MTT results, the concentrations of 4 18-C FAs were 0, 25, 50, 100 μmol/L for detecting TG contents, and the results showed that TG contents in medium were increased in a concentration-dependent manner from 0 to 100 μmol/L ($P < 0.05$). In conclusion, high concentration (200 or 400 μmol/L) of 18C-FAs can inhibit the cell proliferation, and TG accumulation can be increased as the concentration of 18-C FAs increase.

Key Words: bovine mammary epithelial cells, 18-carbon fatty acids, cell proliferation

T274 Lipopolysaccharide-induced alterations in milk fatty acid composition and mRNA expression of genes related to fatty acid metabolism. Y. D. Zhang, J. Q. Wang,* D. P. Bu, T. Hu, X. M. Nan, H. Hu, R. L. Cui, and L. Y. Zhou, *State Key Laboratory of Animal Nutrition, Institute of Animal Science, Chinese Academy of Agricultural Sciences, Beijing, China.*

Two experiments were conducted to evaluate the effect of lipopolysaccharide (LPS) on milk fat production and fatty acid composition. Eight multiparous Holstein cows (185 ± 30 DIM) received external pudic arterial administration of LPS (*E. coli* O111:B4) at 0.01 μg/kg BW in 10 mL of sterile saline (0.9% NaCl; treatment) or saline only (control) according to a crossover design. The experiment consisted of a 7-d preliminary period and 2 7-d treatment periods. Milk samples were collected at 0, 6, 12, and 24 h after LPS infusion on d 1 and twice daily from d 2 to 7. In the second experiment, the expression of genes for fatty acid metabolism in dairy cows was studied by incubating mammary epithelial cells with LPS at 0, 0.1, or 10 ng/mL for 24 h using RT-qRCR. All data were analyzed using the MIXED procedure of SAS (SAS Institute Inc., 2001, Cary, NC). In the in vivo study, milk yield ($P = 0.19$), milk fat concentration ($P = 0.34$), and milk fat yield ($P = 0.56$) were not affected with LPS infusion. LPS altered the milk fatty acid composition, resulting in an increase in the proportion of unsaturated fatty acids and short-chain fatty acids (<16:0) and a decrease in the proportion of saturated fatty acids and long-chain fatty acids (>16:0). In the in vitro experiment, LPS did not affect fatty acid-binding protein FABP3 or FABP4 mRNA expression ($P > 0.05$), but increased transporter CD36 mRNA expression ($P < 0.01$). Treatment with 0.1 ng/mL LPS increased fatty acid synthesis enzyme FASN, ACACA, ACSS2 and fatty acid metabolism gene PPARG, PPARGC1A mRNA expression ($P > 0.05$) compared with the control. Differential regulations of fatty acid synthesis enzyme FASN, ACACA, ACSS2 and fatty acid metabolism gene PPARG, PPARGC1A mRNA expression were observed with 10 ng/mL LPS. LPS alters fatty acid metabolism, functioning as an important factor affecting milk fat synthesis.

Key Words: fatty acids metabolic-related gene, LPS, milk fat composition

T275 Hepatic expression of GH-IGF axis genes in Holstein cows with different nutritional managements during early lactation. A. L. Astessiano*[1], P. Chilibroste[2], M. Fajardo[2], J. Laporta[1], J. Gil[2], D. A. Mattiauda[1], A. Meikle[3], and M. Carriquiry[1], *[1]1School of Agronomy, UDELAR, Montevideo, Uruguay, [2]2School of Veterinary Medicine, UDELAR, Paysandú (EEMAC), Uruguay, [3]3School of Veterinary Medicine, UDELAR, Montevideo, Uruguay.*

Multiparous cows (n = 25) were used in a randomized block design to study the effects of nutrition during the first 60 d postpartum (DPP) on endocrine profiles and hepatic gene expression. Cows were assigned to 3 treatments (TREAT): TMR) total mixed rations (30 kg DM/d offered; 45% forage, 55% concentrate); G1) 50% pasture in one (am) grazing session (7 h; pasture allowance = 15kg DM/d) + 50% TMR (15kg DM/d offered) and G2) 50% pasture in 2 (am/pm) grazing sessions (11h; pasture allowance = 15 kg DM/d) + 50% TMR (15 kg DM/d offered). Blood and liver biopsies were obtained at −40, −20, 10 and 55 DPP to quantify insulin and IGF-I, and mRNA expression of GH-IGF axis by real time PCR. Means from a repeated measures analysis differed when $P < 0.05$. Cow BCS decreased during the postpartum and at 55 DPP was greater in TMR than G1 and G2 cows. Milk energy output did not differ among TREAT (27.8, 26.4 and 23.4 ± 1.4 Mcal/d for TMR, G1 and G2). Serum IGF-I decreased from pre to postpartum and did not differ among TREAT while serum insulin decreased from pre to postpartum in G1 and G2 remaining stable in TMR cows. Hepatic GHR and IGFBP4 mRNA were not affected by TREAT or DPP. Expression of GHR1A mRNA decreased from −20 to 55 DPP while IGF-I mRNA tended ($P < 0.10$) to decrease from −20 to 10 DPP and to increase at 55 DPP. The IGFBP2 mRNA increased from −20 to 10 DPP but decreased thereafter at 55 DPP, being its abundance at 55 DPP less in TMR than G1 and G2 cows. In contrast, IGFBP3 mRNA tended ($P < 0.10$) to decrease from −20 to 10 DPP and increased at 55 DPP, being the decrease at 10 DPP more evident In G1 and G2 cows. The IGFBP1 mRNA increased from −20 to 55 DPP while IGFBP5 and IGFBP6 mRNA increased from −40 or −20 to 10 DPP and remained elevated at 55 DPP. However, IGFBP6 mRNA tended ($P = 0.06$) to be greater in G2 than TMR and P1 cows. Decreased serum IGF-I in early lactation was associated to decreased IGF-I mRNA and to changes in hepatic IGFBP synthesis which modulate bioavailability and stability of circulating IGF-I. Cows fed TMR showed a better metabolic status (greater BCS, serum insulin, IGBP3/IGBP2 mRNA ratio) during early lactation

Key Words: nutrition, transition cow, somatotropic axis

T276 New discovery on bovine glutathione peroxidase 3. H. R. Khazanehei,* P. Eck, and J. C. Plaizier, *University of Manitoba, Winnipeg, MB, Canada.*

Due to a high-energy demand for milk production, high-yielding dairy cows often experience a negative energy balance during early lactation. As a consequence, lipid is mobilized from adipose tissues and transported to the liver to provide energy through β-oxidation. This process produces reactive oxygen species (ROS), which can cause many disorders and cell damages. An experiment was conducted to assess the liver gene expression pattern before and after parturition and at the initiation of lactation. Liver biopsies were obtained at wk −3, 1 and 4 relative to parturition. Differential gene expression was assessed by affymetrix microarray analysis and FlexArray 1.6.1. An FDR-adjusted P lower than or equal to 0.1 and a fold-change greater than 2 were considered as a cut-off point to indicate significant up- or downregulation of genes. Gene networks were assembled using Ingenuity Pathway Analysis (IPA). The most overexpressed gene (5.08 fold change) at wk 1 was glutathione peroxidase 3 (GPX3). This indicates its non-redundant function in situations of metabolic and oxidative stress, where it detoxifies hydrogen peroxide. A further database query revealed that the bovine glutathione peroxidase 3 gene has not been characterized. Therefore we combined information from genetic databases (NCBI Gene Bank, UniGene, UCSC, ENSMBL) to hand curate and annotate the genetic locus and transcript variants, using assemblies in Sequencher 4.8. We identified 5 exons, and based on EST alignments exon 2 can be skipped in a minority of transcripts. This seems to be a bovine specific splice variant, since this event is not observed in other species alignments (http://genome.ucsc.edu/cgi-bin/hgTracks).

Key Words: dairy cow, gene expression, glutathione peroxidase 3

Ruminant Nutrition: Dairy: Feed Additives II

T277 Effect of post-ruminal supplementation of phytonutrients on total-tract digestibility, nitrogen losses, and milk production and composition in dairy cows. J. Oh*[1], A. N. Hristov[1], C. Lee[1], K. Heyler[1], T. Cassidy[1], and D. Bravo[2], *[1]The Pennsylvania State University, University Park, [2]Pancosma, Geneva, Switzerland.*

The objective of this experiment was to investigate the effects of post-ruminal supplementation of phytonutrients on ruminal fermentation, apparent total-tract digestibility of nutrients, N utilization, and milk production and composition in lactating dairy cows. Eight ruminally cannulated Holstein cows (232 ± 34.1 d in milk) were used in a replicated 4×4 Latin square design trial with 23-d periods. Treatments were: (1) control (CON), (2) 2 g/d curcuma oleoresin (CU), (3) 2 g/d garlic extract (GE), and (4) 2 g/d capsicum oleoresin (CA). The phytonutrients were dissolved in ethanol solution and pulse-dosed into the abomasum of the cows once daily, 2 h after feeding for 9 d during each experimental period. Control cows received ethanol solution only. Ruminal pH and ammonia and volatile fatty acid concentrations were not affected ($P =$ 0.40 to 0.97) by treatment. Apparent total tract digestibility of nutrients (dry and organic matter, crude protein, and fiber fractions) was similar ($P = 0.34$ to 0.91) among treatments. Total urinary-N, urinary urea-N, fecal-N, and total-N excretions were also not affected ($P = 0.22$ to 0.91) by treatment. Relative to CON, GE decreased ($P = 0.04$) dry matter intake (DMI, 21.2 vs. 19.9 kg/d, respectively). Milk yield was decreased ($P = 0.04$) with GE and CA compared with CON (35.8, 35.2 and 37.4 kg/d, respectively). Treatments did not affect milk composition and somatic cell count, 4% fat-corrected milk yield, and milk fat and true protein yields. In conclusion, post-ruminal supplementation of phytonutrients had no effect on ruminal fermentation, nutrient digestibility, N utilization, and milk composition in dairy cows. The decreased DMI with GE resulted in decreased milk yield and CA decreased milk yield without affecting DMI. The production effects from this trial have to be interpreted with caution due to the short duration of the treatment and milk data collection periods (9 and 6 d, respectively).

Key Words: phytonutrients, digestibility, dairy cow

T278 Effects of plant extracts on microbial population, methane emission and ruminal fermentation characteristics in in vitro. E. T. Kim*[1], K.-S. Min[2], C.-H. Kim[2], S. C. Kim[1], and S. S. Lee[1], *[1]Division of Applied Life Science (BK21 Program), Gyeongsang National University, Jinju, Gyeongsangnamdo, Republic of Korea, [2]Hankyong National University, Anseong, Gyeonggido, Republic of Korea.*

This study was conducted to evaluate effects of plant extracts on methanogenesis and rumen microbial diversity in in vitro. Plant extracts (*Artemisia princeps* var. *orientalis*; wormwood, *Allium sativum* for. *Pekinense*; garlic, *Allium cepa*; onion, *Zingiber officinale*; ginger, *Citrus unshiu*; mandarin orange, *Lonicera japonica*; honeysuckle) were obtained from Plant Extract Bank at Korea Research Institute of Bioscience and Biotechnology. The rumen fluid was collected before morning feeding from a fistulated Holstein cow fed timothy and commercial concentrate (TDN; 73.5%, crude protein; 19%, crude fat; 3%, crude fiber; 12%, crude ash; 10%, Ca; 0.8%, P; 1.2%) in the ratio of 3 to 2. The 30 mL of mixture, comprising McDougall buffer and rumen liquor in the ratio of 4 to 1, was dispensed anaerobically into serum bottles containing 0.3 g of timothy substrate and plant extracts (1% of total volume, respectively) filled with O_2-free N_2 gas and capped with a rubber stopper. The serum bottles were held in a shaking incubator at 39°C for 24 h. Total gas productions in all added plant extracts were higher ($P < 0.05$) than that of control, and that of ginger extract was highest ($P < 0.05$). The methane emission was highest ($P < 0.05$) at control, but lowest ($P < 0.05$) at garlic extract which was reduced about 20% of methane (40.2 vs. 32.5 mL/g DM). Other plant extracts were also led to decrease methane emission (wormwood; 8%, onion; 16%, ginger; 16.7%, mandarin orange; 12%, honeysuckle; 12.2%). Total VFAs concentration and pH were not influenced by the addition of plant extracts. Acetate to propionate ratios of garlic and ginger extracts were lower ($P < 0.05$, 3.36 and 3.38 vs. 3.53) than that of the control. Real-time PCR indicted that all plant extracts affected to the decrease of the ciliated-associated methanogen population, while the fibrolytic bacteria population was increased. In particular, *F. succinogens* community was increased by wormwood, garlic, mandarin orange and honeysuckle extracts, while *R. flavefaciens* population was inhibited by wormwood and garlic extracts, and *R. albus* diversity was influenced by mandarin orange and honeysuckle extracts.

Key Words: methanogenesis, plant extracts, real-time PCR

T279 Adding plant oils to dairy goat diets: Changes in milk fatty acids with sampling time. A. L. Martínez Marín[1], P. Gómez-Cortés[2], G. Gómez Castro[1], M. Juarez[2], L. M. Pérez Alba[1], M. Pérez Hernández[1], and M. A. de la Fuente*[2], *[1]Universidad de Córdoba, Córdoba, Spain, [2]Instituto de Investigación en Ciencias de la Alimentación, Madrid, Spain.*

Knowing the time at which the responses to dietary plant oil addition are clear in milk fat could shorten experimental periods and give clues on rumen and mammary metabolism of fatty acids (FA). Our aim was to find out changes in milk fat FA composition from 1 h to 21 d after introducing 3 differently unsaturated plant oils in dairy goat diets. Twelve midlactation multiparous goats were randomly allocated to one of 4 dietary treatments: Control (basal diet, no added oil) or the same basal diet added with 48 g/d of either high oleic sunflower oil, regular sunflower oil (RSO), or linseed oil (LO). Basal diet was made of alfalfa hay (0.33) and pelleted concentrate (0.67). Milk samples were taken at 0 (covariate), 1, 12, 24, 72, 120, 192, 312 and 504 h. Milkings at 0, 1 and 12 h were stripped out by hand after an intravenous dose of oxytocin. Analysis of fatty acid methyl esters (FAME) was performed by gas chromatography. MIXED procedure of SAS was used to analyze milk fat FA contents (g/100 g total FAME). Seventy 2 FA were identified and quantified in milk fat. The same differences between Control and oil treatments found at 504 h were also observed at 312 h in 12 chosen relevant FA, 5 sums of FA (saturated, mono- and polyunsaturated, total trans-18:1 and total conjugated linoleic acid) and linoleic to α-linolenic acid ratio. Both vaccenic (VA) and rumenic acid (RA) contents with LO treatment started showing differences with Control at 12 h (1.65 vs. 0.61; $P < 0.001$ and 0.60 vs. 0.30; $P < 0.001$). Between RSO and Control, differences of VA contents started at 12 h (1.87 vs. 0.69; $P = 0.016$) and that of RA at 24 h (0.79 vs. 0.36; $P = 0.048$). Content of α-linolenic acid with LO was different of Control at 1 h (0.18 vs. 0.13; $P = 0.019$); this difference increased at 12 h (0.34 vs. 0.13; $P < 0.0001$) and kept growing until 504 h (0.73 vs. 0.17; $P < 0.0001$). Reliable results of milk FA changes can be obtained at sampling times lower than 21 d and these modifications can help in the study of rumen and mammary metabolism of dietary FA.

Key Words: dairy goat, plant oil, fatty acid

T280 Supplementing rumen-protected Met and Lys in low protein diets based on corn distillers grains fed to lactating dairy cows.

N. E. Lobos*[1], G. A. Broderick[2], and M. J. de Veth[3], *[1]University of Wisconsin, Madison, WI, [2]U.S. Dairy Forage Research Center, Madison, WI, [3]Balchem Corporation, New Hampton, NY.*

Feeding rumen-protected Met (RPM) and Lys (RPL) may allow feeding lower CP diets to dairy cows, thereby increasing N efficiency and reducing environmental impact. Moreover, RPL supplementation may improve the value of corn distillers dried grains plus solubles (DDGS) because its RUP is limiting in Lys. A trial tested experimental preparations of RPM and RPL that provided 15 g/d of DL-Met and 26 g/d of L-Lys. Forty lactating Holstein cows were blocked by DIM and parity into 8 squares in a replicated 5 × 5 Latin square trial with 5 dietary treatments: 1) low CP control (14.9% CP) without supplement, diet 1) top-dressed with 2) RPM, 3) RPL, 4) RPM + RPL, and 5) high CP control (16.8% CP) without supplement. As fed, all diets contained (DM basis): 31% alfalfa silage, 31% corn silage, 7.7% DDGS, 2.4% mineral-vitamin premix and 31% NDF. Diets 1–4 contained 25% corn grain plus 3.3% solvent soybean meal (SBM); diet 5 contained 21% corn grain, 1.9% solvent SBM, 3.6% expeller SBM, and 1.9% corn gluten meal. Periods were 3-wk (total 15 wk); data from wk-3 were analyzed using Proc Mixed in SAS. Contrasts and LS-means are reported in the table. Relative to the low CP control, feeding higher CP increased DMI and yield of milk and protein, but also increased MUN. No RPM main effect was observed; however, the RPM*RPL interaction for milk yield was significant because RPM increased milk 1.2 kg/d but milk was unaltered on RPM + RPL. Feeding RPL reduced ECM/DMI because numerically greater DMI had no effect on ECM yield. In this trial, feeding RPM, but not RPL, increased milk yield on low CP diets containing SBM plus DDGS.

T281 Performance and diet digestibility of dairy cows supplemented with *Bacillus subtilis* spores.

V. L. Souza[2], V. A. Silveira[1], N. M. Lopes[1], O. F. Zacaroni[1], R. A. M. Pereira[3], J. A. de Freitas*[2], R. Almeida[2], and M. N. Pereira[1], *[1]Universidade Federal de Lavras, Lavras, Brazil, [2]Universidade Federal do Parana, Curitiba, Brazil, [3]Empresa de Pesquisa Agropecuaria de Minas Gerais, Lavras, Brazil.*

This experiment evaluated the supplementation of dairy cows with *B. subtilis*. Trial 1 used 18 Holsteins (246 DIM) in a crossover design, with 39-d periods, and a 10-d washout between periods. Treatments were orally dosed daily: 3x10^9 viable spores/d of *B. subtilis* C-3102 (Calpis Co. Ltda, Tokyo, Japan) or placebo. Cows were individually fed a TMR: 50% corn silage, 4.1% Tifton hay, 20.2% soybean meal, 11.2% high moisture corn, and 10.2% citrus pulp. Diet digestibility was evaluated by total collection of feces during d 33 to 35. The NDF digestibility was 52.6% of intake for *B. subtilis* and 55.8 for placebo ($P = 0.28$), OM digestibility was 72.1 and 72.6, respectively ($P = 0.69$). No treatment effect on digesta passage rate and chewing activity were detected ($P > 0.21$). Milk yield was 25.2 kg/d for placebo and 25.4 for *B. subtilis* ($P = 0.66$), DMI was 18.3 ($P = 0.91$). There was no treatment effect on milk solids and MUN ($P > 0.17$). Milk SCC was 97,000 cells/mL for *B. subtilis* and 99,000 for placebo ($P = 0.91$). Proportion of cows with positive *B. subtilis* culture in feces was 22% for placebo and 67% for *B. subtilis*. In trial 2, 30 cows (161 DIM) received the treatments for 16 weeks, in a covariate adjusted randomized block design. Milk samples were obtained weekly. Body weight and condition score were evaluated at 4-week intervals. The TMR contained 42.4% corn silage, 21.8% soybean meal, 15.6% ground corn, and 15.8% citrus pulp. Data was analyzed as repeated measures over time with Mixed of SAS. *B. subtilis* increased the daily secretions of milk (25.3 vs. 23.6 kg, $P = 0.02$) and protein (0.816 vs. 0.763 kg, $P = 0.01$), and had no effect on fat and lactose secretions ($P > 0.35$). The milk and protein yield response was consistent along the entire trial ($P > 0.90$ for the interaction of week and treatment). Milk SCC was 952,000 for *B. subtilis* and 747,000 for placebo ($P = 0.56$). *B. subtilis* tended to decrease MUN from 20.8mg/dL to 19.3 ($P = 0.06$). There was no treatment effect on body weight and condition score ($P > 0.33$). The supplementation of *B. subtilis* spores increased milk and protein yield when the trial was performed with high SCC cows, but the mechanism for the response was not elucidated.

Key Words: *Bacillus subtilis*, direct-fed microbial, probiotic

T282 Milk fatty acids composition of dairy ewes fed increasing levels of an unprotected CLA (UnCLA) supplement.

D. R. M. Alessio[1], M. Baldin[1], R. Dresch[1], J. Souza[2], M. A. S. Gama[3], M. P. Soares[4], and D. E. Oliveira*[5,1], *[1]Centro de Ciências Agroveterinárias, UDESC, Lages, SC, Brasil, [2]Esalq/USP, Piracicaba, SP, Brasil, [3]Embrapa, CNPGL, Juiz de Fora, MG, Brasil, [4]Instituto Federal Catarinense, Araquari, SC, Brasil, [5]Centro de Educação Superior do Oeste, UDESC, Chapecó, SC, Brasil.*

This study aimed to evaluate the changes in milk fatty acids (FA) composition in ewes fed increasing doses of UnCLA (29.9% of trans-10, cis-12 CLA as methyl esters). Twenty-three primiparous Lacaune ewes with 40 ± 10 DIM, milk yield of 1.73 ± 0.26 kg/d and 52.1 ± 5.0 kg of BW were fed the following dietary treatments during 14d in an 28-d experimental period: Control (C): 30g of Megalac-E, n = 5; T10: 20g of Megalac-E plus 10g of UnCLA, n = 6; T20: 10g of Megalac-E plus 20g of UnCLA, n = 5 and T30: 30g of UnCLA; n = 7. The fat supplements were mixed into the concentrate (1.0 kg/d) and fed individually in 2 equal meals after a.m. and p.m. milkings. Ewes grazed paddocks of a tropical pasture as the only source of forage. Milk samples were collected on the 14th d of experimental period and analyzed for FA profile. Data were analyzed as a completely randomized design using the REG procedure of SAS. The desaturase indexes and the concentration of ≤C16 FA were linearly decreased, whereas the concentration of >C16, trans-10 C18:1 and the sum of trans-C18:1 FA was linearly increased as the CLA dose increased (Table 1). Moreover, treatments T10, T20 and T30 resulted in 191, 445 and 745% increases in milk trans-10, cis-12 CLA content and 131, 320 and 424% increases in trans-10, cis-12 CLA secretion into milk fat, respectively. The transfer efficiencies of trans-10, cis-12 CLA from diet into milk were 2.16, 1.97 and 1.63% (SE = 0.16; $P = 0.39$) for T10, T20 and T30, respectively. Incremental inclusion of UnCLA changed in a linear manner the milk fatty acid profile to a greater proportion of trans monounsaturated, longer chain fatty acids.

Table 1. Milk fatty acid responses to increasing levels of UnCLA

T283 Effect of monensin and tallow on methane estimation and protozoan and bacterial populations in dairy cows rumen.

A. R. Castillo-Gonzalez*[1], M. E. Burrola-Barraza[1], J. A. Ortega-Gutierrez[1], M. I. Rivas-Martinez[2], and A. Chavez-Martinez[1], [1]*Facultad de Zootecnia y Ecología, Chihuahua, Chihuaha, México,* [2]*Colegio de Postgraduados, Texcoco, Edo. de México, México.*

The objective was to evaluate the effect of monensin and/or tallow in the diet of lactating cows on the populations of protozoa and bacteria and the estimation of methane. The ruminants have a significant contribution to the greenhouse gases, due to the production of methane. Recent efforts have been made to explore the effect of different additives (monensin, tallow, etc) on rations and its effect on rumen's microbial populations responsible of methanogenesis. The basal diet was formulated in a ration F:C (Forage:Concentrate) of 40:60. The treatments were: The control diet without additive (T1), control diet plus monensin (3.3g/d, T2), control diet plus tallow (3.0%, T3) and control diet plus monensin and tallow (3.3 g/d, 3.0%, T4). The animals were fed 2 times daily (0800 and 1500 h) and milked twice a day (0400 and 1300 h). An experimental design of 4 × 4 Latin square were used. Samples were collected from 13 to 15 d. Quantification of protozoa, bacteria and VFA′s (to estimate the production of methane with the Wollin equation) were conducted. Data were analyzed using PROC MIXED of SAS; means comparison was made using orthogonal contrasts. Results showed that protozoan population exhibited changes upon the inclusion of different additives to rations ($P \leq 0.06$) among treatment, the combination of monensin and tallow resulted in the lowest protozoan population size ($P \leq 0.0001$) with an average of 5.49 ± 0.07 Log10. Bacteria population size did not change ($P \geq 0.83$) ; however, it was observed a reduce on the population size from 1.3 to 0.68 fluorescence unity (FU). Meanwhile, methane estimate was reduced ($P \leq 0.05$), from 57.3 ± 1.1 mmol/mL in the control diet (T1) to 53.2 ± 1.1, 55.4 ± 1.1 and 54.4 ± 1.1 mmol/mL in T2, T3 and T4, respectively. In conclusion, the most efficient additive to reduce methane production was monensin (3.3%).

Key Words: additives, ionophores, ruminal microorganisms

T284 Hepatic transcriptomics in dairy cows supplemented with SmartamineM or MetaSmart during the peripartal period.

J. S. Osorio*[1], P. Ji[1], S. L. Rodriguez-Zas[1], D. Luchini[2], R. E. Everts[1], H. A. Lewin[1], J. K. Drackley[1], and J. J. Loor[1], [1]*University of Illinois, Urbana,* [2]*Adisseo, Alpharetta, GA.*

We used a newly-developed bioinformatics tool (Dynamic Impact Approach, DIA; M. Bionaz, P. Kathiravan, S. Rodriguez-Zas, W. Hurley, and J. Loor, PLoS One; http://dx.doi.org/10.1371/journal.pone.0032455) that allows visualizing the dynamic adaptations of biological pathways to evaluate the impact of Methionine (M) supplementation on liver transcriptome. Twenty 4 multiparous Holstein cows were fed a control diet (ME, n = 8; 1.47 Mcal/kg DM prepartum and 1.67 Mcal/kg DM postpartum), ME plus MetaSmart (MS, n = 8; Adisseo France S.A.S.), or ME plus Smartamine M (SA, n = 8; Adisseo France S.A.S.). All cows received a common diet (1.24 Mcal/kg DM) during the far-off period [-50 to −21 d in milk (DIM)]. Treatments started at −21 DIM and continued through 30 DIM. MetaSmart (0.19% of DM prepartum and 0.18% of DM postpartum) and SA (0.07% of DM prepartum and postpartum) were top-dressed on the ME diet. Percutaneous liver biopsies for microarrays using a 13,000-gene oligonucleotide microarray were performed at −10, 7, and 21 DIM. Analysis of variance with a false discovery rate (FDR) correction resulted in 2,664 differentially expressed genes (DEG) with a treatment × day (T × D) interaction (FDR <0.10, uncorrected $P = 0.02$). For the DIA analysis the whole data set with Entrez gene IDs, FDR, fold-change, and post-hoc P value between the 3 treatments at each time point were uploaded. A cut-off of FDR = 0.05 and p-value = 0.05 was applied during analysis. The greatest degree of change in terms of up- and downregulated DEG due to T × D occurred with MS vs. ME, e.g., more than half DEG were downregulated by MS at −10 but at 7 DIM ca. 500 DEG were downregulated and > 300 downregulated. The pattern at 21 DIM resembled closely that at −10 DIM. The DIA analysis revealed that MS vs. ME led to an inhibition of cyanoamino acid metabolism at −10, 7, and 21 DIM but it activated taurine/hypotaurine metabolism at 7 DIM. Another novel feature of MS vs. ME was the activation at 7 DIM of riboflavin and nicotinamide metabolism and pantothenate (CoA) biosynthesis. Analysis of DEG due to T × D within treatments revealed that carbohydrate metabolism was among the top-impacted pathways due to ME and SA particularly at 7 vs. −10 DIM when flux of gluconeogenesis and TCA cycle were markedly activated. In contrast to cows fed MS, both ME and SA led to marked activation of glutathione metabolism at 7 vs. −10 DIM. Overall, results from the bioinformatics analysis seem to suggest that the 2 sources of M elicit distinct effects on the liver transcriptome. Such adaptations might be of biological relevance in terms of liver function, dry matter intake, and optimal milk production.

Key Words: systems biology, pathway analysis, genomics

T285 Production response of lactating dairy cows in a confinement operation to a commercial probiotic.

J. K. Bernard* and N. A. Mullis, *University of Georgia, Tifton.*

Thirty-six lactating Holstein cows from the Dairy Research Center at the University of Georgia -Tifton Campus were used in a 10 wk randomized design trial to determine the effects of feeding a commercial probiotic (ProDairy, Donaghys Industries Ltd., Christchurch, New Zealand) on dry matter intake, milk yield and milk composition of lactating Holstein cows. The probiotic is a blend of non-viable lactobacillus species and fermentation extracts including amino acids, vitamins, amylase, and cellulose. During the first 2 wk of the trial all cows were fed the control diet and data collected were uses as a covariate in the statistical analysis. At the end of wk 2, cows were assigned randomly to one of 2 treatments (control (CONT) or supplemental probiotic (PRO) for the following 8 wk. A basal diet was fed to cows once daily behind Calan gates as a TMR in amounts to provide at least 5% refusal. PRO was added to the TMR at a rate of 10 mL/cow/d and mixed for 10 min before feeding. There were no differences in DMI between treatments; 25.3 and 25.4 kg/d for CONT and PRO, respectively. Cows fed PRO have increased yield (kg/d) of milk ($P = 0.001$), protein ($P = 0.05$), and SNF ($P = 0.002$) compared with CONT; 32.7, 0.94 and 2.74 and 30.9, 0.91, and 2.58, respectively. Interactions of treatment and wk were observed for these variables because the difference between CONT and PRO increased throughout the 8 wk experimental period. No differences ($P > 0.10$) were observed among treatments in concentration of milk fat, protein, lactose, or SNF or yield of milk fat and lactose. Concentrations of MUN tended ($P = 0.10$) to be lower for PRO compared with CONT (15.03 and 15.44 mg/dl, respectively). No differences were observed in change of BW or body condition score. Results of this trial indicate that PRO stimulated improvements in nutrient utilization that supported higher yield of milk, protein and SNF.

Key Words: probiotic, milk yield, milk composition

T286 Evaluating in situ procedures for testing lipid encapsulated products — lysine as an example. T. F. Gressley*[1], M. J. de Veth[2], N. K. Diana[1], and E. Mackey[1], [1]*University of Delaware, Newark,* [2]*Balchem Corporation, New Hampton, NY.*

Standardized in situ methods for evaluating lipid encapsulated products have not been described. This study evaluated the effect of bag size and rinsing technique on in situ DM and Lys disappearance from 2 Lys products encapsulated using different technologies. Product A was a matrix type encapsulate (Italian manufacture) and product B was a core-shell encapsulate (US manufacture). Products were tested in 5 × 10 and 10 × 20 cm in situ bags with 50 µm pores (1 g and 5 g product/bag, respectively). Bags were placed without pre-wetting in the rumen of a lactating cow and incubated for 4 or 24 h, removed, and either hand or machine rinsed. Hand rinsed bags were individually rinsed in running tap water at 13°C for 90 s. Machine rinsed bags were rinsed in a front-loading washing machine using the cold water gentle cycle for 8 rinses of 1 min each. Rinsed bags were immediately dried at 50°C for 48 h. Unground subsamples from each bag were analyzed for N by combustion, and Lys content calculated as N × 5.22. Initial samples analyzed 29 and 52% Lys for products A and B, respectively. DM and Lys retention following in situ incubation were calculated as percent of initial sample. All combinations of product, bag size, time in the rumen, and rinsing technique were assessed in quadruplicate. For Lys retention, coefficients of variation (CV) averaged across all quadruplicates were 6.6% for 5 × 10 cm bags, 2.5% for 10 × 20 cm bags, 2.9% for hand rinsing, and 3.9% for machine rinsing. Both DM and Lys retention were affected by product, time, and product × time ($P < 0.001$). Product A retained 92% of DM and 85% of Lys at 4 h and 79% of DM and 50% of Lys at 24 h. Product B retained 95% of DM and 95% of Lys at 4 h and 89% of DM and 84% of Lys at 24 h. Lys retention was not impacted by bag size but was affected by rinsing technique ($P = 0.01$; 80% for hand rinsing vs. 77% for machine rinsing). This small difference may be due to greater microbial N retention in the hand rinsed bags or greater loss of product during machine rinsing. We recommend that in situ testing of rumen protected lipid encapsulated products use 10 × 20 cm bags and machine rinsing.

Key Words: encapsulate, rumen-protected lysine, in situ

T287 Effects of PEG and water on condensed tannin deactivation and nutrient digestibility of sainfoin in Holstein cows. H. Khalilvandi-Behroozyar*[1,2], M. Dehghan-Banadaky[1], K. Rezayazdi[1], and F. Ghaziani[1], [1]*Department of Animal Science, University of Tehran, Karaj, Tehran, Iran,* [2]*Department of Animal Science, University of Urmia, Urmia, West Azerbaijan, Iran.*

Antinutritional factors such as condensed tannins affect nutritive value of forages for ruminants. Antinutritional factors can decrease nutrient availability for ruminants through limitations in microbial digestion or reduced enzymatic activity in post ruminal sections of gastrointestinal tract. Sainfoin is a legume forage with medium to high tannin content. Sainfoin is high quality hay, but little information is available about effects of condensed tannins on nutrient availability of sainfoin. The objective of this study was to examine tannin deactivation effects on nutrient availability from sainfoin. Second cut forage was shade dried and chopped (3 to 5 cm length), and then exposed to nothing (Control) or 5% (wt/vol) solution of polyethylene glycol (PEG 6000 MW) that was sprayed on the forage (vol/wt ratio of 1:1). Water soaking was applied with tap water (vol/wt ratio of 4:1). Treatments were carried out at an ambient temperature of 25°C for 20 min with hand shaking for water, and overnight for PEG. Water was added to forage just before feeding in an in vivo trial. The extractable CT content was determined (Butanol-HCl reagent). Ruminally fistulated Holstein cows (3 multiparous, 680 ± 20kg of BW) were used in 3 × 3 change over design. Each period consisted of 10 d for adaptation and 7 d for rectal fecal and forage sample collection. Acid insoluble ash was used as internal marker for determining digestibility of nutrients. Forages were fed as sole diet (0800 and 1600) along with mineral/vitamins to meet 110% of maintenance requirements of dairy cows. Digestibility coefficients determined and MIXED PROC of SAS was used for statistical analysis at 0.05 probability level. Water and PEG deactivated 92.06 and 98.57% of CT, respectively. Digestibility coefficients of ether extract, organic matter and acid detergent fiber were not statistically different ($P \leq 0.05$). Differences of means for neutral detergent fiber and CP digestibility among treatments were statistically significant. Tannin deactivation might be responsible for increasing digestibility of crude protein and plant cell wall.

Table 1. Effects of tannin deactivation with PEG and water on nutrient digestibility of sainfoin (g/100 g, CP %)

Treatment	EE	NDF	ADF	CP	OM
Control	72.16	49.25[b]	45.53	63.26[b]	60.41
Water	76.72	58.44[ab]	53.72	73.86[ab]	71.93
PEG	73.81	60.18[a]	51.55	75.42[a]	69.30

T288 Effect of dietary methionine supplementation in early lactation dairy cows I: dry matter intake, milk yield, milk composition and component yields. A. H. Souza*[1], P. D. Carvalho[1], A. R. Dresch[1], L. M. Vieira[1,2], K. S. Hackbart[1], D. Luchini[3], S. Bertics[1], N. Betzold[4], M. C. Wiltbank[1], and R. D. Shaver[1], [1]*University of Wisconsin-Madison, Madison,* [2]*University of Sao Paulo-VRA, SP 05508, Brazil,* [3]*Adisseo, Alpharetta, GA,* [4]*U.S. Dairy Forage Research Farm, Prairie du Sac, WI.*

Experimental objectives were to measure the effects of supplementing methionine during the postpartum period on lactation performance by dairy cows. Holstein cows (n = 72), were housed in a single pen from day −21 to calving and fed the same basal diet (6.68 Lys % MP, 2.24 Met %MP and 1.23 MCal/kg). From calving to 70 DIM cows were housed in tie-stalls and milked twice daily. Animals were blocked by parity and calving date and randomly assigned to 2 treatments differing in level of dietary methionine supplementation: 1) Methionine (MET); diet composed of (%DM) corn silage (39.7), alfalfa silage (21.8), HMSC (17.2), roasted soybeans (8.6), grass hay (4.6), canola meal (4.0), mineral-vitamin mix (2.7) and ProVAAL Ultra (w/Smartamine, 1.4), formulated to deliver 2875 g MP with 6.8 Lys %MP and 2.43 Met %MP; 2) Control (CON); cows fed the same basal diet but replacing ProVAAl Ultra by ProVAAL Advantage (no added Smartamine), formulated to deliver 2875 g MP with 6.8 Lys %MP and 1.89 Met %MP. Data were analyzed with repeated measures model (proc Mixed, SAS 9.3) including fixed effects of treatment, week and treatment by week interaction, parity as a covariate, and the random effect of cow. The DMI and milk yield measurements were daily and milk samples were collected from both AM/PM milkings twice weekly for determination of milk composition. Methionine supplementation increased ($P < 0.01$) milk protein% (2.92 vs. 2.75) and solids-not-fat (SNF) % (8.73 vs. 8.54). Intake of DM, milk yield, milk fat% and MUN were unaffected ($P > 0.10$). Interestingly, although milk protein yield was not different ($P = 0.11$) between the treatments, an interaction between methionine supplementation and milk production was detected ($P < 0.01$); with ~9% increase in milk protein yield for cows producing below 34 kg/d compared with ~3% increase in cows producing above this level starting at 2nd week of lactation. Dietary methionine supplementation increased milk protein and SNF% in milk in early lactation cows; however, milk protein yield response to methionine supplementation varied by production level. Supported by Adisseo, USDA Grant 2010-85122-20612.

Key Words: dairy cow, methionine, milk production

T289 Effect of dietary antioxidant and increased rumen unsaturated fatty acid load on milk fat yield and fatty acid composition.

J. C. Ploetz,* C. L. Preseault, and A. L. Lock, *Michigan State University, East Lansing.*

This study examined the impact of increasing rumen unsaturated fatty acid load (RUFAL) in the absence or presence of an antioxidant on feed intake, yield of milk and milk components, and milk fatty acids (FA). Twenty-eight Holstein cows (172 ± 59 DIM) were assigned to treatment in a randomized complete block design. Treatments were a control diet (CON) or an antioxidant (AOX; Agrado Ultra [dry blend of ethoxyquin and propyl gallate], Novus International, Inc.) supplemented diet (6.1 g/d). In period 1 (3 wks) no supplemental corn oil was fed; in periods 2, 3, and 4 (2 wks each) corn oil was supplemented at 0.75, 1.5, and 3.0% of the diet (DM basis) to incrementally increase RUFAL. Total dietary fatty acids were 2.7, 3.3, 3.9, and 5.1% of the diet for the 0.0, 0.75, 1.5, and 3.0% corn oil diets, respectively. The final 3 d of each period were used for sample and data collection. Data were analyzed using date as a repeated measure and preliminary 3.5% fat-corrected milk (FCM) as a covariate. There was no effect of AOX on any of the variables measured; thus data from AOX and CON were combined to assess the effects of dietary corn oil concentration (increasing RUFAL). Increased RUFAL decreased milk yield (44.3, 44.2, 43.0, and 38.4 kg/d, $P < 0.001$), fat concentration (3.38, 3.34, 3.10, and 2.43%, $P < 0.0001$), and fat yield (1.49, 1.46, 1.33, and 0.93 kg/d, $P < 0.001$). DMI decreased (30.2, 29.5, 28.2, and 27.8 kg/d, $P < 0.0001$) and there was a quadratic response for feed efficiency (FCM/DMI, 1.44, 1.46, 1.43, and 1.15, $P < 0.001$) with increased RUFAL. Milk FA concentration of C18:1 *t*10 was 0.84, 1.10, 1.92, and 6.29 g/100 g FA ($P < 0.001$) and for C18:2 *t*10, *c*12 was 0.001, 0.001, 0.007 and 0.030 g/100 g FA ($P < 0.001$) with increased RUFAL. On a FA yield basis, increasing RUFAL decreased < C16 FA (394, 376, 309, and 162 g/d, $P < 0.001$) and C16 FA (533, 477, 400, and 258 g/d, $P < 0.001$). There was a quadratic effect on > C16 FA (560, 609, 616, and 511 g/d, $P < 0.001$). Increasing RUFAL through the addition of corn oil to the diet decreased milk fat production and feed efficiency, and altered the FA composition of milk fat. Supplementation with AOX did not overcome the milk fat depression induced by increased RUFAL.

Key Words: milk fat depression, unsaturated fatty acids, antioxidants

T290 Effects of condensed tannins on ruminal VFA profile in fistulated Holstein cows fed sainfoin (*Onobrychis vicifolia*).

H. Khalilvandi-Behroozyar*[1,2], M. Dehghan-Banadaky[1], K. Rezayazdi[1], and F. Ghaziani[1], [1]*Department of Animal Science, University of Tehran, Karaj, Tehran, Iran,* [2]*Department of Animal Science, University of Urmia, Urmia, West Azerbaijan, Iran.*

Condensed tannins as antinutritional factors can limit different microbial actions in ruminants digestive tract. Sainfoin is a tanniferous forage with variable content of phenolic compounds. Our previous experiments using sainfoin showed that sainfoin condensed tannins are very active and limit ruminal protein and cell wall degradability, as shown incremental trend in forages treated for tannin deactivation. In previous experiments, treatment of sainfoin hay with water and polyethylene glycol (PEG) have major effects on deactivation of phenolic compounds and increased significantly ruminal cell wall and protein degradability, compared with alkaline chemicals (data not shown). The objective of this study was to examine effects of sainfoin treatment with water and PEG on ruminal VFA production and profile. Second-cut forage was shade dried and chopped (3 to 5 cm length), and then exposed to nothing (Control) or 5% (wt/vol) solution of polyethylene glycol (PEG 6000 MW) that was sprayed on the forage (vol/wt ratio of 1:1). Water soaking was applied with tap water (vol/wt ratio of 4:1). Treatments were carried out at an ambient temperature of 25°C for 20 min with hand shaking for water, and overnight for PEG. Water was added to forage just before feeding in an in vivo trial. The extractable CT content was determined (butanol-HCl reagent). Ruminally fistulated Holstein cows (3 multiparous, 680 ± 20kg of BW) were used in 3 × 3 change over design. Each period consisted of 10 d for adaptation and 7 d for sample collection. Forages were fed as sole diet (0800 and 1600) along with mineral/vitamins to meet 110% of maintenance requirements of dairy cows. Rumen fluid was obtained in 2 consecutive days (d 15 and 16) from ventral rumen via vacuum pump at before feeding ($t = 0$) and 2, 4 and 8 h after morning meal. Rumen fluid instantly squeezed through 4 layer cheesecloth and preserved with 1 mL of 50% sulfuric acid and frozen at −20°C until analysis for VFA. Volatile fatty acids were determined using a Philips PU4410 apparatus. Peaks of individual fatty acids were determined according to pure standards and quantified. Methyl-4-valeric acid was used as internal standard. MIXED PROC of SAS 9.1 was used for statistical analysis at 0.05 probability level. Treatments were able to decrease condensed tannin up to 90 percent compared with control, but there were no statistical differences among dietary treatments. Total concentration of VFA increased until 4 h after feeding and then slightly decreased. Polyethylene glycol treated sainfoin was resulted in higher molar concentration of total VFA, compared with control and water treated forages in 4 and 8 h after feeding.

Table 1. Effects of sainfoin treatment with water and PEG on rumen VFA (percentage of total; total VFA represented as mM)

	PEG	Water	Control	SEM
Before feeding				
Acetate	81.76	79.80	80.18	0.571

T291 Influence of ionophore source and a proprietary nutrition supplement on the performance and rumen metabolism of Holstein calves previously fed a high plane of milk replacer.

K. K. Guatam*[1], C. J. Cobb[1], B. S. Obeidat[1], M. L. Galyean[1], B. L. Miller[2], J. A. Davidson[2], K. L. Perfield[3], T. A. Brooks[1], and M. A. Ballou[1], *[1]Department of Animal and Food Sciences, Texas Tech University, Lubbock, [2]Land O' Lakes Purina Feed, Gray Summit, MO, [3]Elanco, Greenfield, IN.*

Objective was to evaluate the effect of ionophore source with or without a proprietary nutrition package on performance and rumen metabolism in Holstein calves (3 mo old; initial BW = 101 kg) previously fed a high plane of milk replacer. In Exp. 1, 125 calves were randomly assigned to 5 treatments in 25 pens (5 calves/pen). Treatments were administered in a concentrate pellet and included: lasalocid without package (BOV-N), lasalocid with package (BOV-Y), monensin without package (RUM-N), monensin with package (RUM-Y), and High-forage control with monensin without package (HF). The respective pellet was restricted to a DMI of 4.1 kg/calf in BOV-N, BOV-Y, RUM-N, AND RUM-Y and 1.6 kg / calf in HF. Alfalfa hay was offered ad libitum. No differences ($P >$ 0.05) in DMI were reported among diets; however, metabolizable energy intake and ADG were less ($P < 0.05$) for calves fed the HF. Gain:feed was greater ($P < 0.05$) in HF diet compared with BOV-Y, RUM-N, RUM-Y; whereas BOV-N did not differ from all groups. In exp. 2, 10 cannulated calves were used to evaluate rumen metabolism. Calves were fed with same diets used in Exp. 1. Alfalfa DM digestibility (DMD) at 24 and 36 h was greatest ($P < 0.05$) in HF. In addition, alfalfa DMD at 36 h was greater ($P < 0.05$) for RUM-Y vs. BOV-Y and RUM-N, and tended to be greater ($P = 0.11$) than BOV-N. Pellet DMD at 24, 36, and 48 h was greatest ($P < 0.05$) for HF. In addition, pellet DMD at 24, 36, and 48 h for RUM-Y was greater ($P < 0.05$) and tended to be greater (P < 0.07) for BOV-N and BOV-Y, respectively. Ammonia concentration was greater ($P < 0.05$) for BOV-N than BOV-Y, RUM-N, and HF at 6 h. The use of ionophore and a proprietary nutrition package did not improve the performance of growing calves; however, as expected HF calves consumed less metabolizable energy and had lower ADG than calves fed the higher concentrate diets. Calves fed the high-forage diet had improved DMD of both the alfalfa hay and the concentrate pellet. In addition, among calves fed the higher concentrate diets, monensin plus the nutrition package had improved dry matter digestibility of both the alfalfa hay and pellet.

Key Words: ionophore, performance, rumen metabolism

T292 Effect of feeding *Bacillus subtilis* spores on performance of Holstein dairy calves.

V. L. de Souza[1], J. A. de Freitas*[1], S. L. Viechinieski[5], P. H. N. Pinto[2], M. N. Pereira[3], and J. C. Souza[4], *[1]Federal University of Parana, Curitiba, Parana, Brazil, [2]FAG, Cascavel, Parana, Brazil, [3]Federal University of Lavras, Lavras, Minas Gerais, Brazil, [4]Federal University of South of MAto Grosso, Aquidauana, Mato Grosso do Sul, Brazil, [5]Iguacu Farm - Star Milk, Vera Cruz do Oeste, Parana, Brazil.*

The objective was to determine effects of feeding *Bacillus subtilis* spores on performance of dairy calves in the first 60 d of age. Twenty Holstein female calves were allocated to a sequence of 2 treatments (*Bacillus subtilis* or placebo) in a completely randomized design. Treatments were: 0.3 g/calves/d (3×10^9 viable spores/cow/d) of *Bacillus subtilis* C-3102 (Calpis Co. Ltda, Tokyo, Japan) or placebo. The *Bacillus subtilis* spores were mixed with milk and fed directly to the calves. The animals were housed in individual hutches, with free access to water, starter feed (20% CP), and 8L of liquid diet (milk, 3 times a day) until weaning which occurred abruptly at the ninth week of life. The starter feed intake was recorded daily and body weight measurements were taken on d 0 and 60 of the comparison period. The initial weight was 37.8 kg for control and 35.5 for direct-fed microbial. Weaning weight was 77.55 kg for calves control and 81.6 kg for *Bacillus subtilis*, respectively. There was no treatment effect ($P > 0.05$) on DM of liquid or starter intake between the 2 groups. The average daily gain was 0.664 kg/d for placebo and 0.769 kg for *Bacillus subtilis* ($P = 0.25$), respectively. Feed conversion (ADG/DM intake) was 0.50 for placebo and 0.49 kg for *Bacillus subtilis* ($P =$ 0.99). The supplementation of *Bacillus subtilis* spores did not induce lower performance of dairy calves.

Key Words: *Bacillus subtilis* spores, dairy calves, performance

T293 Interaction between vitamin E and rumen-protected conjugated linoleic acid on milk composition in grazing dairy cows.

M. Ramírez-Mella[1], O. Hernández-Mendo[1], J. E. Ramírez-Bribiesca[1], R. D. Améndola-Massiotti[2], M. M. Crosby-Galván[1], J. A. Burgueño-Ferreira[3], and G. Aranda-Osorio*[2], *[1]Colegio de Postgraduados, Montecillos, Texcoco, México, [2]Universidad Autónoma Chapingo, Chapingo, Texcoco, México, [3]Centro Internacional de Mejoramiento de Maíz y Trigo, Estado de México, México.*

The objective of this study was to evaluate the effect of supplementing protected conjugated linoleic acid (CLA) and vitamin E on the amount of milk fat from lactating grazing dairy cows. Eight milking Holstein cows were used in a rotational grazing system on a mixed pasture of lucerne (*Medicago sativa*) and orchard grass (*Dactylis glomerata*). They got 2 kg of concentrated during each milking (4 kg/d), which contained 5 g of protected CLA. Treatments were: T1) control (basal diet + CLA), T2) 4000 (control + 4000 IU of vitamin E), T3) 8000 (control + 8000 IU of vitamin E), and T4) 12000 (control + 12000 IU). Milk production was measured individually, and determination of milk fat, protein and lactose content were carried out by using an infrared milk analyzer. A crossover experimental design was used and the results were analyzed using the SAS MIXED procedure. There was no difference ($P \geq 0.05$) in milk production or protein and lactose content among treatments, which agrees with those results reported by other authors, who included similar amounts of vitamin E, when adding fat in the diet. Milk fat content was similar ($P \geq 0.05$) among treatments, however, it remained low (2.6%, on average), which, according with different authors, was due to the inclusion of fat on the diet. Thus, it is concluded that even using high doses of vitamin E in the diet of grazing milking cows, these amounts were insufficient to alleviate the milk fat decline when CLA are added to the diet, so it is indeed necessary more research to reverse this effect, because it is important to have milk with higher levels of CLA.

Key Words: CLA, dairy cattle, milk quality

T294 Assessment of lysine released from rumen-protected lysine products exposed to high and low moisture TMR over 24 hours. P. Ji,* C. S. Ballard, R. E. Clark, B. M. Sweeney, and C. Kokko, *William H. Miner Agricultural Research Institute, Chazy, NY.*

A study was conducted to evaluate the stability of 6 rumen-protected lysine products (RPL) when incorporated into TMR diets with different DM contents. Three loads (~350 kg/load) of each of 2 TMR diets only varying in DM content (40.5% as LD vs. 51.8% as HD) were prepared with Super Data Ranger. Duplicate Ziploc bags containing RPL (2 ± 0.03 g) and no RPL (as control samples) were filled and mixed well with 200 ± 1 g TMR from each load. Bags were stored at room temperature (21°C) for 0, 6, 18, and 24 h to simulate RPL exposure to TMR when mixed and delivered once per day. At the end of each time point, bag contents were transferred to strainer bags and soaked in 1 L Milli-Q water containing 500 mg Arg (as internal standard) for ~1 min to solubilize the Lys released in the TMR. Solution was filtered (0.45 μm) and frozen (−80°C) until filtrate was analyzed for Lys using ultra performance liquid chromatography. The Lys content for samples containing RPL were corrected for background Lys measured in control samples and Lys release (LR, %) was calculated. Data were analyzed as split-plot design with PROC MIXED of SAS. Results show that all RPL exhibited increased LR when exposed to TMR over time with differing magnitudes of LR ($P < 0.01$). The DM of TMR did not affect LR of most RPL; however, the overall LR of AminoShure-L was greater in TMR with LD than HD (5.9 and 3.0%, respectively; $P < 0.01$). A significant interaction of TMR DM and exposure time was observed for AminoShure-L and MetaboLys ($P < 0.01$). Our results indicate that less feeding frequency may result in greater Lys loss from RPL due to longer exposure in TMR before consumption by the cow.

Table 1. Lysine release (%) of RPL at 0, 6, 18, and 24 h in TMR

RPL product	0	6	18	24	SEM	*P*-value
AminoShure-L	0.2^{ax}	1.3^{ay}	6.4^{b}	9.8^{c}	0.47	≤ 0.01
LysiPEARL	6.2^{a}	39.7^{b}	47.0^{c}	48.4^{c}	1.66	≤ 0.01
Megamine-L	3.4^{a}	9.8^{b}	16.5^{c}	19.2^{d}	0.76	≤ 0.01
MetaboLys	0.7^{a}	0.8^{a}	2.2^{b}	3.8^{c}	0.25	≤ 0.01
USA Lysine	0.4^{a}	54.2^{b}	51.4^{b}	53.4^{b}	1.72	≤ 0.01
AjiPro-L	0.5^{a}	0.7^{a}	1.3^{b}	1.3^{b}	0.17	≤ 0.01

$^{a\text{–}d}P < 0.05$; $^{x,y}P < 0.10$.

T295 Does mechanical mixing of TMR compromise protection efficacy of rumen-protected lysine products? P. Ji,* C. S. Ballard, R. E. Clark, B. M. Sweeney, and C. Kokko, *William H. Miner Agricultural Research Institute, Chazy, NY.*

A study was conducted to determine if mechanical mixing of TMR compromises the ruminal protection efficacy of 6 rumen-protected Lys products (RPL). A Super Data Ranger (SDR) loaded with 350 kg of TMR formulated for high producing cows was used to simulate the routine mixing procedure on a dairy farm. Dacron bags were filled with 1 ± 0.03 g RPL and heat-sealed. Triplicate bags per in situ time point were either mixed with diet for 6 min at full speed in SDR as treatment or indwelled in a bucket of same TMR diet for 6 min as control. Three loads of mixing were performed. After mixing, bags were incubated in the rumen of 3 cannulated cows for 0, 6, 12, and 24 h, one mixing load (control and treatment) per cow. After incubation, bags were gently hand-washed and paper-patted, then air-dried for more than 24 h. Dried RPL residue collected from each bag was acid hydrolyzed with 3 N HCl at 90°C in oven for 60 min and brought to a 100 mL volume with 0.2 mol/L HCl buffer. The solution was filtered and the concentration of Lys was determined by ultra performance liquid chromatography for calculation of ruminal disappearance of Lys (RD, %). Data for each RPL were analyzed separately as a randomized complete block design with MIXED procedure of SAS. The results showed that mechanical mixing increased RD ($P < 0.05$) of LysiPEARL (68.5 vs. 74.7%), MetaboLys (15.0 vs. 17.1%), and USA Lysine (72.2 vs. 75.9%), and tended to increase RD of Megamine-L (51.2 vs. 52.9%; $P = 0.06$), but did not affect that of AminoShure-L (30.6 vs. 33.0%; $P = 0.12$), and AjiPro-L (13.0 vs. 13.1%; $P = 0.92$). Length of ruminal incubation significantly increased RD of all RPL with varying magnitudes ($P < 0.01$). All RPL except AminoShure-L exhibited a significant interaction between mixing treatment and length of ruminal incubation ($P < 0.05$). In conclusion, some RPL are more vulnerable than others to damage caused by mechanically mixing in a TMR that compromises their ruminal protection. However, due to different shape and particle size of RPL, the specific gravity and ruminal passage rate may vary and should be considered when comparing potential ruminal Lys loss of RPL.

Key Words: rumen-protected Lys, mechanical mixing

T296 Ionophore source in a calf starter influences the performance of calves during the immediate post-weaned period. C. J. Cobb*[1], B. S. Obeidat[1], D. L. Hanson[1], M. D. Sellers[1], B. L. Miller[2], J. A. Davidson[2], K. L. Perfield[3], and M. A. Ballou[1], *[1]Department of Animal and Food Sciences, Texas Tech University, Lubbock, [2]Land O' Lakes Purina Feed, Gray Summit, MO, [3]Elanco, Greenfield, IN.*

Objective was to determine if the source of ionophore (monensin vs. lasalocid) in a calf starter influences the performance of calves during the first 3 mo of life. One hundred and 21 Holstein calves (2 ± 1 d old) were randomized to 1 of 2 treatments: Calf starter supplemented with 50 g / ton of monensin (n = 60) or 50 g / ton of lasalocid (n = 58). The ingredient composition of the 2 calf starters were identical and contained 22% crude protein on dry matter (DM) basis. The starter was offered ad libitum after the first week of life. All calves were fed a similar high plane of milk replacer nutrition before weaning. Weaning was initiated during the 7th wk by removing the PM feeding and calves were completely weaned when consuming 800 g DM daily after d 53. Body weights were measured at d 0, 10, 21, 53, 67, and 91. Peripheral blood samples were collected at d 3, 10, 21, 45, 47, 53, and 91 and analyzed for plasma concentrations of glucose, urea nitrogen, and haptoglobin. There was a treatment × time interaction ($P < 0.01$) on starter DM intake; whereas calves fed lasalocid consumed more starter DM during the post-weaning period, from wk 8 to 13 (average of 9.1% increase in starter DM intake among lasalocid). In addition, average daily gains of calves fed lasalocid were greater ($P < 0.05$) during the immediate post-weaned period from d 53 to 67 (0.903 vs. 0.822 ± 0.0259 kg/d). There were no treatment differences in average daily gains ($P > 0.271$) at any other periods. There was no treatment ($P = 0.189$) or treatment × time interaction ($P = 0.617$) on the efficiency of feed utilized for body weight gain. Last, there were no treatment ($P > 0.346$) or treatment × time interactions ($P > 0.339$) on the plasma concentrations of glucose, urea nitrogen, or haptoglobin. Feeding a calf starter with lasalocid increased starter intake over the entire post-weaning period and increased average daily gains, but only during the immediate post-weaning period.

Key Words: calf starter, ionophore, performance

T297 Effects of microbial additives on nutrient metabolism in continuous culture of rumen contents. W. Braman* and L. C. Solórzano, *Chr. Hansen Inc., Milwaukee, WI.*

Reports indicate that microbial additives based on multiple strains of *E. faecium* show positive responses in ruminal fiber and nitrogen metabolism both, in vitro and in vivo. A study was conducted to determine the effects of microbial additives on nutrient metabolism in continuous culture of rumen content when the diet contained 28% starch. Lactation rations were formulated to support 45.5 kg of milk production. The study was comprised of 5 treatments: Control Diet, Control Diet + 3 strains of *E. faecium* + yeast (T1), Control Diet + 2 strains of *E. faecium* + 1 strain of *Lactococcus lactis* (T2), Control Diet + 2 strains of *E. faecium* + yeast (T3); Control Diet + 3 strains of *E. faecium*, + 1 strain of *Lactococcus lactis* + yeast (T4), Control Diet + 2 strains of encapsulated *E. faecium* + Lactococcus lactis (T5) and Control Diet + *Lactobacillus plantarum* (T6). All treatments were added at 2 g/head/day equivalent. Continuous culture fermentations were conducted using conditions simulating rumen parameters of a lactating dairy cow. These conditions were: liquid dilution rate of 13%/h, solids dilution rate of 4.55%/h, solids retention time of 22 h, feed intake 100 g DM/d, a feeding frequency of 25 g DM, 4 times daily at 6 h intervals, a fermentation temperature of 39°C. Culture pH was recorded at 0.5 h intervals. Each diet was fermented in triplicate 9-d fermentations, with effluent samples composited for analysis during the last 3 d. Parameters analyzed included: DM, OM, CP, ADF, NDF, NSC, VFAs, nitrogen partitioning, microbial growth and microbial efficiency. Data were analyzed using the General Linear Model Procedures of SAS. A Duncan's Multiple Range Test at the 5% level of probability was used to detect differences among treatments. There were no differences from the control in the digestibility of OM ($P > 0.33$), CP ($P > 0.35$), NDF ($P > 0.81$), ADF ($P > 0.33$) and NSC ($P > 0.33$) for any of the treatments. There was a numerical ($P < 0.14$) increase in DM digestion compared with the control (67.7%) for treatments T2 (71.9%), T4 (73.8) and T6 (69.8%). Compared with that of the control (0.064), the production of butyrate (moles/d) was suppressed ($P < 0.01$) by treatments T2 (0.054), T3 (0.053), 4T (0.045) and T6 (0.049). This resulted in lower ($P < 0.01$) molar proportions of butyrate in these treatments as well. There were no differences due to the treatments for the partition of N ($P > 0.31$), microbial growth ($P > 0.19$) and microbial efficiency measurements ($P > 0.31$). The microbial parameters results from this experiment are not in agreement with previously published studies. Microbial additives reduced the production and molar proportions of butyrate and numerically increased the digestibility of DM.

Key Words: digestion, microbial additives, rumen culture

T298 Immunometabolic indices in dairy cows supplemented with Smartamine M or MetaSmart during the peripartal period. J. S. Osorio*[1], E. Trevisi[2], P. Ji[1], D. Luchini[3], J. K. Drackley[1], G. Bertoni[2], and J. J. Loor[1], *[1]University of Illinois, Urbana, [2]Universita Cattolica del Sacro Cuore, Piacenza, Italy, [3]Adisseo, Alpharetta, GA.*

The early postpartal period is characterized by marked changes in hormonal, metabolic, and immune/stress-like conditions all of which may contribute to regulating dry matter intake (DMI) and the supply of nutrients to mammary gland. Peripartal cows are in negative methionine (M) balance due to increased requirements of tissues and cells for methylated compounds and M for milk protein production. Therefore, supplementation of rumen-protected M during the peripartal period may improve yield of milk and protein, and also help coordinate immunometabolic adaptations of the cow. Twenty-four multiparous Holstein cows were fed a control diet (ME, n = 8; 1.47 Mcal/kg DM prepartum and 1.67 Mcal/kg DM postpartum), ME plus MetaSmart (MS, n = 8; Adisseo France S.A.S.), or ME plus Smartamine M (SA, n = 8; Adisseo France S.A.S.). All cows received a common diet (1.24 Mcal/kg DM) during the far-off period [-50 to −21 d in milk (DIM)]. Treatments started at −21 DIM and continued through 30 DIM. MetaSmart (0.19% of DM prepartum and 0.18% of DM postpartum) and SA (0.07% of DM prepartum and postpartum) were top-dressed on the ME diet. Blood samples were collected at −21, −10, 7, 14, and 21 DIM for profiling of 21 markers of liver function, metabolism, oxidative stress, and inflammation. Concentration of cholesterol (CHOL) and the negative acute-phase protein albumin (ALB) decreased (time $P < 0.05$) around calving but increased by 21 DIM regardless of treatment. Paraoxonase concentration followed a similar pattern (time $P < 0.01$) as CHOL and ALB. Whereas glutamic-oxaloacetic transaminase (GOT) concentration increased (time $P < 0.01$) from −10 through 21 DIM regardless of treatment, bilirubin (BIL) increased between −10 and 7 DIM and then decreased through 21 DIM. However, the increase in BIL tended (treatment × time $P = 0.09$) to be lower in cows fed SA. Those responses were indicative of alterations in liver function particularly after calving. The concentration of haptoglobin, inflammation marker, did not change markedly at 7 vs. −21 or −10 DIM and decreased gradually by 21 DIM regardless of treatment. However, cows fed ME tended ($P = 0.09$) to have greater overall ceruloplasmin concentration due to markedly greater (treatment × time $P = 0.03$) concentration at −10 DIM. That response was suggestive of a more pronounced inflammatory-like status precalving. Despite an increase (time $P < 0.01$) in concentration after calving, reactive-oxygen metabolite concentration did not differ between treatments. Overall, preliminary data provide some evidence that M supplementation during the peripartal period could ameliorate inflammatory-like conditions characteristic of this period. As such, M may play a role in stimulating DMI after calving and promoting normal milk production.

Key Words: methionine, oxidative stress

T299 Ruminal biohydrogenation and abomasal fatty acid flow in dairy cows fed with fatty acids unsaturated sources. J. E. Freitas Jr.*[1], R. V. Barletta[1], K. Havartine[2], S. L. D. A. Robassini[1], M. D. S. Oliveira[3], B. C. Venturelli[1], E. F. Jesus[1], F. G. Vilela[1], G. D. Calomeni[1], J. R. Gandra[1], T. S. Canaes[1], and F. P. Rennó[1], *[1]University of São Paulo, Pirassunumga, SP, Brazil, [2]Penn State University, University Park, [3]State University Julio de Mesquita, Jaboticabal, SP, Brazil.*

The aim of this study was to evaluate ruminal biohydrogenation and abomasal fatty acids flow in dairy cows supplemented with unsaturated fatty acids sources. Eight Holstein cows in the mid lactation (80 ± 20 d in milk; mean ± SD) cannulated in the rumen and abomasum (580 ± 20 kg of weight; mean ± SD) with milk yield of 25 kg/d were assigned randomly into 2 4 × 4 Latin squares and fed the following diets: 1) control (C); 2) refined soybean oil (inclusion of 3% in the total dry matter); (SO); 3) whole soybean raw (WS) (inclusion of 16% in the total dry matter) and; 4) calcium salts of unsaturated fatty acids (CSFA) (inclusion of 3% in the total dry matter). Milk yield and the dry matter intake were measured daily throughout the experimental period. The marker NDFi was used to determine the abomasal dry matter flow. Ruminal contents were evacuated manually through the ruminal cannula at 4.5 h after feeding on d 20, and at 2.5 h before feeding on d 21 of each period. Fractional rates of fatty acids biohydrogenation and passage by the rumen were calculated utilizing the model that accounts for transfer of fatty acids among ruminal pools. Data were analyzed using PROC MIXED of SAS 9.1 according with the orthogonal contrasts (C vs SO + WS + CSFA); (SO vs WS + CSFA) and (WS vs CSFA). The diet with SO increased the biohydrogenation rate to the C18:2 in relation the WS and CSFA diets ($P \leq 0.05$) (93.71 vs 86.35; 82.34% respectively). There was tendency to decrease of the biohydrogenation rate of fatty acid C18:3 by contrast 2 (93.18 vs 86.49; 80.36%; $P \leq 0.06$). The cows fed CSFA showed 29.46% more C18:3 in the abomasal fatty acid flow in relation the cows fed with WS diet (5.60 vs 3.95 g/d). The use of whole soybeans raw and calcium salts of unsaturated fatty acids decrease ruminal biohydrogenation rate in dairy cows in the mid lactation.

Key Words: abomasum, linoleic acid, whole soybeans

T300 Evaluation of models ruminal biohydrogenation in dairy cows fed unsaturated fatty acids sources. J. E. Freitas Jr.*[1], R. V. Barletta[1], K. Harvatine[2], V. P. Bettero[1], M. D. S. Oliveira[3], B. C. Venturelli[1], R. Gardinal[1], J. R. Gandra[1], C. E. Araújo[1], F. G. Vilela[1], V. G. C. Lacuna[1], and F. P. Rennó[1], [1]*University of São Paulo, Pirassununga, SP, Brazil,* [2]*Pennsylvania State University, University Park,* [3]*State University Julio of Mesquita, Jaboticabal, SP, Brazil.*

The aim of this study was to evaluate 2 models ruminal biohydrogenation in dairy cows fed unsaturated fatty acids sources. Eight Holstein cows in the mid lactation (80 ± 20 d in milk; mean ± SD) cannulated in the rumen and abomasums (580 ± 20 kg of weight; mean ± SD) with milk yield of 25 kg/d were assigned randomly into two 4 × 4 Latin squares, fed following diets: 1) control (C) (inclusion of 2.66% of fatty acids); 2) refined soybean oil (inclusion of 5.14% of fatty acids) (SO); 3) whole soybean raw (WS) (inclusion of 5.00% of fatty acids) and; 4) calcium salts of unsaturated fatty acids (CSFA) inclusion of 5.10% of fatty acids). Corn silage was used as roughage in 50% of the total dry matter). Two models were used to calculate the rate biohydrogenation: Model A): calculated by disappearance rate using abomasal fatty acids flow, and fatty acids intake and; Model B): calculated by ruminal turnover, fractional passage rate and fractional biohydrogenation rate and ruminal pool for each fatty acid. The marker NDFi was used to determine the abomasal dry matter flow. Ruminal contents were evacuated manually through the ruminal cannula at 4.5 h after feeding on d 20, and at 2.5 h before feeding on d 21 of each period. Data were analyzed using PROC MIXED of SAS 9.1 according with the orthogonal contrasts (C vs SO+WS+CSFA); (SO vs WS+CSFA) and (WS vs CSFA). The mean biohydrogenation rate (C18:2) to the model A was 88.58% and to model B 81.95% including all diets. The diets with lipids sources showed greater biohydrogenation rate of the linolenic acid in relation to control diet by model A ($P \leq 0.05$) (76.31 vs 80.01%). Model B caused tendency ($P \leq 0.09$) to decrease biohydrogenation rate of linolenic acid when compared with SO and CSFA diets (88.45 vs 77.5%). Diet WS decreased the biohydrogenation of C18:2 in 16.68% and 5.09% in relation to SO diet. Model B results in higher rates of BHB compared with model A. However, lower rates of ruminal biohydrogenation can occur due to methodological errors.

Ruminant Nutrition: Feeds

T301 Evaluating the mineral composition of *Vernonia amygdalina* leaf.

A. H. Ekeocha,* *University of Ibadan, Ibadan, Oyo, Nigeria.*

An experiment was conducted to determine the mineral composition of *Vernonia amygdalina* (Va). The atomic absorption spectrophotometer was used to determine any of the minerals (except P) using appropriate lamps. The P was determined with vanadomolybdate using spectrophotometer at 425nm.The principal elements present in Va are Ca, P, K, Na and Mg while the essential trace elements (macro nutrients) are Fe, Mn, Cu and Zn. The Va contained Ca 0.46%, P 0.13%, K 1.21%, Na 0.53%, Mg 0.27%, Fe 468.2mg/g, Cu 26.2mg/g, Zn 580.5mg/g. The high level of minerals found in Va was due to the high ash content recorded. Mineral assayed in this study in order of abundance was K 1.21%, Zn 0.58%, Na 0.53%, Ca 0.46%, Mg 0.27%, P 0.13%, Fe 468.2mg/g, Cu 26.2mg/g. Normally, plant materials are not good sources of Ca and P but the high levels reported in Va would easily satisfy animal needs if they occur in a readily available form. It is often postulated that a mineral supply in excess of dietary requirements is capable of blocking the availability of another. The result of mineral analysis on *Vernonia amygdalina* showed that the leaf contains high levels of micro and macro elements, which is an indication that the productivity of ruminant animals is sustainable.

Key Words: mineral composition, *Vernonia amygdalina* leaf

T302 Determination of the nutritional value of some perennial forage species for ruminants.

C. Bayourthe*[1,2] and C. Julien[1,2], [1]*INRA, UMR1289 TANDEM, Tissus Animaux Nutrition Digestion Ecosystème et Métabolisme, Castanet Tolosan Cedex, France,* [2]*Université de Toulouse, INPT-ENSAT, INP-ENVT, UMR1289 TANDEM, Castanet Tolosan Cedex, France.*

Ruminal OM and CP degradability of cardoon (*Cynara cardunculus* L.; CY), switchgrass (*Panicum virgatum* L.; SW) and immature cereals (IC) were studied with in sacco technique. Two mid-lactating (185 d in milk) and ruminally cannulated Holstein cows were used and fed a TMR (22 kg/d DMI) composed on a DM basis by 63.3% corn silage, 17.4% soybean meal and 19.2% wheat during a 25-d experimental period (21 d of diet adaptation, 4 d of measurements). Ruminal degradation rate of OM and CP was estimated as percent OM (DgOM) and CP degradability (DgCP) from polyester bags incubated in rumen for 2, 4, 8, 16, 24, 48, and 72h. Data were fitted to the nonlinear regression equation: $Dg(t) = a + b(1 - e^{-ct})$ where Dg is percentage disappearance of OM or CP at time t, *a* the soluble fraction and *b* the less rapidly degradable fraction which disappears at the constant fractional rate *c* per time t. Intestinal digestibility of CP was estimated using the in vitro procedure of Calsamiglia and Stern (1995). Switchgrass had numerically greater crude cellulose (41.1% of DM) and lower CP (5% of DM) contents than the other forage sources. Cynara and SW had a low soluble CP fraction (13.9 and 18.6%). The potentially degradable CP fraction was numerically greater and the rate of degradation numerically lower for CY (66.3% and 3.7% h^{-1}) compared with SW and IC (respectively, 21.6% and 5.0% h^{-1}; 33.3% and 5.5% h^{-1}). Effective degradability of CP followed the order IC > CY > SW. Intestinal digestibility of CP was 19% for CY and SW, and 37% for IC. The PDIN and PDIE contents (g/kg DM) were respectively: 23 and 67 for CY, 22 and 45 for SW, and 51 and 70 for IC. Compared with IC and SW, CY exhibited a high estimated energy NE_L value (Mcal/kg DM): 1.77 *vs* 0.90 and 1.03. Immature cereals offer a better nutritional value than CY and SW.

Key Words: nutritional value, perennial forages, ruminal degradability

T303 Dry matter changes in corn silage with rain.

H. A. Rossow[1], L. Kallaway*[1], N. Falcony[2], and T. Meister[3], [1]*Veterinary Medicine Teaching and Research Center, School of Veterinary Medicine, University of California-Davis, Tulare,* [2]*Alpha Dairy Consulting, Visalia, CA,* [3]*John Deere Forage Products, Moline, IL.*

Dry matter (DM) is the most important nutrient analysis because changes in DM effect total quantity of nutrients supplied in a ration. Since forages have the most variability associated with their DM content, forage DM is measured weekly and new values are entered into feed management software to correct weighing of forages in the ration. The purpose of this research is to determine how much forage (corn silage) DM changes with weather and how it affects ration DM. Corn silage and ration were sampled twice a day at feeding for 5 d and DM was measured according to AOAC methods using a forced-air drying oven at 100°C for 24 h. Corn silage DM was also measured using HarvestLab (near infrared reflectance stationary desktop model, John Deere). Corn silage on average accounted for 55% of the ration on an as fed basis and was correlated with ration DM ($P < 0.05$) with an R2 = 0.52 when ration DM regressed on corn silage DM. Rain (approximately 1 inch) occurred on the afternoon of the second sampling day and resulted in decreases of 3.6% corn silage DM and 6.6% in ration DM (AOAC method) and in a decrease of 2.28% corn silage DM (HarvestLab). By the next feeding, corn silage DM had increased back to pre-rain levels (34.3% vs. 33.9%). Corn silage DM was the primary source of moisture in the ration and rain caused a short-term decrease in ration DM because in a storm of short duration, most exposed silage was fed at the next feeding. Therefore it would be beneficial to adjust corn silage DM in the short-term according to rain events. Currently, feed management software does not allow storage of alternate DM settings that could be used for rain exposure. To determine how much DM should be adjusted for degree and duration of rain and predictability of DM using HarvestLab, more data are needed.

Key Words: dry matter, corn silage

T304 Canola meals from different production plants differ in ruminal protein degradability.

G. A. Broderick*[1], S. Colombini[2], M. A. Karsli[3], L. Nernberg[4], and D. Hickling[4], [1]*U.S. Dairy Forage Research Center, Madison, WI,* [2]*University of Milan, Milan, Italy,* [3]*Yüzüncü Yıl University, Van, Turkey,* [4]*Canola Council of Canada, Winnipeg, MB, Canada.*

Lactation trials have shown that production and N-efficiency were improved when dietary soybean meal was replaced with equal CP from canola meal. Three or 4 canola meal samples were collected from each of 12 Canadian production plants (total = 37) and analyzed for differences in chemical composition and in vitro and in situ ruminal protein degradability. In situ incubations were conducted at 0 and 12 h only and estimated rates used to compute rumen-undegraded protein (RUP) assuming first-order degradation and a ruminal passage rate of 0.06/h. The Michaelis-Menten inhibitor in vitro (MMIIV) method was used as described by Colombini et al. (J. Dairy Sci., 94:1967–1977, 2011) to quantify degradation rates and RUP, assuming passage rates of 0.16/h and 0.06 for the soluble and insoluble protein fractions. Differences among plants were assessed using GLM in SAS; LSD-separated means are in the table. Although fraction B3 (NDIN – ADIN) was unaffected, there were differences among plants in CP and NDF contents of canola meals produced. There also were differences among plants in RUP estimated by MMIIV: the only expeller meal had the highest RUP (47.4%),

but meals from 4 other plants had similar RUP values (43.0–46.3%). The RUP estimates from the other 7 meals were lower, including 4 that were different from the 4 meals with the highest RUP values. Estimates of RUP made using in situ methods tended to rank the meals differently from the MMIIV assay. Results indicated that, depending on the plant of origin, canola meal RUP may range from 37 to 47%, a difference greater than 25%.

T305 Influence of different levels of exogenous enzymes preparation at two application methods on in vitro ruminal fermentation of some fibrous feeds in sheep.

A. Z. M. Salem*[1], H. Gado[2], N. E. Odongo[3], R. Rojo[4], M. M. Y. Elghandour[1], and A. Olmido[4], [1]*Facultad de Medicina Veterinaria y Zootecnia, Universidad Autónoma del Estado de México, Toluca, Estado de Mexico, Mexico,* [2]*Faculty of Agriculture, Ain Shams University, Cairo, Egypt,* [3]*Animal Production and Health Section, Joint FAO/IAEA Division of Nuclear Techniques in Food and Agriculture, International Atomic Energy Agency, Vienna, Austria,* [4]*CU-UAEM- Temascaltepec, Universidad Autónoma del Estado de México, Estado de México, México.*

The present experiment was aimed at investigating the effect of different levels of exogenous enzymes preparation (ENZ - mixture of cellulase, xylanase, α-amylase and proteases enzymes) on in vitro gas production, some ruminal fermentation parameters (pH, NH3-N and VFA (total and individual acids) and fiber degradability (ADF and NDF) of three fibrous feeds (FF - corn stover, oat straw, sugarcane bagasse) at two methods of application (direct addition or pretreatment for 24h with ENZ) in sheep. The levels of ENZ used were 0, 0.06, 0.12 and 0.24 g/g DM of each FF, and ENZ was dissolved in distilled water to obtain the concentration of each level in 1 mL. Rumen liquor was collected before the morning eating from 4 sheep (40 ± 3.2 kg BW, fed on a total mixed ration of 50% commercial concentrate and 50% alfalfa hay) fitted with permanent rumen cannula. In vitro gas production was recorded at 2, 4, 6, 8, 10, 12, 24, 48 and 72 h of incubation. After 72 h, the incubation was stopped and the inoculant's pH was determined and filtered to determine ADF and NDF degradability, VFA (total and individual acids) and NH_3-N concentrations. In vitro organic matter digestibility and metabolizable energy, were estimated. Data were analyzed as 4 (four doses of ENZ) × 3 (three FF) × 2 (two methods of application) factorial experimental design. Addition of ENZ increased ($P<0.05$) gas production, NH_3-N and VFA concentrations with the FF used. Acetic acid concentration was increased with the addition or pretreatment of FF with ENZ without effect on butyric or propionic acids concentrations. Pretreatment of FF for 24 h with ENZ was increased the ruminal fermentation and fiber degradability (ADF and NDF) of FF. Highest in vitro gas production and ruminal fermentation activities were found in sugarcane bagasse compared with oat straw and corn stover. It is concluded that pretreatment the FF with ENZ for 24 h before the in vitro incubation could improve the ruminal fermentation and fiber degradability in sheep compared to the direct addition in diets. Sugarcane bagasse treated with ENZ could be considered a good roughage for ruminants.

Key Words: exogenous enzymes, fibrous feeds, gas production

T306 Composition of diets fed to different groups of lactating cows on California dairies.

A. R. Castillo*[1], N. Silva del Rio[2], N. R. St-Pierre[3], and W. P. Weiss[3], [1]*University of California, Cooperative Extension, Merced,* [2]*University of California, Cooperative Extension, Tulare,* [3]*The Ohio State University, Department of Animal Science, Columbus.*

The objective of this survey was to describe TMR dietary groups and TMR nutrient contents in lactating dairy cows. Forty dairies in Merced County, California, were selected based on the number of cows (mean 787 ± 592 from 210 to 2435 lactating cows/farm) and milk yield per cow (mean 31.8 ± 5.19 from 20.6 to 43.5 kg/d 3.5%FCM). Samples of TMR fed to different groups (n = 118) were taken in duplicate on 2 non-consecutive days and assayed for DM, NDF, ADF, lignin, CP (N*6.25), crude fat, and ash. The grouping systems and nutrient composition of the TMR (means ± SD) are in Table 1. Nine of 40 dairies (22%) fed a single diet to all lactating cows and 31 dairies fed multiple TMR diets to their lactating cow groups. Average milk production per cow for dairies feeding a single diet and multiple diets were 27.5 ± 5.5 and 33.0 ± 4.5 kg/d 3.5% FCM. All dairies with multiple diets had a high and low TMR. Fifty-eight, 32, and 15% of dairies with multiple diets prepared TMR for fresh, first lactation, and mid groups, respectively. Average (Table 1) and ranges of dietary NDF content on dairies with one diet (from 32.9 to 42.2%NDF) were close to the low TMR diets (from 30.6 to 43.5%NDF). Crude Protein contents in multiple diets TMR (fresh, 1st lactation, high, and mid) were similar averaging 17.5%CP. Across farms, CP content for 1st lactation diets were most consistent ranging from 16.7 to 18.0%CP, whereas for the other production groups ranged from 14% to more than 19%. Based on the limited variation in average nutrient concentrations among different diet groups, opportunities may exist to better match cow requirements with TMR composition.

Table 1. TMR dietary groups and nutrient contents

TMR of lactating cows	Dairies (n)	Nutrient content

T307 Ruminal degradability, duodenal flow, and intestinal digestibility of protein from canola meal or corn and wheat distillers grains in growing beef heifers.

C. Li[1,2], J. Q. Li[2], K. A. Beauchemin[1], and W. Z. Yang*[1], [1]*Research Centre, Agriculture and Agri-Food Canada, Lethbridge, Alberta, Canada,* [2]*College of Animal Science, Inner Mongolia Agricultural University, Hohhot, Inner Mongolia, China.*

The objective of this study was to evaluate the ruminal degradability, duodenal flows and intestinal digestibility of protein from canola meal or dried corn and wheat distillers grains with solubles (DDGS) in growing beef heifers. Five ruminally and duodenally cannulated Angus heifers (initial BW 386 kg) were assigned to a 5 × 5 Latin square design. The diets consisted of 60% barley silage and 40% barley grain-based concentrate (DM basis) with differing protein supplements: control (CON; no protein supplement), canola meal (CM), wheat DDGS (wDDGS), corn DDGS (cDDGS) or fractional corn DDGS (fDDGS). Contents of CP were 12.5, 14.6, 14.3, 14.1 and 14.2% (% DM), respectively, for CON, CM, wDDGS, cDDGS and fDDGS diets. DMI (kg/d) was lower ($P < 0.05$) for CON (8.9) than for the other diets (average of 10.0) which were not different. Intake (g/d) of N followed the same pattern of DMI with lower N intake ($P < 0.05$) for CON (177) than the other diets (240). There were no differences in mean ruminal pH (6.22 to 6.30) but total VFA concentration (mM) was the greatest ($P < 0.05$) for wDDGS (127) and fDDGS (124), and lowest ($P < 0.05$) for CON (115) and cDDGS (116). Ruminal NH_3 N (mM) was greatest ($P < 0.05$) for CM (7.4) and lowest ($P < 0.05$) for CON (4.9), while the DDGS diets were intermediate (6.2). Ruminal degradability of protein was not different among diets (53 to 57%). Flows (g/d) of NAN and microbial N to the duodenum were lower ($P < 0.05$) for CON (196 and 117) than for other diets (247 and 142). Digestibility (% intake) of N in the intestine (74%) was not different among diets. The results indicate that the 4 sources of feed protein delivered no differences in the amount of protein at the small intestine when the diets were formulated to be isonitrogenous. Corn and wheat DDGS can be used to replace CM to supply the protein requirements of growing cattle fed backgrounding diets based on barley grain.

Key Words: beef heifer, flow and digestibility of N, protein supplement

T308 Tables of nutritive values for farm animals in tropical and Mediterranean regions: an important asset for improving the use of local feed resources.

D. Sauvant*[4,1], G. Tran[1], V. Heuze[1], D. Bastianelli[2], and H. Archimède[3], [1]*Association Française de Zootechnie, Paris, France,* [2]*CIRAD, Systèmes d'élevage et produits animaux, Montpellier, France,* [3]*INRA, UR143 Unité de Recherches Zootechniques, Petit-Bourg, Guadeloupe, France,* [4]*AgroParisTech-INRA, Paris, France.*

The demand for livestock products has been growing steadily in emerging and developing countries and with it the need for information about animal feeds. However, users of these countries often have to resort to feed data that are either obsolete or from temperate countries. The project "Tables of nutritive values for farm animals in tropical and Mediterranean regions" led by INRA, CIRAD and AFZ (and supported by FAO) aims to create an updated and comprehensive set of datasheets for more than 500 fodders and raw materials. Collaborations have begun with research groups in Belgium, Morocco and Spain. A major goal of the project is to better identify and characterize the local feed resources to improve the technical and economic performance of farms. Nutrition modeling, collaborations between research teams and identification of gaps in knowledge are part of the scientific objectives. The datasheets are created by a group of 20 scientists and engineers, who rely on a massive collection of scientific literature and experimental data to write qualitative and quantitative syntheses (via methods such as meta-analysis). A database containing more than 2 million raw data has already been established. Each datasheet provides information such as physical descriptions, pictures, feed availability, forage management, processes and environmental impact, as well as consistent chemical compositions (mean values and variability), feeding recommendations and nutritional values, potential concerns etc. for the main species of farm animals (Ruminant, swine, poultry, rabbit, fish). The publication of the datasheets is due in 2013, first as a FAO website and later in a book form.

Key Words: feed data base, multispecies, nutritive value

T309 Quality evaluation of italian rye grass and whole crop barley with homofermentative and heterofermentative lactic acid bacteria.

H. Lee[1], M. Jeong[1], S. Kim[1], L. Mamuad[1], B. Cha[1], E. Kang[1], C. Jeong[1], D. Kim[1], D. Kim[2], and S. Lee*[1], [1]*Sunchon National University, Suncheon, Republic of Korea,* [2]*National Institute of Animal Science, Suwon, Korea.*

This study was conducted to determine the quality of Italian rye grass (IRG) and whole crop barley (WCB) with addition of monoculture and co-culture of homofermentative and heterofermentative LAB on in situ fermentation. Strains of homofermentative LAB (*Lactobacillus casei* KACC 12416) and heterofermentative LAB (*Lactobacillus reuteri* KCTC 3594) were used in this study. *L. casei* and *L. reuteri* had the highest propionic acid production, thus they were used in fermenting the forage. The forages were fermented using monoculture and co-culture of *L. casei* and *L. reuteri* for 60 days ensiling. Microbial analyses, dry matter, NDF and ADF digestibility were determined and evaluated using SAS (2003). Addition of LAB in IRG inhibits the growth of molds. Dry matter digestibility of IRG was significantly higher on co-culture of *L. casei* and *L. reuteri* at 6and 24 hours of ensiling. On the other hand, dry matter digestibility of WCB was significantly higher in *L. casei* monoculture at 12 hours of incubation and in co-culture at 6 and 12 hours of incubation. ADF digestibility of IRG was significantly higher in L. casei monoculture at 6 hours of ensilage and in co-culture at 6 and 48 hours of ensilage. Furthermore, ADF digestibility of WCB was significantly higher in *L. reuteri* monoculture and in co-culture at 24 hours of ensilage. The result of this experiment suggests the addition of co-culture homofermentative and heterofermentative LAB which improves silage quality as well as inhibits molds.

Key Words: homofermentative and heterofermentative LAB, Italian rye grass, whole crop barley

T310 Sunflower cake in multiple supplements for cattle grazing in the dry season: pH and ruminal ammonia nitrogen.

R. P. da Silva*[1], A. C. Mesacasa[1], J. T. Zervoudakis[1], L. K. Hatamoto-Zervoudakis[1], L. da Silva Cabral[1], F. de Paula Leonel[2], R. G. F. da Silva[1], J. Q. Soares[1], L. C. R. P. Silva[1], A. J. Neto[1], A. de Oliveira Zanette[1], and J. F. W. Koscheck[1], [1]*Federal University of Mato Grosso, Cuiaba, Mato Grosso, Brazil,* [2]*University of ST John King Del, Sao Joao Del-Rei, Minas Gerais Brazil.*

The research aimed to evaluate the inclusion levels of sunflower cake as protein source to replace soybean meal in multiple supplements for cattle grazing during dry season on nutritional parameters. Five steers were used, Nellore, uncastrated, with age and average initial weights of 20 months and 354.7 kg, respectively, divided into 5 paddocks of 0.25 ha each, consisting of *Brachiaria brizantha* 'Marandu'. The experiment was divided into a 5 × 5 Latin square design, composed of 5 experimental periods of 15 d each and 5 animals. The strategy adopted was the inclusion of sunflower cake in increasing levels of 0, 270, 406, 540 g / kg supplement as well as an mineral mixture ad libitum (MM). Supplements were formulated to be isonitrogenous (25% CP) and provided the amount of 1.5 kg / animal / day of natural matter. The availability of total dry matter and potentially digestible were 3.120 and 2.379 kg/ha respectively. The different levels of protein replacement of soybean meal by sunflower cake protein did not cause major changes in ruminal pH ($P > 0.10$), it remained around 6.72 at time 0 hours, and 6.57 4 h after supplementation, does not impair the growing rumen microbiota. There was a statistically significant difference ($P < 0.10$), for concentrations of NH_3-N among the animals that received only MM and cattle that received protein supplements in 4 h, that can be explained by the increasing concentration of NH_3-N in the rumen, enhancing the degradation of forage and therefore higher intake. Among the animals that received supplementation, was also observed statistically significant difference ($P < 0.10$), in which the increase in the supply of sunflower cake promoted a decrease in the concentration of NH_3-N in time 4 hours after supplementation, that it can be explained by the higher indigestible portion of sunflower cake compared to soybean meal. It is concluded that the inclusion of sunflower cake in the formulation of supplements did not affect the nutritional parameters, in which it can replace soybean meal in up to 100%, at this level of supplementation evaluated.

Key Words: cattle, co-products, pasture

T311 Prediction of carbohydrate fractions in some tropical grasses.

R. S. Fukushima,* C. B. Bacha, A. P. Fuzeto, A. C. R. Port, and A. V. Vargas, *Universidade de Sao Paulo, Pirassununga, SP, Brazil.*

Balancing ruminant diets for maximum production requires appropriate levels and types of dietary carbohydrates (CHO). The Cornell Net Carbohydrate and Protein System (CNCPS) has equations based on NDF content that estimate fermentation and passage of feed CHO and protein fractions which can be used to predict ME and protein utilization. In previous versions of the CNCPS, CHO fractions were categorized into 4 fractions: A (sugars, organic acids, and oligosaccharides), B1 (starch and soluble fiber), B2 (available NDF) and C (unavailable NDF). Later, scientists at Cornell University (Lanzas et al., 2007) proposed an expanded CHO scheme. Among some changes, fraction B1 turned out to be only starch, B2 was soluble fiber, B3 was available NDF and C was unavailable NDF. They compared it with the original CNCPS scheme by using a database which involved ingredients commonly used in ruminant rations and mathematical analyses. The present work agrees with the expanded CHO scheme, however, using a different approach: CHO fractions were predicted in 5 tropical forage samples, stalk and leaf tissues, at 3 maturity stages, using the original CNCPS and alternative equations (Queiroz et al., 2008) where NDF was substituted for by another fibrous preparation, crude cell wall (CW) which is obtained after treating the sample with water and organic solvents in a Soxhlet equipment. CW was used because NDF does not provide a complete measure of cell wall components such as pectin, β-glucans and galactans (soluble fiber) that are dissolved by NDF solution. Estimates of CHO fractions were compared by *F* tests from SAS. NDF substitution for CW showed that soluble fiber went to fraction A of CNCPS, the rapidly digestible carbohydrates. Because of its own degradation characteristics it is suggested that the soluble fiber fraction be accommodated in a specific fraction (B2) while the slowly digestible NDF be placed in a new fraction, B3. The fraction B1 would be only starch. Fraction C is still unavailable NDF. The approach used here allowed estimation of soluble fiber by subtracting NDF from CW. Expanded CHO scheme seems to provide better estimation of carbohydrate pools. This work was funded by FAPESP, Brazil.

Key Words: cell wall, CNCPS, NDF

T312 Using the acetyl bromide lignin method to quantify lignin content in forages.

M. H. Ramos[1], R. S. Fukushima*[2], and M. S. Kerley[1], [1]*University of Missouri, Columbia, MO,* [2]*Universidade de Sao Paulo, Pirassunumga, SP, Brazil.*

Lignin is a phenolic polymer that gives structural rigidity to plants; however, it inhibits cell wall digestion by microbial enzymes in herbivores. As a consequence, energy utilization is reduced. To better understand such inhibition it is important the correct quantification of lignin. The spectroscopic method acetyl bromide lignin (ABL) was used to quantify lignin in 21 grass samples (perennial ryegrass, tall fescue, annual ryegrass, sorghum Sudan and Caucasian bluestem) and 18 legume samples (alfalfa, lespedeza and red clover). Estimates of lignin concentrations were compared by *F* tests. SAS was used to draw linear regressions to measure main lignin effects and to correlate lignin content with in vitro forage dry matter digestibility. Grasses showed higher ABL concentrations than did legumes: 62.5 and 43.7 g/kg, respectively. It is pointed out that ABL, as a spectroscopic method, may possess the sensitivity to detect soluble lignin components that would be lost by conventional gravimetric analyses. Grasses, but not legumes, contain substantial levels of ester-linked low molecular weight phenolic acids which could contribute to the UV absorbance. The importance and magnitude these phenolics may be measured together with condensed lignin require more studies. IVDMD was negatively correlated with ABL method ($P < 0.005$) for both grasses and legumes. Grasses showed slightly higher digestibility, although without statistical difference ($P > 0.16$). Regression equations were, grass: $Y = -4.26X + 906.6$ ($R^2 = 0.81$) and legumes: $Y = -4.11X + 811.5$ ($R^2 = 0.61$). Curves had similar slopes ($P > 0.98$). These parallel lines indicate that the degradability of grasses and legumes had similar pattern as lignin concentration increased. In other words, it seems that grass lignin is no more inhibitory to digestion than legume lignin. These results add strength to the hypothesis that lignin's effect on degradability of forage cell walls is primarily related to concentration. In this context, ABL method may be a good alternative to quantify lignin content and to predict forage digestibility. Other lignin methods were studied and their data are being processed. This work was funded by CAPES, Brazil.

Key Words: digestibility, forages, lignin

T313 Estimates of kinetic degradability parameters and passage of materials originated from intercropping between brachiaria grass and plantations of corn and soybeans.

T. S. de Oliveira*[1], V. S. de Oliveira[1], T. M. de Oliveira Alves[1], J. C. Pereira[1], and R. A. M. Vieira[2], [1]*Universidade Federal de Viçosa, Viçosa, Minas Gerais, Brazil,* [2]*Universidade Estadual Norte Fluminense, Campos dos Goytacazes, Rio de Janeiro, Brazil.*

The study was conducted to determine the kinetic parameters of in situ DM and NDF and the movement of materials from the intercropping of brachiaria grass and crops with corn and soybeans. Three experiments were used, as follows: Experiment 1 – Brachiaria grass and corn consortium at different plant ages. Experiment 2 – Brachiaria grass and corn consortium set in sowing arrangements. Experiment 3 – Brachiaria grass and soybeans consortium. The kinetics of particles transit were determined by the recovery of the indicators in the faces of the animal.

In the degradation test the samples were incubated in the nylon bags at the times of 0, 3, 6, 9, 12, 24, 48, 72, 96, 120 and 144 h. Kinetics data of rumen degradability and particles passage of silages made from material derived from the intercropping of brachiaria grass and crops of corn and soybeans are scarce, which makes comparisons difficult. However, the kinetics of particles passage from corn and brachiaria grass silage (CBS) was 0.030 and Brachiaria grass (BG) was 0.023 had values close to those found in the literature, for soybean and Brachiaria grass silage (SBS) was 0.018 was lower than the data from literature, which were compared with corn and brachiaria grass silage in exclusive culture. The rate of digestion from corn and brachiaria grass silage (CBS) was 0.018 and Brachiaria grass (BG) was 0.0353 had values close to those found in the literature, for soybean and Brachiaria grass silage (SBS) was 0.021. The materials that come from the intercropping caused ruminal repletion. The degradation rates were lower when correlated with data from literature. The values obtained for the parameters of degradation kinetics and passage of materials obtained from the various forms of intercropping of brachiaria grass and crops of corn and soybeans do not compromise the recommendation of the use of forage to increase the profitability of the system.

Key Words: grasses, kinetics of particles transit, degradability

T314 Utilization of infrared thermography image analysis in ruminant feeding experiments.

M. S. V. Salles*[1], S. C. Silva[1], L. C. Roma Junior[1], C. E. L. Oliveira[2], F. A. Salles[1], C. M. M. Bittar[3], and L. El Faro[1], *[1]APTA Centro Leste, Ribeirao Preto, Sao Paulo State, Brazil, [2]FZEA USP, Pirassununga, Sao Paulo State, Brazil, [3]ESALQ USP, Piracicaba, Sao Paulo State, Brazil.*

Infrared thermography (IRT) is an alternative, noninvasive method, which has been studied as a tool in the identification of several physiological and pathological processes related to changes in body temperature. Heat production in ruminants is increased by high intake of forages. This study aimed to detect through IRT, changes in temperature caused by the ingestion of diets with different amounts of forage. For this purpose an experiment was conducted with 24 Jersey heifers (average body weight of 227 kg), in a replicated Latin square design, with repeated measures in time, with the following treatments: 30, 50 and 70% forage (corn silage) in relation to the diet dry matter (DM). Feeding consisted of a total mixture ration offered (3% of body weight) from 08:00 to 14:00. Each collection period (4 d) was preceded by 7 d of diet adaptation. The thermography images (right and left flank and eyes, feet and forehead), heart rate, respiratory rate and rectal temperature were obtained every 2 h, from 06:00 to 18:00h. Temperature values of the thermography images of the right flank in the 30, 50 and 70% treatments were 29.95, 30.11 and 29.89°C, with a significant difference between the last 2 ($P = 0.0339$). The 50% treatment, which showed the highest temperature of the right flank, also had higher DMI (6.50, 7.24 and 5.95 kg for 30, 50 and 70, $P < 0.0001$); while for NDF intake, there was an interaction ($P = 0.0007$) between treatment and time (1.72, 2.31, 2.86 for 30%; 2.36, 3.03, 3.49 for 50%, and 2.02, 2.78, 3.45 for 70%, at 08:00, 10:00 and 12:00h, respectively). Other variables did not differ between treatments. Although the difference between treatments were of small magnitude, the use of thermographic images enabled detection of a temperature increase associated with higher dietary fiber intake. Financial support FAPESP.

Key Words: dry matter intake, NDF intake, ruminant

T315 Evaluating and refining the CNCPS feed library.

R. J. Higgs,* L. E. Chase, D. A. Ross, and M. E. Van Amburgh, *Department of Animal Science, Cornell University, Ithaca, NY.*

The Cornell Net Carbohydrate and Protein System (CNCPS) model includes a library of >800 ingredients which is the reference database for describing the chemical composition of a diet. The objective was to evaluate the current feed library against commercial laboratory data, and update the library as required. To conduct the analysis, data sets were provided by 2 commercial laboratories (n > 100,000 analyses; Dairy One, Ithaca, NY and Cumberland Valley Analytical, Hagerstown, MD). The procedure followed 4 sequential steps and bound each feed to the following constraint (Eq 1): (CP + EE + ash + NDF + acetate + propionate + butyrate + lactate + organic acids + sugars + starch + soluble fiber) = 100. In the first step, components used to differentiate farm level characteristics of the same feed were fixed (DM, NDF, CP). Second, linear regression equations were derived from the data provided and used to calculate components from other correlated components within the same feed (R2 > 0.65). Third, factors not predicted using standard linear regression and not in Eq. 1 were calculated using a matrix of regression coefficients derived from data generated using a Monte Carlo (MC) simulation. To complete the analysis, probability density functions of each chemical component of each feed were fit and correlated to each other in @Risk (Palisade, Ithaca, NY). A MC simulation was run for 30,000 iterations, which generated a standardized data set of likely feed compositions. These data were then used to calculate the coefficients for the matrix. Lastly, components that were not assigned values in any of the preceding steps were calculated using a genetic algorithm optimizer (RISKOptimzer, Palisade). Minimum and maximum boundaries for each component within a feed were set using the data sets provided to constrain the optimizer to a likely range of values (mean ± SD). The optimizer was also constrained to satisfy the assumptions of Eq 1. The approach provided an efficient and repeatable way of evaluating and refining the composition of a large number of different feeds against commercially generated data similar to that used by CNCPS users on a daily basis.

Key Words: feed chemistry, optimization, library

Ruminant Nutrition: General II

T316 Investigation on the nutritive value of *Vernonia amygdalina* leaves (bitter leaves) for ruminant animals.

A. H. Ekeocha,* *University of Ibadan, Ibadan, Oyo, Nigeria.*

An experiment was conducted to determine the proximate composition of *Vernonia amygdalina* (Va). Proximate composition of Va was determined according to AOAC (1990). The DM content of Va was high (88.7%) due to the air drying process the leaves were subjected before milling. The crude protein (CP) was 19.7% and this is commensurable when compared with tropical grass species which seldom exceed a CP level of 10%. It compared favorably with that of cassava leaf meal (16.7%), Sunflower leaf meal (16.6%) far exceeds the minimum protein requirement (10–12%), for ruminants. This value is not far from the CP levels of *Leuceana* sp. (22.2%) and *Gliricidia* sp. (22.5%). The crude fiber (CF) level of 15.7% for Va is low compared with that of tropical grass species, which may be as high as 45 – 50% at more matured stages of growth. It is comparable to the CF level of *Chromolaena odorate* leaf meal (16.0%), Cassava leaf meal (15.6%), deep litter manure (16.6%) and guava leaf (16.1%) but lower than the CF leaf of *Tithonia diversifolia* (21.8%). The ether extract content was low (5.6%). This value was lower than the value of 8.1% reported for *Chromolaena odorate* leaf but greater than the value of 2.8% reported for *Tithonia diversifolia* leaf. The total ash content 13.9% was high and this was comparable to the ash content of *Tithonia diversifolia* (14.7%) but greater than the value of 8.3% reported for *Acacia albida* used as a browse plant for sheep in the semi-arid region of Nigeria and greater than the value of 11.0% reported for *Leucaena* sp. to feed Yankassa sheep and 11.5% reported for *Chromolaena odorate* leaf meal but commensurable with the value reported for cassava leaves which has an ash content of 10.1%. The gross energy (GE) value was 2720.0kcal/kg. This is comparable with the GE value of Groundnut cake (2600kcal/kg). The nitrogen free extract level of 33.9% for Va is low compared with that of *Tithonia diversifolia* leaf (44.4%) used to feed West African Dwarf sheep. On average the chemical composition of Va appeared to be suitable as a protein concentrate for ruminants, a suitable replacement for *Gliricidia* and *Leuceana* sp.

Key Words: nutritive value, ruminant animals, *Vernonia amygdalina* leaves

T317 Screening of dairy cows for ketosis by routine analysis of β-hydroxybutyrate in DHI test milk samples.

D. E. Santschi* and D. M. Lefebvre, *Valacta, Ste-Anne-de-Bellevue, Quebec, Canada.*

Fourier transform infrared analysis (FTIR) was used to determine β-hydroxybutyrate (BHB) concentration in DHI test milk samples, as a fast and inexpensive method to measure herd level subclinical ketosis incidence. Based on a previously published trial comparing blood and milk BHB concentrations, threshold levels were established as follows: cows with milk BHB concentrations ≥0.20 mM were declared ketotic (POS); cows with milk BHB concentrations below 0.15 mM were declared non-ketotic (NEG); and cows with intermediate BHB concentrations were classified as potentially ketotic (SUSPECT). Routine testing of DHI milk samples started in October 2011. Over 235,600 samples were tested, of which 23,577 were from cows between 1 and 35 DIM (7,825 primiparous and 15,752 multiparous cows). Results indicate an average subclinical ketosis incidence (POS and SUSPECT) of 27% over the first 5 weeks of lactation. Distribution of incidence in relation to week after calving was different between primiparous and multiparous cows. Highest incidence for primiparous cows (33.8%) was in the first week postpartum but in the third week for multiparous cows (33.3%). By wk 5 after calving, incidence declined to 19.9% and 22.8% for primiparous and multiparous cows, respectively. Milk yield and composition were affected by the ketotic status of cows (see Table 1). Milk BHB concentration was inversely correlated to the protein:fat ratio ($R = -0.38$; $P = 0.0001$). Routine analysis of milk BHB among DHI test samples provides a fast and inexpensive tool for accurate screening of subclinical ketosis incidence at the herd level.

Table 1. Milk yield and composition according to ketotic status of cows between 1 and 35 DIM

	POS	SUSPECT	NEG	SE	*P*-value
Test-day milk yield (kg)	30.3^{a}	32.4^{c}	31.8^{b}	0.2	0.001
Fat (%)	4.92^{c}	4.48^{b}	4.05^{a}	0.01	0.001
Protein (%)	3.15^{a}	3.18^{b}	3.24^{c}	0.01	0.001
SCC (1000 cells)	365^{b}	349^{b}	243^{a}	14	0.001
Urea (mg N/dL)	8.6^{a}	9.5^{b}	10.0^{c}	0.1	0.001
Protein:Fat ratio	0.66^{a}	0.73^{b}	0.82^{c}	0.003	0.001
TCI[1]	-57^{a}	189^{c}	36b	22	0.001

T318 Prediction of empty body weight of adult Pelibuey ewes.

A. J. Chay-Canul[1], J. C. Ku-Vera*[2], A. J. Ayala-Burgos[2], J. G. Magaña-Monforte[2], and L. O. Tedeschi[3], [1]*División Académica de Ciencias Agropecuarias, Universidad Juárez Autónoma de Tabasco, Villahermosa, Tabasco, México,* [2]*Facultad de Medicina Veterinaria y Zootecnia, Universidad Autónoma de Yucatán, Yucatán, México,* [3]*Department of Animal Science, Texas A&M University, College Station.*

The aim of this work was to assess the relationships between shrunk body weight (SBW), empty BW (EBW), warm carcass weight (WCW) and cold CW (CCW), to develop prediction equations to estimate EBW in non pregnant, non lactating, adult Pelibuey ewes fed fibrous rations. Twenty four ewes with BW of 37.2±4.0 kg were randomly assigned to four groups of six animals each. Six ewes were slaughtered, for baseline measurements of carcass traits. The remaining, were randomly assigned to three groups of six animals each. Ewes were individually housed in metabolic crates, and were fed at levels of metabolizable energy intake (MEI): Low (L), Medium (M) and High (H) for 65 d, to achieve desirable changes in BW. Levels of feeding were established as proportions of ME energy requirement for maintenance (0.426 MJ/kg $BW^{0.75}$/d). Grass was offered in equal portions twice daily, supplying 44 g DM/kg $BW^{0.75}$/d for all treatments, and the concentrate at a rate of 0, 16 and 32 g DM/kg $BW^{0.75}$/d for treatments L, M and H, respectively. Before slaughter, SBW was taken after feed and water were withdrawn for 24 h, gastrointestinal tract (GIT) was weighed before and after emptying. EBW was computed as the difference between SBW and contents of the GIT. Data recorded at slaughter were weight of WCW, and then carcass was chilled at 6°C during 24 h. After refrigeration, the weight of CCW was recorded. Two ewes were removed of the experiment because of illness. Mean (±SD) values (kg) of SBW, WCW, CCW and EBW of adult Pelibuey ewes (n =22) were 35.63±5.02 kg; 14.95±2.40 kg; 14.52±2.50 kg and 27.92±4.19 kg, respectively. Relationships between BW, EBW, WCW and CCW were estimated by regression using PROC REG of SAS. Relationships between SBW, WCW and CCW between EBW, were all significant ($P<0.0001$) and the R^2 ranged between 0.94 and

0.96. The regressions equation were, EBW = −0.945 + 0.809 SBW (R^2 = 0.94; RSD = 1.009); EBW = 2.219 + 1.718 WCW (R^2 = 0.96; RSD = 0.812) and EBW = 4.363 + 1.622 CCW (R^2 = 0.94; RSD = 1.070). Data obtained, indicated that weight of GIT content was approximately 19% of SBW of adult ewes, additionally, WCW and CCW could be employed to predict reliable the EBW of adult Pelibuey ewes.

Key Words: Pelibuey ewes, empty body, carcass

T319 Increased lamb production by implanting melatonin to induce out of season breeding.

T. Wuliji*[1,2], [1]*Lincoln University, Jefferson City, MO,* [2]*University of Nevada, Reno.*

A spring breeding program was evaluated at the Nevada Experiment Station (Reno) in sheep using melatonin or melatonin and progesterone implants. Yearling and mixed aged ewes (n = 120) were randomly allocated to 3 treatments, 40 animals in each group (control, C; melatonin implant, M; and melatonin and progesterone implant, MP). Melatonin implant (one dose contained 18 mg melatonin, released at 0.5 mg/d, Regulin, Schering Pty Ltd., Australia) and progesterone implants (Synchro-Mate-B, USA, gradual release 6 mg/dose) were implanted in accordance to the manufacturer′s specifications. Ewes were managed under natural ambient light and grazed on small pastures for 5 weeks in isolation from rams. Pastures were mixtures of primarily fescue/clover with some winter forbs and native grasses. The M group received one melatonin pellet s.c. at the start of wk 1; the MP group received one pellet at the start of wk 1 and one progesterone implant at the start of wk 4. Ewes were bred with 3 rams randomly for 2 estrus cycles (5 weeks) beginning at wk 6 of the experiment. Data were analyzed by Chi-squared test. Blood melatonin concentration was greater ($P < 0.05$) for M than C group at weekly monitoring during melatonin implantation (Table 1). Number of ewes bred (40, 40 and 30), number of ewes lambed (34, 31 and 13), number of live births (54, 41 and 18), number of weaned lambs (42, 33 and 13), birth weight (4.44, 4.53 and 4.44 kg) and weaning weight (28.57, 29.93 and 28.12 kg) were compared for group C, M and MP, respectively. There was no difference between M and MP for any of measurements, however number of ewes bred, number of ewes lambed, number of live births, and number of weaned lambs were greater ($P < 0.05$) for M and MP compared with C group. This experiment indicated that out of season breeding using melatonin implants can increase sheep reproductive efficiency.

Table 1. Blood melatonin concentration (pg/mL) at weekly intervals

Group	Wk 1	Wk 2	Wk 3	Wk 4
C	12.6	13.1	12.6	14.2
M	83.7	78.7	89.9	109.50

Melatonin concentration was significantly ($P < 0.05$) higher for M group compared with C group at 4 intervals.

Key Words: sheep, breeding, melatonin

T320 Effects of different levels of quebracho tannins and sunflower oil on nutrients digestibility and milk fatty acids composition in dairy ewes.

S. N. Al-Dobaib*[1], H. E. M. Kamel[1], M. A. M. M. Shehab-El-Deen[1], and M. Y. Al-Saiady[2], [1]*Qassim University, Buriedah-51452, Saudi Arabia,* [2]*Arabian Agricultural Services Company, Riyadh-11593, Saudi Arabia.*

In a 3 × 3 factorial setup, the effects of different levels of quebracho tannins (T) and sunflower oil (F) on nutrients digestibility and fatty acids profile in milk fat of dairy ewes have been studied. The levels of both T and F were 0, 2 and 4% of dry matter. Seventy two pregnant ewes were randomly allocated into 9 treatments. The appropriate diet was given to each treatment group from week 2 pre-partum until the end of the trial. In the digestibility trial, the effect of T was negative on the digestibility of organic matter, N, NDF ($P < 0.05$); and ADF ($P < 0.07$). However, digestibility of NDF tended to be reduced by F supplementation ($P < 0.07$). The interaction effect of F×T was negative and tended to reduce digestibility of NDF ($P < 0.06$). Retained N (RN) as a percentage of digested N (DN) enhanced with T supplementation ($P < 0.05$). The highest value of RN/DN detected in treatment group fed F 2% and T 4%. Diets supplemented with either F or T had the highest ratio of unsaturated to saturated fatty acids in milk fat ($P < 0.01$) (Table1). Moreover, the effect of F×T interaction on milk fat content of conjugated linoleic acid (CLA) was significant ($P < 0.05$) (Table1). In conclusion, diet supplementation with F 4% and T 2-4% could be used to increase unsaturated/saturated FA ratio and CLA content of ewes milk fat. The current research was funded by King Abdulaziz City for Science and Technology-Saudi Arabia (No.ARP-28-61).

Table 1. Effects of diet supplementation with quebracho tannins (T; 0, 2, and 4% of DM) and sunflower oil (F; 0, 2 and 4% of DM) on unsaturated (U) to saturated (S) fatty acids ratio and conjugated linoleic acid (CLA) in milk fat

Treatment	U/S FA	CLA (g/100 g FA)

T321 Relationships between residual feed intake and performance of Nellore bulls in feedlot.

T. P. Guimarães[1], J. J. de Resende Fernandes*[1], K. K. G. Moreira[1], M. D. de Freitas Neto[1,2], V. R. M. Couto[1], B. J. M. Lemos[1], L. F. N. Souza[2], and É. G. Moraes[2], [1]*Universidade Federal de Goiás, Goiânia, Goiás, Brazil,* [2]*Nelore Qualitas, Goiânia, Goiás, Brazil.*

The objective of this study was to evaluate performance and efficiency parameters of 114 Nellore bulls classified for residual feed intake (RFI). The animals, with an average of 24 mo of age, were located in individual pens and were weighed at the beginning of the trial and each 21 d, so the average daily gain (ADG) could be determined. The diet was composed by 18.0% corn silage, 5.0% sugar cane bagasse, 24.3% soybean hulls, 3.5% soybean meal, 46.8% sorghum, 0.8% urea and 1.6% mineral mix. Dry matter intake (kg/d) was determined weighing the orts every day. The animals were initially divided into 3 treatments: high RFI, medium RFI and low RFI. RFI was calculated as the difference between observed and predicted feed intake based on $LW^{0.75}$and average daily gain (ADG). Animals were classified as high RFI (>0.66 standard deviation - less efficient, n = 38), medium RFI (±0.66 standard deviation, n = 38), and low RFI (<0.66 standard deviation - more efficient, n = 38). The results were analyzed using the statistical software R (2011). There were differences in initial and final LW, dry matter intake (DMI), NDF intake (NDFI) and crude protein intake (CPI) among RFI levels. The higher DMI observed in the group of low RFI animals may be due to the greater initial BW of these animals. Low RFI animals also were better in feed efficiency (FE) and feed conversion (FC). The average daily gain (ADG) did not differ among treatments. The RFI was positively correlated with FC (−0.25; $P < 0.05$), NDFI (0.50; $P < 0.05$), CPBI (0.59; $P < 0.05$) and negatively correlated with FE (−0.58; $P < 0.05$) and DMI (−0.39; $P < 0.05$). There were no significant correlations with initial and final BW and ADG. Significant correlations between feed conversion and initial LW (0.45; $P < 0.05$) and ADG (−0.65; $P < 0.05$) were detected. The bulls with low RFI can be up to 13.6% more effective than bulls with high RFI.

Key Words: beef cattle, efficiency parameters, selection

T322 Adipose tissue preferences for acetate in finishing steers.

W. A. D. Nayananjalie,* T. R. Wiles, D. E. Gerrard, M. A. McCann, and M. D. Hanigan, *Virginia Polytechnic Institute and State University, Blacksburg.*

Increased marbling enhances the quality grade of beef, and as such, high starch diets are often used by feedlots to stimulate this type of fat deposition. In vitro studies suggest that adipocytes from intramuscular fat (IMF) and subcutaneous fat (SCF) may have different preferences for acetate and glucose, and thus may be vulnerable to strategic changes in feeding regimens. We hypothesized, however, that SCF, IMF, and visceral fat (VF) tissue have similar preferences for acetate in vivo. Therefore, the objective of this study was to assess acetate incorporation rates into adipose tissue from SCF, IMF, and VF depots. Four Angus × Simmental steers had been fed corn silage based finishing ration for 120 d. They (513 ± 12 d age and 569 ± 35 kg BW) were infused continuously with [$^2H_3$] acetate (0.2 mol/h) over a 12 h period immediately before harvest. Blood samples were collected from each animal before and after infusion. Blood samples were collected at 1 h intervals from 2 animals during the first 11 h of the infusion, and every 15 min during the last 1 h of infusion. Plasma acetate enrichment levels were determined by GC-MS. Post-harvest tissue samples were collected from SCF, IMF and VF depots. Lipids were extracted from tissues and fatty acid methyl esters were prepared and analyzed in GC-MS for palmitate enrichment. Enrichment of acetate in blood and fat in each depot was used to calculate fractional synthesis rates (FSR, % per h) of palmitate in each depot. DNA concentration, palmitate enrichment in each tissue and FSR were analyzed for the fixed effect of tissue using the GLIMMIX procedure of SAS 9.2. DNA concentration in each tissue was used as a covariate for FSR analysis. A contrast statement was used to compare the VF and the average FSR of IMF and SCF. DNA concentration was different ($P = 0.003$) between IMF and VF, and SCF and VF. Enrichment of palmitate in adipose tissues was not different across depots nor was FSR, though a trend ($P = 0.09$) for a higher FSR was observed in VF as compared with IMF and SCF. These data show that differences in acetate preference by major fat depots do not exist in finishing feedlot steers.

Key Words: acetate, fat depot, fractional synthesis rate

T323 Effects of different amino acid patterns on the expression of four major milk protein genes in primary cultured bovine mammary epithelial cells.

X. F. Zhang[1], M. Gao*[2], R. P. Du[2], D. X. Lu[2], C. J. Ao[1], K. Erdene[1], and H. Zhang[1], [1]*Inner Mongolia Agricultural University, Hohhot, Inner Mongolia, China,* [2]*Inner Mongolia Academy of Agricultural & Animal Husbandry Sciences, Hohhot, Inner Mongolia, China.*

The objective of this study was to determine whether different amino acid (AA) patterns could affect milk protein gene (αs1-casein, αs2- casein, β-casein, κ-casein) expression in bovine mammary epithelial cells. Mammary tissues were collected from a 3-yr-old lactating Chinese Holstein dairy cow (DIM 100-d), Primary mammary epithelial cells were isolated by modifications of the methods of Miranda et al., (2009). A completely random design was used with 4 AA patterns as treatments (Table 1), each treatment has 3 replicates, and all experiments were repeated 3 times. The expression of genes was determined by RT-QPCR method. Data were analyzed by the ANOVA using the GLM procedure of SAS (9.0). The concentration of total AA in each medium was 534 mg/L. The results showed that different patterns of AA can induce the expression of αs1-casein, β-casein and κ-casein genes differently ($n = 3$; $P < 0.05$), in contrast, the expression of αs2-casein gene was not significantly affected ($n = 3$; $P = 0.26$). The milk pattern, casein pattern and combination pattern of AA increased the expression of αs1-casein and κ-casein genes significantly ($n = 3$; $P < 0.05$) compared with blood AA pattern. The milk pattern, casein pattern and blood pattern of AA upregulate β-casein gene expression significantly ($n = 3$; $P < 0.05$) compared with combination AA pattern. The milk AA pattern might increase major milk protein genes expression, perhaps, an appropriate AA pattern will play a role in milk protein synthesis.

Table 1. Percentage of amino acids in different patterns

AA, %	Blood	Milk	Combination	Casein
Tyr	2.18	5.67	6.30	6.63

T324 Evaluation of equations to predict body composition in Nellore bulls.

L. F. Costa e Silva,* S. C. Valadares Filho, E. Detmann, M. I. Marcondes, and P. P. Rotta, *Universidade Federal de Viçosa, Viçosa, Minas Gerais, Brazil.*

The equations developed by Hankins and Howe (1946), Valadares Filho et al. (2006), Marcondes et al. (2010) and Marcondes et al. (2011) were evaluate to predict the body composition from the 9-10-11th rib cut in Nellore bulls. These equations estimate the physical and the carcass chemical composition and empty body chemical composition. This experiment used a comparative slaughter technique. Thirty-seven Nellore bulls (14 mo old) with initial shrunk body weight of 259 ± 24.9 kg were used. The bulls were randomly divided into 3 groups: 5 bulls to the reference group, 4 bulls were fed at maintenance level and 28 bulls were fed ad libitum. The bulls fed ad libitum were separated into 4 groups, one of which was slaughtered every 42 d. The reference group was slaughtered at the start of the experiment. All the animals were fed with corn silage and concentrate (55:45). After slaughter, the 9–10–11th rib cut was dissected into muscle, fat and bone fractions. The remaining carcass was similarly dissected. The others parameters evaluated were: empty body weight, dressing percentage, visceral fat percentage and organ and viscera percentage. The regression was evaluated according to the following statistical hypothesis: H0: $\beta 0 = 0$ and $\beta 1 = 1$ and Ha: not H0. The equations obtained by Marcondes predicted correctly ($P > 0.05$) the carcass physical composition. However, the muscle and fat tissues were under- and overestimated ($P < 0.05$), respectively, by Hankins and Howe. The equations obtained by Marcondes predicted correctly ($P > 0.05$) the carcass and empty body chemical composition. The carcass water was underestimated ($P < 0.05$) by Hankins and Howe. The equations by Valadares Filho did not predict ($P < 0.05$) the carcass or empty body chemical composition. The carcass physical and chemical composition and empty body chemical composition can be predicted from the composition of 9-10-11th rib cut by equations obtained by Marcondes while the composition of these components cannot be predicted by Hankins and Howe in Nellore bulls.

Key Words: chemical composition, comparative slaughter, rib cut

T325 Performance of Holstein dairy cows under different feeding strategies in early lactation. M. Fajardo*[1], D. A. Mattiauda[1], A. Meikle[2], M. Carriquiry[1], J. Gil[2], G. Motta[1], G. Guala[1], G. Ortega[1], D. Pelaez[1], P. Sorhouet[1], F. Souza[1], and P. Chilibroste[1], *[1]Facultad de Agronomía, Universidad de la República, Montevideo, Uruguay, [2]Facultad de Veterinaria, Universidad de la República, Montevideo, Uruguay.*

The objective of this study was to determine milk yield, body condition score and live weight changes of multiparous Holstein dairy cows (n = 36) subjected to contrasting feeding strategies during the first 10 weeks of lactation. A complete randomized block design was used that included initial BCS and BLW (3.2 ± 0.2 and 731 ± 73.5 kg). Three treatments were compared: TMR: 100% Total mixed ration, G1: 50% TMR + 50% pasture (one grazing session), and G2: 50% TMR + 50% pasture (2 grazing sessions). All the treatments were offered 30kg DM cow/d. TMR cows were always confined. G1 cows grazed from 0700 to 1400 staying confined with access to TMR after pm milking. G2 cows grazed exactly as G1 and had another grazing session from 1600 to 2000, staying thereafter confined with access to TMR. The TMR offered had 151 ± 2.6 g/kg DM of CP, 342 ± 5.0 g/kg DM of NDF and 187 ± 3.5 g/kg DM of ADF. Data were analyzed with a mixed model with repeated measures (GLIMMIX, SAS 9.2). TMR cows produced more milk than G1 and G2 (36.5 ± 0.3 vs. 33.0 ± 0.3 and 33.3 ± 0.4 L/d, $P < 0.05$). G1 cows had higher milk fat content than cows in TMR, but did not differ from G2 cows (3.97 vs. 3.67 and 3.87%, ± 0.08 respectively; $P < 0.05$). Fat production was not significantly different between treatments (1.3 kg/day ± 0.03). Treatments did not differ in milk protein content (3.4 ± 0.06%) but TMR cows had higher milk protein production than G2 and G1 (1.2 vs. 1.1 and 1.1 kg ± 0.03 respectively $P < 0.05$). TMR cows differed from G2 in BCS but not from G1 (2.9, 2.7 and 2.8 ± 0.04 respectively; $P < 0.05$), and G1 tended to be different from G2 ($P < 0.13$). Treatment with one grazing session plus TMR (G1) achieved similar productive results as offering 100% TMR (TMR). On the other hand, treatment with 2 grazing sessions (G2) showed no productive advantages over G1 besides a lower BCS, probably due to the greater energy requirements for walking and/or grazing.

Key Words: autumn calving, nutrition, ruminants

T326 Effect of dietary cation-anion difference (DCAD) on beef tenderness. J. P. Schoonmaker,* K. T. Korn, K. N. Condron, C. N. Shee, M. C. Claeys, T. D. Nennich, and R. P. Lemenager, *Purdue University, West Lafayette, IN.*

The manipulation of acid-base balance has been extensively investigated as a means of altering calcium homeostasis and managing milk fever in dairy cows. A low pre-partum dietary cation anion difference (DCAD) increases urinary Ca, blood-ionized Ca, and responsiveness to Ca-homeostatic hormones. Very little attention, however, has been focused on the possibility of using a low dietary DCAD to increase muscle Ca availability, calpain activity, and meat tenderness of beef cattle. Thus, 90 Angus × Simmental crossbred steers were allotted by weight (590.1 ± 2.4 kg) and breed composition to 3 treatments (6 pens per treatment, 5 steers per pen) to evaluate the effects of DCAD on beef tenderness. Treatments were initiated 2 weeks before slaughter and consisted of 3 DCAD (mEq/100 g) concentrations: +16, 0, and −16. Hydrochloric acid treated soybean meal (PasturChlor, West Central, Ralston, IA) was added to diets to decrease DCAD and sodium bicarbonate was added to diets to increase DCAD. Basal diets (DM basis) were 62 to 64% corn, 6 to 9% soybean meal, and 20% corn silage and were formulated to contain similar concentrations of protein, energy and minerals, with the exception of sodium and chlorine. Performance before initiation of the study did not differ ($P > 0.22$) among treatments. Urine pH did not differ ($P > 0.57$) at the initiation of the study, but did decrease (linear and quadratic, $P < 0.02$) on d 7 (8.13, 7.69, 6.37) and d 14 (8.03, 7.66, 5.68) of the study as DCAD decreased from +16 to 0 to −16, respectively. ADG and feed efficiency responded quadratically ($P < 0.01$) to DCAD, increasing from +16 to 0 DCAD and decreasing from 0 to −16 DCAD. Hot carcass weight, dressing percent, fat thickness, longissimus muscle area, yield grade, marbling score, quality grade distribution, and 48 h muscle pH did not differ ($P > 0.16$) among treatments. In addition, DCAD did not affect ($P > 0.23$) Warner-Bratzler shear force among treatments after 7 and 21 d of aging. Although urine pH was decreased by lowering DCAD, potentially increasing calcium influx into muscle, beef tenderness was not affected.

Key Words: beef, DCAD, tenderness

T327 Performance of early lactation cows fed whole versus chopped sugarcane. J. E. P. de la Ossa*[1,2], R. Lana[1,2], and E. M. Balbino[1], *[1]Universidade Federal de Viçosa, Viçosa, MG, Brazil, [2]FAPEMIG, Viçosa, MG, Brazil, [3]CNPq, Viçosa, MG, Brazil.*

Eight crossbred Holstein-Gyr cows with 450 ± 30 kg body weight were used to evaluate the effect of whole sugar cane (WSC) compared with chopped sugar cane (CSC) on intake, milk yield and milk composition in early lactation dairy cows fed sugarcane plus 4 levels of supplement (600, 1200, 2400, and 4800 g/cow/day) containing 60% corn meal and 40% soybean meal as nitrogen source. One Latin square with 4 treatments based on level of concentrate comprised rations with WSC, and another Square comprised rations with CSC also differing in concentrates. Periods of 14 d consisted of 7 d of adaptation and 7 d of measurements. Dry matter and neutral detergent fiber (NDF) intakes decreased ($P < 0.05$) in WSC compared with CSC, with values of 25.12 kg/day versus 22.77 kg/day. Milk yield increased ($P < 0.05$) as a function of level of supplement, but not as a function of sugarcane processing. There was no significant difference ($P > 0.05$) for milk composition as a function of treatments. Therefore, sugarcane can be furnished in a whole form for dairy cattle after adaptation of ingestion, reducing production costs such as with machinery and labor, and without processing, the feed decreases losses by fermentation and increases life time of conservation in the feed bunk.

Key Words: chopped sugar cane, whole sugar cane

T328 The relationship of feed efficiency and visceral organ size in growing lambs fed a concentrate or forage-based diet.

R. A. Vraspir,* M. J. Ellison, K. M. Cammack, and A. M. Meyer, *Department of Animal Science, University of Wyoming.*

We hypothesized that a portion of individual differences observed for feed efficiency can be attributed to gastrointestinal tract (GIT) size, which would vary based on diet. Growing wethers (n = 77; 51.3 ± 1.2 kg BW) were fed a concentrate (CONC; 12.1% CP, 17.6% NDF, 2.98 Mcal/kg ME) or forage-based pelleted diet (FOR; 16.2% CP, 36.3% NDF, 2.31 Mcal/kg ME) for 49 d. Individual intake was measured with the GrowSafe^{TM} System to determine residual feed intake (RFI). The 20% most (low RFI, n = 8) and 20% least (high RFI, n = 8) efficient lambs from each diet were slaughtered (66.6 ± 2.3 kg BW; n = 32 total), and the viscera was dissected and weighed. Data were analyzed as a 2 × 2 factorial with RFI class (low vs. high RFI), diet type (FOR vs. CONC), and the interaction in the model. Organ mass was not affected ($P > 0.10$) by the RFI class x diet type interaction. Low RFI lambs tended to have greater ($P = 0.09$) pancreas and spleen mass than high RFI, although RFI class did not affect ($P > 0.15$) other organ actual (g) or proportional (g/kg BW) mass. Lambs fed FOR vs. CONC had greater ($P \leq 0.01$) actual and proportional reticulum, omasum, large intestine, and kidney mass and tended to have greater ($P \leq 0.09$) actual and proportional small intestine mass. However, CONC fed lambs had greater ($P \leq 0.05$) rumen, heart, liver, and proportional rumen mass than FOR fed lambs. All other visceral organs were unaffected ($P > 0.11$) by diet type. Proportional abomasum mass tended to be positively correlated ($P = 0.08$) with RFI, whereas pancreas and spleen mass tended to be negatively correlated ($P \leq 0.09$) with RFI. Intake was positively correlated ($P \leq 0.04$) with reticulum, omasum, abomasum, large intestine, kidney, and proportional omasum mass, and tended to be positively correlated ($P \leq 0.10$) with total GIT, small intestine, and proportional large intestine mass. Proportional spleen and heart mass tended to be negatively correlated ($P \leq 0.09$) with intake. Results of this study suggest that visceral organ size in growing lambs is more affected by diet type than individual feed efficiency.

Key Words: feed efficiency, feed intake, gastrointestinal tract

T329 Performance of Nellore young bulls grazing *Brachiaria brizantha* 'Xaraés' supplemented with different lipid sources.

A. L. S. Valente,* R. A. Reis, T. T. Berchielli, T. Borgui, I. P. Carvalho de Carvalho, and L. G. Rossi, *Sao Paulo State University, Jaboticabal, Sao Paulo, Brazil.*

Dietary supplementation with different lipids source is not a common practice in livestock production in Brazil. However, this alternative may increase the energy balance of the supplementation, and improve the animal performance. So, an experiment was conducted at the forage sector of the São Paulo State University, Jaboticabal – SP, to evaluate the effects of concentrate supplementation with different lipids sources on the intake and animal performance of grazing animal during the period rainy seasons. Ninety Nellore young bulls with average BW of 347 kg were used in completely randomized design with 5 treatment, and 2 replications (paddocks) with 9 animals in each one. Three periods of 28 d were analyzed by repeated measures. The animals were housed in *Brachiaria brizantha* 'Xaraés' pasture in continuous stocking rate grazing system and received one of the following supplements during the experimental period: ad libitum mineral (control) or 0.5 g/kg BW of concentrated supplements formulated with palm oil, linseed oil, soybean grain or Megalac E. All supplements presented the same content of crude protein, and total digestible nutrients (TDN), 260 g/kg DM, and 980 g/kg DM, respectively. The grazing animal behavior measure was taken during daytime (12 h) for 2 consecutive days. Supplements used did not affect the forage chemical composition; it was observed mean values of crude protein, neutral detergent fiber and acid detergent fiber of 89.4, 615.7, and 374.2 g/kg DM, respectively. Grazing time varied due to the supplements and periods ($P < 0.05$). Animals in the control treatment spent more time in grazing 5.7 h following for soybean grain and linseed oil treatment 4.5 h, and the animals in the palm oil treatment spent less time in grazing 3.7 h, and that Megalac E spent 4.1 h in grazing. There was effect of the treatments in the animals weight gain ($P < 0.05$). Animals of control group, and those supplemented with palm oil, soybean grain, linseed oil, and protected fat showed average daily gain of 0.724, 0.697; 0.780, 0.759, 0.864 g/day, respectively. Megalac E supplementation may improve animal performance.

Key Words: *Brachiaria*, lipid, Nellore

T330 Seminiferous tubule traits of lambs fed with cottonseed co-products (*Gossypium* ssp.).

T. Paim*[1], P. Viana[2], E. Brandão[2], S. Amador[2], T. Barbosa[2], C. Cardoso[2], A. Abdalla[1], C. McManus[3], and H. Louvandini[1], [1]*Center of Nuclear Energy in Agriculture, Piracicaba, SP, Brazil,* [2]*College of Agronomy and Veterinary, University of Brasília, Brasília, DF, Brazil,* [3]*Animal Production Department, University of Rio Grande do Sul, Porto Alegre, RS, Brazil.*

This study aimed to evaluate the influence of supplementation with cottonseed co-products on testis structure of lambs. Twenty-four Santa Inês lambs (5 mo old and mean live weight 20.6 ± 1.9 kg) were used. The lambs were housed in individual pens and received 4 treatments: 20% of DMI (Dry Matter Intake) whole cottonseed, 20% of DMI cottonseed meal with low oil (MEAL), 20% of DMI cottonseed meal with high oil (CAKE) and a control without use of cottonseed. The concentrate:forage proportion in diet was 60:40. Coast Cross hay (*Cynodon dactylon*) was used as forage, and ground corn was used in the remainder of the concentrate. At the end of experimental period, the animals were slaughtered and samples of testis collected. These samples were fixed in paraffin and contrasted with hematoxylin and eosin for light microscopy analyses. Twenty-five photos of each animal testis were taken. Tubule and lumen diameters of 5 seminiferous tubules were measured in each photo. Seminiferous epithelium thickness was obtained by difference between tubule and lumen diameters. ANOVA was performed with SAS to verify the influence of independent effects (treatment, tubule by photo, animal weight at slaughter and squared animal weight at slaughter) on seminiferous tubule measurements. A factor analysis was used to verify the relation between seminiferous tubule measures, sperm concentration, animal weight at slaughter and gossypol level on diet. Animal weight at slaughter had a significant influence on all seminiferous tubule measures. The animals from the CAKE group had the lowest tubule diameter, lumen diameter and seminiferous epithelium thickness, while the animals that received MEAL had the largest tubule diameter and seminiferous epithelium thickness. The factor analysis showed that heavier animals had larger tubules measurements, as expected. The gossypol level in diet was not related to seminiferous tubule measures. Therefore, feed containing cotton co-products did not have a direct effect on seminiferous tubule measurements. Supported by CNPq and FAPESP.

Key Words: male reproduction, nutrition, testis

T331 Fatty acid profile of meat from lambs fed with cottonseed co-products. T. Paim[1], P. Viana[2], E. Brandão[2], S. Amador[2], T. Barbosa[2], C. Cardoso[2], B. Berenchtein[1], C. McManus[3], A. Abdalla[1], and H. Louvandini*[1], *[1]Center of Nuclear Energy in Agriculture, Piracicaba, SP, Brazil, [2]College of Agronomy and Veterinary, University of Brasília, Brasília, DF, Brazil, [3]Animal Production Department, University of Rio Grande do Sul, Porto Alegre, RS, Brazil.*

The amounts and type of fats in animal products is a topic of frequent public discourse. This study evaluated the changes in fatty acid profile of meat from lambs fed with cotton co-products, as well as, the impact of these diets on carcass traits. Twenty 4 lambs (5 mo old and mean live weight of 20.6 ± 1.9 kg), which received 4 diets: whole cottonseed (40% of concentrate (C)), meal cottonseed (40% of C), high oil meal cottonseed (Cake) (40% of C) and a control group without cottonseed co-products, were used. The concentrate:forage proportion in diet was 60:40. Soybean oil was added to concentrate in control, meal and cake diets, aiming to equalize the ether extract. After 90 d, the lambs were slaughtered and carcass traits were measured. Then, meat samples of Longissumus dorsi muscle at 12th rib were taken for fatty acid profile analyses. Carcass traits and fatty acid profile data were analyzed using GLM and FACTOR procedures in SAS®. The animals that received meal showed a higher hot carcass weight, carcass yield and rib eye area, being significantly greater ($P < 0.05$) than those that received whole cottonseed. This demonstrated that cottonseed meal is a good protein alternative source for lambs. The treatments not differ in fat content and proportion, nor ether extract in 12th rib. The meat from the group that did not received cotton co-products had higher n-3 fatty acid content, higher desirable fatty acids and better n-6 to n-3 ratio compared with others. The meat from animals that received whole cottonseed showed higher saturated fatty acids, related, principally, to higher palmitic acid (C16:0) and stearic acid (C18:0) levels. Animals that received meal and cake had the highest values to vaccenic acid (C18:2 t11) and conjugated linolenic acid (C18:2c9t11), demonstrating that these diets can produce a meat with high levels of CLA, which is good to human health. Therefore, aiming to reduce feed cost by using these cotton products, the recommendation is that the more processed cottonseed co-products (meal and cake) must be preferred for use in ruminant feed rather than whole cottonseed. Supported by CNPq and FAPESP.

Key Words: carcass traits, conjugated linolenic acid, muscle

T332 Inclusion of urea in spineless cactus diets for Girolando steers. R. A. S. Pessoa*[1], R. da Silva Lima[2], W. G. do Nascimento[2], I. Ferraz[3], and P. C. Vasconcelos[2], *[1]Universidade Federal Rural de Pernambuco, Animal Science Department, Recife, Pernambuco, Brazil, [2]Universidade Federal Rural de Pernambuco, Unidade Acadêmica de Garanhuns, Garanhuns, Pernambuco, Brazil, [3]Instituto Agronômico de Pernambuco, Recife, Pernambuco, Brazil.*

The objective of this study was to evaluate the effect of the substitution of cottonseed meal by urea in diets for Girolando steers (5/8 Holstein-Zebu) on the intake, apparent digestibility of nutrients, weight gain, feed conversion and efficiency of microbial protein synthesis. Eighteen animals were used with approximately 320 kg live weight and 24 mo of age, kept in feedlot system and assigned to a randomized block design, established in accordance with the weight of animals, being 3 treatments and 4 blocks. The treatments were 3 urea levels (0.0, 1.5 and 3.0%) in substitution of cottonseed meal (23.0, 11.5 and 0.0%) in diets based on spineless cactus with approximately 12.0% of crude protein and 65.0% of total digestible nutrients. The control diet was composed of 60.0% of spineless cactus, 15.0% of sorghum silage, 0.0% of urea:ammonium sulfate mixture (9:1), 23.0% of cottonseed meal and 2.0% of mineral mixture, in dry matter basis The experimental period lasted 84 d divided into 3 periods of 28 d. The data were submitted to ANOVA using the SAS. The intake and digestibility of dry matter were not influenced ($P > 0.05$) by the inclusion of urea in the diets (average of 7.9 kg/day and 69.0%, respectively). However, there was observed higher ($P < 0.05$) nonfibrous carbohydrate intake and neutral detergent fiber digestibility for control diet (0.0% of urea), being 2.89 kg/day and 48.0%, respectively. The feed conversion and weight gain were higher ($P < 0.05$) for the treatments with 0.0 and 1.5% of urea (average weight gain of 0.92 and 0.86 kg/day, respectively). The efficiency of microbial protein synthesis did not differ ($P > 0.05$) between treatments (average of 115.0g of microbial crude protein/kg of total digestible nutrient). The partial replacement of cottonseed meal by urea did not alter the performance parameters of Girolando steers feed diets based on spineless cactus.

Key Words: nitrogen, *Opuntia ficus indica*, performance

T333 Levels of roughage supplementation with cottonseed hull for cattle grazing during the rainy transition season: Performance. A. J. Neto*[1], J. T. Zervoudakis[1], L. da Silva Cabral[1], L. K. Hatamoto-Zervoudakis[1], R. L. Galati[1], P. V. R. Paulino[2], R. P. da Silva[1], L. C. R. P. Silva[1], J. Q. Soares[1], and A. P. de Souza Borges[1], *[1]Federal University of Mato Grosso, Cuiabá, Mato Grosso, Brazil, [2]Federal University of Viçosa, Viçosa, Minas Gerais, Brazil.*

The objective was to evaluate levels of roughage supplementation with cotton hulls in the body weight of cattle grazing in the in the dry/rainy transition season on performance. Were used 20 Nelore steers with age and initial body weight average of 22 months and 366 kg, respectively. The experimental area consisted of four paddocks of 1.6 ha with *Brachiaria brizantha* 'Marandu' with forage mass for 1966.87 and potentially digestible dry matter of 1147.32 kg/ha. The experiment was structured in a completely randomized design in the levels of roughage supplementation with cottonseed hull as a function of body weight (BW) cattle, evaluated in relation to total weight gain and average daily gain (ADG) were: 3.6; 4.9 and 6.1 g / kg of the average body weight (BW). The roughage supplementation was given daily at 10 a.m. with the respective amounts: Cap1 - 1.5; Cap2 - 2.0 and Cap3 - 2.5 kg / animal and control animals (MM) were supplemented only with mineralized supplement (ad libitum). The performance was of 0.425 for MM and 0.438; 0.688 and 0.654 kg/animal/day for the respective levels of supplementation: 3.6; 4.9 and 6.1 g/kg of BW. There were differences ($P < 0.10$) between the levels of supplementation and the control group on average daily gain of animals, the level of 4.9 g/kg body weight, which provided better performance.

Key Words: coproducts, pasture, weight gain

T334 Blood cell and metabolic profile of Nellore bulls ranked by residual feed intake. K. K. G. Moreira[1], J. J. de Resende Fernandes*[1,4], T. P. Guimarães[1], E. A. Bento[3,4], E. Arnhold[1], H. F. Oliveira[1], M. D. de Freitas Neto[1,2], V. R. M. Couto[1], É. G. de Moraes[2], and L. F. N. Souza[2], *[1]Universidade Federal de Goiás, Goiânia, Goiás, Brazil, [2]Nelore Qualitas, Goiânia, Goiás, Brazil, [3]Instituto Federal Goiano, Rio Verde, Goiás, Brazil, [4]Conselho Regional de Medicina Veterinaria e Zootecnia, Goiânia, Goiás, Brazil.*

The objective of this study was to evaluate the possible differences in metabolic and blood profile among the classes of RFI (residual feed intake; los, medium and high) in Nellore bulls. Therefore, 30 animals (BW = 407.71 kg ± 34.71), with average of 24 mo of age, were used, and housed in individual pens. The animals were fed the same diet composed of 18.0% corn silage, 5.0% in natura sugarcane bagasse, 24.3% soybean hulls, 3.5% soybean meal, 46.8% sorghum, 0.8% urea and 1.6% mineral mixture. The animals were initially separated from a total of 120 in 3 treatments, high RFI (n = 10), medium RFI (n = 10) and low RFI (n = 10). RFI was calculated as the difference between observed and predicted feed intake based on LW 0.75 and average daily gain (ADG). Animals were classified as high RFI (>0.66 standard deviation - less efficient), medium RFI (±0.66 standard deviation), and low RFI (<0.66 standard deviation – more efficient). The results were analyzed by Pearson correlation using the statistical software R (2011) and mean comparisons were carried out by Tukey test at 5% probability level. No significant correlations ($P > 0.05$) were found among RFI and the variables erythrocytes and platelets; however, there were significant correlations ($P < 0.05$) for hematocrit, hemoglobin and leukocytes (0.38, 0.36 and −0.32, respectively). Regarding the biochemical profile, positive correlation was observed among RFI and total protein (TP) and total cholesterol (0.50 and 0.29, respectively ($P < 0.05$)). The RFI was not correlated ($P > 0.05$) with the other metabolic variables aspartate transaminase (AST), alkaline phosphatase (ALT), urea, creatinine, albumin (Alb) and gamma-GT (GGT). Among the classes of RFI (low, medium and high), the amount TP was lower for the group of animals with low RFI, which suggests an increased synthesis of tissue protein as plasma proteins play a fundamental role in this synthesis; the other variables did not differ among treatments.

Key Words: beef cattle, efficiency parameters, metabolism

T335 Carcass evaluation of subjected to feed restriction. A. R. C. Lima,* M. H. M. da Rocha Fernandes, I. A. M. de Almeida Teixeira, K. T. de Resende, and R. G. Aparecido, *Sao Paulo State University, Faculty of Agriculture and Veterinary Sciences, Jaboticabal, Sao Paulo, Brazil.*

Diet significantly affects costs of goat production, then alternatives to minimize the costs have been studied to evaluate if these alternatives can influence animal responses, such as carcass traits. One of the studied alternatives to minimize meat goat production costs is the use of feed restriction, then. The aim of this study was to evaluate the effect of feed restriction on carcass traits of 18 male crossbred (3/4 Boer 1/4 Saanen) goat kids, with initial BW of 20 ± 0.24 kg. The kids were randomly allocated to 3 levels of DMI: ad libitum (0%) and restricted to 30 and 60% of the ad libitum) within 6 groups (blocks). A group was slaughtered when the ad libitum treatment kid reached 35 kg BW. The hot carcass was obtained after separation of the hands and feet in the carpal metacarpal and tarsal metatarsal joint respectively, and the removal of the kidneys, kidney fat and diaphragm. The data were analyzed in complete randomized block Feed restriction had no effect on carcass biological yield percentage and loss by cooling, however hot carcass weight (0% = 17.4 kg, 30% = 14.2 kg, 60% = 10,1 kg), cold carcass weight (0% = 16.95 kg, 30% = 13.82 kg, 60% = 9.8 kg) and ribeye area (0% = 13.56 cm ^{3}, 30% = 12.10 cm ^{3}, 60% = 9.21 cm^3) decreased linearly ($P < 0.0001$) as level of feed restriction increased. Shoulder, neck and loin yields were not influenced by the level of feed restriction, on the other hand ribs yield decreased, while leg yield increased linearly with increasing level of feed restriction. It is concluded that increasing levels of feed restriction resulted in a reduction of hot and cold carcass weight, without affecting dressing percentage and cut yields, which are the main focus of the meat goat industry.

Key Words: Boer, intake level, prime cuts

T336 Carcass traits and meat quality of goats subjected to feed restriction. A. K. Almeida,* L. S. Fonseca, D. C. Soares, S. P. Silva, I. A. M. A. Teixeira, K. T. Resende, and H. Borba, *Universidade Estadual Paulista, UNESP, Jaboticabal, São Paulo, Brazil.*

The objective of this study was to evaluate the effect of feed restriction on carcass characteristics and meat quality of female, intact and castrated male goats. A total of 51 dehorned Saanen goats (18 intact males, 18 castrated males, and 15 females) were used. They were randomized allocated to one of 3 treatments (0, 25 and 50% restriction), the dry matter intake for the 0% restriction treatment animals determined the dry matter intake for the animals in the 25% and 50% restriction treatment. When the animals in the 0% restriction treatment group reached 44.1 ± 1.95 kg BW, the animals in the 25% and 50% restriction treatment groups were also slaughtered. After skinning and evisceration the hot carcass weight (HCW) was determined, the carcasses were placed in a chilled room for 24 h and chilled carcass weight (CCW) recorded. The carcasses were cut longitudinally into 2 halves and the left half was sectioned into retail cuts: neck, shoulder, brisket, 1–5 rib, 6–13 rib, chump and leg. The chump was stored for later analysis, after defrosting, the measures of pH, color (L* a* b*), shear force and cooking losses were performed. The data were analyzed as a completely randomized blocks design in a factorial scheme. Dressing percentage was not affected by feed restriction (mean of 45.9 ± 1.98). Chilling losses (g/kg HCW) were not affected by feed restriction (mean of 34.2 ± 3.14 g/kg HCW). Females showed greater subcutaneous fat deposition (1.3 ± 0.12 mm) then intact (0.7 ± 0.13 mm; $P < 0.001$) and castrated males (0.9 ± 0.11 mm; $P = 0.01$). The retail cuts evaluated (g) were affected by feed restriction and intact males presented heavier 1–5 rib ($P = 0.01$) and neck ($P < 0.001$) than females and castrated males, as result of sexual dimorphism. Color lightness (L*) and pH was influenced by the sex ($P = 0.03$ and $P = 0.04$, respectively). On the other hand meat redness (mean of 17.6 ± 0.38) and yellowness (mean of 6.3 ± 0.22), shear force (2.3 ± 0.08) and cooking losses (32.8 ± 1.69) were not affected by feed restriction neither sex. Despite of the changes caused by the level of restriction on goats BW, the extension of the changes did not affect goat meat quality. FAPESP process number: 2010/02482–4

Key Words: gender, kids, nutrition plan

T337 The relationship between feed efficiency and pancreatic α-amylase and trypsin activity in growing lambs. F. E. Doscher*[1], A. M. Meyer[2], M. J. Ellison[2], K. M. Cammack[2], and K. C. Swanson[1], [1]*North Dakota State University, Fargo,* [2]*University of Wyoming, Laramie.*

The objective of this study was to examine pancreatic protein, as well as α-amylase and trypsin activities in lambs fed concentrate- or forage-based diets with differing feed efficiency as measured by using residual feed intake (RFI). Seventy-seven growing wethers (51.3 ± 1.2 kg BW) predominantly of Rambouillet, Suffolk or Hampshire breeds were fed either an ad libitum concentrate- (CONC; corn-based) or forage-based (FOR; alfalfa- based) pelleted diet for a period of 49 d. Individual feed intake was measured using the GrowSafe Feed Intake system. Residual feed intake was calculated as the actual feed intake – expected feed intake (expected feed intake calculated from regressing metabolic midweight and ADG on actual DMI). The lambs were then ranked based on their RFI and the 20% most efficient (n=8) and 20% least efficient (n=8) lambs from each diet type (forage or concentrate) were slaughtered. The pancreas was removed and weighed, and a tissue sample was taken and immediately flash-frozen on dry ice. The sample was stored at −80°C until further analysis for total protein concentration and trypsin and α-amylase activity. Data were analyzed as a completely randomized design with a 2 × 2 factorial arrangement of treatments with RFI class, diet type, and the interaction in the model. No RFI × diet interactions (P > 0.10) were observed. Pancreatic weight (g) was greater (P = 0.09) in low RFI than high RFI lambs. Pancreatic protein (mg/g, g/pancreas, and mg/kg of BW), pancreatic α-amylase activity (U/g, KU/pancreas, and U/kg of BW), and pancreatic trypsin activity (U/kg of BW, U/pancreas, and U/kg of BW) did not differ (P > 0.10) between low and high RFI lambs. These results suggest that pancreatic weight may be greater in lambs with improved feed efficiency (low RFI), although α-amylase and trypsin activity are not associated with changes in feed efficiency in lambs fed concentrate- or forage-based diets.

Key Words: growing lambs, feed efficiency, pancreatic enzyme

T338 Effect of zinc concentration on performance and carcass characteristics of feedlot steers.

E. Caldera*[1], J. J. Wagner[1,2], K. L. Neuhold[1], G. I. Zanton[3], K. S. Sellins[1], and T. E. Engle[1], [1]*Colorado State University, Fort Collins,* [2]*Southeast Colorado Research Center, CSU, Lamar,* [3]*Novus International Inc., St. Charles, MO.*

Three-hundred sixty cross-bred steers (348.1 kg ± 28.9) were utilized to investigate the effects of Zn concentration on performance and carcass characteristics of feedlot steers. Steers were blocked by weight and randomly assigned to 1 of the 5 supplemental Zn treatments (8 pens per treatment; 9 hd per pen). Treatments consisted of: 1) Control (CON; 360 mg Zn/hd/d from $ZnSO_4$); 2) Methionine CON (360 mg Zn/hd/d from $ZnSO_4$ + MHA to equalize 2-hydroxy-4-(methylthio) butanoic acid (HMTBa) across all treatments; MHA contains 84% HMTBa and 12% Ca; 5.4 g/hd/d of HMTBa total); 3) 360 Zn (360 mg Zn/hd/d from Zn-HMTBa + MHA); 4) 720 Zn (720 mg Zn/hd/d from Zn-HMTBa + MHA); and 5) 1080 Zn (1080 mg Zn/hd/d from Zn HMTBa). All steers were fed a typical high concentrate steam-flaked corn based finishing diet twice daily. Steers were individually weighed on d −1, 0, 144, and 145 and pen weighed on d 28, 56, 84, and 111. Ractopamine HCl was fed for the final 29 d of the finishing period to all treatments. On d 145, steers were transported to a commercial abattoir for slaughter. Initial and final body weight, ADG, DMI, and feed efficiency (g/f), were similar across treatments. However, there was a trend ($P < 0.07$) for ADG to be increased when MHA® was added to the control diet when compared with 360 Zn, 720 Zn, and 1080 Zn treatments (4.01, 3.81, 3.79, and 3.93 ± 0.08, respectively). Fat thickness, longissiumus dorsi area, hot carcass weight, KPH, marbling score, and dressing percentage were similar across treatments. Steers receiving 1080 Zn had a greater ($P < 0.01$) yield grade compared with steers receiving 360 Zn (2.99 vs. 2.76 ± 0.08; respectively). There was a trend ($P < 0.07$) for steers receiving MHA® to have a greater yield grade compared with controls (2.82 vs. 2.67 ± 0.08; respectively). These data indicate that under conditions of this trial, increasing Zn concentration in the diet above NRC recommendations has little impact on performance, however, may impact lipid partitioning in steers.

Key Words: feedlot performance, ractopamine HCl, zinc

T339 Effects of feeding corn- or legume/grass silage-based diets on ruminal bacteria and archaea communities.

A. Lettat,* F. Hassanat, and C. Benchaar, *Agriculture and Agri-Food Canada, Dairy and Swine Research and Development Centre, Sherbrooke, QC, Canada.*

Nine lactating cows (DIM = 75 ± 19; BW = 688 ± 66 kg) were used in a triple replicated 3 × 3 Latin square (31-d periods, 14-d adaptation) to examine the effects of replacing legume/grass silage with corn silage in the TMR on bacteria and archaea communities. Cows were fed (ad libitum) TMR (60:40, forage:concentrate ratio) with the forage portion being either legume/grass silage (0% CS), corn silage (100% CS) or a 50:50 mixture (50% CS). Total rumen content was sampled before and 4h after feeding and used for RNA extraction to target the metabolically active microbes. Changes in bacteria and archaea communities were monitored by quantitative and length heterogeneity PCR (qPCR and LHPCR) by targeting the *rrs* (bacteria and archaea) and *mcrA* (archaea) genes. To determine treatments effects, data were analyzed by the MIXED procedure of SAS with Tukey's adjustment. Significance was declared at $P \leq 0.05$. Quantitative PCR revealed that total bacteria, *Prevotella* spp. and archaea densities were greatest for 100% CS compared with 0 and 50% CS diets ($P < 0.05$), whereas the cellulolytic bacteria *F. succinogenes* and *R. albus* as well as the lactate-utilizer bacterium *M. elsdenii* populations remained similar among diets. Similarly archaea population number was greatest for 100% CS compared with 0% CS ($P < 0.05$) and 50% CS ($P < 0.1$), when the *mcrA* gene was targeted. The preliminary fingerprinting (LHPCR) results revealed that the diets changed the microbial structure. In a companion study, feeding 100% CS was associated with a decrease in enteric CH_4 emissions. This is in agreement with the increase in *Prevotella* spp. that favors propionate production which is a concurrent sinks to methanogenesis. On the contrary, the increase in archaea population while CH_4 production was reduced with 100% CS clearly demonstrates that CH_4 production is not directly linked with the number of archaea (*rrs* gene) or their activity (*mcrA* gene). As a conclusion, quantification of both *rrs* and *mcrA* genes is not accurate enough to reflect changes in rumen methanogenesis. Characterization of the community structure could bring more accurate information.

Key Words: archaea, methanogenesis, rumen

T340 Biochemical blood parameters and liver enzymes of Saanen dairy goats fed with diets containing tannin and polyethylene glycol supplement.

A. Rahimi[1], A. A. Naserian[1], R. Valizadeh[1], A. Tahmasbi[1], B. Saremi*[2], and A. R. Shahdadi[3], [1]*Ferdowsi University of Mashhad, Mashhad, Khorasan Razavi, Iran,* [2]*Institute of Animal Science, Physiology & Hygiene Unit, University of Bonn, Germany,* [3]*Agricultural Sciences & Natural Resources University of Gorgan, Gorgan, Golestan, Iran.*

Consumption of feeds containing tannins might lead to lower absorption of nutrients such as glucose and amino acids into the blood. Polyethylene glycol (PEG) reacts preferentially with condensed tannins and prevents the formation of tannin-protein complexes, therefore could be increase absorption of nutrients into the blood. In this study, 9 multiparous dairy goats after the peak of lactation were used in a 3 × 3 Latin square design with 21-d periods, including 14 d of adaptation followed by 7 d of sampling. The individual animals randomly distributed into metabolic cages to evaluate the effect pistachio hull (PH, source of tannin) and PEG (source of tannin binding) on the blood biochemical parameters. Three treatments were formulated: T1) Control, without PH, T2) 30% PH (DM basis) that provided 18.1 g condense tannin per kg DM of diet and T3) 30% PH + 1% PEG (DM basis). In T2 and T3, PH was replaced with alfalfa hay. Blood samples were taken from the jugular vein before and 3 h after morning feeding. Data were analyzed as a repeated measurement design using PROC MIXED of SAS ($P < 0.05$). BUN (Blood Urinary Nitrogen) was significantly decreased at T2 and was compensated by addition of PEG in T3. Plasma concentration of triglycerides in T2 and T3 was higher than control, although significantly in T3. There were no differences between plasma concentrations of glucose, total protein, albumin, and cholesterol. Liver enzymes such as alanine aminotransferase (ALT) and aspartate aminotransferase (AST) were stable. In conclusion, the negative effect of tannins on nitrogen metabolism can be covered by PEG supplementation.

Table 1.

	Experimental diets

T341 Levels of concentrate for crossbred Holstein-Zebu cows under grazing. C. P. Ghedini[1], R. P. Lana[1], A. S. Oliveira[2], J. Perottoni[4], D. C. Abreu*[1], R. L. Albino[1], J. E. P. de la Ossa[1], R. M. Paula[1], P. E. P. Barros[3], and F. G. Silva[1], *[1]Universidade Federal de Viçosa, Viçosa, MG, Brazil, [2]Universidade Federal do Mato Grosso, Sinop, MT, Brazil, [3]Universidade Federal de Lavras, Lavras, MG, Brazil, [4]Universidade Federal de Santa Maria, Santa Maria, RS, Brazil.*

This study investigated the effects of increasing levels of concentrate on milk yield and composition in lactating crossbred dairy cows. Eight crossbred Holstein-Zebu cows (second or third parity; BW = 493 ± 22kg; DIM = 110 ± 82) in pasture were distributed in 2 4x4 Latin squares, in 4 periods of 14 d (samples collected on the last 7 d of each period). All cows were fed on tropical pasture during the rainy season (*Brachiaria decumbens* with 70% of NDF and 8% of CP) as a foraging source (ad libitum) and 4 levels of concentrate (0.6, 1.2, 2.4 and 4.8 kg/day/cow) with 24% of crude protein. The results were analyzed using Minitab. None of the 4 levels of concentrate had any affect on milk production ($P > 0.05$), milk composition ($P > 0.05$), or body weight ($P > 0.05$) (Table 1). This suggests that crossbred Holstein-Zebu under grazing can meet their nutritional demand with only pasture supply and 0.6 kg/day of concentrate with 24% of crude protein in the rainy season, because higher levels of concentrate did not increase milk production, milk composition, or body weight. Supported by Fundação de Amparo à Pesquisa do Estado de Minas Gerais (FAPEMIG) and CNPq.

Table 1. Milk yield and milk composition as a function of increased concentrate levels for crossbred Holstein-Zebu in tropical pasture

	Concentrate (kg/d/cow)				Effect (*P*-value)

T342 The relationship between feed efficiency traits and fertility in young beef bulls. B. J. Awda*[1], S. P. Miller[1], Y. R. Montanholi[1], G. Vander Voort[1], T. Caldwell[1], M. M. Buhr[2], and K. C. Swanson[3], *[1]Department of Animal & Poultry Science, University of Guelph, Guelph, ON, Canada, [2]Department of Animal and Poultry Sciences, College of Agriculture & Bioresources, University of Saskatchewan, Saskatoon, SK, Canada, [3]Department of Animal Sciences, North Dakota State University, Fargo.*

The objective of this study was to examine the relationship between feed efficiency traits and bull sperm fertility (sperm motility, viability and scrotal circumference (SC)). From a total of 328 crossbred beef bulls that were subjected to a performance test (112 d), SC was measured and semen collected from 110 bulls (average age ± SE = 417.28 ± 2.55 d). Sperm were extended, cooled, and frozen in liquid nitrogen. Two residual feed intake (RFI) measures were considered with different prediction models for dry matter intake (DMI), RFI_{Koch} included size and growth rate and RFI_{bkft} included the additional adjustment for backfat thickness (BKFT). At the end of the experiment, bulls were slaughtered and a complete carcass separation of a 21-cm rib section conducted. Data were analyzed using the CORR procedure and Tukey-Kramer multiple comparisons to test for trait effect. Body weight (BW) was positively correlated with SC ($P < 0.001$) and DMI was positively correlated ($P \leq 0.05$) with sperm viability, motility, and SC. Feed to gain ratio (F:G) was positively correlated with sperm viability, and progressive motility ($P \leq 0.01$). RFI_{Koch} was positively correlated with sperm viability ($P < 0.05$). RFI_{bkft} was positively correlated with sperm viability and motility ($P \leq 0.05$). The percentage of subcutaneous, intramuscular, and total fat relative to total rib weight were positively correlated with SC ($P < 0.01$). BKFT was positively correlated with sperm viability ($P < 0.01$). Sperm viability, motility and progressive motility of the 10 bulls with the greatest RFI_{Koch} (Hi-RFI_{Koch}) were greater than that of the 10 bulls with the lowest RFI_{Koch} (Lo-RFI_{Koch}; $P < 0.05$, 0.01, and 0.05 respectively). Sperm motility ($P < 0.01$), progressive motility and SC ($P < 0.05$) of the 10 bulls with the greatest RFI_{bkft} (Hi-RFI_{bkft}) were greater than that of the 10 bulls with the lowest RFI_{bkft} (Lo-RFI_{bkft}). F:G for Hi-RFI_{Koch} or Hi-RFI_{bkft} was greater ($P < 0.005$ and 0.05 respectively) than that of Lo-RFI_{Koch} or Lo-RFI_{bkft} groups. In summary, these data indicate that the young beef bulls in this experiment with greater efficiency (low RFI, Koch and bkft) and F:G have decreased sperm motility, viability and SC.

Key Words: beef cattle, fertility, RFI

T343 Influence of tannins extract addition on feedlot-performance of bulls fed sorghum-based diets. R. Barajas*[1], B. J. Cervantes[2], M. A. Espino[1,3], A. Camacho[1], M. Verdugo[1], L. R. Flores[1], S. C. Aréchiga[1], J. J. Lomeli[1], and J. A. Romo[1], *[1]FMVZ-Universidad Autonóma de Sinaloa, Culiacán, Sinaloa, México, [2]Ganadera Los Migueles S.A. de C.V., Culiacán, Sinaloa, México, [3]Pronutrient Developers, León, Guanajuato, México.*

Eighty *Bos taurus* × *Bos indicus* bulls 341 kg were used to determine the influence of tannins extract addition on feedlot-performance of bulls fed sorghum-based diets. Next day after arrival to the feedlot, bulls were weighed and blocked by initial weight, and in groups of 5 were placed in 16 ground floor pen (6 × 12 m). In agreement with a complete randomized block design, in each block, bulls were randomly assigned to one of next treatments: 1) Feeding with a finishing diet containing ground sorghum grain 61.83%, corn dry distiller grain 13.66%, peanut meal 1.77%, sugar-cane molasses 8.57%, mineral premix 2.86%, and corn straw 11.31% (Control); or 2) Diet similar to Control, added with

0.3% (dry matter basis) of a tannins extract (TE). Tannins extract was supplied as ByPRO (Pronutrient Developers; Mexico), a premix that contains 72% of a condensed (Quebracho tree) and soluble (chestnut) tannins-blend. In pens assigned to TE treatment, the corresponding amount of tannins extract was dispersed in 1 kg of ground sorghum that used as carrier and top dressed delivery in the feed-bunk. Pens in Control treatment received daily 1 kg of ground sorghum to equilibrate feeding conditions. Diet was offered ad libitum. Bulls were weighed in d 1 and 56. Day 28 blood samples were taken from jugular vein for plasma urea nitrogen (PUN) determination. Mean daily tannins extract intake was 33.6 g by bull, equivalent to 0.28% of the dietary DMI. At end of the experiment TE-fed bulls were 2.13% heavier ($P = 0.06$) than Control (452.13 vs. 461.75 kg). TE supplementation increased ($P = 0.05$) average daily gain 9.17% (1.972 vs. 2.153 kg/d). Tannin extract improved ($P = 0.02$) DMI 6% DMI (11.44 vs. 12.13 kg/d). Feed efficiency was not affected by treatments ($P = 0.30$). TE decreased ($P = 0.04$) the PUN concentration in 18% with mean values of 15.3 and 12.5 mg/dL for TE and Control bulls, respectively. Results suggest, that feeding an extract of condensed and soluble tannins in low dosage proximate to 0.3% of dietary DM, decreases PUN and increases feedlot-performance of bulls even when they are fed sorghum-based diets.

Key Words: bulls, feedlot-performance, tannins

T344 Performance of milking crossbred cows under pasture as a function of levels of concentrate in the diet.

D. C. Abreu*[1], R. P. Lana[1], A. S. Oliveira[2], C. P. Ghedini[1], R. M. Paula[1], R. L. Albino[1], F. G. Silva[1], and E. M. Balbino[1], *[1]Universidade Federal de Viçosa, Viçosa, MG, Brazil, [2]Universidade Federal do Mato Grosso, Sinop, MT, Brazil.*

The effects of 4 levels of concentrate (1.0, 1.5, 2.0 and 2.5 kg/cow/day) with 24% crude protein on performance of milking cows were evaluated. Four crossbred Holstein-Zebu cows with 453 ± 35 kg were distributed in a 4 × 4 Latin square in 4 14-d periods for evaluation of effects of treatments. The experiment was conducted on brachiaria grass (*Brachiaria decumbens*) pasture in the rainy season and the concentrates consisted of corn meal and soybean meal. The milk production, milk components, and body weight were not affected ($P > 0.05$) by levels of concentrate (Table 1). Cows on pasture during the rainy season and producing 11 kg of milk/day can receive 1.0 kg/day of concentrate. Supported by Fundação de Amparo à Pesquisa do Estado de Minas Gerais (FAPEMIG) and CNPq.

T345 Effect of supplementation of tannin-extract in corn silage based-diets on performance of growing bulls under commercial feedlot conditions.

M. A. Espino[1,2] and R. Barajas*[2], *[1]Pronutrient Developers, León, Guanajuato, México, [2]Facultad de Medicina Veterinaria y Zootecnia, Universidad Autónoma de Sinaloa, Culiacán, Sinaloa, México.*

Three hundred and 14 *Bos indicus* × *Bos taurus bulls* 253.24 ± SE 10.20 kg were involved in an experiment to determine the effect of tannin-extract supplementation in corn silage based-diets on performance of growing bulls under commercial feedlot conditions. The study was conducted simultaneously in 3 feedlot yards in the State of Sinaloa in the Northwest of Mexico. In feedlot 1, 122 bulls were randomly placed in 2 ground floor pens; in feedlot 2, 120 bull-calves were allotted in 2 ground floor pens; and in feedlot 3, 72 bulls were positioned in 2 ground floor pens, in the 3 feedlots pens size was proximately 25 × 30 m, diets contained 40% of corn-silage, and dry-ground sorghum grain. Each feedlot integrated by 2 pens constituted a block, and the pen was considered as the experimental unit. In a completely randomized block design, inner each block, pens were randomly assigned to receive one of 2 dietary treatments: 1) Regular growing diets of the feedlot yard (Control); or 2) Diet similar to control supplemented with a tannin-extract (TE). Tannin-extract was supplied as ByPRO (Pronutrient Developers; Mexico), a premix that contains 72% of a condensed (Quebracho tree) and soluble (Chesnutt) tannin-blend, and was included in proportion equivalent of 0.3% of dietary DM. The animals were weighed at the beginning (d 1) and at re-implant time, that mean was 57 d (47, 61 and 63 d for feedlot 1, 2 and 3, respectively). Results of ANOVA indicated that final weight was not affected by treatments ($P = 0.14$), period weight gain was 5.4% higher ($P = 0.05$) in Bulls that received tannin with mean values of 93.36 vs. 98.37 kg for Control and TE, respectively. Average daily gain was increased ($P < 0.01$) 4.1% by tannin-extract supplementation, with means of 1.659 vs. 1.727 kg/d for Control and TE, respectively. Dry matter intake and feed efficiency were not altered by treatments ($P > 0.15$). It is concluded that tannin-extract supplementation improves feedlot performance of growing bulls fed corn silage-sorghum grain based-diets, under commercial feedlot conditions.

Key Words: growing cattle, performance, tannin

T346 Effect of pasture type and dietary lipid supplementation on animal performance, carcass composition and fatty acid composition of muscle and adipose tissue in lamb.

N. S. Brooks*[1], J. L. Duynisveld[3], D. M. W. Barrett[1], Y. A. Papadopolous[1,4], J. Wort[2], A. H. Fredeen[1], and K. E. Glover[1], *[1]Nova Scotia Agricultural College, Truro, NS, Canada, [2]AgraPoint, Truro, NS, Canada, [3]Agriculture and Agri-Food Canada, Nappan, NS, Canada, [4]Agriculture and Agri-Food Canada, Truro, NS, Canada.*

Altering the fatty acid content of meat and other agricultural animal products has potential to benefit human health and create niche marketing opportunities for producers. The objective of this study was to determine the effects of red clover (RC) and tall fescue (TF) pasture types as well as different dietary lipid supplements on animal performance, carcass composition, and fatty acid content of muscle and subcutaneous adipose tissue (subQ) of the market lamb. Thirty-two Suffolk-cross ram lambs were randomly assigned to 1 of 2 pasture types for approximately 12 wk. Lambs were removed from pasture, transitioned to hay and grain and gradually introduced to 1 of 4 lipid supplements [soybean oil (SBO), 50% *c*9*t*11 and *t*10*c*12 conjugated linoleic acid (CLA) isomers + 50% SBO (C+S), enriched fish oil (FO) or control (no supplement)], receiving

50mL/d for 2 wk before slaughter. Lambs assigned to RC had 38.9% ($P \leq 0.01$) greater weight gains on pasture, 8.52% ($P \leq 0.08$) higher carcass weights and 20.7% ($P \leq 0.04$) higher fat depth measurements at the twelfth rib, when compared with lambs on TF. Lipid treatment had significant effects on carcass weight (SBO: 20.8, C+S: 21.6, FO: 19.6 and control: 21.7kg; $P \leq 0.001$). Fat depth at the twelfth rib was significantly affected by pasture type (RC: 11.9, TF: 9.42mm; $P \leq 0.05$) and lipid supplement (SBO: 10.5, C+S: 11.8, FO: 9.5 and control: 10.8mm; $P \leq 0.1$). In comparison to TF, RC tended to increase the fat content of the *longissimus dorsi* muscle from 11.3 to 12.3% ($P \leq 0.1$) while lipid treatment had no effect. There were significant effects of pasture on EPA (eicosapentaenoic acid) content of muscle (RC: 2.14%, TF: 1.61%; $P \leq 0.06$) and EPA and DHA (docosahexaenoic acid) content of subQ (RC: 0.08%, TF: 0.16%; $P \leq 0.03$ and RC: 0.10%, TF: 0.24%; $P \leq 0.05$, respectively), 5 wk post grazing. With no supplemental lipid, the EPA and DHA content of muscle and subQ tended to be greater in lambs that had grazed RC. Lipid supplementation significantly affected the EPA and DHA content of both tissues and the CLA content of subQ.

Key Words: lamb, pasture species, polyunsaturated fatty acids

T347 The effect of diet on feed intake traits and relationships with carcass traits in sheep.

M. J. Ellison,* R. R. Cockrum, K. W. Christensen, R. A. Vraspir, L. Speiser, W. J. Means, A. M. Meyer, and K. M. Cammack, *Department of Animal Science, University of Wyoming.*

The objectives of this study were to 1) determine the effects of diet on feed intake traits, and 2) determine the relationship of residual feed intake (RFI) with carcass characteristics in lambs fed either a concentrate or forage-based diet. Growing wethers (initial BW = 51.3 ± 1.2 kg; n = 77) of Rambouillet, Hampshire, and Suffolk breed types were randomly allocated to receive a concentrate (CONC; 50% corn, 31% wheat middlings; 91.6% DM, 12.1% CP, 17.6% NDF, 2.98 Mcal/kg ME; n = 39) or forage-based (FOR; 67.7% alfalfa, 27.5% wheat middlings; 92.3% DM, 16.2% CP, 36.3% NDF, 2.31 Mcal/kg ME; n = 38) pelleted diet. Individual feed intake was measured by the GrowSafe System for 49 d, and BW was recorded weekly. The 20% most (n = 8) and the 20% least (n = 8) efficient wethers from each diet (n = 32 total) were slaughtered, and carcass data were recorded. The MIXED procedure of SAS was used to determine the effect of diet on feed intake, ADG, and G:F using data from all wethers (n = 77), and the effects of diet, RFI class (most or least efficient), and their interaction on carcass traits using data from selected wethers (n = 32); breed and pen were included as random effects. The CORR procedure was used to determine relationships between RFI and carcass characteristics. Overall, feed intake of CONC wethers varied less ($\sigma^2 = 0.08$) than intake of FOR wethers ($\sigma^2 = 0.21$); variation in ADG and RFI did not differ across diets. Feed intake and ADG were greater ($P < 0.001$) in FOR fed compared with CONC fed wethers, although G:F was not affected by diet type ($P = 0.23$). Boneless cut percentage tended ($P = 0.10$) to be greater in FOR versus CONC wethers; there were no other effects ($P > 0.13$) on carcass measures. Residual feed intake and USDA quality grade tended ($P = 0.10$) to be positively correlated, but no other relationships ($P > 0.17$) between RFI and carcass measures were found. These data suggest that feed intake and ADG are affected by diet type, and that greater variation in feed intake is associated with a forage-based pelleted diet. Furthermore, selection for RFI should not unfavorably affect carcass traits in sheep.

Key Words: carcass, residual feed intake, sheep

T348 Effects of roughage level and corn processing method on finishing performance of Nellore bulls.

M. Caetano*[1], R. S. Goulart[2], P. M. Rizzo[1], S. L. Silva[3], P. R. Leme[3], J. S. Drouillard[4], and D. P. D. Lanna[1], *[1]University of Sao Paulo, ESALQ, Piracicaba, SP, Brazil, [2]North Dakota State University, Fargo, [3]University of Sao Paulo, FZEA, Pirassununga, SP, Brazil, [4]Kansas State University, Manhattan.*

The objective of this study was to investigate the optimal level of NDF from forage (NDFf) for finishing *Bos indicus* cattle with high-concentrate, corn-based diets. Nellore bulls (n = 112; 384.1 ± 29.5 kg) were used in a randomized complete block design in a 4 × 2 factorial arrangement. Four NDFf levels from sugarcane silage (3, 8, 13 and 18% of diet DM) were evaluated for 2 corn processing methods (CPrc): high moisture corn (HMC) and finely ground dry corn (FGC). Animals were offered ad libitum access to diets delivered twice daily in individual pens. Sugarcane silage contained 64.0% NDF, corn had 77.2% vitreousness, and corn geometric particle sizes were 1.30 and 5.84 mm for FGC and HMC, respectively. Bulls were adapted to the finishing diet over a 21-d period and fed a total of 81 d. To determine fecal starch (FS) concentration, each animal was sampled by rectal palpation on d 46 and 74 of the feeding period. The first derivative was solved of a 2nd order polynomial to determine optimal NDFf level. There was a quadratic effect of NDFf ($P < 0.01$) on final BW and ADG, with 13% NDFf yielding the highest final BW and greatest ADG ($P < 0.05$). Gain efficiency was 12.2% greater ($P < 0.01$) for animals fed HMC compared with those fed FGC (0.172 vs. 0.151, respectively). An interaction was observed between CPrc and NDFf ($P = 0.05$) for DMI; peak DMI occurred with 11.3 and 13.7% NDFf for FGC and HMC, respectively. An interaction between CPrc and NDFf also was observed for FS ($P < 0.05$). Bulls fed FGC had a linear decrease in FS with increasing levels of roughage, while there was no change in FS for bulls fed HMC with different levels of NDFf. Average FS were 13% and 3% for FGC and HMC, respectively. In conclusion, HMC improved growth efficiency of Nellore cattle by 12.2%, and the level of NDFf required to optimize performance was dependent on method of corn processing.

Key Words: fecal starch, feedlot, zebu

T349 Estimation of carcass and body fat composition using biometric measurements of grazing beef cattle.

N. F. De Paula[1,2], L. O. Tedeschi[2], M. F. Paulino[1], H. J. Fernandes[3], M. A. Fonseca*[1,2], V. R. M. Couto[1], I. F. S. Maciel[1], and D. M. Almeida[1], *[1]Universidade Federal de Viçosa, Viçosa, Minas Gerais, Brazil, [2]Texas A&M University, College Station, [3]Universidade Estadual do Mato Grosso do Sul, Aquidauana, Mato Grosso do Sul, Brazil.*

The objective with this study was to develop equations to predict carcass and body fat compositions using biometric measures (BM) and body postmortem measurements and to determine the relationships between BM and carcass fat (CF) and empty body fat (EBF) compositions of 44 animals. Animals were from different crossbred genetic groups (at least 50% Nellore breed) with initial age of 8.4±0.8 mo and shrunk BW (SBW) of 203±35 kg. Animals were grazing under tropical conditions and receiving supplementation. Animals were serially slaughtered in four groups at approximately 84 d (n = 4), 168 d (n = 8), 235 d (n = 8), and 310 d (n = 24) of growth. The day before each slaughter, animals were weighed and BM were taken, including hook bone width (HBW), pin bone width (PBW), abdomen width (AW), body length (BL), rump height (RH), height at withers (HW), pelvic girdle length (PGL), rib depth (RD), girth circumference (GC), rump depth (RuD), body diagonal length (BDL), and thorax width (TW). Other measurements included were subcutaneous fat (SF), internal fat (InF), intermuscular fat (ImF), carcass physical fat (CF), empty body physical fat (EBF), fat thickness in the 12th rib (FT), and 9 – 11th rib section fat (HHF). The stepwise procedure was used to select influential variables. The r^2 and the root mean square error (RMSE) were used to select the equations. Results indicated that BM in association with SBW were precise in accounting for the variability of SF (r^2 = 0.967 and RMSE = 0.94 kg), InF (r^2 = 0.984 and RMSE = 1.26 kg), CF (r^2 = 0.981 and RMSE = 2.98 kg), and EBF (r^2 = 0.985 and RMSE = 3.99). The RD and GC were important in predicting CF and EBF variations. Results also suggested that approximately 70% of body fat was deposited as CF and 30% as InF. Furthermore, the equation with HHF and SBW as predictor of CF and EBF was more adequate than using HHF by itself. We concluded that the prediction of CF and EBF composition of grazing animals can be improved with BM.

Key Words: Adipose tissue, body composition, modeling

T350 Performance of dairy kids submitted to different sources of goat milk replacers.

M. I. Marcondes,* L. S. Knupp, A. L. Silva, L. M. Carvalho, M. M. S. Santos, J. S. A. A. Santos, C. G. Vitor, and C. M. Veloso, *Universidade Federal de Viçosa, Viçosa, MG, Brazil.*

The health care and nutrition during suckling are essential for obtaining high productivity. During this period, attention should be given to diseases such as caprine arthritis encephalitis, which can be transmitted by goat milk and promote great morbidity, and decrease production. In addition, goat milk is expensive, and it is also the main source of income for producers. Thus, the objective was to evaluate the performance of kids fed alternative sources to replace goat milk. Forty-eight male kids of Saanen (24) and Alpine Brown (24) were randomly assigned to the treatments, and divided into age groups based on feeding milk for 60 or 90 d. They were offered coast-cross hay, starter ad libitum, and one liter of milk, or replacer, per day. The treatments were goat milk (GM), cow milk (CM), fermented cow colostrum (FC) and lactal - commercial milk replacer (LAC). The statistical analysis was conducted separately for animals fed 60 or 90 d. The data was analyzed as a completely randomized design, and a Tukey test was conducted when a P value less than 0.05 was observed. The average daily gain (ADG), empty body gain (EBG), and carcass weight gain (CWG) were measured after the slaughtering. Animals fed CM up to 90 d had greater ADG, and EBG, when compared with other treatments ($P < 0.05$). No differences were observed in CWG when comparing CM and GM ($P > 0.05$). The ADG, EBG, and CWG were not different for animals fed CM and GM up to 60 d ($P > 0.05$). The ADG in kg/day, for kids fed CM, GM, LAC, and FC up to 90 d, respectively, were 0.178, 0.145, 0.135, and 0.108; the EBG, in kg/day, were 0.143, 0.118, 0.106, 0.083, respectively, and the CWG, in kg/day, were, 0.075, 0.063, 0.055, 0.041, respectively. The ADG in kg/day, for kids fed CM, GM, LAC and FC up to 60 d, respectively, were 0.151, 0.135, 0.110, 0.070; the EBG, in kg/day, were 0.127, 0.113, 0.088, 0.051, respectively, and the CWG, in kg/day, were, 0.067, 0.060, 0.044, 0.023, respectively. In conclusion, kids fed CM have best performance, while feeding FC provide the worst performance. Supported by CNPq/INCT-CA.

Key Words: average daily gain, goat, suckling

T351 Early feeding of low levels of fat supplement suppresses postprandial in vitro rumen metabolism.

Q. Baptiste,* K. D’Souza, S. Simpson, S. Chavez, E. Nestor, M. Knights, and E. Felton, *West Virginia University, Morgantown.*

The effects of time of low level fat supplementation on postprandial rumen metabolism were investigated with in vitro rumen fermenters. All fermenters were fed a basal diet of orchard grass hay in unequal portions throughout the day, with the largest meals being fed at 0600h and 1800h. Soybean oil was the fat supplement and was fed to fermenters at 3% of total daily dry matter. Control (C) fermenters did not receive any supplement at any time. Three supplementation times were tested. Supplement was introduced to fermenters at either 0600h (AM), 1800h (PM), or in evenly divided doses at both times (AP). Fermenter effluent samples were collected at eight 3-h intervals over a 21-h period and were analyzed to determine concentration of rumen metabolites (ammonia nitrogen; [NH_3-N], and volatile fatty acid; [VFA]). Fermenter pH was measured each time effluents were collected. Individual VFA concentrations for each sample were summed and reported as total volatile fatty acid concentration [TVFA]. A quadratic postprandial time × treatment interaction ($P < 0.001$) was observed for ruminal pH, [NH_3-N] and [TVFA]. Feeding 3% soybean oil suppressed postprandial [TVFA] between 12 to 18 h (AM and PM) and [NH_3-N] between 15 to 18 h (AM), but did not have similar effects when oil was fed in split doses (AP). The magnitude of suppression in [TVFA] was apparently lower with PM treatment compared with AM treatment. Postprandial ruminal pH fluctuated greatest in AM treatment and least in PM treatment. In AM treatment, postprandial pH increased ($P < 0.01$) by 3h, remained elevated until 9 h, and then declined to lowest ($P < 0.01$) values by 18 to 21 h. In AP treatment, postprandial pH was generally flatlined except for lowest ($P < 0.01$) pH by 15h which was lower ($P = 0.04$) than the pH at 6 h. Control treatment postprandial pH essentially flat lined, but pH at 15 h was greater than at 12 h ($P = 0$ 0.04). Postprandial PM treatment pH was also flat lined. Therefore, feeding low levels of soybean oil (3%) with the first meal fed to in vitro fermenters suppressed postprandial in vitro rumen metabolism.

Key Words: fat supplement, in vitro rumen, metabolism

Ruminant Nutrition: Young Stock

T352 Effects of limiting concentrate during growing period on performance and plasma variables, and gene expression of hepatic gluconeogenic enzymes in Holstein calves. J. D. Lohakare,* N. K. Singh, J. Ghassimi Nejad, K. I. Sung, and S. L. Ingale, *College of Animal Life Sciences, Kangwon National University, Chuncheon, Kangwon Province, South Korea.*

This study elucidated the effects of limited concentrate feeding on growth, plasma profile, and gene expression of gluconeogenic enzymes in the liver of dairy calves. The study utilized 12 Holstein male dairy calves (100 d of age) divided into 2 groups of 6 calves each for 155 d. Control group calves received 1.8 kg/(calf × day) of concentrate, whereas calves in the restricted group only received 1 kg/(calf × day). Good quality forage (Timothy hay) was available for ad libitum consumption to both groups. Body weights (BW) were recorded at start and at fortnightly intervals. Blood samples were collected at start and approximately 50 d interval. On d 100 and 155, liver biopsies were collected from all animals in each group. The BW was not different between the groups at the end of the study, however, at 6,7,8 and 9 fortnights higher ($P < 0.05$) BW were recorded in the control group than the restricted. Total BW gain in the control group was 114 kg as opposed to 98.2 kg in restricted group that led to average BW gain of 736 g/day and 634 g/day in respective groups, and the differences were significant ($P = 0.051$). As planned, the calves in the control group had higher concentrate and lower forage intake than the restricted group. The plasma variables (glucose, total protein, albumin, urea nitrogen, alanine aminotransferase (EC: 2.6.1.2) and amylase (EC: 3.2.1.1)) were within the normal range in both groups, but aspartate aminotransferase (EC: 2.6.1.1) was higher ($P < 0.05$) in control than restricted group and plasma triglycerides tended to be higher ($P = 0.069$) in restricted group than control. The mRNA expressions for the gluconeogenic enzymes, cytosolic phosphoenol pyruvate carboxykinase (EC 4.1.1.32) and pyruvate carboxylase (EC 6.4.1.1) measured by quantitative real-time PCR in liver biopsies showed no differences between groups. Overall, restricting concentrate moderately reduced the growth intensity without affecting the normal plasma indices and gene expression indicating that both concentrate feeding schemes can be successfully applied.

Key Words: calf, concentrate, gluconeogenic enzymes

T353 Plane of nutrition during the pre- and post-weaned periods influences the performance and innate immune activity of Jersey calves. D. L. Hanson*[1], C. J. Cobb[1], M. D. Sellers[1], T. J. Earleywine[2], and M. A. Ballou[1], [1]*Department of Animal and Food Sciences, Texas Tech University, Lubbock,* [2]*Land O'Lakes, Animal Milk Products Co., Shoreview, MN.*

Objective was to determine the influence of plane of nutrition during the pre- and post-weaned periods on the performance and innate immune activity of Jersey calves. Forty six (3 ± 1 d old) calves were randomly assigned to 2 treatments. Treatments were a low (LP; n=23) and high plane of nutrition (HP; n=23). Calves in LP treatment were fed 409 g/d DM of a 20/20 milk replacer; whereas calves in HP treatment were fed 610 and 735 g/d DM of a 28/25 during the 1st wk and wk 2-6, respectively. Weaning was initiated during the 7th wk by removing the PM feeding and calves were completely weaned when they were consuming 800 g of calf starter after d 49. Calves were fed their respective calf starter until the end of the study. Peripheral blood samples were collected on d 0, 7, 21, 28, 42 and 77 for biochemical analyses. Blood samples collected on d 7, 21, 42, and 77 were analyzed for ex vivo innate immune responses. As expected, metabolizable energy intake, crude protein intake, and average daily gain were greater ($P < 0.001$) during the pre-weaning period for HP calves. There were treatment × time interactions ($P < 0.001$) on plasma concentrations of glucose and urea nitrogen. Glucose concentrations were greater ($P < 0.01$) on d 21, 28, 42 and tended to be greater ($P < 0.10$) on d 77 among HP calves. Urea nitrogen concentrations tended to be greater ($P < 0.10$) on d 7 among HP calves, but were less ($P < 0.01$) than LP calves on d 42 and 77. Secretion of tumor necrosis factor-α from diluted whole blood when co-cultured with lipopolysaccharide was greater ($P < 0.05$) among HP calves on d 7. In contrast, neutrophil expression of L-selectin was greater ($P < 0.05$) among LP calves on d 7, 21, and 42. No treatment or treatment × time differences ($P = 0.798$) were observed for neutrophil oxidative burst capacities during the study. Lastly, plasma haptoglobin concentrations were decreased (P 0.05) among HP calves on d 21. These data suggest that HP may prime the pro-inflammatory response of calves on d 7, but that a LP increases the basal expression of L-selectin on circulating neutrophils during the entire preweaned period.

Key Words: calf, immune, plane of nutrition

T354 Influence of tannins-extract supplementation on plasma urea nitrogen concentration of bull-calves grazing Bermuda grass. D. González*[1,2], M. A. Espino[2], and R. Barajas[2], [1]*Instituto Nacional de Investigaciones Forestales, Agrícolas y Pecuarias. Campo Experimental Valle de Culiacán, Culiacán, Sinaloa, México,* [2]*Facultad de Medicina Veterinaria y Zootecnia, Universidad Autónoma de Sinaloa, Culiacán, Sinaloa, México.*

Forty *Bos indicus* × *Bos taurus* bull-calves 176.43 ± SD 17.74 kg were used to determine the influence of tannins-extract supplementation on plasma urea nitrogen concentration of bull-calves grazing Bermudagrass. The experiment was performed from May 6 to June 3 of 2011 in the coast-plains of Sinaloa, localized in the Northwest of Mexico. Bull-calves were individually ear-tagged, weighed and randomly assigned to one of the next treatments: 1) Grazing in Bermuda paddock and receiving 1.5 kg/d of a protein supplement (Control); or 2) Similar to Control plus tannins-extract supplementation (TE). In groups of 20 bull-calves were placed in 2 3-ha paddocks of irrigated prairies of Bermudagrass (*Cynodon dactylon* L.), exclusively fertilized with feedlot cattle-manure. The protein supplement was formulate to contains 21% CP and 1.99 Mcal of NEm by kg of DM, and its composition was as follows: 70.5% Corn dried distillers grains with solubles, 10% ground corn, 2.5% sugar cane molasses, and 17% of sea salt. Protein-supplement was delivery daily in amount equivalent to 1.5 kg/animal. Bull-calves in TE treatment receiving daily 33 g of TMP-Protein Enhancer (Técnica Mineral Pecuaria, México) a premix that contains 56% of condensed and soluble tannins-blend. Tannins extract was incorporated in the protein supplement. In d 1 and 28, blood samples were taken from jugular vein for plasma urea nitrogen (PUN) determination. At the beginning of the experiment in d 1, plasma urea nitrogen concentration was similar ($P = 0.10$) between treatments, with mean values of 16.40 and 17.95 mg/dL for Control and TE treatments, respectively. In d 28, TE-supplementation decreased ($P < 0.01$) 21.6% PUN concentration, with means values of 15.75 and 12.35 mg/dL for Control and TE treatments, respectively. The results suggest that tannins-extract supplementation is able to decreases plasma urea nitrogen concentration of bull-calves grazing tropical grasses as Bermudagrass.

Key Words: tannins, plasma urea nitrogen, bull-calves

T355 The influence of grassland management and housing on voluntary dry matter intake in heifers. O. Latal*[1], J. Pozdisek[2], and J. Bezdicek[1], *[1]Agrovyzkum Rapotin Ltd., Vikyrovice, Czech Republic, [2]Research Institute for Cattle Breeding Ltd., Vikyrovice, Czech Republic.*

The aim of this study was to determine the voluntary dry matter intake (VDMI) of silage from grasslands managed in 3 ways. Fourteen experiments were conducted in 2010 on 2 groups of heifers, 6 per group (Czech Fleckvieh, 300 ± 15 kg LW) and housed in 2 ways: loose-box housing (4 automatic roughage intake control troughs) and tie-stall housing (manual feeding). Each experiment was divided into a habituation period (14 d) and a testing period (10 d). Grasslands were managed as follows: A [Medium Intensive Utilization] - 3 cuts per year, $N_{90}P_{30}K_{60}$ pure nutrients in kg per year and ha; B [Low Intensive Utilization] - 2 cuts per year, $N_{90}P_{30}K_{60}$; and C [Extensive (control) Utilization] - 2 cuts per year, nil-fertilization. The grass silage was made by cutting grass and leaving it to dry naturally in the field. After wilting, (dry matter 38%) the mowed fodder was compressed into round bales. The data were analyzed using GLM with the software R version 2.9.1. The results of the VDMI for each group of heifers was calculated in grams (dry matter) per metabolic body unit ($W^{0.75}$); next displayed as (g/MBU). Value of VDMI ($P < 0.01$) was higher in A (88.41 g/MBU, SE = 0.57) and B (72.14 g/MBU, SE = 0.60) than in C (68.34 g/MBU, SE = 0.63). Value of VDMI ($P < 0.05$) was higher too for the loose-box housing system (80.33 g/MBU, SE = 0.61) than the tie-stall housing system (74.42 g/MBU, SE = 0.65). On average from grasslands managed in 3 ways (from A to C), the NDF content rose from 486.8 to 571.1 g/kg dry matter (DM) and the net energy for lactation (NEL) decreased from 5.4 to 4.9 MJ/kg DM. There was a significant negative correlation between VDMI and the NDF ($r = -0.82$; $P < 0.05$), as well as a positive correlation between the VDMI and NEL ($r = 0.79$; $P < 0.05$). On the basis of the results, we can conclude that the value of the VDMI and nutrient intake was influenced by the grassland management (the higher the intensity of utilization, the higher the VDMI and nutrient intake) and housing system (greater VDMI was found for the loose-box housing).

Key Words: voluntary dry matter intake, grassland

T356 Effect of time of access to temperate forage on intake and digestibility of organic matter and fiber fractions in heifers. A. Félix[1], N. Hernández[1], P. Restuccia[1], S. Ruiz[1], M. Aguerre[1], A. Pérez-Ruchel[2], J. L. Repetto[1], and C. Cajarville*[2], *[1]Departamento de Bovinos, Facultad de Veterinaria, UdelaR, Montevideo, Uruguay, [2]Departamento de Nutrición Animal, Facultad de Veterinaria, UdelaR, Montevideo, Uruguay.*

Twenty-four Hereford × Angus heifers (BW = 153 ± 18 kg) were used in a randomized complete block design to determine the effect of time access to forage (*Lolium multiflorum*, *Trifolium repens*; 19.1% CP, 48.2% NDF, 23.2% ADF DM basis) on OM, NDF and ADF intake (OMI, NDFI and ADFI, respectively) and apparent digestibility of OM, NDF and ADF (D_{OM}, D_{NDF} and D_{ADF} respectively). Pasture was daily cut and offered ad libitum as sole feed during 4, 6, 8 or 24 h from 0800 h (h0), for the treatments T4, T6, T8 and T24, respectively. Daily OMI, NDFI and ADFI were measured for 10 d as the difference between offer and refusal and D_{OM}, D_{NDF} and D_{ADF} were studied for 5 consecutive days determining the daily total amount of food consumed and feces produced. All data were compared between treatments using a mixed linear model. Mean OMI were 40.6, 54.9, 58.8, 70.3 g OM/kg $BW^{0,75}$ (SEM = 3.8), mean NDFI were 21.3, 29.1, 31.1 and 37.3 g NDF/kg $BW^{0,75}$ (SEM = 2.1) and mean ADFI were 10.6, 14.3, 15.3, 18.5 g ADF/kg $BW^{0,75}$ (SEM = 1.0) for treatments T4, T6, T8 and T24, respectively. Organic matter intake, NDFI and ADFI were lower ($P < 0.001$) in the more restricted animals (T4 and T6) than in T24, but no differences were detected between treatments T6 and T8, or T8 and T24. Apparent digestibility of OM, D_{NDF} and D_{ADF} were high for all treatments (mean values: 81.7% (SEM = 1.4), 69.7% (SEM = 3.4) and 55.6% (SEM = 5.5), respectively) with no differences among them ($P > 0.10$), despite the large differences observed in intake. We conclude that restricting time of access to a high quality pasture below 8 h reduced OMI, NDFI and ADFI, but it did not affect its digestibility.

Key Words: feed restriction, pasture

T357 Assessment of bone metabolism in pregnant heifers with high and low residual feed intake. R. Dias[1], J. Kim*[1], S. Lopez[2], Y. Montanholi[1], B. Smith[1], S. Miller[1], and J. France[1], *[1]University of Guelph, Guelph, Ontario, Canada, [2]Universidad de León, Leon, Leon, Spain.*

It is known that ruminants with lower residual feed intakes (RFI) use nutrients more efficiently than animals with higher RFI. However, the biological reasons and metabolic consequences underlying the variation in RFI between animals are not clear. There is also no information on whether RFI is related to differences in bone metabolism. Within this context 26 pregnant heifers (13 low RFI + 13 high RFI) in their first trimester of gestation were used for a bone metabolism study. Their blood was sampled once in the morning before feeding through jugular catheterization for analysis of osteocalcin and crosslaps in serum. These compounds are biochemical markers of bone formation and resorption respectively considered important clinical tools for assessment and monitoring of bone metabolism. Both markers were determined quantitatively using an immunoassay kit specifically for bovines. The results showed a lack of difference between animals with high and low RFI in the concentration of osteocalcin in serum with average concentration of 27 ± 10.9 ng/mL similar for both groups ($P > 0.05$), indicating that the efficiency of feed utilization by pregnant heifers does not affect their bone formation. Likewise the concentrations of bovine crosslaps were similar between the 2 groups of animals ($P > 0.05$), though the more efficient animals had a mean concentration of 16 ± 10.3 ng/mL and the group of animals with higher RFI gave a mean concentration of 8 ± 7.7 ng/mL. These findings suggest bone resorption is not affected by feed efficiency in pregnant heifers. Thus, this research provides an indication that bone metabolism is similar for pregnant heifers with lower and higher RFI. However more research is needed to provide further information.

Key Words: bone marker, feed efficiency, pregnant heifer

T358 Dried citrus pulp alters feedlot performance of crossbred heifers during the receiving period. J. T. Cribbs*[1], T. R. Young[1], M. A. Jennings[1], N. C. Burdick[2], J. A. Carroll[2], T. R. Callaway[3], T. B. Schmidt[4], B. J. Johnson[1], and R. J. Rathmann[1], *[1]Texas Tech University, Lubbock, [2]USDA-ARS, Livestock Issues Research Unit, Lubbock, TX, [3]USDA-ARS, Food and Feed Safety Research Unit, College Station, TX, [4]Mississippi State University, Department of Animal and Dairy Science, Starkville.*

A study was designed to determine the effects of feeding dried citrus pulp pellets (DCP) on feedlot performance of newly received English × Continental heifers. Heifers (n = 180) were sourced in 2 loads (188.7 ± 18.0 kg and 225.2 ± 22.2 kg, respectively) from commercial auction barns and placed on trial at the Texas Tech University Beef Center in New Deal, Texas. A completely randomized block design was used by blocking by

BW nested within arrival load with 3 treatment diets being applied (36 pens; 5 heifers/pen; 12 blocks; 3 pens/block; 12 pens/treatment). Treatment diets were formulated to contain: 1) 0%; 2) 10%; or 3) 20% DCP on a DM basis. Diets containing DCP were formulated to be exchanged with steam flaked corn on a 1:1 basis. Cattle were fed a 63, 73, and 83% concentrate diet from d 0 to 28, d 28 to 42, and d 42 to 56, respectively. From d 0 to 28, there was a linear decrease in DMI ($P < 0.0001$) which resulted in a linear decrease in ADG ($P < 0.0001$) and G:F ($P < 0.01$) as the proportion of DCP in the diet was increased. From d 28 to d 42, DMI decreased linearly ($P = 0.02$) as the proportion of DCP in the diet increased; however, no difference in ADG was observed and G:F increased linearly ($P < 0.01$) in favor of treatments with a higher proportion of DCP. From d 42 to d 56, DMI did not differ across treatments, but ADG ($P = 0.02$) and G:F ($P = 0.04$) decreased linearly as the proportion of DCP in the diet increased. Over the entire 56 d trial period, as the proportion of DCP in the diet increased DMI decreased ($P = 0.02$; 6.70, 6.13, and 5.96 kg, for 0, 10, and 20% DCP, respectively), ADG decreased ($P < 0.0001$; 1.88, 1.27, and 1.00, respectively), and G:F decreased ($P = 0.02$; 0.225, 0.210, 0.91, respectively). Collectively, it appears that regardless of the level of roughage in the diet, the inclusion of DCP pellets at levels of 10% or greater lowers DMI such that feedlot performance suffers. Future studies will need to evaluate inclusion levels of DCP less than 10% or evaluate alternative processing strategies of DCP to offset the negative effects of DCP on intake in diets of newly received calves.

Key Words: newly received cattle, feedlot performance, citrus pulp

T359 Effect of time of access to temperate pasture on nitrogen utilization, digestibility of nitrogen and microbial protein synthesis in heifers.

N. Hernández[1], A. Félix[1], A. Pérez Ruchel[2], M. Aguerre[1], C. Cajarville[2], and J. L. Repetto*[1], [1]*Departamento de Bovinos, Facultad de Veterinaria, UdelaR, Montevideo, Uruguay,* [2]*Departamento de Nutrición, Facultad de Veterinaria, UdelaR, Montevideo, Uruguay.*

The aim of this study was to evaluate if the time of access to forage (*Lolium multiflorum*, *Trifolium repens*; 19% CP, 48% NDF, DM basis) affects the nitrogen (N) utilization, apparent digestibility of N (D_N) and the microbial protein synthesis (MPS) in heifers consuming temperate pastures. Twenty-four cannulated heifers (153.1 ± 18.1 kg BW) in a randomized complete block design were housed in individual cages and assigned to one of 4 treatments: T4, T6, T8 and T24 according to the time of access to fresh forage: 4, 6 8 or 24h/d, respectively. Pasture was daily cut and offered ad libitum as sole feed for all the treatments. Daily intake of N was measured for 10 d and D_N was determined for 5 consecutive days. Urine N was studied based on the daily total urine collected during 5 d. The retained N was calculated as: N intake (g/d) - (N removed in feces (g/d) + N eliminated in urine (g/d)). MPS was estimated by the determination of urinary purine derivatives excretion using the HPLC technique. All data were analyzed using a linear mixed model. The D_N was high for all treatments (mean value: 80.9%,SEM = 1.5) with no differences among them ($P > 0.10$), despite the large differences that were observed in intake. Mean N intake were 1.4, 1.9, 2.0 and 2.4 gN/kg $BW^{0.75}$ (SEM = 0.1, $P < 0.001$) for T4, T6, T8 and T24, respectively. The fecal excretion of N was higher for the T24 group than for the T4 group ($P < 0.001$). Similarly, there was a trend for the urinary N removal to increased for animals that were fed all day regarding to T4 group ($P = 0.07$). Animals in T4 had lower N retention than animals in T8 and T24 with mean values of 6.0, 24.3 and 30.1 gN/d (SEM = 3.5, $P < 0.001$). We observed a strong trend toward greater MPS for the unrestricted group (T24) than for the T4 group (46.7 and 20.0 gNM/d respectively; SEM = 7.2, $P = 0.057$). However, there was no difference between treatments ($P > 0.10$) in the efficiency of synthesis expressed as gMN/kgDOMI. We conclude that restricting time of access to forage reduced N intake that could have affect microbial protein synthesis.

Key Words: heifers, microbial protein, nitrogen utilization

T360 Comparison of pH, volatile fatty acids, and microbial quantification on rumen samples from young calves obtained via cannula or stomach tube.

M. Terré*[1], Ll. Castells[1], and A. Bach[2,1], [1]*Institut de Recerca i Tecnologia Agroalimentàries, Caldes de Montbui, Spain,* [2]*Institució Catalana de Recerca i Estudis Avançats, Barcelona, Spain.*

The objective of this study was to compare rumen samples from young dairy calves obtained via a stomach tube (ST) or a ruminal cannula (RC). Five Holstein male calves (46 ± 4.0 kg of BW and 11 ± 4.9 d of age) were ruminally cannulated at 15 d of age. Calves received 4 L/d of a commercial milk replacer (25% CP and 19.2% fat) at 12.5% DM, and starter and chopped oat hay ad libitum throughout the study (56 d). A total of 29-paired rumen samples, obtained at different ages by each extraction method, were used to determine pH, VFA concentration, and quantify *Fibrobacter succinogenes* by qPCR. A paired *t*-test was used to determine whether the evaluated parameters differed between the rumen samples obtained from the different methods. There was a difference ($P < 0.05$) of 0.30 pH units between ST and RC samples, being greater in ST than in RC samples. Furthermore, the total VFA concentration was greater ($P < 0.001$) in RC than in ST samples. However, when analyzing the proportion of each VFA, the method of sampling only affected ($P < 0.05$) the relative proportion of butyric, isovaleric, and valeric acid. Probably, saliva contamination diluted ST samples lowering the VFA concentrations and causing small changes in VFA profile. On the other hand, the quantification of *Fibrobacter succinogenes* by qPCR was not affected ($P = 0.43$) by the extraction method. In conclusion, when comparing rumen parameters from different studies, it is preferred to use VFA profiles rather than total VFA concentrations, as the latter is more affected by the method of collection. Furthermore, while pH comparisons across studies should be avoided when samples are not obtained by the same sampling method, the comparison of specific rumen bacteria can be acceptable.

Key Words: rumen cannula, rumen samples, stomach tube

T361 Effects of limiting concentrate during growing period on performance and plasma variables, and gene expression of hepatic gluconeogenic enzymes and visfatin in Korean native beef calves.

J. D. Lohakare*[1], S. S. Chang[2], N. K. Singh[1], E. G. Kwon[2], J. Ghassimi Nejad[1], K. I. Sung[1], and S. K. Hong[2], [1]*College of Animal Life Sciences, Kangwon National University, Chuncheon, South Korea,* [2]*Hanwoo Experimental Station, National Institute of Animal Science, RDA, Pyeongchang, South Korea.*

This study elucidated the effects of limited concentrate feeding on growth, plasma profile, and gene expression of gluconeogenic enzymes and visfatin in the liver of Hanwoo beef calves. The study utilized 20 Korean native beef calves (Hanwoo; 60–70 d of age) divided into 2 groups of 10 calves each for 158 d. Control group calves received the amount of concentrate as per the established Korean feeding standards for Hanwoo, whereas calves in the restricted group only received half the amount of concentrate as per standard requirements. Good quality forage (Timothy hay) was available for ad libitum consumption to both groups. Since calves were with their dam until 4 mo of age in breeding pens before weaning, the intake of milk before weaning was not recorded, however, the concentrate and forage intakes were recorded daily. Body weights (BW) were recorded at start and on 10–15 d interval. Blood samples were collected at start and at 50 d interval. On the final day of the experiment, liver biopsies were collected from all animals in each group. The BW was not different between the groups at all times, but tended to be higher ($P = 0.061$) only at final BW in control than restricted group. Total BW gain in the control group was 116.2 kg as opposed to 84.1 kg in restricted group that led to average BW gain of 736 g/day and 0.532 g/day in respective groups, and the differences were significant ($P < 0.01$). As planned, the calves in the control group had higher concentrate and lower forage intake than the restricted group. The plasma variables (glucose, total protein, albumin, urea, triglycerides, aspartate aminotransferase (EC: 2.6.1.1), alanine aminotransferase EC: 2.6.1.2) and amylase (EC: 3.2.1.1)) were within the normal range in both groups, but plasma total protein, and urea were higher ($P < 0.05$) in control than restricted group and aspartate aminotransferase, alanine aminotransferase levels were lower ($P < 0.05$) in control than restricted group showing the effects of diet. The mRNA expressions for the gluconeogenic enzymes such as cytosolic phosphoenol pyruvate carboxykinase (EC 4.1.1.32) and pyruvate carboxylase (EC 6.4.1.1), and visfatin measured by quantitative real-time PCR in liver biopsies showed higher expression ($P < 0.05$) in restricted group than control. Overall, restricting concentrate severely reduced the growth intensity and gene expression in liver and few plasma indices indicating that restricting concentrate in the feeding schemes during early growth for beef calves is not advocated.

Key Words: Hanwoo calves, concentrate, gluconeogenic enzymes

T362 How the provision of forage in pre-weaned calves affects performance and digestibility after weaning. Ll. Castells*[1], A. Bach[1,2], C. Montoro[1], E. M. Rodríguez[1], P. Ureña[1], and M. Terré[1], *[1]Department of Ruminant Production, IRTA, Caldes de Montbui, Spain, [2]ICREA, Barcelona, Spain.*

The objective of this study was to evaluate performance and diet digestibility after weaning in young Holstein calves fed non-forage and forage-supplemented diets during the pre-weaning phase. Sixty female Holstein calves (BW = 39.5 ± 3.76 kg) were randomly assigned to one of the 2 dietary treatments according to age and BW. Calves were individually housed and bedded with wood shavings. Dietary treatments consisted on feeding a pelleted starter (19% CP, 19% NDF) without any forage supplementation during the pre-weaning phase, and oats hay (68% NDF) supplementation post-weaning (CTR) or the same starter and forage fed during the pre and post-weaning phase (OAT). All calves were offered 3 L of milk replacer (MR) at 12% DM fed twice daily until 28 d of age, from 29 to 44 d of age calves received 1.5 L of MR at 12% DM fed twice daily, and from 45 to 51 d of age calves received 1.5 L of MR at 12% DM. Animals were weaned at 52 d of age. Intakes of starter and forage were recorded daily and BW weekly. Two weeks after weaning, total tract apparent digestibility was determined in 6 calves per treatment. Data were analyzed with a mixed-effects model with repeated measures, except for digestibility values that had no repeated measures. Starter intake was greater ($P < 0.05$) in OAT compared with CTR animals (600 vs 503 ± 40.1 g/d, respectively) during the pre-weaning period. As a result, calves in OAT treatment grew faster ($P < 0.01$) than CTR animals (520 vs 419 ± 22.9 g/d, respectively) during the pre-weaning period. After weaning, OAT animals consumed more ($P < 0.01$) forage than CTR animals (146 vs 90 ± 11.7 g/d, respectively), but there were no differences between treatments in ADG and starter intake. Similarly, there were no differences in total tract apparent digestibility between treatments (78.3% DM digestibility, 43.0% NDF digestibility). Offering forage to young calves is necessary, and when offered early in life it allows improvements in growth before weaning.

Key Words: calves, forage, performance

Small Ruminant: Production

T363 The effects of confinement and protein levels on carcass traits of kids raised under mixed-species grazing system. S. Gebrelul,* L. Gray, R. Marshall, and C. Chisley, *Southern University Ag Center, Baton Rouge, LA.*

A long-term mixed-species grazing project was designed to determine the performance of goats and cattle grazing together or separately in continuous or rotational systems. To evaluate the carcass traits and lean yield, 50 kids that were born and weaned under the mixed-specie system were randomly assigned to 4 treatments in a 2 × 2 factorial arrangement. The treatments were housing (confinement vs. semi-confinement) and protein levels in the diet. Kids under confinement system were divided into 2 groups and fed ad lib rations which contained 13% or 16% CP. Kids under semi-confinement were allowed to graze on bermudagrass pastures during the day (for 8h) and supplemented with the same experimental rations during the night. After an adjustment period of 2 wk, live weights (LW) and BCS, (1 = thin, 5 = fat) were taken every 14 d for 8 wk. At the end of the study, 24 male kids (14 from confinement and 10 from semi-confinement groups) were humanely harvested and deboned for carcass study. Hot carcass weight and cold carcass weights (CCW), dressing percentages, cold carcass yield, live grades (LG, Selection 1, 2 or 3), conference grade (CG), fat score, etc. were taken at harvest. Ribs, shoulder, shank, leg, back, and neck were cut from each carcass, weighed and deboned to determine percent of lean meat (PLM) and weight of lean meat yield (WLM). Data were analyzed using SAS MIXED procedure where kids were considered random effects. Stepwise regression was used to determine best live measurement predictors for PLM and WLM. No differences in carcass weights were observed due to housing effect or level of CP in the diet. BCS was the best predictor for PLM ($r^2 = 0.34$) followed by LW and CG. LW was the best indicator for WLM ($r^2 = 0.89$) followed by BCS, CG and LG. WLM yield was significantly ($P < 0.05$) correlated with LW (r = 0.92), HCW (r = 0.96), BCS (r = 0.77), CG (r = −0.52), and LG (r = −0.86). Similar relationships were observed for PLM. Ribs, legs, shoulder, shank, back and neck cuts represented 29.4%, 25.2%, 15.1%, 10.1%, 8.6% and 5.6% of the total carcass weight, respectively. Based on these results, one can feed a lower CP level of 13% without negative effect on carcass traits and lean meat yield.

Key Words: mixed-grazing, carcass, goats

T364 Fatty acids profile in *Longissimus dorsi* of Santa Ines lambs fed with different energy levels. P. C. L. Arruda, E. S. Pereira,* P. G. Pimentel, G. M. B. Moreno, J. N. Rocha Junior, J. G. L. Regadas Filho, and R. M. Fontenele, *Federal University of Ceara, Fortaleza, Ceara, Brazil.*

Nutritional strategies have been used to modify the content and the concentrations of the different fatty acids in animal muscle. The assessment of the nutritional quality of lipids in ruminant carcasses has been performed based on the composition of fatty acids, through the determination of indexes that relate the content of saturated fatty acids (SFA), monounsaturated (MUFA) and polyunsaturated (PUFA) n-6 and n-3. The objective of this study was evaluated the influence of rations with different levels of metabolizable energy on the content of total lipids, cholesterol and fatty acid profile of the *Longissimus dorsi* of Santa Ines lambs. Twenty Santa Ines lambs were used, with age and BW of 50 d and 13.0 ± 0.56 kg, respectively, fed rations with different energy levels: 2.08; 2.28; 2.47 and 2.69 Mcal/kg DM. The animals were weighed weekly to follow the ADG and when the mean BW of the treatments reached 28 kg the animals were slaughtered. The reading of the esters of fatty acids was performed by gas chromatography. The atherogenicity (AI) index AI = [(C12:0 + (4 × C14:0) + C16:0)]/(ΣMUFA + Σn-6 + Σn-3), thrombogenicity (TI = (C14:0 + C16:0 + C18:0)/ [(0.5 × ΣMUFA) + (0.5 × Σn-6 + (3 × Σn-3) + (Σ n-3/Σn-6)]), relation between hypocholesterolemic and hypercholesterolemic fatty acids (h:H = (C18:1cis9 + C18:2n-6 + C20:4n-6 + C18:3n-3 + C20:5n-3 + C22:5n-3 + C22:6n-3)/(C14:0 + C16:0) and the sum of desirable fatty acid = MUFA + PUFA + C18:0 were calculated. The analysis of the lipid profile of the *Longissimus dorsi* muscle presented linear increasing and decreasing effect for the Cis-10 heptadecanoic acid (C17:1) and eicosatrienoic (C20:3), respectively, with the increasing levels of dietary energy. The levels of total cholesterol (mg/100g) decreased with the inclusion of energy in the diets. The relations PUFA:SFA (0.13), PUFA:MUFA (0.12), MUFA:SFA (0.97), desirable fatty acids (66.3), n-6:n-3 (2.19), atherogenicity index (0.63), thrombogenicity index (1.63), relation between hypocholesterolemic and hypercholesterolemic fatty acids (1.98) and the relation (C18:0+C18:1):C16:0 (2.54) were not affected by energy levels ($P > 0.05$). Variation of the energy levels in total mixed rations to lambs influences the lipid profile in *Longissimus dorsi* of Santa Ines lambs.

Key Words: atherogenicity index, lamb meat, unsaturated fatty acids

T365 The effect of induction hypothyroidism on carcass quality and performance in lamb. Y. Baghcheghi,* A. Yousefi, A. Z. Shahneh, M. G. Khanlo, and M. Poorhamdollah, *University of Tehran, Karaj, Tehran, Iran.*

This study was conducted to investigate the effect of induced transient hypothyroidism by propyl-2-thiouracyl (PTU) on the carcass characteristics of Lori-Bakhtiari lambs. In a completely randomized design, 18 Lori-Bakhtiari male lambs (36 ± 4 kg BW, 5 mo old) were divided to 3 groups (n = 6) and subjected to one of 3 treatments: control (C: 0 mg PTU/kg BW), low (L: 10 mg PTU/kg BW), or high (H: 20 mg PTU/kg BW) dose by gavages. Animals were assigned in single pens (2 × 2 m) under ambient conditions for 60 d. Lambs had ad libitum access to fresh water and a fattening diet. Blood samples were collected every week using sterile vacuum tubes before feeding at 8:00 a.m., weekly. Plasma was separated and stored at −20°C before determination of thyroid hormone concentrations. At the end of experimental period, lambs were slaughtered for determination of carcass characteristics. Mean concentrations of T4 and T3 decreased significantly in L and H groups compared with C group (0.72 ± 0.06, 0.90 ± 0.06 and 2.27 ± 0.06, respectively, $P < 0.05$). There were no significant differences among treatment in carcass length, longissimus muscle cross section area, weight of primal cuts, weight of offals, and ADG ($P < 0.05$). Average feed conversion (G: F) ratio in H and L groups improved compared with C group (6.7 ± 0.39, 7.4 ± 0.39 and 8.9 ± 0.39, respectively, $P < 0.05$). Weight percentage of heart decreased in induced hypothyroidism groups (L and H) compared with C group (0.77 ± 0.03, 0.73 ± 0.03 and 0.92 ± 0.03 respectively, $P < 0.05$). Decreased percentages of heart weight and G:F might be a result of decreased basic metabolism in induced hypothyroidism groups.

Key Words: hypothyroidism, meat quality, Lori-Bakhtiari

T366 Effect of transient hypothyroidism on lamb's meat quality. Y. Baghcheghi*[1], A. Z. Shahneh[1], A. Yousefi[1], M. Poorhamdollah[1], and M. Joki[2], *[1]Department of Animal Sciences, University of Tehran, Karaj, Tehran, Iran, [2]Department of food Sciences, University of Tehran, Karaj, Tehran, Iran.*

This study was conducted to investigate the effect of induced transient hypothyroidism by propyl-2-thiouracyl (PTU) on the meat quality of Lori-Bakhtiari lambs. Eighteen Lori-Bakhtiari male lambs (Average BW, 36 ± 4 kg and 5 mo of age) were divided to 3 groups (n = 6) and received one of the 3 treatments as Control (C: 0 mg PTU/kg BW), Low (L: 10 mg PTU/kg BW) and High (H: 20 mg PTU/kg BW) by gavages during 60 d of experimental period. Lambs had free access to fresh water and were fed ad libitum with fattening diet. Blood samples were collected by sterile vacuum tubes before feeding, weekly. At the end of experimental period, lambs were slaughtered and meat quality was determined on *longisimus dorsi* muscle. Data was analyzed by GLM and Mixed procedure of SAS. Mean concentration of T4 and T3 decreased significantly in H and L groups compared with C group (0.72 ± 0.06, 0.90 ± 0.06 and 2.27 ± 0.06, respectively) ($P < 0.05$). There was no significant difference among treatment for pH, chemical composition and shear force value of *longisimus dorsi* muscle ($P < 0.05$). H group had higher ($P < 0.05$) L* (lightness) compare with L and C group (43.0 ± 0.72, 45.2 ± 0.72 and 45.8 ± 0.72, respectively). There were no differences ($P > 0.10$) regarding a* (redness) and b* value among treatments ($P < 0.05$). Hypothyroidism decreased ($P < 0.05$) H and L group cooking loss compared with C group (0.38 ± 0.01, 0.39 ± 0.01 and 0.43 ± 0.01, respectively) ($P < 0.05$). We concluded that, using 10 and 20mL/kg BW of PTU could induce hypothyroidism leading to changes in color and cooking quality of lamb's meat.

Key Words: hypothyroidism, meat quality, Lori-Bakhtiari

T367 Biochemical and hormonal response and chemical composition of milk following ACTH administration in goats fed lemongrass (*Cymbopogon citratus* (DC.) Stapf). T. S. Canaes*[1], S. N. Macedo[1], C. G. Lima[1], V. A. Pimentel[2], and J. A. Negrão[1], *[1]Sao Paulo University, Sao Paulo, Sao Paulo, Brazil, [2]Federal University of Espirito Santo, Sao Mateus, Espirito Santo, Brazil.*

It is evidence that lemongrass can be used as tranquilizer. The aim of this study was to evaluate 4 levels of lemongrass (LG) and their influence on the intravenous ACTH to mimic a stressful response on hormonal (cortisol) and biochemical responses (glucose, urea, creatinine, albumin, cholesterol and HDL cholesterol), milk yield and physico-chemical composition of goat's milk. Forty-four Saanen goats 3 yr of age at 75 d of lactation, BW of 59.2 ± 2.69 kg; BCS of 3.0 and milk yield of 2.58 ± 0.27 kg were used. The animals were kept in 4 feedlot pens (11goats/pen) during 152 d. Four diets were used (roughage:concentrate of 53:47) and provided once a day after milking. The variation was the substitution of corn silage (CS) by lemongrass (LG): T1 control (100% CS), T2 (33.5% LG), T3 (66.5% LG) and T4 (100% LG). They were injected 0.6 IU/kg of BW of ACTH into the jugular vein after 142 d of diet and before the daily feeding. Sterile saline solution was used as the control. Blood samples were collected at 20 min before and 0, 60, 120 and 300 min after application of ACTH. The interval between injection of saline and ACTH was 7 d. The biochemical and hormonal profiles were measured by commercial kits. Milk yield and composition were evaluated for 3 d following application of ACTH. PROC MIXED in SAS 9.1 was used with a repeated week statement to analyze plasma results. Orthogonal contrasts were used to determine the linear and quadratic effects of LG. There was quadratic effect in DMI as the addition of LG was increased. Cortisol concentration was affected ($P < 0.05$) by ACTH and time but not by LG and increased in the plasma of ACTH-treated goat's immediately after application and remained increased throughout 120 min sampling period. The LG in the diet had an influence on concentrations of blood glucose in animals subjected to ACTH application but the interaction of ACTH × LG was observed only in T1. There was no interaction between time groups (saline or ACTH) or diets for the others biochemical variables in plasma. The LG increases the milk yield for T3, but did not change milk composition.

Key Words: cortisol, goat milk, stress

T368 Forage yield and quality changes in mixed cattle and goats grazing practices. Y. Ghebreiyessus,* S. Gebrelul, M. Berhane, and R. Payne, *Southern University Ag Center, Baton Rouge, LA.*

To evaluate the effect of mixed-species grazing on forage yield and quality, 80 Spanish goats and 28 Brangus cows were randomly assigned to continuous or rotational grazing systems, and 3 grazing schemes (goats alone, cattle alone, and goats mixed with cattle) in a 2x3 factorial arrangement of treatments. A forage field of 31 ha of bermudagrass was divided into 6 pastures, 8 ha each for mixed-species grazing, 2 ha each for goats-alone grazing and 5.5 ha each for cattle-alone grazing. The rotational pastures were further divided into 4 paddocks and each paddock was grazed for 7d and allowed to rest for 21d. Animals were stocked at 0.8 ha/AU. Forage samples were collected weekly to determine plant height, forage yield and quality. Forage available for consumption by animals was estimated as the difference of yield of forage from un-grazed (inside a ring) and grazed plots. Forage consumption per animal per day was then determined by multiplying the available forage by the grazing area and dividing the result by the number of animal days. Five goats were assumed to be equivalent to a cow. Data was analyzed using SAS GLM procedure. Plant height ranged from 16 cm in June to 35 cm in April and was significant ($P < 0.05$) in all treatments, including months, years, grazing species, grazing systems, specie x grazing interaction. Available forage yield range was 756 to 2,394 kg/ha in June and April, respectively, while forage available for consumption ranged from 253 to 841 kg/ha for the same period. There was no difference ($P > 0.05$) in available forage between cattle-alone and mixed with goats, indicating presence of goats did not affect negatively the potentially available forage. However, consumption per cow was higher in cattle-alone treatment. Goat consumption of 6.7 kg/hd/d was the lowest ($P < 0.05$) despite the highest available forage. Crude protein content ranged from 8.9 to 11.8%. Acid detergent fiber and NDF values ranged from 31.9% to 39.1% and 47.1 to 62.2% respectively. None of the forage quality measures were affected ($P > 0.05$) due to main effects of months, years, grazing species, grazing systems or interactions. Results demonstrated that goats could graze with cattle without bringing any negative effects to cattle's performances.

Key Words: mixed-grazing, goats, forage quality

T369 Quantitative traits of carcass of Ile de France lambs fed diets containing different percentages of hay mulberry. V. T. Santana, A. G. Silva Sobrinho, L. G. A. Cirne,* V. Endo, N. L. L. Lima, F. A. Almeida, G. M. Manzi, and N. M. B. L. Zeola, *Universidade Estadual Paulista, Jaboticabal, São Paulo, Brazil.*

Alternative protein sources such as mulberry hay can partially or totally replace concentrate feeds commonly used in intensive sheep production system in Brazil. It is essential to study the effect of such rations on quantitative carcass characteristics. This experiment was conducted to evaluate the quantitative carcass traits of Ile de France lambs fed diets containing various percentages of mulberry hay. Twenty-four Ile de France lambs (15.0 kg BW, 3 mo old) were confined in individual stalls and fed one of 3 diets: sugar cane + concentrate with 0.00% mulberry hay; sugar cane + concentrate with 25.0% mulberry hay; or sugar cane + concentrate with 50.0% mulberry hay. The sugar cane was used as forage (variety IAC 86–2480) that gave a total dietary roughage to concentrate ratio of 50:50, with 10.0% surplus allowance. The confinement period comprised of 80 d, and the first 14 d were allowed for adaptation of animals to the diet and the stalls. The data were analyzed using SAS as a completely randomized design, with 3 treatments (n = 8), and the means were compared using the Tukey test. The lambs were slaughtered at 32.0 kg BW and carcasses were weighed to obtain the HCW and kept in cold storage at 6°C for 24 h, to assess the cold carcass weight (CCW). The HCW (14.1 kg) and CCW (13.7 kg) were not affected ($P > 0.05$) by different percentages of mulberry hay in the diet. There was also no difference ($P > 0.05$) in empty BW (25.9 kg) and true yield (54.7%). The results showed that inclusion of mulberry hay in the diet did not alter carcass characteristics, indicating that it can be used in lamb feeding without negative effects on production.

Key Words: confinement, protein sources, sheep

T370 Relationships among internal fat depots and subcutaneous fat in sheep.

R. C. Gomes,* C. Constantino, F. Fernandes Jr., N. A. Koritiaki, M. V. G. Niwa, M. N. Marconato, F. A. B. Castro, and E. L. A. Ribeiro, *Department of Animal Science, State University of Londrina, Londrina, Parana, Brazil.*

The understanding of the relationships among the different adipose tissue depots as well as accurately predicting their masses is critical for animal growth modeling. Thus, the aims of this study were 1) to evaluate the phenotypic correlations among internal fat masses and subcutaneous fat thickness in sheep and 2) to predict the internal total fat mass using KPH fat weight and subcutaneous fat thickness information. Sheep in this study were either Texel-cross or Santa Ines-cross, 6 to 61-mo old and 27.3 ± 6.5 kg empty BW, composed of ewes (n = 7), ewe lambs (n = 15) and ram lambs (n = 26). Ewes were grazing (*Brachiaria* spp.) whereas ram and ewe lambs were feedlot finished before slaughter. The sum of kidney, pelvic and heart fats (KPH, kg), the mesenteric (MES, kg) and omental (OME, kg) fats were measured at slaughter. The subcutaneous fat thickness was measured 24 h postmortem (0 to 2°C) on the *Longissimus dorsi* muscle, at the 12th-13th rib region. Pearson correlation analyses were carried out. Simple and multiple regressions were employed to generate prediction equations with VISC as the dependent variable and both SFT and KPH as predictors. Linear and quadratic terms were tested. High correlations of KPH with OME, MES and VISC were observed (0.79; 0.70 and 0.92; $P < 0.001$). However, the correlations were only moderate between SFT and OMEN (0.43; $P < 0.01$) and between SFT and VISC (0.43; $P < 0.01$). Correlations between SFT and MES (0.20; $P = 0.12$), and between SFT and KPH (0.53; $P = 0.0001$) were both non-significant and moderate, respectively. The equation generated for predicting VISC as a function of KPH was VISC, kg = 0.31571 + 2.51105*KPH, kg ($R^2 = 0.8418$; RMSE = 0.214 kg). SFT did not entered ($P > 0.05$) in the model with KPH as predictor. The prediction equation using SFT as independent variable was VISC, kg = 0.68429 + 0.2508*SFT, mm ($R^2 = 0.1826$; RMSE = 0.4867 kg). No quadratic terms were significant for both KPH and SFT. The KPH fat weight, unlike SFT, is highly correlated with the fat mass presented on the gastrointestinal tract. Accordingly, the KPH fat but not SFT can be used to predict the total internal fat mass in sheep with relative accuracy.

Key Words: channel fat, visceral fat, *Ovis aries*

T371 Impact of different stocking rates of goats under pine silvopasture systems on understory biomass, crown cover density, and animal productivity.

I. Howard,* A. S. Kumi, N. K. Gurung, U. Karki, R. Smith, S. G. Solaiman, W. H. McElhenney, and B. R. Min, *Tuskegee University, Tuskegee, AL.*

Meat goat production has potential to be integrated into the pine silvopasture systems as a means of supplemental income for forest land owners. Objectives were to determine changes in understory plant biomass, crown cover density and animal productivity using different goat stocking rates. A completely randomized design was used on an 11 years old loblolly pine silvopasture systems at the Federation of Southern Cooperatives in Epes, Alabama with 36 Kiko male goat kids ((21.0 ± 1.04 kg initial BW and 4 to 5 mo of age) using low (L; 4 goats/acre), medium (M; 8 goats/acre), and high (H; 12 goats/acre) stocking rates from July through October, 2011. Goat BW, understory plant biomass and plant cover density (CD) were determined before and at the end of grazing. The initial understory plant biomass was similar among treatments ($P > 0.05$) but decreased linearly ($P < 0.05$) with increasing stocking rates at the end of grazing. Goats were similar in BW at the start and at the end but did not grow as expected. Although the initial CD values were similar among treatments ($P > 0.05$), a significant treatment x height interaction was detected for the final CD values. Differences among treatments were detected ($P < 0.05$) at the lower heights (0.5 m and 1.0 m), but no differences among treatments were detected at heights above 1.0 m. Overall fecal DOM and CP ratios were 4.9, 5.1, and 4.8 for L, M, and H stocking rates, respectively and were not different among treatments ($P > 0.05$) indicating that the diet quality selected by goats were similar. Based on these data, goats can be utilized to minimize understory up to 1.0 m in pine silvopasture systems; however, feed supplementation may be required to improve animal performance.

Key Words: meat goats, silvopasture, stocking rate

T372 Influence of trenbolone acetate and estradiol ear-implant level on feedlot-performance of hair lambs.

B. Ortiz*[1], J. J. Álvarez[2], and R. Barajas[1], [1]*FMVZ-Universidad Autonóma de Sinaloa, Culiacán, Sinaloa, México,* [2]*Productores de Ovinos de Guanajuato, SPR de RL, Silao, Guanajuato, México.*

Four hundred and 80 hair lambs (21.83 ± SD 2.28 kg) were used to determine the influence of trenbolone acetate and estradiol ear-implant level on feedlot-performance of hair lambs. Lambs were weighed, grouped by initial weight in 4 blocks of 120 lambs, and placed in 4 × 5 m elevated pens fitted with plastic-slot floor (30 lambs per pen). Each block contained 4 pens, and the pen constituted the experimental unit. In a complete randomized block design experiment, inside of each block, pens were randomly assigned to receive one of 4 treatments: 1) Feedlot diet without additional implant (CTRL); 2) Ear-implanted with 20 mg of trenbolone and 4 mg of estradiol (T20); 3) implanted with 40 mg of trenbolone and 8 mg of estradiol (T40); and 4) implanted with 60 mg of trenbolone and 12 mg of estradiol (T60). Trenbolone /estradiol levels were obtained with the application of one, 2 or 3 pellets contained in the regular implant-cartridge of Component TES (Elanco). Lambs were weighed on d 1 and 30. Results were analyzed by ANOVA and the quadratic trend tested by polynomial contrasts. Final weight showed a quadratic response ($P = 0.02$) to implant-level with values of 27.7, 28.3, 28.5 and 28.4 kg for CTRL, T20, T40 and T60 treatments, respectively. A quadratic trend ($P = 0.03$) was observed in ADG, with mean values of 195, 216, 223 and 220 g/day for CTRL, T20, T40 and T60 treatments, respectively. Dry matter intake was not affected by implant level ($P > 0.30$). Gain:feed ratio responded in a quadratic form to implant-level ($P < 0.01$), with mean values of 207, 229, 229, and 222 g of gain/kg of DMI for CTRL, T20, T40 and T60 treatments, respectively. It is concluded that implants containing trenbolone and estradiol improves performance of feedlot lambs, and that dose of 40:8 of trenbolone-estradiol induces the highest biological response.

Key Words: feedlot-performance, lambs, trenbolone

T373 Femur biometry and densitometry of Saanen goats subjected to feed restriction. D. C. Soares,* K. T. Resende, A. K. Almeida, S. P. Silva, M. H. M. R. Fernandes, E. M. Oliveira, S. M. B. Artoni, and I. A. M. A. Teixeira, *UNESP/Sao Paulo State University, Jaboticabal, Sao Paulo, Brazil.*

The aim of this study was to evaluate the effect of sex and feed restriction on biometric aspects and bone mineral density (BMD) of femurs from 51 growing goats (18 non-castrated males, 18 castrated males, and 15 females) with initial BW of 30 ± 0.21kg. The animals were randomly allocated into 17 groups (blocks) of 3 animals of the same gender, subjected to 0, 25 or 50% feed restriction. A group was slaughtered when the animal set in the 0% restriction reached 44.1 ± 1.95 kg BW. After slaughter and evisceration, the carcasses were weighed and cooled at 4°C for 24 h. At the end of this period, the femur of the left leg of each animal was removed for further analysis. The BMD assessment craniocaudal radiographs were taken of femur using a Lunar DPX (DEXA). In the femur, the following measurements were made: weight, length (LE), diameter of the diaphysis (DDIA) and the proximal (DPE) and distal (DDE) epiphysis, length of the latero-lateral (LLD) and craniocaudal (LCCD) diaphysis. The data were analyzed as a randomized block design in a factorial scheme (3 × 3) using SAS. The BMD decreased linearly as feed restriction increased (ranged from 1.02 to 0.83 g/cm^2) and it was greater for female (0.96 g/cm^2) and male (0.93 g/cm^2) than for castrated (0.87 g/cm^2). The biometrics variables were not affected by level of feed restriction, except for femur weight and LE that decreased linearly ($P < 0.001$) as feed restriction increased. All biometric variables were affected by gender ($P < 0.05$), except for LLD (17.74 ± 0.19 cm). The biometric variables DPE, DDE and DDIA were greater ($P < 0.05$) for male (14.1 cm, 17.0 cm and 7.0 cm, respectively) and castrated (14.9 cm, 17.1 cm and 6.9 cm, respectively) than for female (13.1 cm, 15.8 cm and 6.8 cm, respectively). The LCCD was greater for male (19.8 cm) than for castrated (19.1 cm) and female (18.6 cm). In conclusion, BMD is affected by gender and nutritional levels, emphasizing its importance as a tool to investigate bone metabolism in goats (FAPESP project number 2011/04786–3).

Key Words: bone, density, nutrition

T374 Influence of dry period length on blood leukocyte subsets of Sarda dairy ewes and their offspring. P. Bonelli[1], C. Carzedda[2], A. Fenu[2], G. Spanu[2], C. Dimauro*[2], R. Re[1], P. Nicolussi[1], and SPG Rassu[2], [1]*Istituto Zooprofilattico Sperimentale della Sardegna, Sassari, Italy,* [2]*Dipartimento di Agraria, Sezione di Scienze Zootecniche, University of Sassari, Italy.*

The aim of the present work was to evaluate the effects of different dry period lengths on blood leukocyte subpopulations in ewes and lambs during the first month postpartum. Two groups of 8 lactating ewes were dried off 60 d (short dry off—SDO) and 90 d (long dry off—LDO) before lambing. After birth, 6 lambs were included in the same treatment group of their mothers. Ewe and lamb blood samples were collected at 1, 2, 7 and 30 d postpartum and were analyzed for white blood cell differential count (WBC) and lymphocyte subsets. Ovine specific monoclonal antibodies were used to identify T-helper lymphocytes (CD4+), T-cytotoxic lymphocytes (CD8+) and a subset of γδ T lymphocytes (WC1) in flow cytometry. Data were analyzed by a GLM model, using dry off length, sampling time and their interaction as fixed factors. The SDO ewes compared with LDO ewes, had lower WBC (9.9 vs 13.1 cells × 10.000/μL; $P = 0.001$) and eosinophil counts (2.4% vs 4.1%; $P = 0.002$) as well as an increased number of lymphocytes (51.1% vs 47.7%; $P = 0.009$). No significant differences were found between lambs, except for monocytes which were higher in SDO than LDO ewes (3.4% vs 2.1%; $P = 0.006$). Ewe lymphocyte subsets were similar in both groups, while SDO lambs had lower CD4+ (44.6% vs 50.1%; $P = 0.042$) and WC1+ (7.1% vs 9.6%; $P = 0.039$) values compared with LDO lambs. Although differences between groups of ewes and lambs were observed for WBC and for lymphocyte subsets, values were always within the normal reference interval for the ovine species. Our results evidenced that shortening the dry period to 60 d did not significantly affect leukocyte subpopulations of ewes and lambs during the first month postpartum. Further research is required to determine to what extent dry period shortening could influence immune response to possibly, enable lengthening of lactation and milk yield increase without any detrimental effect on animal health. Research funded by OIGA (MiPAAF) and PRIN 2009 (MIUR) Projects.

Key Words: dry period, sheep, leukocytes subsets

T375 Effects of plant extracts and monensin on metabolite status and performance of peripartum ewes. H. Mirzaei Alamouti,* H. Namdarpor, H. Amanlo, M. H. Shahir, and D. Aliyari, *University of Zanjan, Zanjan, Iran.*

Thirty-two estrus-synchronized multiparous Afshari ewes (BW 90 kg and BCS 3, based on 1–5 scale) were used in a completely randomized design and assigned to one of 4 dietary treatments to evaluate the effects of a blend of plant extracts and monensin on metabolite status and performance of ewes in the periparturient period. Afshari is a major fat-tail dual purpose (milk and meat) sheep breed in northwest Iran. Dietary treatments contained 1) no additive (CO), 2) 30 mg/d monensin (M), 3) 2 g/d commercial plant extract containing extracts of peppermint and Plantago major (PE), and 4) a mix of 30 mg monensin and 2 g commercial extract (MPE). Ewes (8/treatment) were individually fed diets with 65:35 forage to concentrate ratio from −21 d relative to expected lambing until 28 d after lambing. Blood was sampled weekly relative to lambing. Data from pre-partum and postpartum was separately analyzed using proc mixed in SAS software. The result showed that ewes fed the M diet had lower DMI pre-partum and ewes fed the MPE diet had greater DMI ($P < 0.05$). Ewes fed the MPE diet had lower ($P < 0.05$) BCS postpartum. There were no differences in DM and organic matter digestibility in the periparturient period. There was no effect of diet on plasma concentration of glucose and albumin in the periparturient period however, the PE diet increased ($P < 0.01$) plasma concentration of cholesterol. The MPE diet increased milk production when compared with others, 1.19 vs 0.87, 0.98, 0.85 kg /d (MPE vs CO, PE, and M, respectively). The PE diet increased milk fat content ($P < 0.05$). Ewes fed the MPE diet produced more milk protein and were more efficient in nitrogen utilization. In conclusion, this study showed some plant extracts have health benefits and a mix of monensin and plant extract peripartum can improve production of fresh ewes.

Key Words: monensin, plant extracts, peripartum ewes

T376 Efficacy of a bovine colostrum replacement product for goat kids.

S. Hart*[1], S. Genova[2], D. M. Haines[3,4], and B. Bah[1], *[1]American Institute for Goat Research, Langston Univ., Langston, OK, [2]Boren Veterinary Teaching Hospital, Oklahoma State Univ., Stillwater, [3]Department of Veterinary Microbiology, Western College of Veterinary Medicine, University of Saskatchewan, Saskatoon, SK, Canada, [4]The Saskatoon Colostrum Co., Saskatoon, SK, Canada.*

For various reasons, adequate doe colostrum is not always available for neonatal goat kids and thus, an alternative source of colostrum is necessary to support health of the neonate. The objective of this study was to determine the efficacy of a commercially available bovine colostrum replacement product (Land O'Lakes Colostrum Replacement, manufactured by The Saskatoon Colostrum Co. Ltd., Saskatoon, Canada) for neonatal goat kids. Alpine goat kids ($n = 29$) were removed from does at birth and a jugular blood sample was taken for analysis of serum IgG. The colostrum replacement containing 100 g IgG/470 g of powder was reconstituted with water using 76 mL of warm water to 40 g of colostrum powder and mixed using a plastic jar with a spring similar to those used to mix protein drinks for athletes. Kids were fed reconstituted colostrum replacement at 10% of BW divided into 3 feedings over a 16-h period. At 6 h after the last feeding, another blood sample was collected for determination of serum IgG. Kids were observed for 10 min after each feeding for any adverse reactions. After the 3 feedings of colostrum, kids were fed a milk replacer twice daily at 470 mL per meal, along with offering a starter diet. Health and BW gain were compared with other kid cohorts fed heat treated goat colostrum up to 3 wk of age. Prefeeding levels of IgG were approximately 0.2 mg/dL and were increased ($P < 0.01$) to 18.9 mg/dL (SE = 0.9) post-feeding. There were no cases of scours or off-feed in test animals or cohorts. Gain of BW was similar for kids fed bovine colostrum replacement or heat treated doe colostrum (138 vs. 121 g/d; $P > 0.10$). In conclusion, the bovine colostrum substitute resulted in satisfactory blood levels of IgG in kids and similar health and BW gain as cohorts consuming heat treated goat colostrum.

Key Words: goats, kids, colostrum

T377 Effect of chromium supplementation on carcass traits and blood parameters of Mahabadi goat kids.

A. Emami, M. Ganjkhanlou,* A. Zali, A. Akbari, and A. Hojabri, *University of Tehran, Tehran, Iran.*

The objective of this study was to evaluate the possible effects of supplementing chromium-methionine (Cr-Met) on carcass traits and selected blood parameters of goat kids. Thirty-two male kids (BW = 22 ± 2 kg, 4 mo old) were used in a completely randomized design with 4 treatments: 1) control (without Cr),2) 0.5, 3) 1.0 and 4) 1.5 mg Cr as Cr-Met/animal/d. Diets were formulated to meet NRC requirements with forage (alfalfa and corn silage):concentrate ratio of 30:70 in TMR form. Diets were the same except for top-dress addition of Cr-Met fed in 2 equal meals (0800 and 1600 h). Animals were kept in individual pens with self-mangers for 90 d. Kids were weighed after 14 d of adaptation and at 21 d intervals after feed restriction and slaughtered at the end of the trial. Jugular vein blood samples drawn via EDTA vacuum tubes on d 70 of the experiment were analyzed for selected parameters via an autoanalyzer apparatus and commercial kits. Data were analyzed by the GLM procedure of SAS 9.1 and Tukey test ($P \leq 0.05$). Weight at slaughter (WAS), HCW and carcass yield (CY) were not affected ($P > 0.05$) by the Cr supplementation. Addition of different levels of Cr failed to significantly affect red blood cells, neutrophils and monocytes. However, Cr supplementation increased white blood cells count [$P = 0.051$; 8.46, 9.39, 11.8, 12.1 (10^3 μL) for treatment 1, 2, 4, and 3, respectively[. These results indicate that supplementation of goat kid diet with Cr-Met did not influence carcass traits and most blood parameters but increased white blood cells.

Table 1. WAS, HC and CY of kids fed different levels of Cr-Met

	Treatment (mg of Cr)				
Trait	0 (control)	0.5	1.0	1.5	SEM
WAS (kg)	32.2	31.3	32.6	32.9	1.64
HC (kg)	13.1	12.3	13.9	12.7	0.85
CY%	40.8	39.0	42.7	38.8	0.13

Key Words: chromium-methionine, carcass traits, white blood cell

T378 Pasture lambing: An alternative to intensive indoor management at lambing.

N. L. Pettifor* and M. L. Thonney, *Cornell University, Ithaca, NY.*

Advantages of pasture lambing include reduced labor and lessened exposure to infectious disease, and the decreased stocking density allows for improved expression of maternal care relative to barn conditions. But, if a flock of sheep has been barn-lambed for decades, is it reasonable to expect those ewes to lamb successfully and raise their offspring on pasture? To test this, 35 Dorset, Finnsheep and Dorset × Finnsheep ewes were lambed on pasture during 30-d June and August lambing seasons. They were compared with random samples of equal numbers of barn-lambing ewes. At the time of ear-tagging and recording, a maternal behavior score (MBS) was recorded. Scores ranged from 1 (ewe flees at approach of the shepherd and does not return to her lamb(s) when ear-tagging is completed) to 5 (ewe makes physical contact with her lamb(s) while they are being ear-tagged). Survival of lambs to weaning (85.7 to 95.5%) did not differ by chi-squared analysis between barn- and pasture-lambing. The statistical model for weight per day of age (WPDA) included main effects of season (June or August), lambing type (pasture or barn), litter size (1 or 2), and all 2- and 3-way interactions. The linear and quadratic effects of ewe age were included as covariates. WPDA was affected ($P < 0.01$) by litter size, ewe age, and the season x lambing type interaction. There were different ($P < 0.003$) quadratic effects of ewe age for lambing type. These effects translated into increasing WPDA with increasing ewe age for barn-lambing ewes, but not for pasture-lambing ewes; suggesting that older ewes on pasture were not able to consume sufficient digestible feed components to maximize milk production. In addition and not surprisingly, for all but the June barn-lambing ewes, WPDA was greater for single than twin lambs ($P = 0.03$). WPDA increased 22.6 ± 9.18 g/d for each increase in MBS for pasture-lambing ewes ($P = 0.021$). Thus, scoring maternal behavior may be a tool to predict a ewe's performance in raising lambs on pasture. These results indicated that moving a barn-lambing flock to pasture lambing should not be a difficult transition, even for a flock that has been barn-lambed for generations.

Key Words: sheep, management, maternal behavior

T379 Evaluation of the impact of dietary sericea lespedeza on rumen microflora and innate immunity in goats.

A. Abdalla,* H. Ismail, S. Ibrahim, N. Whitley, and M. Worku, *North Carolina A&T University, Greensboro.*

Gastrointestinal nematodes have developed resistance to chemical anthelmintics resulting in the need for alternative control strategies such as the use of sericea lespedeza (SL) as a high-quality, low input forage that suppresses gastro-intestinal parasites in goats. However, little is known about its effect on rumen micro flora and innate immunity in goats. A diverse collection of microorganisms is found in the goat rumen. Bifidobacteria are important organisms in the immunity of the gastrointestinal tract and its presence in the goat rumen is not fully studied. The objective of this study was to evaluate the impact of a diet containing SL on goat rumen microflora, especially bifidobacteria and on markers of goat innate immunity. Blood was collected from female goats (n = 16) fed a diet of 75% SL (n = 9) and a control group (n = 7), 0% SL. Serum was extracted and used for evaluation of secretion of pro-inflammatory cytokines (TNFa, IFNr, GCSF, GMCSF, IL-1a, IL-8, IP-10 and RANTES) using a commercial ELISA kit. Rumen contents were collected at slaughter and stored at −20°C. Microbial DNA was isolated from frozen rumen samples using the QIAamp DNA kit (Qiagen) to test for the presence of bifidobacteria. The concentration and purity of DNA were determined using a Nanodrop spectrophotometer. The 16S rDNA targeted genus specific PCR primers for *Bifidobacterium* were used to amplify specific DNA. Amplified samples and DNA markers were separated by electrophoresis on a 2% agarose gel, stained with ethidium bromide and visualized. Data was analyzed by GLM of SAS 9.2. A 580-bp *Bifidobacterium* specific band was observed in samples from goats fed the SL free diet. *Bifidobacterium* DNA was not detected in goats fed a diet containing SL. However, diet affected the secretion of proinflammatory cytokines by increasing ($P < 0.0002$) the serum level of TNFa, IFNr, GCSF, GMCSF, IL-1a, IP-10 and decreasing ($P < 0.0001$) IL-8, and RANTES in goats fed SL in the diet. Dietary tannins may affect the goat′s innate immune response and the composition of rumen micro flora. This approach may be useful in studies to assess the recommended level of SL in the diet and the significance of Bifidobacteria in the immunity of the goat.

Key Words: sericea lespedeza, cytokines, *Bifidobacterium*

T380 Effect of continuous suckling/ewe-rearing and supplementation on growth performance of Katahdin lambs.

S. L. Rastle-Simpson,* K. N. D’Souza, M. Knights, and Q. S. Baptiste, *West Virginia University, Morgantown.*

The effects of continuous-suckling and supplementation on growth performance of crossbred Katahdin lambs (Birth weight 4.2 kg ± 0.2 kg) were investigated. Lambs (n = 68; 17.2 kg ± 1.0 kg) were randomly assigned within birth-type to be weaned at approximately 75d or to continuously suckle ewes. All lambs were given ad libitum access to hay, and half of the lambs in each rearing method were randomly assigned to be supplemented (10% CP, 3.5% crude fat lamb pellet) ad libitum (weaned + supplemented, WS (n = 16); suckling + supplemented, SS (n = 17) or received no further treatment (weaned + no supplementation, WNS (n = 18); suckling + no supplementation, SNS (n = 17). All lambs were weighed at birth, at the initiation of the trial and at approximately biweekly intervals for another 3 (3) mo. An ANOVA was used to determine the effect of type of rearing, supplementation and the interaction between the 2 main effects on ADG and final weights of lambs. Average daily gain during the pretrial period (~75 d) did not differ among treatment groups (0.18 kg ± 0.01 kg/d). The ADG during the trial period was greater ($P < 0.001$) in supplemented (WS, 0.22 kg ± 0.01 kg/d; SS, 0.24 kg ± 0.01 kg/d) than in un-supplemented (WNS, 0.06 kg ± 0.01 kg/d; SNS, 0.05 kg ± 0.01 kg/d) lambs. Among supplemented lambs, there was a tendency ($P = 0.1$) for greater growth rates in continuous suckled than in weaned lambs. Average final weights were greater ($P < 0.001$) in supplemented (WS, 36.2 kg ± 1.36 kg; SS, 40.2 kg ± 1.36 kg) compared with un-supplemented groups (WNS, 21.7 kg ± 1.36 kg; SNS, 20.6 kg ± 1.36 kg). Final weights were greater in the SS lambs compared with lambs in all other groups. The results of the current study indicated that supplementation of lambs increased total ADG and end-weight. Furthermore, continuous suckling along with supplementation resulted in the greatest ADG and end weights.

Key Words: continuous suckling, ewe-rearing, weaning

T381 Pre-partum nutritional supplementation strategies in goats managed under grazing conditions: 2. Serum glucose concentration profiles and milk production.

V. Contreras-Villarreal[1], O. Angel-Garcia[1], J. M. Guillen-Muñoz[1], R. Rodriguez-Martinez[1], G. Arellano-Rodriguez[1], C. A. Meza-Herrera[2], M. Mellado[3], and F. G. Véliz*[1], [1]*Universidad Autónoma Agraria Antonio Narro, Torreón, Coahuila, México,* [2]*URUZA, Universidad Autónoma Chapingo, Gómez Palacio, Durango, México,* [3]*Universidad Autónoma Agraria Antonio Narro, Saltillo, Coahuila, México.*

The aim of this study was to evaluate the effect of nutritional supplementation on d 15 or 35 pre-partum upon both serum glucose levels at kidding and milk yield in goats grazing a semiarid range. Ranging goats (n = 31; 1200 to 1800 h) were divided in 3 experimental groups during the last third of gestation: i) control group (CG; n = 7) without nutritional supplementation, ii) 15-Group (15G; n = 14) which received a 15d pre- to 7d postpartum supplementation of 500 g per animal per day of a mixed ration (20% chicken manure, 37% rolled corn, 37% bran, 4% treacle, 2% salt) during the morning at 0800 h, and iii) 35-Group (35G; n = 10) which received the same mixed ration on 35d pre- to 7d postpartum. Before the onset of the supplementation period and immediately after parturition, blood samples were taken to quantify blood glucose concentration in all animals. In addition, milk yield was measured on d 7 and 15 postpartum; all goats were milked at 2000 h, separated from their off-spring, and milk yield was recorded the next day at 0800 h. Serum glucose concentrations (mg/dL) and milk yield (kg) among groups were compared by ANOVA (SYSTAT 12, 2007, USA). While no differences ($P > 0.05$) for serum glucose concentration were observed among experimental groups on d 35 pre-partum, supplemented groups depicted greater serum glucose concentrations ($P < 0.05$) on d 7 postpartum with respect to control goats. In addition, a greater ($P < 0.05$) milk yield was observed in the supplemented groups either at d 7 or d 15 postpartum with respect to control group (Table 1). Present results demonstrated that a 15-d supplementation period increased both serum glucose levels at parturition and milk production of goats under range-grazing conditions in northern Mexico. Such nutritional scheme represents an important strategy to increase not only the goat’s energy balance but also milk production, while may potentially increase the survival rate of the offspring.

Table 1. Pre-partum serum glucose concentrations (mg/dL) and milk production (kg/day) in goats receiving different nutritional supplementation strategies under grazing conditions in northern Mexico

	Glucose (mg/dL)		Milk production (kg)

T382 Comparison of different mathematical models applied to lactation adjustment of F_1 sheep in an organic production system. J. C. Angeles Hernandez,* B. Albarran Portillo, A. V. Gomez Gonzalez, N. Pescador Salas, and M. Gonzalez Ronquillo, *Universidad Autonoma del Estado de Mexico, Facultad de Medicina Veterinaria y Zootecnia, Toluca, Estado de Mexico, Mexico.*

The appropriate adjustment of mathematical models applied to lactation curves, allows the analysis of biological and environmental factors affecting milk yield. The lactation curve models generally come in 2 categories: mechanistic models based on the biology of lactation and empirical models, based on current records on milk production. The aim of the present study was to compare the degree of fit of mathematical lactation curve models, empirical and mechanistics, and to determine the effect of environmental factors affecting lactation curve parameters of F1 sheep under an organic production system. A total of 5,382 weekly records from 150 dairy sheep lactations of F1 (East Friesian × Pelibuey, Suffolk or Blackbelly) were used. Four mathematical models were applied: 2 empirical models, Wood (WD), Wilmink (WL), and 2 mechanistic models, Pollott multiplicative 2 parameters (POL2) and 3 parameters (POL3), to determine the degree of adjustment of each function, using the following criteria: coefficient of determination adjusted to the number of parameters (R2), sum of mean square predicted error (MSPE), and the correlation between the observed and the predicted value (R), plus the comparison of the values of total milk yield (TMY), peak yield (PY), and peak time (PT) estimated from each mathematical model. Factors like number of parity (1,2,3,4), type of lambing (single or twin) and season of lambing (spring, summer, autumn, winter) were analyzed to determine their influence on TMY of each function. The parameters of each model were estimated from a non-linear regression analysis using the NLIN procedure of SAS with Marquardt methodology. There were no differences ($P > 0.05$) for environmental factors, as well as for the adjustment in different mathematical models. The values of R2 and R were higher than 0.90 and 0.95, respectively for all models. Both empirical models (WD and WL) had difficulty to calculate the TMY. Only the WL model presented no difference ($P > 0.05$) between observed and estimated PY, and this parameter was underestimated by the other models. The mathematical models have an adequate lactation curve fitting, whereas empirical models have difficulty estimating PT and PY, due to the shape of sheep's lactation curve in this study showing no PY, resulting in erroneous values of the parameters. Mechanistic models POL2 and POL3 were more flexible at this. According to the evaluation criteria curve fitting, the WL model presented the best adjustment.

Key Words: sheep, mathematical model, curve lactation

T383 Pre-partum nutritional supplementation strategies in goats managed under grazing conditions: 1. Doe and offspring BW dynamics. V. Contreras-Villareal[1], O. Angel-Garcia[1], J. M. Guillen-Muñoz[1], R. Rodriguez-Martinez[1], G. Arellano-Rodriguez[1], C. A. Meza-Herrera[2], M. Mellado[3], and F. G. Véliz*[1], *[1]Universidad Autónoma Agraria Antonio Narro, Torreón, Coahuila, México, [2]URUZA, Universidad Autónoma Chapingo, Gómez Palacio, Durango, México, [3]Universidad Autónoma Agraria Antonio Narro, Saltillo, Coahuila, México.*

The aim of this study was to evaluate the effect of nutritional supplementation on d 15 or 35 pre-partum upon both doe and offspring BW managed under a grazing-semiarid system. Ranging goats (n = 31; 1200 to 1800 h) were divided in 3 experimental groups during the last third of gestation: i) control group (CG; n = 7) without nutritional supplementation, ii) 15-group (15G; n = 14) which received a 15 d pre- to 7 d postpartum supplementation of 500 g per animal per day of a mixed ration (20% chicken manure, 37% rolled corn, 37% bran, 4% treacle, 2% salt) during the morning at 0800 h, and iii) 35-group (35G; n = 10) which received the same mixed ration 35 d pre- to 7 d post-kidding. Before the onset of the supplementation period, (35 d) and at parturition, all goats were weighed; besides, the offspring of the 3 experimental groups were weighted at parturition, and at 7 d and 15 d after birth. Doe and offspring BW of the experimental groups were compared by ANOVA; afterward paired mean comparisons considered X^2 analysis (SYSTAT 12, 2007, USA). While no differences ($P > 0.05$) for doe BW were observed on d35 pre-partum among experimental groups, supplemented does (15G and 35G) depicted greater BW values at kidding ($P < 0.05$) with respect to control goats. Doe BW differences ($P > 0.05$) among groups were observed on 7 d postpartum. Regarding offspring BW, the 35G depicted the largest BW values at birth ($P < 0.05$), without differences among groups on 7 d postpartum. Nonetheless, supplemented groups, either 15G or 35G, depicted the largest offspring weights values ($P < 0.05$) on 15 d post-kidding with respect to the other experimental groups (Table 1). Present results demonstrated that either 15 d or 35 d supplementation period prepartum increased both doe and offspring BW. Such supplementation regimen could be of particular importance because of the well established kid-meat market for milk-fed kids in this region of Mexico with the potential increases in the survival rates of replacement kids.

Table 1. Effect of feed complementation over the mother and kid body weight at parturition in goats from northern Mexico in grazing conditions

	Mother weight (kg)			Kid weight (kg)		
	−35 d	Birth	7 d	Birth	7 d	15 d
CG	54 ± 3.1^{a}	44 ± 2.2^{a}	44 ± 2.2^{a}	3.5 ± 0.2^{a}	4.4 ± 0.2^{a}	5.4 ± 0.3^{a}
G15	54 ± 2.3^{b}	$46 \pm 2.0^{a,b}$	44 ± 1.6^{a}	3.4 ± 0.2^{a}	5.0 ± 0.2^{a}	6.3 ± 0.1^{b}
G35	55 ± 1.3^{b}	49 ± 1.3^{b}	47 ± 1.2^{a}	3.8 ± 0.1^{b}	4.7 ± 0.1^{a}	6.2 ± 0.1^{b}

Key Words: goats, offspring

T384 Pre-partum nutritional supplementation (energy or protein) strategies in goats managed under grazing conditions: 3. Offspring growth dynamics and doe milk production. V. Contreras-Villarreal[1], O. Angel-Garcia[1], J. M. Guillen-Muñoz[1], R. Rodriguez-Martinez[1], G. Arellano-Rodriguez[1], C. A. Meza-Herrera[2], M. Mellado[3], and F. G. Véliz*[1], *[1]Universidad Autónoma Agraria Antonio Narro, Torreón, Coahuila, México, [2]URUZA, Universidad Autónoma Chapingo, Gómez Palacio, Durango, México, [3]Universidad Autónoma Agraria Antonio Narro, Saltillo, Coahuila, México.*

The effect of 3 nutritional pre-partum regimens in goats under semiarid grazing conditions in northern Mexico upon offspring growth dynamics and doe milk yield were evaluated. Ranging goats (n = 31) were divided in 3 experimental during the last third of gestation: i) Control Group (CG; n = 8) without nutritional supplementation, ii) Protein Group (PG; n = 13) which received a 500 g per animal per day of a mixed protein ration (40% chicken manure, 27% rolled corn, 27% bran, 4% treacle, 2% salt) and iii) Energy Group (EG; n = 11) received 500 g per animal per day of a mixed energy ration (20% chicken manure, 37% rolled corn, 37% bran, 4% treacle, 2% salt). Supplements were offered 25-d pre- to 7-d postpartum during the morning at 0800 h. While kids were weighed at birth, d-7 and d-15 post-kidding, milk production was recorded on d-7 and d-15 postpartum; goats were milked at 2000 h, separated from their offspring, and milk yield was recorded the next day at 0800 h. Offspring BW and milk production of the 3 experimental groups were compared with ANOVA (SYSTAT 12, 2007, USA). While the greatest offspring birth weight ($P < 0.05$) was observed in the EG-group, no differences ($P < 0.05$) among groups occurred on 7-d for offspring BW; however, on d-15, supplemented groups depicted the greater ($P < 0.05$) BW with respect to the CG. The same was true regarding milk production; both supplemented groups, had the greatest ($P < 0.05$) milk production values at either d 7 or d 15 postpartum (Table 1). Present results demonstrate that either energy or protein before and immediately after parturition enhanced both the offspring growth dynamic as well as milk production of goats under range-grazing conditions in northern Mexico, enabling us to recommend a management strategy for goats under marginal production systems.

Table 1. Effect of two diets, one protein and one energetic, given to adult pregnant goats near parturition on their offspring BW and milk production

	Offspring BW			Milk production	
	Parturition	7 d	15 d	7 d	15 d
CG	3.5 ± 0.2	4.5 ± 0.2	5.4 ± 0.2	1.1 ± 0.2	1.0 ± 0.2
PG	3.4 ± 0.2^{a}	4.8 ± 0.2^{a}	6.1 ± 0.2^{b}	1.7 ± 0.1	1.6 ± 0.2
EG	3.6 ± 0.1^{b}	4.8 ± 0.2^{a}	6.4 ± 0.2^{b}	1.5 ± 0.1	1.6 ± 0.1

Key Words: offspring, goat, milk

T385 Effects of ground linted cottonseed on growth and carcass characteristics of feedlot lambs fed high-concentrate diets. R. A. Souza, R. S. Gentil, E. M. Ferreira, D. M. Polizel, M. I. C. Alves, L. G. M. Gobato, A. V. Pires, and I. Susin,* *Escola Superior de Agricultura Luiz de Queiroz (ESALQ)/University of São Paulo (USP), Piracicaba, São Paulo, Brazil.*

Linted cottonseed is an ingredient of high interest in ruminant nutrition due to its high content in protein, fiber and energy. The objectives of this experiment were to determine the effects of ground linted cottonseed on growth and carcass characteristics of lambs fed high-concentrate diets. Forty-five Dorper × Santa Inês ram lambs (initial BW 21.3 ± 3.7 kg and 79 ± 6 d old) were assigned to a randomized complete block design defined by BW and age at the beginning of the trial. The experimental diets were isonitrogenous (16% CP) and composed of 90% concentrate and 10% coastcross hay. The levels of ground linted cottonseed (DM basis) were: 0 (CS0), 7 (CS7), 14 (CS14), 21 (CS21) or 28% (CS28). Diets were fed once a day as a TMR and the trial lasted 56 d. At the end of the performance trial, lambs were slaughtered, after a 16-h fast period, and carcass measures (dressing percentage, LM area and back fat thickness) were recorded. There was a linear ($P < 0.01$) decrease in DMI (1.24, 1.12, 1.16, 1.02 and 0.83 kg) as CS increased in the diet. ADG (342, 290, 309, 259 and 182 g), and G:F were 0.29, 0.26, 0.29, 0.25 and 0.22, for CS0, CS7, CS14, CS21 and CS28, respectively. Carcass characteristics followed the linear decrease observed with the performance data. Increasing levels of ground linted cottonseed adversely affected lamb performance and carcass characteristics. However, dietary cottonseed inclusion may be dictated by its cost compared with soybean meal.

Key Words: co-product, feedlot, sheep

T386 Effect of concentrate versus forage diet on feed intake and reproductive traits in crossbred ewes. R. R. Cockrum,* S. L. Lake, R. H. Stobart, and K. M. Cammack, *University of Wyoming, Laramie.*

The aims of this research were to 1) evaluate the effects of ration differences on measures used to determine individual residual feed intake (RFI), 2) establish if individual RFI ranking (most efficient to least efficient) is affected by changes in diet composition, and 3) determine if more or less efficient ewes differ in reproductive parameters. Targhee × Rambouillet (n = 61; 7 mo of age) ewes were evaluated on the GrowSafe System to determine individual RFI values and ranking. Ewes were first tested on a concentrate diet (14.2% CP) for 62 d, and then retested (10 mo of age) with a forage diet (15.2% CP) for 66 d. Differences in RFI, ADG, average feed intake, and metabolic mid-weight (MMWT) from the concentrate and forage diets were analyzed using the GLM procedure in SAS. Residual feed intake rankings from the 2 rations were analyzed for similarity with the CORR procedure using the Spearman method. Ewes (n = 18) were further selected to measure reproductive efficiency based on their forage ration RFI ranking: highly efficient (HE, n = 6), moderately efficient (ME, n = 6) and lowly efficient (LE, n = 6). Age of puberty, date bred, and pregnancy status were determined in RFI selected groups and analyzed using the GLM procedure in SAS. Overall, average intake, ADG, and MMWT were higher ($P < 0.001$) in the forage diet compared with the concentrate diet. There was a high positive correlation ($r = 0.69$; $P < 0.001$) between RFI rankings based on the concentrate and forage rations in both overall and selected ewes. Residual feed intake and average feed intake on the concentrate ration were lower ($P \leq 0.002$) in the HE and ME ewes compared with the LE ewes, but did not differ ($P = 0.161$) between the HE and ME ewes. As expected, RFI and average feed intake differed ($P < 0.001$) between the HE, ME, and LE ewes when on the forage diet. Age of puberty, day bred, and pregnancy status did not differ ($P \geq 0.337$) among selected ewes. Results indicated that the least efficient animals remained in the bottom 15% of RFI ranked ewes regardless of diet (forage versus concentrate). However, re-ranking of RFI is possible in more efficient animals when diet is changed. Additionally, this study and previous literature provide little evidence to support that RFI selection negatively affects reproductive parameters in sheep.

Key Words: diet, reproduction, residual feed intake

T387 Influence of level of zilpaterol hydrochloride supplementation at different live weight on carcass characteristics of feedlot lambs. J. C. Robles-Estrada*[1], H. Dávila-Ramos[1], A. Estrada-Angulo[1], F. G. Ríos[1], K. I. Leyva-Medina[1], and A. Plascencia[2], *[1]Universidad Autónoma de Sinaloa, Culiacán, Sinaloa, México, [2]Universidad Autónoma de Baja California, Mexicali, Baja California, México.*

Fifty-four male lambs Pelibuey × Katahdin (41.8 ± 1.64 kg) were used in a 33 d feeding trial (3 pens per treatment in a completely randomized design with a 3 × 3 factorial arrangement) to evaluate the effect of zilpaterol hydrochloride on the carcass characteristics, using the final live weight as covariate. The lambs were fed on cracked corn-based finishing diet (1.40 Mcal/kg of NE_g). Three weight groups (31.6 ± 1.27, 41.8 ± 1.85 and 51.8 ± 1.42 kg) were assigned to receive 0 (Z0), 0.15 (Z15), and 0.30 (Z30) mg/kg of live weight d-1 zilpaterol (as zilpaterol chlorhydrate, Zilmax, Intervet México, México City) during 30 d and withdrawn from zilpaterol for the last 3 d on feed. No interactions ($P > 0.10$) were observed between levels of zilpaterol and weight groups. The HCW was greater ($P < 0.01$) for Z30 compared with Z15, but both were greater with respect to Z0 (24.2, 25.1 y 26.0 kg for Z0, Z15 and Z30, respectively). The dressing percent (52.2, 54.7, and 55.7% for Z0, Z15 and Z30, respectively) and LM (5.81, 6.29 and 6.60 cm^2 for Z0, Z15 and Z30, respectively) were higher ($P < 0.01$) for Z30 and Z15 compared with Z0. The zilpaterol supplementation did not affect ($P > 0.10$) the KPH fat (2.18%) and fat thickness (2.46 mm). We concluded that the zilpaterol response was not affected by the weight group; however, the zilpaterol improved the HCW, dressing percent and LM area without affecting the deposited fat.

Key Words: β-agonist, lambs, zilpaterol

T388 Fatty acids in milk of goats fed sunflower seeds at different crude protein levels in the diet and thrombogenicity and atherogenicity indexes.

C. Vázquez Fontes*[1], A. Domïnguez López[1], N. Pescador Salas[2], L. R. Bernal Martinez[1], and M. Gonzalez Ronquillo[2], *[1]Universidad Autónoma del Estado de Mexico. Facultad de Ciencias Agricolas, [2]Facultad de Medicina Veterinaria y Zootecnia, Toluca, Estado de Mexico. Mexico. 50000.*

Fatty acids are part of the human diet and are involved in important functions. In the 70s, a concern began to reduce saturated fats in the human diet. One approach focuses on its intake, an important factor in determining the fat content and composition of the milk. The amount and type of fatty acid supplement is the result of fat in the animal feed, particularly those products from extraction of oils. The objective was to identify the profile of fatty acids in milk from goats fed on pasture and supplemented with 2 levels of protein (12 vs 14% CP). Milk was obtained from 8 dairy goats (60 ± 2 kg BW) fed on pasture (35%), corn silage (20%), supplemented with a concentrate of 12% or 14% CP, based on sunflower seed, corn grain, soybean meal and minerals. Chemical analysis were performed using the infrared Ecomilk Milk Analyzer (Milkana Kam 98–2 meetings, Hillerød, Denmark). The fatty acid profile was performed by detergent solution with 50 g of sodium hexametaphosphate (SHMP) and 24 mL of Triton X-100 dissolved in distilled water. Samples were processed in water bath (90°C) until fat separation from the milk. Samples were injected into the gas chromatograph (Perkin Elmer Autosystem 9000). The percentage of each fatty acid was calculated by dividing the area under the curve of each peak by the sum of the integrals of the fatty acids identified. To calculate the index of atherogenicity (IA) and thrombogenicity (IT) the formulas proposed by Ulbricht and Southgate (1991) was used. Animals were distributed in a 2 × 2 Latin square design, repeated 4 times. Experimental periods consisted of 15 d for adaptation and 5 d for sample collection. There were no differences ($P > 0.05$) between treatments with 12% and 14% CP in milk content and fatty acids profile (Table 1). Also there were no differences ($P > 0.05$) in terms of atherogenicity and thrombogenicity indexes. Levels of IA and IT for the treatment of 12% CP were 1.23 and 0.78, respectively. This content is low and is not indicative of promoting increased serum cholesterol levels in humans. There are similar characteristics of the 2 treatments, suggesting that a diet containing 12 or 14% protein did not change fatty acid profile of milk.

Table 1. Effect of the crude protein supplemented to dairy goats on the fatty acids (FA) profile (g/100g) of milk

Item	C8:0	C10:0	C12:0	C14:0	C16:0	C18:0	C18:1	C18:2	C18:3
14% CP	3.98	13.01	5.33	9.81	23.1	10.1	25.4	3.34	0.80
12% CP	3.92	13.0	5.34	10.03	24.6	10.5	25.1	3.09	0.76

Swine Species II

T389 Genistein decreases LPS-stimulated production of TNF-α in porcine peripheral blood mononuclear cells. L. Seefeldt* and J. Clapper, *South Dakota State University, Brookings.*

Endotoxemia is often manifested by an overproduction of circulating pro-inflammatory cytokines, such as tumor necrosis factor-α (TNF) in response to lipopolysaccharide (LPS). Genistein, a non-steroidal tyrosine kinase inhibitor, has been shown to decrease the release of TNF from circulating peripheral blood mononuclear cells (PBMC) in response to LPS in several species. To further examine if genistein could be used to reduce LPS stimulated TNF release in the pig the following experiment was performed. Blood (20 mL) was collected by jugular venipuncture from 5 mo old barrows and the isolated leukocyte rich plasma was layered over Histopaque 1077 and centrifuged to obtain an enriched PBMC population. PBMC were washed twice in sterile DPBS, counted, diluted and added to 24-well culture plates (5×10^5 cells/well) and incubated at 37°C in 5% CO_2 for 2 h to allow cells to adhere. Non-adherent cells were decanted and adherent cells covered with RPMI 1640 plus 1% FBS and 0, 10 μM, 20 μM and 40 μM genistein with and without 10 ng/mL LPS (*E. coli* O111:B4). Cells were incubated for 10 h at 37°C in 5% CO_2 after which the media was collected and frozen at −80°C until assayed for TNF by ELISA. Triplicate wells were prepared for each genistein-LPS combination. Optimal cell number and LPS concentration were determined by a previous dose response experiment. Differences in media concentrations of TNF were determined by ANOVA. LPS treatment increased media concentrations of TNF 7 fold over controls ($P < 0.01$). Genistein dose dependently decreased ($P < 0.01$) media concentrations of TNF. The 40 μM dose of genistein decreased ($P < 0.01$) media concentrations of TNF to a greater extent than 10 and 20 μM, however, all doses of genistein decreased ($P < 0.01$) media concentrations of TNF compared with LPS stimulated controls. Additionally, 20 and 40μM genistein decreased ($P < 0.01$) media concentrations of TNF in non-LPS-stimulated cells but no difference ($P > 0.05$) was detected between the 2 doses. These preliminary data suggest genistein may be useful in ameliorating LPS stimulated TNF production in the pig.

Key Words: pig, LPS, genistein

T390 Effort on an oral endotoxin challenge in pigs. S. Schaumberger* and G. Schatzmayr, *Biomin Research Center, Tulln, Austria.*

The effect of endotoxin (lipopolysaccharide - LPS) of *E. coli* O55:B5 was tested in vivo in weaners. The aim of the study was, to develop an oral endotoxin challenge model to better understand the mechanism of endodoxic shock. In the first trial, 3 groups with 3 pigs in each were conducted: group I received 200 μg LPS per kg body weight intravenously. Pigs in group II were administered 20 mg LPS per kg body weight orally. Group III served as a negative control which was orally given 40 mL physiological saline. The trial lasted for 14 h where blood samples were drawn hourly. At the end, all pigs were euthanized and necropsy was performed. Blood samples were analyzed for LPS, tumor-necrosis-factor-α (TNF- α) and interleukin-6 (IL-6). Pigs of group I showed severe clinical signs (hyperventilate, cyanosis, vomiting) starting 15 to 20 min after administration and one pig had to be euthanized within the first hour due to muscle spasms. Five hours after administration, a second pig died. The third pig recovered. The 3 pigs of group II did not show severe clinical signs. They laid down most of the time as did the animals in the negative control. An increase of LPS values as well as IL-6- and TNF- α-values were observed within blood samples in group I, compared with the other groups. As this trial did not reveal a positive oral endotoxin challenge in another attempt, 9 piglets were weaned at 3 weeks of age and were fed a diet with a higher protein source for one week, to trigger permeability of the intestinal wall and to ensure that, orally administered LPS can enter the circulation. Pigs were divided into 3 groups: group I orally received 20 mg of LPS per kg body weight. Pigs in group II were orally administered 20 mg LPS diluted in sun flower oil per kg body weight, as fatty acids should promote the resorption of LPS from the intestine. Group III served as negative control group which was orally given physiological saline. This trial was elongated to 22 h and again hourly blood sampling and necropsy were performed. After this challenge, no clinical signs were observed during the whole 22 h. No severe macroscopic or histological lesions were observed in the intestine. Blood samples of all 9 animals were inconspicuous. Further approaches have to be investigated for the development of an oral endotoxin challenge model.

Key Words: pigs, endotoxin, challenge

T391 Effect of Actigen supplementation in gestation and lactation on sow and piglet performance, colostrum Ig level and milk composition. R. S. Samuel* and K. M. Brennan, *Alltech Center for Animal Nutrigenomics and Applied Animal Nutrition, Nicholasville, KY.*

Actigen (Alltech Inc.) is a second-generation yeast-cell-wall (YCW) product containing mannanoligosaccharides that have been shown to increase sow body weight gain and reduce piglet mortality. Our aim was to assess whether inclusion of YCW sow diets changes milk composition and improves sow and piglet performance. Sows were fed non-medicated gestation (n = 657) and lactation (n = 633; parity 1–8) diets without or with YCW (900 ppm). Feed from d 3–100 of gestation was provided as per body condition. Additional feed (909 g/d) was fed after d 100. Sows were offered lactation feed ad libitum after d4 post-farrowing. Piglets (including stillborns) were weighed after farrowing. Cross-fostering within treatment was completed within 24 h post-farrowing and post-foster litter weights recorded. Sow BW was recorded pre- and post-farrowing. Milk samples (120 per treatment) were analyzed for immunoglobulin and nutritional content. Conception rate tended to be greater ($P \leq 0.09$) among sows fed YCW compared with controls. Sows fed YCW had lower ($P \leq 0.05$) post-farrow net BW and lost less BW ($P \leq 0.001$) during lactation (3.2 vs. 11.3 kg; SEM 2.6) than controls. Litter birth weight; piglets born alive and dead per sow; adjusted litter gain; sow ADFI; post-weaning BW; pre- and post-farrowing backfat thickness; and milk fat, lactose, milk energy, somatic cell count, milk urea N, and total solids did not differ between treatments. Protein (%; $P \leq 0.01$) and total solids less fat (%; $P \leq 0.03$) were greater in milk from YCW-fed sows compared with controls. Milk IgG concentrations from parities 1, 3 and 6 were greater ($P \leq 0.05$) with YCW. Number of piglets weaned per sow was greater ($P \leq 0.02$) for parity 4 sows fed YCW. Feeding YCW to sows during gestation and lactation significantly reduced lactating sow BW loss without affecting weaning weight or the number of piglets weaned per sow.

Key Words: mannan oligosaccharides, piglet, sow

T392 Effect of maternal Actigen supplementation during gestation and lactation on piglet gut development and gene expression.

K. M. Brennan* and D. E. Graugnard, *Alltech Center for Animal Nutrigenomics and Applied Animal Nutrition, Nicholasville, KY.*

Our aim was to determine the effect of adding a yeast-cell-wall-based product (Actigen, Alltech Inc., Nicholasville, KY) to maternal gestation and lactation diets on piglet intestinal gene expression and morphology. Sows (parity 1–8) were housed in farrowing crates at a commercial production research facility and randomly assigned to 1 of 2 treatments: commercial gestation and lactation diets without (control, CON) or with 0.90 kg/t of Actigen (ACT). On d 10 post-farrowing, 1 piglet per sow (n = 15 per treatment) was randomly selected and euthanized. Jejunum samples were flash-frozen for microarray analysis and fixed in buffered formalin for histologic analysis. Intestinal morphology was evaluated using H-E staining of the jejunum (n = 6 per treatment). No differences in goblet cell count, goblet cell area or villus height were observed. Intestinal gene expression was evaluated using the Affymetrix Porcine Genome Array. Of the 15,000 transcripts, 659 genes were affected (262 upregulated, 397 downregulated) by maternal ACT ($P \leq 0.05$, FC $\geq$1.2). Genes significantly affected by ACT were classified by biologic function: growth and proliferation, metabolic process, immune system process, response to stimulus, cell cycle, cell communication, or organ development. Different functions showed evidence of positive regulation due to ACT (z-score $\geq$1.5) including cellular growth and proliferation, cell signaling and post-translational modification. Negative regulation was observed (z-score $\leq$ 1.5) in cellular movement and organismal injury and abnormalities. Multiple pathways were activated in piglets from ACT sows including cholecytokinin/gastrin-mediated signaling, ephrin receptor signaling and gonadotropin signaling. Gastrin is a potent cell-growth factor that has been implicated in a variety of biologic processes including maintenance of the gastric mucosa, proliferation of enterochromaffin-like cells, and neoplastic transformation. Ephrin is fundamental for the cell to cell signaling in different pathways related to cell migration and angiogenesis. Gonadotropins are known to play different roles in growth and reproduction. Although performance and intestinal morphology did not differ between treatments, transcriptional changes d10 post-farrowing implies long-term ACT gut health, growth and development benefits.

Key Words: mannan oligosaccharide, gene expression, piglet

T393 Effect of social ranks on oxidative stress status, reproductive performance, and immune status of sows housed in groups during gestation.

Y. Zhao,* W. L. Flowers, and S. W. Kim, *North Carolina State University, Raleigh.*

This study was to determine if social ranks of gestating sows housed in group would affect their oxidative stress status, reproductive performance, and immune status. On d 35 of gestation, 72 multiparous sows were checked for pregnancy and randomly assigned to 24 gestational pens with 3 sows per pen. The social rank of sows within a pen was determined by observing their aggressive behavior for a 4-d period after allotment and classified into high-, middle-, and low-ranking groups (HR, MR, and LR) according to their percentage of winning interactions. On d 109 of gestation, sows were moved to individual farrowing crates. Litter size and piglet weight were recorded during lactation and blood samples from sows were taken during gestation and lactation. Plasma malondialdehyde, protein carbonyl, and 8-hydroxy-deoxyguanosine (8-OHdG) were analyzed. Immunoglobulin G and IgM in sow plasma and colostrum were measured. Sows in HR showed higher ($P < 0.05$) BW than sows in MR and LR. Sows in HR had greater ($P < 0.05$) number of born dead (2.6) than sows in MR (1.2) and LR (1.4). On d 18 of lactation, litter size was greater ($P < 0.05$) in LR (9.6) than in HR (7.2) and MR (8.2). Sows from LR tended to have greater ($P = 0.067$) litter weight (51.8 kg) than sows from HR (43.1 kg). Piglet from LR tended to have smaller ($P = 0.094$) ADG (207 g) compared with HR (233 g). Plasma 8-OHdG in LR (0.61 ng/mL) was greater ($P < 0.05$) than HR (0.36 ng/mL) and MR (0.43 ng/mL). The concentration of protein carbonyl was shown to be negatively correlated ($P < 0.05$) with litter performance in MR and LR. Plasma 8-OHdG was shown to be negatively correlated ($P < 0.05$) with reproductive performance of sows in HR and LR. Sows in HR tended to have greater ($P = 0.068$) IgG (163.8 mg/mL) in colostrums compared with sows in MR (127.5 mg/mL). In conclusion, for all ranks, it was shown that the reproductive performance was related to oxidative stress status of sows. Sows in HR had similar litter size, litter weight, and piglet ADG at wean compared with sows in MR. The farrowing rate of sows in LR was lower compared with HR and MR, which could be caused by higher DNA damage during late gestation and lactation.

Key Words: oxidative stress, social rank, sow

T394 Novel strategies to stimulate GLP-2 secretion and intestinal adaptation in weanling piglets.

I. R. Ipharraguerre*[1], D. G. Burrin[2], G. Tedó[1], D. Menoyo[3], J. J. Holst[4], and A. Mereu[1], [1]*Feed Additives Division, Lucta S.A., Montornés del Vallés, Spain,* [2]*USDA/ARS Children's Nutrition Research Center, Department of Pedriatics, Baylor College of Medicine, Houston, Texas,* [3]*Departamento de Producción Animal, Universidad Politécnica de Madrid, ETS Ingenieros Agrónomos, Madrid, Spain,* [4]*Department of Biomedical Sciences, University of Copenhagen, Copenhagen, Denmark.*

Weaning-induced intestinal atrophy is partly related to reduced secretion of glucagon-like peptide 2 (GLP-2). Recent studies showed that stimulating GLP-2 secretion in total-parentally-fed piglets promotes gut growth. We conducted 2 infusion trials (IT) and 1 feeding trial (FT) to investigate the hypothesis that stimulating GLP-2 secretion immediately after weaning may improve intestinal integrity in piglets. In each trial, 36 piglets weaned on average at 21 d of age and 6.1 kg of BW were individually housed and fed ad libitum. In the IT (n = 12), treatment solutions were chenodeoxycholic acid [60 mg/kg BW, (CDC)] and β-sitoesterol [100 mg/kg BW, (BSE)] in IT1; and CDC (120 mg/kg BW) and zein protein hydrolyzate (1.4 g/kg BW) in IT2. Until d 6 postweaning, all piglets were intragastrically infused once daily with 50 mL of either water (control) or treatment solutions; on d 5, serial plasma samples were obtained from 6 pigs/treatment. In the FT (n = 18), a prestarter diet without (control) or with CDC (60 mg/ kg BW) was fed from 0 to 14 d postweaning; afterward, pigs were fed a starter diet until d 35. In all studies, 6 pigs/treatment were sacrificed and their intestines were collected for later analyses. Data were analyzed as a mixed-effect model with pig treated as random variable. Compared with control, infusing CDC at 60 mg/kg BW increased ($P < 0.05$) mean plasma GLP-2 by 77%, small intestine length, intraepithelial lymphocytes and cleaved caspase in the ileum; tended to increase ileum weight and length ($P < 0.08$) and mean plasma GLP-1 ($P < 0.13$) without affecting intake and final BW. At 120 mg/kg BW, infusing CDC also increased ($P < 0.05$) GLP-1 and GLP-2, but reduced intake, BW, and ileal crypt depth. Other treatments did not affect measured parameters, except that BSE tended to depress GLP-1 (27%) and GLP-2 (42%) compared with control. In the FT, CDC did not affect intestinal weight and piglet performance compared with control. In conclusion, oral CDC treatment potently enhanced GLP-2 secretion in weanling piglets, but the mitigation of weaning-induced intestinal atrophy was apparently counterbalanced by increased inflammation and reduced feed intake.

Key Words: GLP-2, bile acids, pigs

Teaching/Undergraduate and Graduate Education

T395 Student perceptions and moral conflict of animal use in society. M. Amstutz, K. Bennett-Wimbush,* and D. Willoughby, *Ohio State ATI, Wooster.*

Animal production practices have increasingly come under attack from emotion-driven animal rights groups. Therefore, it is imperative that animal science students be able to distinguish animal rights from animal welfare. To determine if students, particularly those majoring in animal sciences, could make this distinction, incoming freshman (n = 136) completed a 20-question survey (Likert scale 1–5; range 20–100, summed and reported as a composite score) regarding perceptions of animal use, rights and welfare. Survey format, scoring and some content was modified from Davey, 2006. Composite scores (CS) ranged from 54.8 to 81. Lower scores were consistent with animal rights positions and higher scores corresponded with animal use values. Composite scores were examined for correlation to varied student demographics. Major ($P < 0.001$); career objective ($P < 0.01$) and history of animal ownership ($P < 0.001$) significantly altered CS. Livestock science majors (70.1 + 1.1) scored higher than either equine (57.7 + 1.3) or horticulture majors (57.9 + 1.4). Students with livestock production career objectives scored higher (69.5 + 1.6) than students interested in either equine production (61.5 + 2.5) or veterinary medicine (61.2 + 1.6). Animal ownership (commercial livestock, show livestock, equine, pets and all possible combinations) were analyzed. Commercial livestock ownership, reported by 39.9% of students, dramatically increased ($P < 0.001$) CS compared with students reporting equine, pet or no animal ownership. Additionally, students from NE Ohio had lower CS than students from SE Ohio, likely due to the increased urban population of the region. As part of the survey, students were asked if they perceived a difference between animal rights and welfare. Sex ($P < 0.05$), age ($P < 0.05$), and home residence ($P < 0.01$) all significantly influenced responses. Males, non-traditional students (age >21), and urban dwellers were less likely to differentiate between animal rights and welfare than females, 17–20 year olds, and students from non-urban backgrounds (farm, rural, suburban), respectively. This study indicates most students CS are consistent with supporting animal welfare and use.

Key Words: animal rights, welfare, undergraduate

T396 Developing horsemanship skills through the understanding of equine behavior. M. Nicodemus* and S. Lindsey, *Mississippi State University, Mississippi State.*

As prey animals, horses are instinctively unique from their human handlers, and thus, these handlers need to understand the innate behaviors that dictate how the horse responds during the training process, and thus, University horsemanship programs are meeting this need with the introduction of behavioral sciences in their equine curriculum. Mississippi State University has offered a behavioral science course, ADS 2102 Equine Behavior & Training, for a decade, but only recently has introduced a lecture component to the laboratory where students study behavioral sciences principles and current research in equine behavioral sciences, and then, supplement their studies with the laboratories focused on these principles and research. Therefore, the study objectives were to determine how effective an equine behavioral science course was in building students' confidence in their potential horsemanship skills. A survey was given to students (n = 28) at the start and conclusion of the course with a 18 question survey focused on students′ evaluation of their horsemanship skills using a 5-point scale with a higher score indicating a stronger confidence in performing a skill. Scores were analyzed by a one-way ANOVA to determine the effectiveness of this course ($P < 0.05$). While 9 questions showed significant improvement in scores by the end of the semester ($P < 0.05$), only 2 questions showed 100% of the respondents scoring 5 by the final survey and these questions focused on the basic ground handling of horses, both trained (initial score = 3.6) and untrained horses (initial score = 3). Of those questions only 4 was focused on riding activities, and that may be due to the lack of riding activities during the laboratories. Only 1 question showed no change in the score, 2.6, and that was focused on riding a green broke horse. Greatest improvement associated with confidence in riding abilities was seen in students' abilities to ride a horse with behavioral problems (initial score = 2.6, final score = 4.2). While the course was not focused on horsemanship, results suggest students understanding of equine behavior strengthened their confidence in their horsemanship skills.

Key Words: equine behavior, horsemanship

T397 A web-based computer simulator to teach dairy farm management. S. Calsamiglia,* L. Castillejos, A. Ferret, G. Vera, and G. Espinosa, *Universidad Autonoma de Barcelona, Barcelona, Spain.*

A web-based software was developed to describe the life cycle of a dairy cow and used to simulate a dairy farm. This e-learning tool has 3 levels of control: the administrator that coordinates the system; the instructor that controls all events in his class, and the student that controls all actions in his farm. Within a class, each student has its own farm defined at random within limits determined by the instructor. Events and variables are defined by default but can be modified within each class by the instructor (i.e., heat detection rate, fertility, incidence of diseases, costs, dietary ingredients). Actions taken by students include: heat detection/synchronization, insemination, dry off, diet specifications, assignment of and transfer of animals between groups, diet formulation, colostrum and milk feeding, weaning, treatment of diseases, milk withdrawal if antibiotics are used, buying and culling of cows or calves, and so on. Modeled events are based on physiologic functions and work at random around a predefined average and ranges. The daily output provides information on milk production and composition, economic performance and counters for errors incurred by the student as a feedback for students and evaluation purposes. Instructors can evaluate student semi-automatically based on performance and error indicators, and may also develop exercises based on their own farm (i.e., calculate required space for cows, land for forages or manure spreading). This e-learning tool has been used by students of first and third year in the Veterinary School with excellent evaluations of the learning process by student's surveys. In a non-planned exam conducted 2 weeks before the final exam, students were 5 times more likely to respond correctly to the same type of questions about dairy cows than other species taught in the same semester. The e-learning program is written in Catalan, Spanish, and English. For information, connect to www.dairyfarm.com.

Key Words: e-learning program, dairy farm management, web-based simulator

T398 Relationships between course schedule and student academic performance and attendance in undergraduate animal science courses.

K. Stutts, M. Beverly,* S. Kelley, M. McMillan, A. Bullion, and L. McMillan, *Sam Houston State University, Huntsville, TX.*

The objective of this study was to evaluate the effect of course schedule (meeting time and day of the week) on academic performance and attendance in undergraduate animal science courses. Data were collected on 2,313 students enrolled during the 16-week fall and spring semesters of 2007 through 2011. Data collected included number of absences and final course grade for each student, and the time of day and day of the week that each course met. Least squares means for final course grades and number of absences were calculated using the mixed procedure of SAS. Significant differences existed for time of day and day of week for final course grades and attendance. Mean final course grade was lowest ($P < 0.01$) for courses that met early in the morning (before 10am; 76.94) compared with courses that met late morning (10am-12pm; 82.05), early (12–3pm; 82.27) afternoon, or late (after 3pm; 82.71) afternoon. Mean number of absences was also greatest ($P < 0.05$) for early morning (4.55) classes. Mean final course grade was greatest ($P < 0.01$) for courses that met once per week on Thursday-only for 3 h (86.21) and lowest for courses that met 3 times per week on Monday, Wednesday, and Friday (76.01). Mean number of absences was lowest ($P < 0.05$) for courses that met only once per week (<1.95), intermediate for courses that met twice per week (<3.75), and greatest for courses that met 3 times per week (6.29). These results indicate that a relationship exists between course schedules and student academic performance and attendance. In this study, student performance and attendance were lowest in courses that met early in the morning and in courses that met 3 times per week. If possible, courses should be scheduled to meet later in the morning or in the afternoon, and should meet no more than twice per week to encourage attendance and increase academic performance of students.

Key Words: undergraduate, course schedules, academic performance

T399 The effects of note-taking method on academic performance in undergraduate animal science courses.

K. Stutts,* M. Beverly, S. Kelley, M. McMillan, A. Bullion, and L. McMillan, *Sam Houston State University, Huntsville, TX.*

Many books and articles on how to succeed in college emphasize the importance of taking good lecture notes. The objective of this study was to evaluate the effect of note-taking method on academic performance and attendance in undergraduate animal science courses. During the first year of the study, students were provided with an outline of material presented in lecture. In the second year, students were provided with a detailed set of notes. Final course grade and attendance data were collected on 814 students enrolled in the fall semesters of 2010 and 2011. Note-taking method data were collected on a subsample of 159 students. Least squares means for final course grades and number of absences were calculated using the mixed procedure of SAS. There was no difference in mean final course grade or mean number of absences for the general population of students between the 2 years. The authors hypothesized that there would be a greater number of absences for the students that were provided with a detailed set of notes since those students were given a complete copy of the material that was covered in class; however, there was no difference ($P = 0.68$) in mean number of absences between the 2 note-taking methods. A significant difference in mean final course grade did exist between the 2 note-taking methods. Students that were provided with only an outline of the material had a higher ($P < 0.05$) mean final course grade (83.70) than students that were provided a detailed set of notes (80.45). These results indicate that students provided with only an outline of course material, and presumably took a more active role in learning by taking additional notes, performed at a higher level than students that were provided with a detailed set of notes.

Key Words: undergraduate, note taking, academic performance

SYMPOSIA AND ORAL SESSIONS

ADSA Multidisciplinary and International Leadership Keynote (MILK) Symposium: How Dairy Exporters Can Provide Food Security

301 Making safe, affordable, abundant food a global reality. T. A. Armstrong,* *Elanco Animal Health, Greenfield, IN.*

A growing wave of food insecurity threatens more than 1 billion people globally. Food costs are near record highs. The number of hungry is increasing and could grow staggeringly as the population reaches 9 billion by 2050. Will we allow this to continue, or will we tackle it with solutions that exist today? Technology solutions can help meet food needs, but consumers do not want technology used in food production. Right? To better understand consumer opinions on technology, Elanco commissioned a research review of 28 studies accounting for more than 97,000 consumers in 26 countries. It found that 1) 95% are food buyers. They are either neutral or supportive of using modern technology to grow food. In general, they make purchases based on taste, cost, and nutrition and 2) 4% are lifestyle buyers. They are looking for gourmet, organic, locally grown, or other types of products. Price is not a factor. Food buyers and lifestyle buyers are not mutually exclusive. That leaves a small fringe group with a loud voice that wants to impose their opinions on others. They want to protect consumers from modern food production threats. It is time to stop being swayed by the fringe and shift the dialog toward a more important question: how can we sustainably feed a growing world? The 2 most important ingredients to safe, affordable, abundant food are technology and choice. Technology enables three basic rights: 1) Food, a basic human right. Every child has the right to be fed. Technology affords a more abundant, more affordable food supply; 2) Choice, a consumer right. Whether it is the Chinese consumer who wants to add animal protein to the diet, or the American consumer who wants locally grown, consumers have the right to a broad variety of food choices. Technology helps allow these choices; and 3) Sustainability, which is environmentally right. We will not be able to feed future generations if we neglect our resources. Technology allows more efficient production, which has made it possible for farmers to feed more people while consuming fewer resources and generating less animal waste. With food supplies tight and prices increasing, we have a unique window of opportunity to act. Together, we can make a difference.

Key Words: technology, food

302 How dairy foods aid in food security. V. Lagrange,* *US Dairy Export Council.*

In the past, the WHO-recommended management of severe acute malnutrition required the administration of highly specialized milk-based liquids (F-100) in a hospital environment. Over the past decade, ready-to-use therapeutic foods (RUTF) have been developed as an alternative to treat severe acute malnutrition. These lipid-based products, that can be used as part of community-based treatments, have revolutionized the effectiveness and coverage of programs addressing malnutrition. Recent clinical trials demonstrate the effectiveness of RUTFs on health outcomes for other vulnerable groups, such as HIV AID patients treated with anti-retro viral therapy. RUTF are typically made with skim or whole milk powder, and the intense use of milk can represent up to 50% of the cost of the rations. Alternative formulations containing whey proteins are being tested for the formulation of ready-to-eat supplementary foods (RUSF). In such a trial, the research team developed a recipe meeting the WHO specifications for RUTF in which milk powder is totally replaced by whey protein concentrate 34% as main source of protein. Based on organoleptic and tolerance acceptability, as well as weight gain (primary outcome), the whey-containing RUSF products were found as effective as traditional RUTF formula. Animal studies are under way to measure the effectiveness of whey permeate in formula used during re-nutrition, and document the application of both lactose and phosphorus found in this ingredient. Other studies pilot the use of RUSF to increase food security for other vulnerable groups such as pregnant and lactating women. Current state of knowledge indicates that cow's milk products have a central role in the treatment of both severe and moderate acute malnutrition. There is growing evidence that their benefit extends to the prevention of malnutrition, and delivery of other desirable health outcomes for vulnerable groups in developing countries.

Key Words: whey protein, milk powder, malnutrition

303 Development of local dairy production: The Indian experience. G. Sohani,* *BAIF Development Research Foundation, Pune, Maharashtra, India.*

Starting from humble levels, India today has the highest aggregate milk production in the world. Production levels have increased from 17 M tons in 1950–51 to over 110 M tons today, with 2022 targets at 180 M tons. In spite of growing population, the per capita milk consumption has also grown from 130 g per day to 263 g per day. Hidden behind the high aggregate production levels there is a skewness - both geographically and among various producer segments. This is a challenge as well as an opportunity. The growth has been through productivity enhancement and creation of processing capacity. Productivity enhancement has been the outcome of not just new technology, but also comprehensive approach covering breeding, feeding and health care, as well the mindset change required for assimilation of new technology. The growth is also unique, through 2 types of bovines: cattle as well as buffalo. The combination has important lessons for dairy development in tropical/sub-tropical parts of the developing world. BAIF, a professional non-profit PVO, has the pride and privilege of having contributed to dairy development in India. BAIF applied cutting-edge technologies for animal production through appropriate adaptations and by creating a novel delivery system to reach the dairy farmers in the remotest locations. This approach is now adopted and emulated across the country. BAIF's program has reached over 4 M farmers directly, and there is regular programmatic contact with close to 3 M farmers in over 50,000 villages of rural India. The value of annual milk production by this group is of the order of US$3 billion. Moreover, this represents income accrual to small farmers, contributes to their food and income security, and to the nutrition security of an even larger number of households. Future challenges will require expanded breeding programs, fodder/nutrition security, health care, and application of newer technologies such as sexed semen, QTL and ET. The paper covers the Indian journey of four decades, the contexts and achievements, their relevance to the developing world, and emerging needs and directions.

Key Words: dairy development, Indian dairy production, milk production and productivity enhancement

Animal Health III

304 Effect of vaccination technique and antibody level on primary and secondary response in beef calves after vaccination against bovine viral diarrhea virus. M. R. Rey*[1], J. C. Rodriguez-Lecompte[1], T. Joseph[3], J. Morrison[2], A. Yitbarek[1], K. M. Wittenberg[1], M. Undi[1], and K. H. Ominski[1], *[1]Department of Animal Science, University of Manitoba, Winnipeg, MB, Canada, [2]Department of Biosystems Engineering, University of Manitoba, Winnipeg, MB, Canada, [3]Veterinary Diagnostic Services, Manitoba Agriculture, Food and Rural Initiatives, Winnipeg, MB, Canada.*

In this study, antibody response was measured in calves following vaccination against bovine viral diarrhea virus (BVDV) using either needle-free (Pulse 250) or needle-syringe (NS) vaccination techniques. The Pulse 250 needle-free (NF) injection device utilizes compressed carbon dioxide to power vaccine injections. At 2 mo of age (d 0), calves were vaccinated either via a needle-syringe injection (n = 39) or a needle-free injection (n = 47) technique, while 10 calves were left unvaccinated (Control). The vaccine administered was a 5-way modified-live respiratory virus containing BVDV types 1 and 2. On d 119 post vaccination, calves received a second immunization using the same product. Body weight was recorded and blood samples were taken on d 0, 21, 42, 119, and 140. Antibody levels in serum, as measured by S/P ratio, were analyzed by a semiquantitative BVDV enzyme-linked immunoassay (ELISA). To understand the effect of antibody level on primary and secondary antibody response in terms of population, calves in each treatment group were ranked by antibody level. Throughout the study, antibody levels against BVDV were not significantly different ($P > 0.05$) between vaccination techniques. Higher ($P < 0.05$) antibody levels in vaccinated relative to unvaccinated calves on d 42, 119 and 140 of the study, demonstrated that animal exposure to BVDV did not occur during the study. The population distribution shows that both vaccination techniques provide homogeneous BVDV antibody production and that anabolic and catabolic trends are dependent on the level of circulating antibodies present before vaccination. The data suggests that the antibody response acquired after vaccinating against BVDV is the same using a needle-syringe or needle-free vaccination technique. However, the level of circulating antibodies (either maternal or vaccination-induced) to BVDV before vaccination seems to have a critical effect on primary and secondary antibody response.

Key Words: needle-free injection, bovine viral diarrhea virus, antibody response

305 Bacteria counts in on-farm pasteurized milk for dairy calves versus season and time post-pasteurization. D. J. Wilson*[1], K. A. Rood[1], and G. M. Goodell[2], *[1]Utah State University, Logan, [2]The Dairy Authority, Greeley, CO.*

On-farm pasteurized milk to be fed to dairy calves was studied for SPC changes over time on 3 commercial farms during 4 seasons. Aseptic milk samples (n = 276) were collected before pasteurization at 63°C for 30 min, then following pasteurization as soon as milk cooled to 49°C, and 1, 2, 3, 4, 5, 6, 7, 8, 10, 12 and 24 h post-pasteurization. All milks had 2 aliquots, one incubated indoors at 4°C (winter/W), 22°C (fall/F, spring/SP) or 37°C (summer/SU), the other outdoors at seasonal temperatures. Outdoor temperature means were W 8°C, F 8°C, SP 10°C, SU 30°C. Only SU had higher outdoor temperature than the other seasons ($P < 0.0001$, ANOVA, Tukey's). Bacterial SPC (cfu/mL) were measured from 6 milk dilutions on Petrifilm. Mean pre-pasteurized SPC was 14,634,257, post-pasteurized was 2,633. A general linear model ($R^2 = 0.70$, $P < 0.0001$) found factors associated with Log SPC: time post-pasteurization, season, farm, time x season, season x farm. Summer had distinctly higher SPC sooner after pasteurization than other seasons; despite the interactions this significant effect was seen on all farms. Fall and SP indoor incubated samples' SPC were not >10,000 for 8 or 12 h respectively, reaching a median of 206,364 and 8,900,000, respectively by 24 h. None of the W samples or F and SP outdoor samples were >1,435 for 24 h. In contrast, SU indoor samples′ SPC were >10,000 by 2 h, 186,800 by 4 h, median 14,500,000 by 24 h. Summer outdoor samples′ SPC were >10,000 by 1 h, 104,733 by 6 h, median 44,000,000 by 24 h. Despite speculation regarding a safe threshold of bacteria count for milk fed to calves, no consensus exists, and there is no definitive health based standard. These data suggest that a reasonable goal would be to feed pasteurized milk to calves if SPC <10,000 cfu/mL. During fall and spring (unless unseasonably warm days occurred) milk could have been safely fed for at least 8 h, in winter for at least 24 h, but in summer for only 2 h post-pasteurization.

Key Words: pasteurization, milk, calves

306 *Salmonella* carriage rates in neonatal dairy calves. E. M. Chavez*[1], R. B. Harvey[2], K. Andrews[2], T. S. Edrington[2], C. M. Scanlan[3], and G. R. Hagevoort[1], *[1]Agricultural Science Center at Clovis, New Mexico State University, Clovis, [2]Food and Feed Safety Research Unit, Agricultural Research Service, USDA, College Station, TX, [3]Department of Veterinary Pathobiology, Texas A&M University, College Station.*

In recent years, it appears that the incidence and carriage rates of *Salmonella* in dairy calves, heifers, and cows have increased. *Salmonella* colonization has induced clinical disease in cattle, but more importantly, has potential implications for foodborne disease. Because the authors have noted *Salmonella* colonization in dairy calves of 6 mo and younger, the present study was conducted to determine the prevalence of *Salmonella* in neonatal dairy calves from calf ranches in the southwestern United States. In 2 studies (February and September, 2011), rectal fecal samples were collected twice weekly from calves 24 h to 4 weeks old and quantitative and qualitative cultivation techniques were used to determine *Salmonella* colonization rates. In the first study, we detected *Salmonella* in 34 of 54 samples (63%) by spiral plating with concentrations of 10^2 to 10^6 cfu/g beginning in calves as early as 24 h old. With an enrichment technique, 100% of calves were positive for *Salmonella* at least one time during sampling and 16.7% were positive at every sample time. In the second study, 9 of 30 calves were positive by spiral plating with fecal concentrations of 10^2 to 10^4 cfu/g at 24 h of age. Upon enrichment, 100% of calves were positive for at least one sampling, and 24 of 30 (80%) were positive at every sampling. *Salmonella* serotypes were not clonal as there were 7 serogroups (C_1, C_2, B, E_1, K, I, and Poly A-I) represented by isolates from both studies. Previous research in our laboratory has reported a high *Salmonella* prevalence in dairy calves from a few days old to a week of age, but this is the first time we examined calves within 24 h of parturition. To the authors' knowledge, this is the first report of dairy calves colonized with *Salmonella* within 24 h of birth. We do not have a ready explanation for this, nor do we understand the biological significance of such high GI tract concentrations of *Salmonella* in neonates. Follow-up studies are being conducted.

Key Words: *Salmonella*, neonatal, dairy calves

307 The association between colostrum bacteria counts and immunoglobulin absorption, calf growth and mortality.

A. Lago*[1], J. Quigley[2], J. Polo[2], and J. Campbell[2], *[1]DairyExperts, Tulare, CA, [2]APC Inc., Ankeny, IA.*

The objective of this analysis was to evaluate the association between both total bacteria count (TBC) and coliform count (CC) in colostrum and the apparent efficiency of absorption (AEA) of immunoglobulin G (IgG), average daily gain (ADG) and mortality before weaning. Records from 172 heifer calves from 8 New England and California dairy farms were used in this analysis. Calves received 3.5 to 3.8 L of colostrum 137 ± 107 min after birth. TBC and CC in colostrum samples collected before feeding averaged $10^{5.31}$ and $10^{2.45}$ cfu/mL, respectively. Colostrum and serum IgG concentrations in serum samples collected from calves between 1 and 7 d of age were measured by radial immunodiffusion and averaged 74 ± 28 and 21 ± 9 mg/ml, respectively. Birth and weaning body weights were only available at the California site; therefore, AEA and ADG were calculated from a subpopulation of 90 calves that were tube fed 3.5 L of colostrum and were bled between 24 and 48 h of age. Multivariable General Mixed models were used for the analysis of AEA and ADG and Cox regression for the mortality outcome. Significant difference was established at $P < 0.05$. AEA was numerically lower when CC were above any of the cutpoints defined in Table 1; however, the difference only was significant when CC $\geq 10^4$ cfu/ml. ADG was not different between the bacteria counts cutpoints. Interestingly, there was a higher mortality in calves receiving colostrum with TBC above 10^6 or CC above any of the cutpoints. Serum IgG was also a significant mortality predictor. However, when including both serum IgG and colostrum TBC or CC in the mortality model, colostrum TBC or CC were still the largest predictors of death.

Table 1. Apparent efficiency of absorption (AEA) and mortality for calves fed colostrum with different total bacteria (TBC) and coliform count (CC) cutpoints

	AEA % (no.)	Mortality % (no.)
TBC $<10^6$ cfu/mL	31^a (70)	8^a (144)
TBC $\geq 10^6$ cfu/mL	29^a (20)	14^b (28)
TBC $<10^5$ cfu/mL	28^a (23)	8^a (110)
TBC $\geq 10^5$ cfu/mL	31^a (67)	10^a (62)
CC $<10^4$ cfu/mL	31^a (83)	7^a (161)
CC $\geq 10^4$ cfu/mL	23^b (7)	36^b (11)
CC $<10^3$ cfu/mL	31^a (64)	7^a (125)
CC $\geq 10^3$ cfu/mL	29^a (26)	15^b (47)

[a, b]Superscripts indicate significance at $P < 0.05$.

Key Words: calves, colostrum, bacteria

308 Adding an anti-inflammatory lactic acid bacteria to a *Bacillus*-based direct-fed microbial improves calf immune development.

M. Duersteler*[1], K. N. Novak[1], C. A. Wehnes[1], M. E. Davis[1], D. R. Shields[2], and A. H. Smith[1], *[1]Danisco USA Inc., Waukesha, WI, [2]Merrick's Inc., Union Center, WI.*

A *Bacillus*-based direct-fed microbial selected for reducing bacterial pathogens increased expression of inflammatory cytokines in vitro and activated immune development in scouring calves. *Enterococcus faecium* ID7 reduced expression of inflammatory cytokines caused by *Bacillus* spores *in vitro*. The objective of this experiment was to determine the effect of adding anti-inflammatory lactic acid bacteria to a *Bacillus*-based DFM on immune development in calves. Calves (72) were randomly assigned to 3 treatments, control, *Bacillus* DFM (2×10^9 cfu/head/day) or *Bacillus* DFM plus ID7 (2×10^9 *Bacillus*, 1×10^9 ID7 cfu/head/day), administered in non-medicated 20:20 calf milk replacer until weaning at 6 weeks. Blood samples were collected at d 7 and 35. Serum was isolated for analysis of α_1-acid glycoprotein (AGP). Leukocytes were isolated for flow cytometric analysis of macrophage phagocytosis activity and immunophenotyping. The *Bacillus* DFM plus ID7 increased ($P = 0.03$) average daily gain and feed efficiency over 8 weeks compared with control calves. At d 35, AGP levels were higher ($P < 0.05$) in *Bacillus* fed calves than control and *Bacillus* plus ID7 fed calves. At d 7, macrophages from *Bacillus* plus ID7 fed calves phagocytosed more ($P = 0.03$) *E. coli* per cell than *Bacillus* fed calves and had a higher ($P = 0.02$) density of CD172a on macrophages than control calves. Calves fed *Bacillus* had a greater ($P = 0.03$) proportion of activated B cells ($AM8^+$) than control calves. Calves fed *Bacillus* plus ID7 had a greater ($P = 0.02$) proportion of activated cytotoxic T cells ($CD26^+$) than calves fed *Bacillus*. *Bacillus* plus ID7 resulted in a greater proportion of $\gamma\delta$ T cells compared with *Bacillus* fed calves ($P = 0.04$) and $CD4^+CD8^+$ cells within the $\gamma\delta$ T cell population compared with control ($P = 0.04$). These results indicate that adding *E. faecium* ID7 alters immune development in calves divergent from the administration of *Bacillus* alone.

Key Words: direct-fed microbial, calf, immunity

309 An evaluation of the efficacy of Metacam NSAID therapy for improving calf vigor, general health and overall performance in newborn Ontario dairy calves.

C. Murray,* S. Deelen, D. B. Haley, T. Duffield, and K. Leslie, *University of Guelph, Guelph, ON, Canada.*

The objective of this research was to evaluate a newborn calf vigor assessment tool. In addition, the usefulness of pain management therapy for excessive trauma and enhancement of newborn calf vigor using meloxicam injectable solution was studied. A total of 842 heifer and bull calves from 10 commercial dairy herds were enrolled in this randomized double blind clinical field trial. At birth, calves were assessed for vigor using a scoring system and given either a 1-mL subcutaneous injection of 20mg/mL Metacam or placebo solution by the producer. A birth record was also completed including information on the calving event, colostrum administration and other details. It was hypothesized that NSAID treatment of calves born from a hard pull would reduce the risk of long-term health problems. At 1, 2, 3 and 6 weeks of age, each calf was assessed for growth and given a standardized clinical score for general health. It was found that calves born from a hard pull had less vigor than individuals from unassisted calvings ($P < 0.001$). However, newborn calf vigor score was not significantly associated with health outcomes. Calves treated with Metacam had better health until 6 weeks of age than placebo treated calves ($P < 0.01$). Better total health score was also significantly associated with increased weight gain ($P < 0.05$). Other factors associated with better total health score were feeding colostrum within 2 h compared with 7–12 h after birth ($P < 0.01$), and for calves born in the fall compared with the winter ($P < 0.001$) or spring ($P < 0.05$). Total weight gain over the 6 week period was significantly lower for calves born in winter ($P < 0.001$) or spring ($P < 0.05$), calves having less responsiveness at birth ($P < 0.001$), having a higher 6 week body temperature ($P < 0.05$) and attitude score ($P < 0.01$) and having been fed frozen/thawed colostrum compared with fresh ($P < 0.05$). Overall, some calf vigor factors and neonatal management practices may be important in long-term calf health. Metacam therapy may be appropriate to decrease long-term health effects in some calves.

Key Words: vigor, newborn calf, health

310 Innate immunological or metabolic status prior to an oral *Salmonella typhimurium* challenge is not predictive of a heightened acute phase response in weaned Jersey calves.

M. A. Ballou,* M. D. Sellers, D. L. Hanson, A. R. Pepper-Yowell, C. J. Cobb, and B. S. Obeidat, *Department of Animal and Food Sciences, Texas Tech University, Lubbock*

Objective was to determine if baseline metabolic and innate immunological variables are indicative of a heightened acute phase response to an oral *Salmonella typhimurium* (ATCC14028) challenge in weaned Jersey calves. Twenty Jersey bull calves (77 ± 1 d old) were classified into 2 groups (positive responders or negative responders) based on their plasma haptoglobin (Hp) response (>2 fold increase) after they were challenged orally with *Salmonella typhimurium*. All calves survived the 10 d observation period. Seven calves were categorized as Hp positive responders, of which 4 showed clinical signs of disease (anorexia, decreased response to stimuli, and distended head) at some point during the observation period; whereas none of the negative Hp calves displayed any clinical signs of disease. Neither the percent of neutrophils positive ($P = 0.501$) for producing an oxidative burst when cocultured with an *Escherichia coli* nor the geometric mean fluorescence intensity of the positive neutrophil population ($P = 0.516$) were different between Hp groups before the challenge. Similarly, baseline neutrophil expression of L-selectin ($P = 0.825$), whole blood secretion of tumor necrosis factor-α when cocultured with lipopolysaccharide ($P = 0.273$), and plasma concentrations of Hp ($P = 0.678$) were not different between the Hp groups. Calves that had a positive Hp response following the *Salmonella typhimurium* challenge had greater rectal temperatures before the challenge (39.12 vs. 38.89 ± 0.062; $P < 0.05$). Following the challenge, Hp positive calves had greater rectal temperatures ($P < 0.01$) over the entire observation period and the neutrophils had increased oxidative burst intensities ($P < 0.05$) beginning 72 h after the challenge, which persisted through the end of the study. No other differences were observed between the Hp groups after the challenge. Rectal temperature before the *Salmonella typhimurium* challenge was the only variable that was predictive of whether calves were at an increased relative risk for a heightened acute phase response following the challenge.

Key Words: calf, health, immune

311 Outdoor group-housed calves have improved performance and heightened innate immune responses during the neonatal and weaning periods compared to outdoor single-housed calves.

C. J. Cobb,* D. L. Hanson, M. D. Sellers, A. R. Pepper-Yowell, B. S. Obeidat, and M. A. Ballou, *Texas Tech University, Lubbock.*

Objective was to determine if outdoor group housing of calves influences metabolic and innate immunological responses compared with individually housed calves. Forty-nine Holstein calves (2 ± 1 d old) were randomly assigned to 2 treatments: individually housed (G1, n = 22) or 3 calves/pen (G3, n = 27). The space allowances per calf were 4.75 and 7.0 m^2 for G1 and G3, respectively. All calves received an identical high plane of milk replacer nutrition. Weaning was initiated during the 7th wk by removing the PM feeding and calves were completely weaned when they consumed 800 g dry matter (DM) daily after d 53. At d 91, calves were randomly commingled into groups of 5 outdoors. Peripheral blood was collected during the neonatal (3, 10, 21 d), weaning (45, 47, 53 d), and commingling periods (91, 94, 99 d) and was analyzed for neutrophil oxidative burst (OB) capacity when cocultured with an *Escherichia coli*, neutrophil L-selectin expression, whole blood secretion of tumor necrosis factor-α (TNF) when cocultured with lipopolysaccharide. Total DM intake was greater ($P < 0.05$) for G3 during the post-weaning period, wk 8 to 12. Average daily gain of G3 tended ($P < 0.10$) to be higher from d 21 to 52 and were higher ($P < 0.05$) from d 53 to 67. During the neonatal period, G3 calves had more activated innate immune responses as evidenced by increased ($P < 0.05$) neutrophil L-selectin expression and tendency for increased ($P < 0.10$) percentage of neutrophils producing an OB. During weaning, G3 calves continued to have more activate innate immune responses with increased ($P < 0.05$) L-selectin expression on d 45 and 47 and a greater OB intensity throughout the period. Immediately before commingling, G1 calves tended to have lower ($P < 0.10$) L-selectin expression with all immune variables being equal ($P > 0.362$) to G3 calves at d 94 and 99. Outdoor group housed calves had improved performance and heightened innate immune responses when compared with individually housed calves, which may be due to increased immunogenic stimulation.

Key Words: calf, housing, immune

312 Immune, health, and growth responses of beef calves administered modified-live virus respiratory vaccine during the presence of maternal antibody versus a traditional vaccination regimen.

J. G. Powell*[1], J. T. Richeson[2], E. B. Kegley[1], K. P. Coffey[1], G. F. Erf[1], A. H. Brown[1], W. Downum[1], and D. T. Ensley[3], [1]*University of Arkansas, Fayetteville,* [2]*West Texas A&M University, Canyon,* [3]*Boehringer Ingelheim Vetmedica Inc., St. Joseph, MO.*

Crossbred beef calves (n = 253) from 3 breeding herds were used to determine the health, performance, and immune response to different pentavalent [bovine herpesvirus-1, bovine viral diarrhea virus (BVDV) types 1 and 2, parainfluenza-3 virus, and bovine respiratory syncytial virus] modified-live virus (MLV) vaccine regimens administered initially at either 62 or 188 d of age. Calves were stratified by date of birth, gender, BW, and dam age then assigned randomly to 1 of 2 vaccine regimens. Calves in the early vaccination (EV) treatment group received a pentavalent MLV respiratory vaccine containing *M. haemolytica* bacterin-leukotoxoid [Pyramid 5 + Presponse SQ, Boehringer Ingelheim Vetmedica, Inc., St. Joseph, MO] and a multivalent clostridial bacterin-toxoid on d 0 (calf age = 62 ± 17 d, mean ± SD), or calves in the traditional vaccination (TV) treatment group received the same respiratory vaccine and a multivalent clostridial bacterin-toxoid on d 126 (avg. calf age = 188 d). Calves in both treatment groups were revaccinated with the MLV respiratory and clostridial vaccines on d 147 (weaning). No calves required treatment for bovine respiratory disease during the study that ended after an 84-d post-weaning period. Interim and overall gain performances were similar ($P \geq 0.84$) between treatments. Antibody titers to BVDV type 1a were present but similar ($P = 0.50$) among treatments on d 0; yet BVDV antibody titers were greater for EV on d 21, 126, and 147. The EV calves had a greater (treatment × day, $P = 0.05$) CD25 expression index of CD8+ cells than TV calves on d 126. Differences in BVDV type 1a titers and CD25 expression indices suggest calves develop humoral and cell-mediated immunity when vaccinated at 62 d of age. Furthermore, growth performance or health were not affected by vaccine regimen, supporting early vaccination as a cost-effective alternative to traditional calfhood vaccine regimens.

Key Words: beef calves, bovine viral diarrhea virus, maternal antibody interference

313 Dietary adjuvanting prior to vaccine administration increases maternal antibody transfer to calves. A. D. Rowson, T. H. Schell, Y. Wang, N. E. Forsberg, and S. B. Puntenney,* *OmniGen Research LLC, Corvallis, OR.*

Several factors have been documented to increase the efficiency of maternal antibody transfer in neonatal calves, including colostrum quantity ingested, timing of colostrum delivery, and concentration of colostral antibodies. Perinatal vaccination protocols targeting increased IgG1 titers have been used successfully to reduce morbidity and mortality to calfhood enteric pathogens. Previous studies with OmniGen-AF pre-fed in bovine diets before vaccination have shown increased serum titer response to IBR, BRSV, and BVD-1. We hypothesized that the pre-fed additive would elicit increased colostral antibody expression to a commercial scours prevention vaccine administered to preparturient cows, potentially increasing passive transfer of maternal antibodies to calves. Multiparous Angus cows were randomly assigned by parity to a control diet or the same diet with 50g of OmniGen-AF pre-fed for 28 d before a booster vaccination with Pfizer's Scourguard 4KC. Blood samples were taken from dams 60 d post-vaccination and at calving, and from calves pre-suckle and at 7 d. A pre-suckle colostrum sample was taken following parturition. Samples were assayed by serum neutralization (SN) and indirect immuflourescence assay (IFA) for rotavirus and coronavirus. Results showed a strong effect of parity between second calf heifers versus 3rd plus parity cows ($P < 0.001$). Aged cows had significantly higher IFA serum titers at calving than non-treated controls for Rotavirus ($P < 0.007$) and higher IFA serum titers at 60 d post vaccination by 1.85× ($P < 0.02$), in colostrum by 1.7× ($P < 0.05$), with calves having 2 fold higher IFA serum titers ($P < 0.01$) for Corona virus. There were no significant differences in serum titers or colostrum antibody concentrations for 2nd calf parity cows. SN assays yielded similar results to IFA assays for all parameters. Serum and colostrum antibody titers for 2nd parity cows were approximately double that of 3rd plus parity cows. This data suggests that the feed additive may have benefit in the restoration of the ability of older animals to initiate antibody production.

Key Words: antibody, vaccination, OmniGen-AF

314 Correlation between circulating white blood cell counts and level of protective immune response against bovine viral diarrhea virus elicited by a modified live vaccine. S. M. Falkenberg*[1], J. Ridpath[1], J. R. Tait[2], B. Vander Lay[1,2], and J. M. Reecy[2], [1]*USDA-ARS-National Animal Disease Center, Ames, IA,* [2]*Iowa State University, Ames.*

Two trials (T1 and T2) were conducted to examine the range of responses elicited against bovine viral diarrhea virus (BVDV) by vaccination with modified live vaccine (MLV) and to determine the level of response required for prevention of clinical disease. For T1, BVDV neutralizing (BVDV VN) titers were determined on 216 spring born beef calves (177.03 ± 30.05 kg BW) 20 d after the booster vaccination (49 d from initial vaccination) with a MLV. The presence of titers against BVDV was also measured using a commercial ELISA to determine if this method gave comparable results to VN titers. Trial 2 utilized 120 fall born beef calves (141.06 ± 29.43 kg BW) that followed the same vaccination protocol in T1, but an extra sample was obtained to determine circulating white blood cell counts (WBC) when blood samples were obtained for determination of antibody response. For T2, titers against BVDV were initially determined using the commercial ELISA. In both trials all calves were stratified into low, medium and high response groups based on standard deviations from the mean. Twelve calves, for each trial, were selected to represent 3 low, medium and high response groups. After selection, serum from selected calves was collected and evaluated for BVDV response by VN. VN values for the 3 groups (n = 4; low (titer <1/4), mid range (titer 1/4 to 1/16) and high (titer >1/16). Calves were moved to BL2 containment and challenged with a high virulence BVDV strain 101 d after the initial vaccination. Blood samples were collected on d −2, 2, 4, 6, 9, 11 and 13 post challenge to determine levels of circulating white blood cells, viral shed and levels of BVDV VN titers. While, overt respiratory or enteric disease was not observed in any of the calves, challenge did result in a decrease in circulating WBC in some animals. Calves in the high response T1 group (titers greater than 1/16) did not have significant decreases in WBC, but calves in the mid and low titer groups had a decrease in circulating WBC and lymphocytes on d 4 ($P < 0.05$). Because a correlation between WBC on day −2 and a protective response elicited by vaccination for the 12 calves in T1 was observed, WBC was determined for all 120 calves at booster vaccination in T2. Similar to the 12 calves in T1, a positive correlation was observed between WBC and level of BVDV antibodies as determined by ELISA for calves in T2. Results from these 2 trials provide evidence that there is a relationship between WBC and the response to vaccination. Further investigation before vaccination is warranted to discern if vaccination changes WBC or if WBC alter response to vaccination.

Key Words: cattle, titer, vaccine

315 Omnigen-AF restores GR-1, L-selectin, and RANTES expression by immunosuppressed murine PMN challenged with lipopolysaccharide in a MyD88-dependent manner. R. J. Ortiz-Marty[1], N. E. Forsberg[2], J. D. Chapman[3], and I. K. Mullarky*[1], [1]*Virginia Polytechnic Institute and State University, Blacksburg,* [2]*OmniGen Research LLC, Corvallis, OR,* [3]*Prince Agri Products Inc., Quincy, IL.*

Bovine mastitis costs the dairy industry billions of dollars every year and presents a health challenge in dairy operations. Immunosuppressive effects of the periparturient period result in an increased risk for mastitis. During this time, cattle experience an increase in circulating cortisol, which reduces neutrophil (PMN) function and ability to clear infection. OmniGen-AF is a feed additive that restores PMN function during periods of immunosuppression in cattle. Signaling pathways involved in restoring PMN function are undetermined. We hypothesized that OmniGen-AF restores PMN function through cross-regulation of TLR signaling. To test our hypothesis, wildtype or MyD88 knockout (KO) mice were unsupplemented or supplemented with OmniGen-AF in the diet, challenged with LPS, immunosuppressed with dexamethasone, or immunosuppressed with dexamethasone and challenged with LPS. PMN were isolated through intraperitoneal lavages and analyzed for gene expression profiles. Results indicate that LPS significantly ($P < 0.05$) upregulated GR-1, L-selectin, and RANTES (genes) in PMN isolated from wildtype mice as compared with immunosuppressed mice. Interestingly, LPS did not upregulate genes in PMN from supplemented wildtype mice as compared with supplemented wildtype immunosuppressed mice. LPS differentially induced genes in PMN from MyD88 KO mice as compared with PMN from supplemented MyD88 KO mice. These results suggest that OmniGen-AF supplementation restores the response of immunosuppressed PMN to LPS challenge and that the restorative role may be MyD88-dependent. Future research needs to determine the specific TLR, transcription factors, and biochemical properties of OmniGen-AF that restore gene expression in immunosuppressed PMN.

Key Words: immunity, neutrophil, OmniGen-AF

ARPAS Symposium: Feed Efficiency: Opportunities for improvement, economics, and integration with environmental sustainability

316 Feed efficiency: Basic principles and opportunities for improvement. M. VandeHaar*[1], L. Armentano[2], D. M. Spurlock[3], J. Patience[3], and J. Taylor[4], *[1]Michigan State University, East Lansing, [2]University of Wisconsin, Madison, [3]Iowa State University, Ames, [4]University of Missouri, Columbia.*

The efficiency of converting feed to meat and milk in the US has increased in over the past century largely as the indirect result of increased productivity (faster lean accretion or more milk per cow) and the resulting dilution of maintenance requirements. Further increases in productivity have a diminishing impact on feed efficiency, and, in fact, if digestibility is depressed at higher intakes, increased productivity has the possibility of decreasing efficiency. Therefore, we must find new ways to improve lifetime feed efficiency through enhanced efficiency of digestion, metabolism, and product formation without impairing health or fertility. Ideally, feed efficiency should incorporate all inputs and outputs of energy, protein, and other nutrients as well as land, fuel, and human-edible foods during an animal's lifetime. However, the traits that are routinely measured in individual animals are outputs such as growth rate or milk yield and not feed inputs; thus the feed efficiency phenotype for most animals is not known. In 2011, USDA-NIFA funded 3 large projects to improve the efficiency with which the beef, dairy, and swine industries use feed. All target genetic improvement using genomic selection. Genomic selection makes use of a reference population of animals with both phenotypic and genotypic data to develop models of predicting genetic merit from genotype, thus enabling genetic selection without phenotypic data. Because the heritability of feed efficiency is likely in the range of 20 to 40%, the reference population must include thousands of animals to produce estimates of breeding value with reasonable accuracy. Our research aims are to develop these reference populations, better characterize the genetic and biological basis of feed efficiency and its interactions with diet, and develop marker-assisted and genomic selection tools for feed efficiency. We will use residual feed intake as our measure of the feed efficiency phenotype and medium/high-density whole genome SNP panels for genotypes. Decision tools and on-farm demonstrations are being developed to enhance adoption of best management practices, and teaching programs are underway to nurture scientists who will lead future improvements in the feed efficiency of animal agriculture.

Key Words: feed efficiency, genomic selection, genetics

317 Impact of milk yield, herd size, and feed efficiency on economic change between and within California dairies from 2006 through 2010. L. Rodriguez*[1], G. Bethard[2], D. Tomlinson[1], and M. McGilliard[3], *[1]Zinpro Corporation, Elk Grove, CA, [2]G & R Consulting, Blacksburg, VA, [3]Virginia Tech, Blacksburg.*

Milk and feed prices have been volatile in the California (CA) dairy industry in the last 5 years, bringing stress and difficult strategic decisions to managers. Our objective was to find financial and production trends that improved profitability of CA dairies. The CA Department of Agriculture milk production cost farm database from 2006 to 2010 (705 herd-years) included milk yield, herd size, feed efficiency (FE), housing type and milking frequency, as well as measures of milk income and various expenses. Variables of expense per 45.5 kg, FE and profit per 45.5 kg were analyzed with a model that included year, breed, linear and quadratic effects of either yield, size, or FE, and all interactions with breed. A second analysis was limited to 97 Holstein (H) herds present in all 5 years to estimate intra-herd linear relationships. Grouped into categories, H herds producing less than 31.8 kg/d differed from those greater than 36.4 kg/d of solids-corrected milk (SCM) in total cost/45.5 kg (TC) of $14.97 and $13.49, respectively. Jersey herds producing less than 25.0 kg/d differed from those greater than 29.5 kg/d of SCM with TC of $17.67 and $15.58. Holstein herds with FE (SCM/DMI) exceeding 1.45 compared with less than 1.33 were $1.29 lower in TC. Milk net income (MNI) per 45.5 kg SCM was -$0.29 versus $1.12 in H herds with less than 31.8 kg/d and more than 36.4 kg/d SCM. Jersey herds producing less than 25.0 kg/d and more than 29.5 kg/d of SCM differed in MNI, -$1.36 and $0.72. The TC decreased linearly and quadratically for larger herds, with H herds of more than 2,000 cows having $1.31 smaller TC compared with herds with fewer than 1,000 cows. Jersey herds of more than 2,000 cows were $2.09 less in TC compared with herds of fewer than 500 cows. From 2006 to 2010, TC increased $0.40/yr in H herds. In H herds increasing SCM by 0.91 kg/yr TC increased only $0.26/yr. In H herds decreasing SCM by 0.91 kg/yr TC increased $0.73/yr. Change in FE/yr and change in MNI/yr increased linearly as SCM change per year increased. Efficient herds had higher profitability in the CA dairy industry.

Key Words: dairy profitability, feed efficiency, herd economics

318 Integrating productivity and whole-farm efficiency to achieve environmental sustainability. J. L. Capper*[1] and D. E. Bauman[2], *[1]Washington State University, Pullman, [2]Cornell University, Ithaca, NY.*

Environmental sustainability (ES) is a crucial consideration for livestock producers as consumers, retailers and policy-makers become more aware of resource use and greenhouse gas (GHG) emissions associated with animal agriculture. Optimal environmental sustainability can only be achieved by improving efficiency throughout the food production system; yet on-farm productivity (resource use per unit of output) and production processes make the greatest contribution to environmental impact and thus offer the greatest opportunity for mitigation. Popular perceptions of ES are often associated with extensive livestock systems, with the concept of "efficiency" being regarded as undesirable. Nonetheless, deterministic models of ruminant production have revealed that improved productivity in modern intensive systems confers considerable reductions in resource use and GHG emissions per unit of food product from dairy or beef. Environmental gains through this "dilution of maintenance" effect result from a combination of improved productivity in the productive (growing or lactating) sector of the population diluting resource requirements over greater output; and reducing resource requirements within the non-productive sector of the supporting population by requiring a smaller number of animals to maintain total output. A significant contribution may also be made via "reduction of maintenance" - reducing the total bodyweight of animals within the supporting population through the use of smaller breeds, while maintaining total animal protein output. Whole-farm analysis may be used within dairy production, yet is an inadequate measure of ES in a fragmented industry such as beef production, where interactions between the cow-calf, stocker and feedlot operation can have long-lasting consequences. For example, despite the perception that feedlot operations are major contributors to GHG emissions, whole-system analysis demonstrates that the cow-calf operation accounts for 72% of carbon output. Ultimately however, the considerable interaction between dairy and beef production systems necessitates a combined dual-system analysis to define the practices that contribute to true sustainability.

Key Words: productive efficiency, carbon footprint, dilution of maintenance

Bioethics Symposium: Bioethical Challenges in Education: New challenges and opportunities

319 Challenges and opportunities in teaching agricultural animal bioethics. C. C. Croney*[1], W. R. Stricklin[2], and D. Scott[3], *[1]Purdue University, [2]University of Maryland, College Park, [3]University of Montana.*

Decisions about acceptable agricultural systems and use and treatment of animals are ultimately based on personal and societal ethics. Thus, it can be argued that there is a growing need to create curricula that address the ethical foundations of animal agriculture. Yet, many people in animal agriculture either do not fully understand or appreciate this need, and contend that "science alone" should dictate standards of animal care and welfare. Certainly, science is necessary to make informed decisions. However, the field of ethics, rather than science has traditionally been viewed as the appropriate domain to address questions pertaining to "what should be." Despite the significant and increasing role of ethics in formulating public opinion about animals, students and professional animal scientists typically receive little or no formal ethics education. Additionally, most animal science curricula either lack an emphasis on animal welfare or include it only as a current issues topic with minimal or no specific emphasis on ethics. Faculty from 5 universities have been funded by a USDA NIFA Challenge Grant to address bioethics education in animal agriculture. The major objectives of the grant include: 1) developing teaching modules and pedagogical strategies that will facilitate fruitful student discussions instead of debate, and 2) extending the educational material and information to other animal science educators. Student participation is a necessity when including ethics in animal welfare courses. Ideally, animal science students learn even more when interacting with students from other majors who may hold differing opinions and values. Thus, it is critical that the instructor create a classroom environment in which students feel safe and free to express their opinions. Well-planned discussion questions and case studies combined with rules regarding respect for the views of all persons are as critical as a properly prepared and informed instructor. We will explore these elements as well as additional pedagogical experiences and strategies for developing agricultural animal bioethics course content that addresses farm animal welfare, policy, agricultural environmental ethics, and rural societal issues.

Key Words: agriculture, animal welfare, bioethics

320 Assessing the merits of animal welfare assessment tools: A philosophical framework from virtue ethics and narrative ethics. R. Anthony,* *University of Alaska, Anchorage.*

This presentation will cover factors conscientious animal scientists and veterinarians struggling to evaluate animal welfare and to facilitate responsible discussions on the topic should consider when welfare priorities collide. The Ethical Matrix (Mepham, 2000), Ethics Assessment Process (Campbell and Hare, 1997) and the Four-Box Method (Jonsen et al., 1992) will be described and discussed in light of an ethic of outcomes and an ethic of responsibility. Limitations and strengths of each will be exposed, and a philosophical basis that is steeped in virtue and narrative ethics will be proposed to guide the ethical assessment process. The philosophical basis of animal welfare assessment that will be articulated is motivated by the context of moral evaluation that recognizes that animal welfare is typically understood as 'feeling well, functioning well, and having the ability to perform species characteristic behaviors.' Decision-making should be integrated into habits that promote the human-animal bond and with an eye toward being a steward for the environment. Humane slaughter and euthanasia of animals will be discussed as examples of the animal welfare philosophy and how to incorporate them into animal production.

Key Words: animal welfare, animal welfare assessment, bio-ethics

321 Challenges and opportunities for bioethicial education in extension/outreach activities. H. M. Zaleski*[1] and D. Newman[2], *[1]University of Hawaii at Manoa, Honolulu, [2]North Dakota State University, Fargo.*

This presentation will address challenges and opportunities for bioethical education in extension/outreach activities in animal agriculture. Extension's challenge is to engage both the general public and those involved in animal production on issues and ethics in animal agriculture. Effective extension personnel need to be prepared to identify issues, provide science-based knowledge, use facilitation, and discuss ethical dimensions related to production agriculture. Extension educators can teach management practices affecting animal bioethics through producer programs, such as Pork Quality Assurance Plus and Beef Quality Assurance, and present standards such as pork's We Care ethical principles. Programs are also needed to educate the public who are not involved in agriculture on animal production methods, the underlying science, and the world's food supply. Nontraditional programs that create new ways of thinking and learning provide an opportunity for extension to address critical issues in bioethics. Since 2010 Hawaii Cooperative Extension has used a case-study approach (adapted from undergraduate classes) that has been effective in helping 4-H youth understand ethical principles. The discussion is controlled by the youth with the leader in the role of facilitator, and there is no pre-determined "right" answer. Although the principles developed may lack sophistication, they have power in that the youth "own" them. Since 2008 North Dakota State University has delivered the "NDSU BBQ BOOT CAMP" program to over 3200 consumers and producers. This extension program goes out into communities and provides face-to-face education about animal agriculture; provides consumers and producers with information about the importance of agriculture and the role of society in providing a safe food supply, including topics on animal welfare; and explains the roles and activities of the extension service. Participants gave the BBQ Boot Camp program an average score of 4.6 on a 5-point scale (5 = highest). Consumers indicate that they prefer this type of programming over social media, television, and radio and that they are more likely to believe facts that are explained by experts in the field of animal agriculture. Extension personnel can play a significant role in educating society on the ethical issues surrounding animal agriculture.

Key Words: extension, bioethics, communication

Breeding and Genetics: Dairy Cattle Breeding II–Applied molecular biology and genomics

322 Effects of genomic inbreeding on production, reproduction, and udder health in Holstein dairy cows. D. W. Bjelland*[1], K. A. Weigel[1], D. J. Nkrumah[2], and N. Vukasinovic[2], *[1]Uinversity of Wisconsin-Madison, Madison, [2]Pfizer Animal Genetics, Kalamazoo, MI.*

The objective of the present study was to assess the effects of genomic inbreeding on production, reproduction, and udder health in Holstein dairy cows. First and second lactation data were collected from 1,061 Holstein dairy cows, which were born between 2006 and 2008, from 5 commercial herds across the United States. All cows were genotyped for 54,609 single nucleotide polymorphism (SNP) markers. SNPs were edited based on call rate and allele frequency. The remaining SNPs were separated into SNPs that were or were not in Hardy-Weinberg (HW) equilibrium. The SNPs that were not in HW equilibrium were assumed to be under selection and were removed from the analysis of genomic inbreeding. Homozygosity of the remaining 43,398 SNPs that were in HW equilibrium was calculated and utilized as the measure of genomic inbreeding in this study. Average homozygosity was 66.7 ± 1.6%, with a minimum and maximum of 60.4 and 75.3% respectively, and cows with a greater percentage homozygous loci were assumed to be more highly inbred. Total lactation milk, fat, and protein yield decreased by 15.8, 1.4, and 0.6 kg, respectively, per 1% increase in homozygosity. Furthermore, days open increased by an average of 1.96 d per 1% increase in homozygosity, but somatic cell score did not change with an increase in homozygosity. The results presented herein suggest a possible relationship between increasing homozygosity and decreasing lactation performance and reproductive ability.

Key Words: genomics, inbreeding

323 Maternal grandsire confirmation and discovery in dairy cattle. G. R. Wiggans[1], T. A. Cooper*[1], P. M. VanRaden[1], J. R. O'Connell[2], and L. R. Bacheller[1], *[1]Animal Improvement Programs Laboratory, ARS, USDA, Beltsville, MD, [2]University of Maryland School of Medicine, Baltimore.*

Accurate pedigree information is essential for selecting dairy animals to improve economically important traits. Two methods of maternal grandsire (MGS) discovery were compared. The first compared one single nucleotide polymorphism (SNP) at a time using a genotype from one or both parents (SNP method). The second compared haplotypes of a potential MGS to the animal′s maternal haplotype, which included linkage information across all loci (HAP method). Modified pedigrees with 5% of true MGS replaced by a random genotyped bull from the same birth year and 5% set to missing were created to test the HAP method. To test the SNP method, the same group of animals (including multiple genotypes for some animals and excluding imputed dams) was used. Both methods ranked the most likely MGS. The SNP method can be performed as soon as a genotype is received because no imputation is required. The HAP method was expected to have greater accuracy because it includes low-density genotypes imputed to the 45,187 SNP used for genomic evaluation as well as additional imputed animals. Accuracy of predicting true MGS was evaluated using genotypes for 4,620 Holsteins, 659 Jerseys, and 160 Brown Swiss with confirmed genotyped sires for the SNP method and modified pedigrees for 4,134 Holsteins, 552 Jerseys, and 142 Brown Swiss for the HAP method. Accuracy of true MGS prediction for Holsteins, Jerseys, and Browns Swiss was 95, 91, and 94%, respectively, with the SNP method and 97, 95, and 97% with the HAP method. Lack of imputed SNP decreased accuracy of the SNP method for low-density genotyped animals (78%) compared with BovineSNP50 genotyped animals (97%). Predicted MGS accuracy with the HAP method was 98% for BovineSNP50 genotypes, 94% for Bovine3K genotypes, and 92% for imputed genotypes. When the HAP method was extended to great grandsires, accuracy of maternal great-grandsire confirmation and discovery was 92% for 652 Holsteins, 95% for 33 Jerseys, and 85% for 20 Brown Swiss. Because most dairy bulls have been genotyped, parentage and MGS analysis can accurately confirm, correct, or discover parents and more distant ancestors for most animals.

Key Words: haplotype, maternal grandsire, SNP

324 Sequence analysis and methylation patterns of the bovine IWS1 gene localized to a region of BTA2 involved in postnatal growth. I. G. Imumorin*[1], M. De Donato[1,2], S. O. Peters[1,3], A. M. Corn[1], Y. Bing[1], H. E. Rudolfo[2,4], M. Al-Abri[1,4], and T. Hussain[1,5], *[1]Cornell University, Ithaca, NY, [2]Universidad de Oriente, Cumana, Venezuela, [3]Federal University of Agriculture, Abeokuta, Nigeria, [4]Sultan Qaboos University, Muscat, Oman, [5]University of Veterinary and Animal Sciences, Lahore, Pakistan.*

Our previous genome scan identified the proximal end of bovine chromosome 2 as containing a putative parent-of-origin effect quantitative trait locus (POE-QTL) affecting postnatal growth in cattle. We embarked on bioinformatics and experimental search for possible positional candidate genes in this region. A search of human and mouse genomes of known and putative imprinted genes identified the homolog of *Saccharomyces cerevisiae* serine protease inhibitor 1 (SPN1 also known as IWS1) in this region. This gene is part of a transcription factor complex that regulates transcription. We previously showed that this gene is expressed ubiquitously in 18 bovine tissues and has 99.9% homology with the predicted mRNA sequence in cattle. A comparison of this sequence with the predicted mRNA sequence in sheep and pig shows 97.9 and 92.9% homology, respectively. A phylogenetic analysis of the protein sequence predicted from these mRNAs and those of dog, panda, horse, human, marmoset, mouse, rat, elephant, opossum and platypus, using the lizard protein as an out group, shows high conservation among all the eutherian mammals but not as much with marsupials and monotremes. In this study we screened the coding region for mutations in 19 cattle breeds and found several SNPs. In addition, we carried out DNA methylation analysis in multiple bovine tissues and showed that this gene is differentially methylated. These further show that this gene may be of significance for the traits of interest mapped to bovine chromosome 2.

Key Words: SNP, cattle, IWS1 gene

325 Characterization of sequence diversity of IFNAA and INFB1 in Pakistani breeds of cattle. T. Hussain*[1,2], M. E. Babar[1], A. Nadeem[1], A. Ali[1], A. Wajid[1], M. Al Abri[2], M. De Donato[2,3], S. O. Peters[2], and I. G. Imumorin[2], *[1]Institute of Biochemistry and Biotechnology, University of Veterinary and Animal Sciences, Lahore, Pakistan, [2]Department of Animal Science, Cornell University, Ithaca, NY, [3]IIBCA, Universidad de Oriente, Cumana, Venezuela.*

Interferons (IFN) are glycoproteins made and released by host cells in response to the presence of pathogens to trigger the protective defenses of the immune system. Among the type I IFNs, IFNA and INFB1 are very important to activate the initial immune response. The objective of this study was to characterize sequence polymorphisms in IFNA and INFB1 genes. We studied 46 samples from Pakistan: 4 Achai, 4 Bhagnari, 6 Cholistani, 4 Dhani, 4 Dajal, 4 Lohani, 4 Nari Master, 6 Red Sindhi, 6 Sahiwal and 4 Tharparker and compared them to sequences from 3 Hereford, 3 Angus and 8 Holstein cattle from the US and 4 Muturu, 11 White Fulani and 4 Sokoto Gudali from Nigeria. Sequences were analyzed by MEGA5 software and Panther to determine the phylogenetic and functional implications of the different variants found. We found 8 polymorphic sites in the amino acid sequence of IFNAA and 20 polymorphic sites in IFNB1. The phylogenetic analysis indicated significant amount of sequence variation and the divergence of Pakistani cattle breeds of these genes from other breeds of taurine cattle. Most of the amino acid changes were non-synonymous and produced changes in the protein structure. The phylogenetic analysis indicated significant divergence of Pakistani cattle breeds from other taurine breeds of cattle, and comparison were made with *Bubalus bubalis*, *Capra hircus* and *Ovis aries*. The functional analysis of the variants show amino acid changes that can affect the structure of the proteins potentially producing changes in the interaction between the other proteins involved in the immune response. This is the preliminary report on Interferon genes in Pakistani cattle breeds. This information is valuable for the association with the resistance or tolerance to infectious agents in cattle in this region.

Key Words: cattle, immune genes, SNP

326 Effect of GHR *Alu*I polymorphism on reproductive performance of Holstein cows.

A. Schneider*[1], M. N. Corrêa[1], and W. R. Butler[2], [1]*Veterinary College, Federal University of Pelotas, Pelotas, RS, Brazil,* [2]*Department of Animal Science, Cornell University, Ithaca, NY.*

The recovery of the growth hormone (GH)/insulin-like growth factor (IGF-I) axis is implicated in an early return to ovulatory cycles and a shorter calving to conception interval in postpartum dairy cows. Based on this, the aim of this work was to determine effects on the reproductive performance of Holstein cows of a GH receptor (GHR) AluI polymorphism, a point mutation upstream from its mRNA start codon. Holstein cows (n = 80) were on the study until 210 days in milk (DIM). Blood samples were collected at 7 and 21 DIM for serum IGF-I determination. For GHR genotyping, DNA was extracted from blood and the presence of the alleles determined after digestion of the corresponding GHR gene region with the *Alu*I enzyme. Milk samples were collected 2 times/week for progesterone analysis. Progesterone higher than 1 ng/mL in 2 consecutive samples was considered indicative of ovulation. Cows were submitted to an OvSynch-TAI protocol at 55 DIM and repeated for cows diagnosed as not pregnant 30 and 60 days after AI. Data was analyzed with SAS for polynomial effects of the presence of the two GHR *Alu*I alleles. Among the cows, 40% had the *Alu*I(+/+) genotype, 50% had *Alu*I(–/+) and 10% were *Alu*I(–/–). Interval from calving to first ovulation was not different among these three genotypes ($P > 0.05$), but reduced for all cows carrying at least one *Alu*I(–) compared to *Alu*I(+/+) cows: 27 ± 3 vs. 33 ± 3 days, respectively ($P = 0.07$). There was a linear effect of the *Alu*I(–) allele on the calving to conception interval, being 80 ± 13, 94 ± 6 and 115 ± 8 days for the GHR *Alu*I(–/–), *Alu*I(–/+) and *Alu*I(+/+) cows, respectively ($P = 0.02$). For serum IGF-I concentration there was a quadratic effect of the *Alu*I(–) allele ($P = 0$ .04): 101 ± 10, 60 ± 5 and 63 ± 5 ng/mL for GHR *Alu*I(–/–), *Alu*I(–/+) and *Alu*I(+/+) cows, respectively. In summary, the presence of the GHR *Alu*I(–) allele in Holstein cows was associated with increased serum IGF-I concentrations and fewer days to first postpartum ovulation that contributed to a shorter calving to conception interval.

Key Words: fertility, GHR, SNP

327 Genomic evaluation of rectal temperature in Holstein cattle.

S. Dikmen*[1], J. B. Cole[2], D. J. Null[2], and P. J. Hansen[3], [1]*Department of Animal Science, Faculty of Veterinary Medicine, Uludag University, Bursa, Turkey,* [2]*Animal Improvement Programs Laboratory, ARS, USDA, Beltsville, MD,* [3]*Department of Animal Sciences, University of Florida, Gainesville.*

Heat stress negatively affects the production, fertility, and health of dairy cattle. Rectal temperature (RT) has unfavorable genetic correlations with production, longevity, economic merit, and somatic cell score in Holstein cows. The objectives of the current study were to perform a genome-wide association study (GWAS) for rectal temperature in dairy cows under heat stress conditions, and to determine with what genes single nucleotide polymorphisms (SNP) of large effect are associated. Rectal temperature was measured between 1500 and 1700 h in 5,590 lactating Holstein cows sired by 3,322 bulls during the summer in north central Florida. Rectal temperature averaged 38.8°C ± 0.57°C, and ranged from 37.0°C to 41.6°C. The model included fixed effects of parity; random effects of herd-year, animal, and permanent environment; and regressions on temperature-humidity index and test-day milk yield. The pedigree file included 886 sires with Illumina BovineSNP50 BeadChip (Illumina, Inc., San Diego, CA) genotypes. After edits for call rates <0.90, minor allele frequencies <0.05, and Mendelian conflicts, 30,0018 markers remained. Genotypes for 9 animals were dropped due to low call rates. (Co)variance components and breeding values were calculated using the AIREMLF90 and BLUPF90 software packages from the University of Georgia (Athens). The GWAS was performed with a one-step procedure as implemented in the POSTGSF90 software. The heritability and repeatability of RT were 0.06 and 0.22, which is lower than recent estimates, possibly because most sires had only a few daughters with records and pedigree ties were limited. The 20 SNP with the largest solutions were examined to determine if they were located in or near genes that could account for heat stress effects. Five SNP were located in introns: *C1H21orf59* on *Bos taurus* autosome (BTA) 1, *INADL* on BTA3, *ZNF335* on BT13, *VPS13* on BTA16, and *FTO* on BTA18. The third-ranked SNP was located in an exon of *CCT6B* on BTA12. These results will help identify genes involved in physiological responses to heat stress. Additional phenotypes are needed to improve estimates SNP effects.

Key Words: rectal temperature, genomic selection, genetic evaluation

328 Feasibility of genomic prediction of fatty acids composition in milk of dairy cattle from Luxembourg using single-step procedure.

P. Faux*[1], V. M.-R. Arnould[1,2], H. Soyeurt[1,3], and N. Gengler[1,3], [1]*Animal Science Unit, Gembloux Agro-Bio Tech, University of Liege, Gembloux, Belgium,* [2]*CONVIS s.c., Ettelbruck, Luxembourg,* [3]*National Fund for Scientific Research (FNRS), Brussels, Belgium.*

Milk composition in fatty acids (FA) portrays a class of novel traits of interest for both human health and animal robustness. With the exception of Wallonia, Luxembourg is currently the only place in the world where, using mid-infrared spectrometry, milk composition in 29 FA is routinely recorded for dairy cows. Since 2007, spectral data has been recorded so far on 87,368 cows from 690 different herds, by 2 main control methods (T-method: one sample of only one milking, morning or evening, and S-method: proportionate sample of all daily milkings).

Additionally, milk, fat and protein yields are available since 1990. The availability of FA allows many options for management use and animal breeding but requires advanced modeling (e.g., adapted to the testing methods). In the context of animal breeding, genomic selection has been widely developed in dairy cattle, where single-step approach (ssGBLUP) is particularly well suited for small-sized populations, as the dairy cattle population of Luxembourg (365,892 animals currently in pedigree) and is completely integrated into mixed modeling of phenotypic data. The objectives of this study were: (1) to assess the potential benefits of a single-step genomic evaluation on milk FA composition in a small-sized population and in particular (2) to quantify the impact of genomic information on reliability (REL) of estimated breeding values (EBV) of FA in Luxembourg. In a preliminary study for a single FA, oleic acid (C18:1 *cis* 9) genetic evaluations were performed on 47,613 milk records; collected by S-method, from 8,000 cows in first parity with a random regression test-day model using second order Legendre polynomials. For this sample, molecular data was simulated for 422 AI sires, ancestors of recorded cows. Prediction error variances (PEV) were used to compute REL and effective daughter contributions (EDC). First results showed a low increase in REL and EDC. Extension of this research to all sampling methods and research on the optimum structure of the reference population (bulls, cows) will be done to fit the Luxembourg-specific situation.

Key Words: genomic selection, fatty acids, small population

329 Microsatellite markers based genetic evaluation of Pakistani cattle breeds.

M. E. Babar*[1], T. Hussain[1,2], A. Nadeem[1], A. Ali[1], A. Wajid[1], S. A. Shah[1], K. Abbas[1], A. Azam[1], Z. Ahmad[1], M. De Donato[1,3], S. O. Peters[1], and I. G. Imumorin[1], *[1]Institute of Biochemistry and Biotechnology, University of Veterinary and Animal Sciences, Lahore, Pakistan, [2]Dept. Animal Science, Cornell University, Ithaca, NY, [3]IIBCA, Universidad de Oriente, Cumana, Venezuela.*

Animal Genetic Resource of Pakistan is very diverse. There are 15 distinct breeds of cattle in Pakistan all belonging to zebu (humped type) cattle (*Bos indicus*) for which very little information on genetic architecture is available. Microsatellite markers are being widely used for breed characterization in animals. In the present study 345 individuals of 11 breeds (10 Pakistani cattle breeds and exotic Holstein Friesian breed) were genotyped using 22 labeled microsatellite markers to assess genetic variation and relationships among them. All markers were polymorphic and observed number of alleles ranged from 8 (TGLA122) to 18 (ILSTS029, BM6526) with mean value 13.54 ± 2.80 per locus. Average values of observed and expected heterozygosity were calculated as 0.462 ± 0.155 and 0.823 ± 0.06. Mean values of Fis, Fit, Fst and gene flow were 0.328, 0.432, 0.155 and 1.362 respectively. The average PIC value was 0.81 showing suitability of these markers for forensic analyses. Nei's genetic distance estimates indicated relatively close genetic identity between Tharparker and Red-Sindhi breeds of Sindh Province of Pakistan while Tharparker and Dajal breeds were found most distinct. The UPGMA-based phylogenetic tree constructed from the genetic distances also indicated that the cattle breeds of Pakistan can be classified into distinct genetic groups based on these markers. This is the first comprehensive report on molecular characterization of Pakistani cattle breeds using microsatellite markers. This study can be helpful for making breed conservation strategies of cattle in Pakistan in future.

Key Words: microsatellite markers, heterozygosity, Pakistani cattle breeds

330 Effects of β-casein, κ-casein and β-lactoglobulin gene allelic variants on milk production and protein composition traits of Brown Swiss cows.

C. Ribeca,* A. Cecchinato, M. Penasa, V. Bonfatti, F. Tiezzi, P. Carnier, and G. Bittante, *Department of Agronomy, Food, Natural Resources, Animals and Environment (DAFNAE), Legnaro, Padova, Italy.*

Milk protein composition influences many aspects of the dairy industry as well as the nutritional value and the technological properties of milk. The aim of this study was to investigate the effect of β-casein (*CSN2*), κ-casein (*CSN3*) and β-lactoglobulin (*BLG*) gene allelic variants on milk production and the relative concentration of the major milk proteins: α-lactalbumin (α-LA), β-lactoglobulin (β-LG), α_{S1}-casein (α_{S1}-CN), α_{S2}-casein (α_{S2}-CN), β-casein (β-CN) and κ-casein (κ-CN) of individual milk of Brown Swiss cows. A total of 1,271 cows distributed in 85 herds were milk sampled once from January 2010 to February 2011. Individual samples were collected during the evening milking and detailed milk protein composition was analyzed using reversed-phase high performance liquid chromatography (RP-HPLC). Genotypes of cows for *CSN2*, *CSN3* and *BLG*, were also derived by RP-HPLC. The allele frequencies for *CSN3* (A: 0.232, B: 0.768) and *BLG* (A: 0.331, B: 0.669) were unbalanced in favor of the B variant. All genes were in Hardy-Weinberg equilibrium. An association study for*CSN2*, *CSN3* and *BLG* allelic variants was performed using a linear model. The model included effects of days in milk, parity, *CSN2*, *CSN3*and *BLG* genotypes, and the random effect of the sire of the cow. Effects of genotypes on milk yield were weak. The *CSN2* genotype influenced the percentage of α_{S1}-CN, α_{S2}-CN and β-CN, calculated on total casein, the CN number, calculated on total protein κ-CN percentage, and total protein content. The *CSN3* genotypes affected the percentage of α_{S1}-CN, α_{S2}-CN, and β-LG, the latter calculated on total whey protein, percentage of β-CN, CN number, κ-CN percentage, and total protein content. The BLG influenced the percentage of β-LG, protein content, total whey protein, CN number, and percentage of β-LG. All these associations were statistically significant ($P < 0.05$). Our findings could be used to identify animals that produce milk with desired composition or desired processing and manufacturing properties.

Key Words: milk protein composition, protein variant, dairy cow

331 Associations between single nucleotide polymorphisms in multiple candidate genes on milk yield, composition, coagulation properties and individual cheese yield in Brown Swiss cows.

A. Cecchinato,* C. Ribeca, M. Penasa, C. Cipolat Gotet, M. De Marchi, A. Maurmayr, and G. Bittante, *Department of Agronomy, Food, Natural Resources, Animals and Environment (DAFNAE), University of Padova, Legnaro, Padova, Italy.*

The fraction of milk used for cheese making is growing worldwide. Although genetic variation for traits related to cheese-making exists, their inclusion as breeding goals in conventional selection programs is hampered by phenotyping costs. A possible solution can be found in the identification of candidate genes that affect milk quality, composition and technological traits and that can be integrated in gene-assisted selection programs. The aim of this study was to investigate the association between 46 single nucleotide polymorphisms (SNP), in 33 candidate genes, and the aforementioned traits in individual milk samples from Italian Brown Swiss cows. A total of 1,271 cows were sampled once in 85 herds. Milk and blood samples were collected during the evening milking concurrently with the monthly test-day milk recording. Individual milks were used for measuring: milk quality traits (i.e., protein, casein and fat percentage), milk coagulation properties and individual cheese yield. Genotyping was performed by using a custom VeraCode

GoldenGate approach. A mixed linear model, considering effects of herd, days in milk, parity, SNP genotype and the random effect of the sire of the cow, was used for the association analysis. Each SNP was analyzed separately. Results showed that 16 out of the 46 SNPs were significantly associated with at least one of the traits. Within these SNPs, the ATP-binding cassette sub-family G member 2 (*ABCG2*) and α_{S1}-casein (*CSN1S1*) genes were found to be associated with technological traits considered. Although further research is needed to validate the SNPs in other populations and breeds, the association between these markers and milk technological traits could be exploited in gene-assisted selection programs for genetic improvement purposes.

Key Words: milk coagulation property, individual cheese yield, candidate gene

332 Sire and vaccine treatment effects on immune response to BVDV 1b challenge.

E. D. Downey*[1], X. Fang[1], C. A. Runyan[1], J. E. Sawyer[2], T. B. Hairgrove[3], J. F. Ridpath[4], C. A. Gill[1], and A. D. Herring[1], [1]*Texas A&M University, College Station,* [2]*Texas AgriLife Research, College Station,* [3]*Texas AgriLife Extension, College Station,* [4]*National Animal Disease Center, USDA-ARS, Ames, IA.*

Yearling Angus-Nelore F_2 and F_3 steers born in spring of 2009 and 2010 (n = 182) were evaluated for immune response to vaccination and viral challenge. Calves were stratified by composition (F_2 or F_3) and sire across 3 vaccination treatment groups of non-vaccinated (NON, n = 61), 2-injection killed vaccine (n = 60), or single-injection modified live vaccine (MLV, n = 61). All calves were determined to be free of bovine viral diarrhea virus (BVDV) persistent infection and challenged with BVDV 1b (d 0); serum was collected on day of vaccination(s) and d 0, 14, 28, and 42 evaluated for neutralizing antibodies against IBR, and BVDV types 1a, 1b, and 2. Titers (reciprocal base 2 log of the highest neutralizing dilution) were analyzed as repeated measures with mixed models; fixed effects included vaccine treatment, day, vaccine treatment by day interaction, year, and sire nested within composition. No differences existed between F_2 and F_3 steers. Large ranges in animistic titer values among steers were observed, particularly for BVDV1b on d 14 among killed (0 to 12) and MLV (0 to 10) and d 28 for NON steers (3 to 9). Sire nested within composition affected ($P = 0.003$) IBR and approached significance ($P = 0.09$) for BVDV1b. LS means for IBR titers ranged from 0 to 2.2 for F_2 sires and 0.12 to 2.2 for F_3 sires. There was vaccine treatment by day interaction ($P < 0.001$) for IBR, and BVDV types 1a, 1b, and 2. Calves vaccinated with killed vaccine had higher ($P < 0.05$) titers at all post-challenge times compared with MLV or NON calves. NON calves had the lowest animistic titers from d 14 to 42 and appeared to reach peak titer at d 42 for all BVDV types (3.9, 7.5, and 2.9 for 1a, 1b and 2, respectively). MLV steers also had peak BVDV titers at d 42 (4.9, 7.4, and 3.0 for types 1a, 1b and 2, respectively). The killed treatment appeared to have peak BVDV titers on d 14 (9.2, 11.2, and 9.2 for types 1a, 1b and 2, respectively). These data indicate that variation among families in antibody response to vaccination and viral challenge can exist and that response across pathogens may not be uniform across families.

Key Words: *Bos indicus* crosses, BVDV challenge, vaccine response

333 Genome-wide DNA methylation fluctuation in mastitis mice infected by *Staph. aureus*.

Y. Yu,* Y. Wei, L. Fan, Y. He, and Y. Wang, *China Agricultural University, China.*

Introduction and objectives: *Staph. aureus* is one of the most crucial causes of mastitis in dairy cattle worldwide. It can survive and reproduce in keratin and phagocyte that normally reject the growth of bacteria. What′s more serious is that *Staph. aureus* can generate β-lactamase which can inactivate antibiotics, resulting in great trouble on clinical therapy. Considering mastitis was corporately affected by bacteria, genetic and epigenetics, in addition, DNA methylation is a key epigenetic marker, which play an important role in the regulation of gene expression in eukaryotes, this study mainly aimed to exploring the DNA methylation changes in mastitis mice infected by *Staph. aureus*. Materials and methods: The *Staph. aureus* mastitis model of dairy cow was established with CD-1 mice by our lab (Fan et al. 2012). A total of 6 *Staph. aureus* mastitis mice and 6 control mice (CD-1) were randomly selected at 12~13 weeks old. We detected the cytosine methylation pattern of the mice genome of breast tissue at 24h post infection. The technique of fluorescent methylation-sensitive amplified polymorphism (F-MSAP) was used, which is a modification of the amplified fragment length polymorphism (AFLP) method to detect DNA methylation on genome-wide (Xu et al. 2005). A total of 7 primer pairs were designed for F-MSAP analysis. Results: The fragments range from 50 to 600bp were count to analyze the DNA methylation levels qualitatively between the 2 groups. Our results showed that a total of 147 bands were detected, and *Staph. aureus* infected group (51%) had decreased incidence of DNA methylation than the controls (55%) although the chi-squared test revealed no significant differences between the 2 groups. DNA methylation fluctuation on specific genes were significantly different between the 2 groups, which depends on the variances of 32 bands. Conclusions: DNA methylation modification is varied after *Staph. aureus* infection in the mastitis mice model. The demethylated and upmethylated region/gene and the role of DNA methylation regulation induced by *Staph. aureus* in dairy cows are warranted to study in further work.

Key Words: DNA methylation, *Staph. aureus* mastitis, F-MSAP

CSAS Symposium: Are We Experiencing a Paradigm Shift in How We Feed Livestock As Industrial Agriculture Evolves in the 21st Century?

334 Are we experiencing a paradigm shift in how we feed livestock as industrial agriculture evolves in the 21st century? J. Newman,* *American Feed Industry Association, Arlington, VA.*

Myriad factors are imposing change in costs, sustainability, utilization and other factors on the animal food industry′s ability to use grains and resources for feedstuffs. An in-depth report commissioned by the feed industry will be presented that will examine the pressure to use feed ingredients for human consumption, the changing dynamics of grain production, the usage of grain for fuel production, environmental issues of using natural resources and the effect of climate change, among other issues. An economic forecast will be presented that will detail the state of the feed industry and future of it and its economic relationship to animal agriculture.

Key Words: future feedstuff availability, economics of livestock feeding, competition

335 Rethinking and expanding the role of co-products and crop residues as livestock feeds. S. S. Donkin*[1] and M. J. Cecava[2], *[1]Purdue University, West Lafayette, IN, [2]Archer Daniels Midland Company, Decatur, IL.*

Food and energy security are critical issues facing the world and it′s population. Population growth coupled with increasing wealth will expand demands for animal source foods. At the same time, the biofuels industry will continue expanding and altering processes resulting in new coproduct feeds having characteristics different than those of existing feed coproducts. Quality, quantity and affordability of energy containing feeds for food animal production will be a keen focus, as will efficiency of protein conversion. Record high corn, cereal and oilseed prices have intensified the adoption of alternative feeds and feed processing technologies for livestock production including increasing use of biofuel coproducts such as distillers grains, glycerol, condensed distillers solubles and most recently, crop residues such as straw and stover. Many of the former are geographically restricted and marketed through commodity channels whereas the latter are mainly disaggregated and geographically dispersed. Crop residues comprise approximately half of the dry weight of plants and therefore a high proportion of energy captured by plant growth is available for recovery once soil sustainability metrics are met. Corn stover and straw represent 2 of the most widely available feedstocks which may be collected and processed on-farm or in centralized depots to improve the metabolizable energy content of the residue. Pre-processing includes shearing-fragmentation followed by chemical and/or enzymatic treatments to partially depolymerize recalcitrant fiber. Historically, because of poor digestibility, stover and straw have been used in low amounts in dairy cattle diets mainly to provide fiber for rumen health. However, pre-processing technologies can improve digestibility of residues thereby increasing their value and use and in particular, feeding in combination with biofuel coproducts may enable substantial grain substitution in cattle rations. Resource assessments and animal performance data point to the potential for improved integration of both crop and livestock production to optimize food and biofuel production per unit of land mass.

Key Words: biofuels crop residues, corn replacement, food security

336 Feeding low starch diets to swine. A. D. Beaulieu*[1] and R. T. Zijlstra[2], *[1]Prairie Swine Centre Inc., Saskatoon, SK, Canada, [2]University of Alberta, Edmonton, AB, Canada.*

The increased cost of feed grains is forcing North American swine producers to consider greater usage of alternative ingredients, including co-products. Distillers dried grains with solubles (DDGS), a co-product from the ethanol industry is widely available, often at competitive prices. Ethanol is produced from fermentation of starch in grains, thus relative to the original grain, DDGS have reduced starch content. A typical corn-soybean diet for finishing pigs contains 50% starch and starch contributes 60% of the NE. High incorporation of DDGS or other co-products such as canola meal and wheat millrun, will reduce starch content by at least 45% and will increase fiber and protein content. Formulating these diets to be isoenergetic requires added fat and/or glycerol. Glucose, fatty acids and amino acids are oxidized within pigs for energy. Adequate amounts of either starch or lipid will spare protein, which is an inefficient fuel source. A starch requirement for pigs has not been defined; however, this requires re-examination with the current and potential further reduction in the starch content of swine diets. When growing pigs (25 to 40 kg BW) were fed semi-purified, isoenergetic diets, the efficiency of CP deposited (g CP/kcal DE intake) increased as starch content increased from 2 to 20% at the expense of crude fiber and fat. Further work is required using low starch diets that represent those encountered in commercial practice. The increased fiber and protein content typical of low starch diets can cause concerns for feed intake and growth performance. While the feed intake response has been variable, lean growth, measured as carcass lean, tends to be reduced when pigs have been fed diets high in low starch co-products. Knowledge of the effects of feeding low starch diets on performance and protein deposition is required to fully exploit low starch co-products for commercial swine production.

Key Words: swine, starch, DDGS

337 Alternatives to starch-based feeding programs for growing and finishing cattle. J. J. McKinnon*[1] and T. A. McAllister[2], *[1]University of Saskatchewan, Saskatoon, Saskatchewan, Canada, [2]Agriculture and Agri-Food Canada, Lethbridge, Alberta, Canada.*

In the last decade, there has been a shift to value-added processing of products from the grain and oilseed sectors. For example, the corn-based ethanol industry now ferments as much corn as the livestock sector uses for feed. While supply has kept pace with demand, corn prices have risen. In western Canada, canola production and processing is at record levels. The increase in seeded canola acreage has come at the expense of wheat, barley and oat. This trend is disturbing to the livestock sector which relies on feed barley and wheat as energy sources. To offset high prices and reduced supply, cattle feeders have turned to by-product feeds as alternatives to starch-based feeds. The nutritional profile of by-product feeds varies with the original grain or oilseed and the nature of processing employed. Consider dried distillers grains with solubles (DDGS), a by-product of ethanol production. Our results indicate that depending on the cereal grain fermented (i.e., corn, triticale or wheat), CP content will range from 30 to 40%, NDF from 33 to 44% and ether extract from 4 to 14%. Originally, fed as a protein supplement, DDGS is now fed as an energy source typically replacing 20% or more of the concentrate (DM basis) in finishing rations. Canola meal, a by-product of the canola crushing industry is also high in CP (36 to 40%) and NDF (20 to 28%). As with DDGS, it has been fed as a protein supplement. Research in our laboratory has shown that it can replace barley grain at levels up to 30% of the diet DM in backgrounding diets, however in finishing diets feed efficiency is comprised when fed at this level. We have also shown that wheat bran, a by-product from pre-processing of wheat for ethanol can replace 50 to 100% of barely grain (DM basis) in backgrounding diets with no effects on daily gain; however, feed:gain is increased by 10 to15%. These are just a few examples of by-product feeds that can be fed to growing/finishing cattle. The key to successful utilization is knowledge of their contribution to metabolizable energy and protein supply, their effect on the site and extent of digestion and pricing relative to cereal grain sources.

Key Words: cattle, cereal grains, by-product feeds

338 Ethanol co-products for dairy cows: There goes our starch... now what? H. Paz and P. J. Kononoff,* *University of Nebraska-Lincoln, Lincoln.*

The rise of the corn-ethanol industry has resulted in a dramatic increase in the availability of distillers grains and solubles (DDGS) which can be used for animal feed. Although the dairy industry utilized approximately 25% of the yearly production of DDGS, research investigating the use of this feed in lactating dairy cow diets has only begun. The cost of ingredients that have traditionally been used for energy continues to grow, thus there is a need to understand the nutritional value of corn milling co-products and their potential impact on milk yield and composition. Two concerns with feeding DDGS are the potential to negatively affect milk fat and protein. Indeed publications note that these situations may occur but usually when diets are poorly balanced. Through a series of studies, we have developed feeding recommendations for DDGS and these will be reviewed. Additionally, using the NRC (2001) and data from a total of 27 published studies and 73 observations, we used a meta-analytical procedure to evaluate the impact of feeding corn milling co-products on lactating dairy cows. Data were analyzed using SAS and a random coefficient model to account for the random effects of experiment as well as the fixed effect for co-product (CoP) inclusion. For each experiment Metabolizable Protein (MP) and Net Energy of Lactation (NEL) were computed using NRC (2001) equations. All studies contained treatment serving as a zero control as well as diet treatments that contained CoP which averaged 17.6% of the ration DM. Based on our model, the inclusion of CoP did not affect DMI ($P = 0.31$) or 3.5% FCM ($P = 0.24$) which averaged 23.4 +/− 0.44 and 34.2 +/− 0.90 kg/d respectively. Additionally, the percent milk fat and protein in the milk was not affected ($P = 0.83$ and 0.51) and averaged 3.09 +/− 0.07 and 3.57 +/− 0.06% respectively. We also retrospectively evaluated the predicted flow of Lys and Met for these studies. As expected the modeled flow of Lys was significantly ($P < 0.01$) reduced from 6.45 +/− 0.06 to 5.81 +/− 0.05% of MP when CoP were included. Conversely the flow of Met was not affected ($P = 0.19$) and averaged 1.90 +/− 0.03% of MP. We tested the effect of CoP on the error associated with MP and NEL allowable milk calculations of the NRC model. The error associated with NEL allowable milk averaged 5.28 +/− 1.18 kg and was not affected by CoP ($P = 0.57$). Conversely error associated with MP was significantly ($P = 0.04$) higher for cows consuming CoP by 1.88 kg/d. These results reinforce the concepts that CoP can be used as a effective feed for lactating dairy cows.

339 The Missouri Show-Me-Select Replacement Heifer Program: A retrospective on marketing and sales. J. M. Nash,* N. T. Martin, J. M. Thomas, B. D. Mayhan, M. F. Smith, S. E. Poock, and D. J. Patterson, *University of Missouri, Columbia.*

The Missouri Show-Me-Select Replacement Heifer Program has improved reproductive efficiency and increased individual farm income for program participants. The objectives of the program include: 1) implementation of a total quality management plan to enhance health and management of replacement beef heifers; 2) improved marketing opportunities for participating producers and added value to Missouri-raised heifers; and 3) creation of reliable sources of quality commercial and purebred replacement beef heifers based on management, reproduction, and genetics. Over the past 15 yr, 719 farms enrolled 99,805 heifers in the program. Heifers undergo a prebreeding evaluation administered by a veterinarian before the breeding season, and are required to meet minimum management requirements, including herd health and vaccination schedules. Heifers meeting the minimum requirements for enrollment are classified as Tier 1 replacements. Heifers are distinguished as Tier 2 replacements based on the sire of a heifer meeting minimum accuracy requirements for specified traits at the time of sale, including: calving ease direct, calving ease maternal, weaning weight, carcass weight, and marbling. Data for sales from fall 2010 through fall 2011 were compared. Tier 2 heifers carrying AI sired pregnancies ($1,751) sold on average for $259 more per heifer than Tier 1 heifers carrying natural service sired pregnancies ($1,492). Similarly, Tier 1 heifers carrying AI sired pregnancies ($1,654) sold for $162 more per heifer than Tier 1 heifers carrying natural service sired pregnancies. To date, the Show-Me-Select Replacement Heifer Program facilitated the sale of 23,936 heifers in 113 sales from 1997 through December 2011. The aforementioned sales generated interest from 8,063 registered buyers and resulted in $27,348,050 in gross sales revenue. Show-Me-Select Replacement heifers have sold into 18 states, including AR, AZ, CO, FL, GA, IA, IL, IN, KY, KS, LA, MO, NE, OK, SC, SD, TN, and TX. The Show-Me-Select Replacement Heifer Program is estimated to have had a $60 million impact on Missouri′s economy since the program′s inception in 1997.

Key Words: heifer development, reproductive management, beef cattle

340 The Missouri Show-Me-Select Replacement Heifer Program: Prebreeding reproductive evaluation of heifers and subsequent pregnancy outcome after fixed-time AI. J. M. Thomas,* J. M. Nash, N. T. Martin, B. D. Mayhan, M. F. Smith, S. E. Poock, and D. J. Patterson, *University of Missouri, Columbia.*

The Missouri Show-Me-Select Replacement Heifer Program has resulted in improved reproductive efficiency and has increased individual farm income for program participants. The objectives of the program include: 1) implementation of a total quality management plan to enhance health and management of replacement beef heifers; 2) improvement of marketing opportunities for beef producers while adding value to Missouri-raised heifers; and 3) creation of reliable sources of quality commercial and purebred replacement heifers based on management, reproduction, and genetics. Over the past 15 yr, 719 farms enrolled 99,805 heifers in the program. Twenty-five regional extension livestock specialists coordinate the program, and work closely with the 212 veterinarians involved with the program statewide. Enrolled heifers must meet minimum management standards and follow approved animal health regimens. Prebreeding exams [reproductive tract scores (RTS)] are performed by licensed veterinarians before the breeding season. Additionally, initial pregnancy diagnoses must be performed within 90 d of the start of breeding and reconfirmed after the end of the breeding season. In recent years, program participants have increased use of fixed-time AI (FTAI) programs in their herds. Data collected from 2010 to 2011 were used to evaluate relationships between RTS and pregnancy outcome after FTAI. The reproductive tract scoring system ranges from 1 to 5: 1 = infantile; 2 and 3 = noncycling/prepubertal; 4 and 5 = cycling/pubertal. A summary of RTS and FTAI pregnancy rate (PR) for heifers evaluated from 2010 to 2011 is provided: RTS 5 (n = 1,816; FTAI-PR = 59.4%); RTS 4 (n = 1,535; FTAI-PR = 52.1%); RTS 3 (n = 1,571; FTAI-PR48%); RTS 2 (n = 189; FTAI-PR = 36.0%); and RTS 1 (n = 15; FTAI-PR = 0.0%). These data support the practice of establishing prebreeding criteria (e.g., minimum RTS = 3 before the breeding season) for identification of heifers that are good candidates for a FTAI program.

Key Words: heifer development, reproductive management, beef cattle

341 The Missouri Beef Project: An industry partnership designed to link economic incentives with technology adoption. D. J. Patterson,* D. S. Brown, S. E. Poock, and M. F. Smith, *University of Missouri.*

The beef industry in Missouri is a leading segment of the state′s economy and efforts to increase the value of Missouri′s cattle have widespread effects throughout the state. The Show-Me-Select Replacement Heifer Program changed production practices related to management of beef heifers in Missouri. Effects of these changes are realized by producers, veterinary practices, feed dealers, the pharmaceutical and AI industries, and related local economies. The addition of Tier Two to the Show-Me-Select Program arose from funding of 2 integrated project proposals funded by NIFA-AFRI in program areas that include Animal Reproduction and Prosperity for Small and Medium-sized Farms. These integrated project awards supported research and development of protocols to successfully inseminate beef cows and heifers at predetermined fixed times. Additionally, funding from these grants supported the initial transfer of fixed-time AI (FTAI) technology to the field coupled with use of genetically superior high-accuracy AI sires. Adoption of these technologies is resulting in 2 significant outcomes: Increased numbers of genetically superior females, and a similar increase in numbers of genetically superior steer mates. Increased domestic and global demand for high-quality proteins including beef, coincident with the decline in the US beef cow inventory, offers the potential to increase premiums for high-quality beef products. Stacking technologies (FTAI and high accuracy AI sires) sets the stage for a new programming effort focused on The Missouri Beef Project. This project streamlines production and marketing of cattle with a focus on high-quality endpoints. The project involves a partnership including the University of Missouri, Irsik and Doll Feed Yard (Garden City, KS), Pratt Feeders (Pratt, KS), Accelerated Genetics, Genex Cooperative, Select Sires Mid-America, and Certified Angus Beef. The project objectives are to: 1) assist beef producers in gaining access to markets for high-quality cattle, and 2) educate Missouri producers to understand and capture the greater economic returns available for high-quality cattle.

Key Words: High-quality beef, artificial insemination, high-accuracy sires

342 Impact of management practices on the value of heifers sold in Texas auction barns.

K. Stutts,* M. Beverly, S. Kelley, and B. Freel, *Sam Houston State University, Huntsville, TX.*

The objective of this study was to evaluate the impact of management practices on the selling price of heifers in Texas livestock markets. Data were collected at 9 weekly Texas livestock auctions on 6,855 lots of heifers consisting of 42,376 head. The data were collected by trained livestock market reporters and included horn status, body condition, fill, health status, lot size, and selling price. An ANOVA was performed. Heifer characteristics were analyzed individually in a model that included BW and location as covariates. Least squares means were generated for each variable and separated based on predicted differences. All selling prices are reported in US dollars per 45.45 kg of BW. Mean selling price of polled ($127.46) heifers was greater ($P < 0.01$) than that of horned ($113.65) heifers and mixed (polled and horned; $125.50) lots. Differences in mean selling price existed among body condition categories as well. Heifers that were classified as very thin ($131.35) and thin ($129.33) had a greater ($P < 0.01$) mean selling price than heifers classified as average ($126.00), fleshy ($125.23) or fat ($125.23) condition. Differences ($P < 0.01$) in mean selling price existed among all fill categories with gaunt, average, and full heifers selling for $131.50, $125.70, and $127.28, respectively. Heifers that were pre-conditioned ($131.00) had a greater ($P < 0.001$) mean selling price than heifers that were classified as healthy ($125.97) or heifers that appeared sick ($83.62). Lot size also influenced mean selling price. Heifers sold in lot sizes of 10 or more ($132.51) had a greater ($P < 0.01$) mean selling price than heifers sold in smaller ($123.56) lot sizes. Lots that were uniform ($127.19) had a greater ($P < 0.01$) mean selling price than lots that lacked uniformity ($125.67). These date indicate that producers can greatly influence the selling price of their heifers through modification of their management practices such as dehorning, monitoring body condition, and selling heifers in larger, more uniform lots.

Key Words: heifers, livestock auction, selling price

343 Phenotypic characteristics that affect the value of heifers sold in Texas auction barns.

M. Beverly, S. Kelley,* K. Stutts, and B. Freel, *Sam Houston State University, Huntsville, TX.*

This study was conducted to evaluate the effect of phenotypic characteristics on selling price of heifers in Texas livestock markets. Data were collected at 9 weekly Texas livestock auctions on 6,855 lots of heifers consisting of 42,376 head. The data were collected by trained livestock market reporters and included subjective identification of age, breed, color, USDA frame and muscle scores, and selling price. An ANOVA was performed. Heifer characteristics were analyzed individually in a model that included BW and location as covariates. Least squares means were generated for each variable and separated based on predicted differences. All selling prices are reported in US dollars per 45.45 kg of BW. The mean selling price of yearling heifers ($128.15) was greater ($P < 0.01$) than the mean selling price of heifer calves ($125.26). Breed type had a significant influence on mean selling price of heifers. Five breed types were analyzed resulting in British ($128.64) breed types having the highest ($P < 0.01$) mean selling price and Continental ($126.38) breed types having the second highest selling prices. American or Brahman-influenced ($118.68) heifers had the lowest ($P < 0.01$) mean selling price. Eleven color categories were analyzed. Gray ($129.39) and black ($129.15) heifers garnered the greatest mean selling prices and were not significantly different from each other. Spotted ($94.57) heifers had the lowest ($P < 0.01$) mean selling price of all color categories. Differences ($P < 0.05$) existed between all frame size categories. Mean selling price for large-, medium-, and small-framed heifers were $130.91, $125.47, $107.18, respectively. Mean selling price also differed ($P < 0.01$) among all muscle scores. Mean selling price for muscle scores 1, 2, 3, and 4 were $132.07, $118.03, $125.36, and $122.99, respectively. These data indicate that producers can influence the selling price of their heifers through proper age, breed selection, and genetic selection within breeds to meet market demand.

Key Words: heifers, livestock auction, selling price

344 Beef Excellence Education for You: A program to teach youth about the beef industry.

L. A. Kriese-Anderson*[1], C. L. Bratcher[1], R. A. Ebert[1], J. B. Elmore[2], R. W. Colquitt[2], and M. K. Stanford[2], [1]*Auburn University, Auburn, AL,* [2]*Alabama Cooperative Extension System, Auburn, AL.*

Since 2008, over 300 youth from Alabama and Florida have participated in a hands-on, interactive Beef Excellence Education for You (B.E.E.F. U) program. At the program's inception, the goal was to teach youth how their feeder or show cattle fit the US Beef Industry. While the goal remains the same, B.E.E.F. U continues to evolve each year to further enhance participants' knowledge of the US Beef Industry. Targeted youth audiences attending the day-long program include 4-H and FFA members and home-school groups, but any interested youth (ages 8 to 18) is welcome. Participants rotate through multiple sessions focusing on live animals, carcasses and further processing. Sessions include live cattle terminology, beef conformation, feeder calf basics, and fed cattle evaluation as well as beef carcass terminology and carcass evaluation. Further processing stations teach participants how to make kielbasa, steak nuggets and main beef meals. Participants learn which ingredients to use when making the product, where meat cuts are fabricated from the carcass, and how to prepare the product. Other modules have included feeds cattle eat, properly giving injections and taste and texture of variety meats. Modules are taught by Animal Sciences faculty, students and staff and Alabama Cooperative Extension System (ACES) specialists and agents. Participants evaluate B.E.E.F. U using a likert scale at the end of the program. When asked if they would attend another B.E.E.F. U program, 78% said yes, 5% said no and 17% said they were unsure. To date, 60% of participants have attended more than one program. When asked how well they understood the material at each rotation, 74% said they understood the material well or very well, 16% said they understood the material some, while 11% said they did not understand the material or in limited amounts. The majority of participants found the materials interesting or very interesting (82.3%), 11.5% found it somewhat interesting and 6.3% found the material boring or somewhat boring. The majority of the youth stated time spent at each rotation was just right (60%), while 21% indicated the time was too long and 17% stated the time was too short.

Key Words: beef industry, youth education

345 A survey of the presence, structure, and effectiveness of Beef Quality Assurance (BQA) or BQA-type programs across the United States.

J. K. Ahola* and R. J. Urie, *Colorado State University, Fort Collins.*

In an effort to improve the effectiveness and impact of Beef Quality Assurance (BQA) Programs in the US, a nationwide survey of state and regional BQA Program coordinators was conducted. In early 2011, coordinators were asked to complete a 37-question on-line survey about the BQA Program that they oversee. Survey questions were intended to summarize basic information about each program, identify unique and successful approaches to educating and(or) certifying producers, and estimate the effect of BQA efforts nationwide. Representatives from 45 of the 50 states completed the survey on behalf of their BQA Program or cattle industry, if no program existed. In 62.2% of states, university extension personnel coordinated the BQA Program. State beef councils provided funding for BQA Programs in 60.0% of states, followed by university extension (53.3%), pilot project grants from the National BQA Program (35.6%), and state cattlemen′s associations (31.1%). User fees were used in 22.2% of states. Formal BQA Certification was offered by 91.0% of states, and 71.1% of states required at least 2 h of face-to-face training in order for an attendee to become certified. Only 13.3% of states offered multiple levels of BQA Certification, and just 11.1% included an on-farm assessment or audit associated with BQA Certification. In terms of additional BQA-related components offered, relatively few states offered dairy BQA Certification (20.8%) or feedyard BQA Certification (35.4%). Youth BQA Certification was available in 43.8% of states, but only 27.1% required youth to be BQA Certified to show and sell an animal at the county fair level. On average, there were 28 trainers per state BQA Program. However, most programs (57.1%) had 1 to 9 trainers, while 22.8% had 10 to 49 trainers. At least 50 trainers were present in 20.0% of programs. Overall, 709 trainers were available to BQA Certify producers across the US In summary, these data suggest that the BQA Program includes a large infrastructure of personnel across the US; however, many states offer little beyond basic BQA Certification. Further, the large amount of variation among programs may make development of a uniform nationwide program challenging.

Key Words: Beef Quality Assurance, cattle, survey

346 National Animal Identification System versus National Livestock Identification System.

K. Semple[1], M. Robert*[2], and H. Pittman[1], *[1]Department of Primary Industries, Melbourne, Victoria, Australia, [2]The National Agricultural Law Center, Fayetteville, AR.*

On December 19, 2003, a major event happened in the animal agriculture industry. At Vern's Moses Lake Meat Co., a dairy cow infected with bovine spongiform encephalitis (mad cow disease) was slaughtered in the US. Inspired by this event, the USDA secretary Ann Venemen announced a need for a national animal identification system (Roberts, Pittman). Nine years later, in 2012, the US still does not have a national animal identification system in place. However, in other countries such as Canada, New Zealand, the European Union and Australia there are similar programs in place for their livestock production. Dairy farmers around the world are taking advantage of all the benefits that an electronic identification program can provide. Benefits such as accurate identification, automatic sorting, disease traceability, accurate record keeping for animal events such as heat, treatments, sire selection etc (Semple). This benefit of electronic identification has improved the dairy industry both on and off the farm in other countries. The American dairy industry can easily apply those same benefits, which would lead to an overall support of a similar animal identification program here in the United States.

Key Words: national identification, international benefits, on-farm benefits

347 Development of the pioneer organic beef supply chain in the Mexican tropics—Promotion of sustainable beef production through integration of extension, education and research.

P. Fajersson*[1,3] and P. Parada[2], *[1]EcoAgroPec, Hueytamalco, Puebla, Mexico, [2]Carnes La Rumorosa, Poza Rica, Veracruz, Mexico, [3]Colegio de Postgraduados, Campus Veracruz, Veracruz, Mexico.*

In 2001, a strategic alliance was formed in Veracruz between academia, a lead producer and an organic certification agency, collaborating in extension, education and research to integrate the pioneer organic beef supply chain (OBSC) in the Mexican tropics. Twenty producers received guided conversion to organic beef production. Training included 2 theoretical-practical courses, then symposia and workshops including students. Teaching originated with a graduate course on sustainable livestock systems that introduced students to the project. Four generations then visited the lead producer and 2 did their course extension project analyzing his supply chain. Applied research evolved from a case study of the newly integrated OBSC to a detailed financial and energy analysis used to evaluate its feasibility and sustainability during a decade. Continuing education, extension visits and exchange of experiences with other states followed. The lead producer converted his traditional beef cattle production system (TBCPS) to an OBSC certified by Bioagricert, IFOAM in 2003. In 2010, 693 crossbred Zebu cattle grazed 736 ha in agroforestry systems and beef from 150 to 200 head/year were sold to organic markets/stores in 7 states with a 35% value added. The return on investment was 16.6% in the TBCPS and 31.2% in the OBSC and marginal gain was USD 43,912 and 93,339, respectively. Energy efficiency was 49.6% for the OBSC and18.3% for the TBCPS and the OBSC remained profitable in 6 future scenarios. Volume of beef produced is increasing without deterioration of natural resources and energy efficiency and economic stability continue to improve, demonstrating the sustainability of the OBSC. More than 500 producers and faculty and students at 14 universities in Mexico have been trained and projects initiated in 8 states. Education material is disseminated nationally and research results also internationally. Integration of extension, education and research has led to the project's success and expansion.

Key Words: organic beef, sustainability, integrated approach

Forages and Pastures I

348 Sustainable goat farming: Pasture enhancement and identification of suitable forages for goats.

U. Karki*[1], L. B. Karki[2], N. K. Gurung[1], and A. Elliott[1], [1]*Tuskegee University, Tuskegee, AL,* [2]*PadmaDal Memorial Foundation, Auburn, AL.*

Meat-goat farming is becoming popular to many small-scale farmers in Alabama. However, making this business sustainable is a challenge, especially with the existing poor pastures and grazing practice. Not much information is available on suitable forages for improving goat pastures and managing them sustainably. The objectives of this study were 1) to improve the existing goat pasture by incorporating selected cool-season forages, and 2) to determine goats' preference for the selected forages. The study was conducted in Selma and Phenix City, Alabama as a completely randomized design with 3 replications in each site. Five treatments: combination of annual ryegrass (*Lolium multiflorum*) and one of the selected cool-season legumes (arrowleaf clover, *Trifolium vesiculosum*; berseem clover, *Trifolium alexandrinum*; crimson clover, *Trifolium incarnatum*; hairy vetch, *Vicia villosa*; and winter peas, *Pisum sativum*) and a control of sole annual ryegrass plantings were tested. Pastures were managed by rotational grazing. Forage biomass before grazing, and forage height both before and after grazing were measured. The average forage-biomass production in Selma (1.0 ± 0.28 t ha-1) and Phenix City (1.4 ± 0.21 t ha-1) remained similar among the treatments. Average height reduction after grazing was much lower for peas (8.0 ± 1.51 cm) compared with other forages (18.0 ± 2.06 cm). Preliminary results show that all selected forage species, except winter peas, were readily grazed by goats. Findings of this research will be very useful to goat producers and Extension personnel for improving and managing goat pastures, and eventually promoting the sustainability of goat farming.

Key Words: cool-season legumes, grazing management, sustainable goat farming

349 Effects of co-grazing on herbivory patterns and performance by cattle and goats grazing native tallgrass rangeland infested by sericea lespedeza (*Lespedeza cuneata*).

L. A. Pacheco*[1], W. H. Fick[2], G. W. Preedy[1], E. A. Bailey[1], D. L. Davis[1], and K. C. Olson[1], [1]*Department of Animal Sciences & Industry, Kansas State University, Manhattan,* [2]*Department of Agronomy, Kansas State University, Manhattan.*

Sericea lespedeza (SL) is classified as a noxious weed in the Great Plains and infests over 0.6 million acres of rangeland in Kansas. Beef cattle avoid grazing SL, presumably due to its high tannin content; however, goats readily graze this plant. Lactating crossbred cows with calves (n = 145; initial BW = 579 ± 91 kg) and non-pregnant, nonlactating Boer × nannies (n = 200; initial BW = 42 ± 1.9 kg) were used to evaluate the effects of co-grazing on herbivory patterns and animal performance while grazing native pastures infested heavily by SL (average SL biomass in October = 2,061 kg/ha; 56% of total forage biomass). Nine pastures were assigned randomly to 1 of 2 season-long grazing systems: 5 pastures (65 ha) were grazed by cows + calves only (single species; 0.8 ha/AUM) and 4 pastures (32 ha) were grazed by cows + calves (0.8 ha/AUM) and goats (multispecies; 0.8 ha/AUE/month). Cows + calves and goats were assigned randomly to pastures. Animal BW was measured at 28-d intervals from June 1 to October 1; BCS were assigned to cows also at those times. Two permanent 100-m transects were marked at the outset of the study (June 15) within each pasture to estimate botanical composition and SL herbivory. Season-long cow BW change, season-long calf ADG, and cow pregnancy rates were not different ($P \geq 0.40$) between multispecies and single-species pastures. Conversely, season-long cow BCS change was greater ($P < 0.01$) on multispecies pastures than on single-species pastures (0.04 vs. −0.38, respectively). Biomass of SL was not different ($P = 0.97$) between pastures at the outset of the study. The percentage of individual SL plants that had been grazed at the end of the trial was greater ($P < 0.01$) on multispecies pastures than on single-species pastures (94.2 vs. 77.5%, respectively). Final SL biomass in multispecies pastures averaged 1,692 kg/ha, whereas final SL biomass in single-species pastures averaged 2,230 kg/ha (SE = 739.4 kg/ha; $P = 0.37$). Residual forage biomass at the end of the study was not different ($P = 0.54$) between treatments and averaged 3,622 kg/ha, indicating that forage availability did not limit forage intake during our trial. Our results were interpreted to suggest that grazing cows + calves and goats in combination increased grazing pressure on SL without negatively affecting beef cow or beef calf performance or residual forage biomass.

Key Words: *Lespedeza cuneata*, multispecies grazing, condensed tannins

350 Effect of different regrowth ages of *Andropogon gayanus* grass silages on intake, digestive efficiency and methane emissions in sheep.

G. O. Ribeiro Junior,* L. C. Gonçalves, and N. M. Rodriguez, *School of Veterinary, Federal University of Minas Gerais, Belo Horizonte, Minas Gerais, Brazil.*

Andropogon gayanus is an important grass due to its high biomass production and its adaptability to withstand a long dry season, and low fertility acidic soils. Currently, there is little research assessing the nutritional quality of *A. gayanus* grass silage at increasing days of regrowth. Thus, the objectives of this study were to determine the effects of different regrowth ages of *A. gayanus* grass silage on dry matter intake (DMI), dry matter digestibility (DMD), net energy, energy balance and CH_4 production in sheep. *A. gayanus* grass silage was made using 56, 84, or 112 d of regrowth in 200 L metallic barrels and fed to sheep (n = 18) for a period of 21 d after which DMI and DMD were measured for 5 consecutive days. Net energy, energy balance and methane emissions were determined with an open circuit respirometry chamber. The animals stayed inside the chamber for 24 h during feeding and fasting. The experimental design was completely randomized with 3 treatments (silage age) and 6 repetitions (sheep). The data were subjected to ANOVA and linear regression. The DMI were similar among treatments ($P > 0.05$) averaging 54.36 g/$BW^{0.75}$; however, DMD reduced linearly ($P < 0.01$) with increasing regrowth age, averaging 52.60, 43.64 and 37.99% for 56, 84 and 112 d of regrowth, respectively. Silage net energy was also reduced linearly ($P < 0.05$) with increasing regrowth age. Furthermore, the energy balance of the animals reduced linearly ($P < 0.01$) with increasing regrowth age and was below zero in the higher regrowth age. Methane emissions (g/kg) of DMD showed a tendency ($P < 0.10$) to increase as regrowth age increased. When methane emissions were expressed in g/kg of digestible cellulose it increased linearly ($P < 0.05$) with increasing regrowth age. Therefore results from this study show that increasing regrowth age of *A. gayanus* grass silage reduced digestive efficiency and increased methane emissions in sheep, which indicates that this forage should be ensiled at younger regrowth age.

Key Words: energy efficiency, grass maturity, methane

351 Effects of feeding perennial peanut hay on growth, development, attainment of puberty, and fertility in beef replacement heifers. K. M. Bischoff*[1], T. E. Black[1], V. R. G. Mercadante[1], G. H. L. Marquezini[1], R. O. Myer[1], A. T. Adesogan[2], N. DiLorenzo[1], and G. C. Lamb[1], *[1]North Florida Research and Education Center, University of Florida, Marianna, [2]Department of Animal Sciences, University of Florida, Gainesville.*

We determined the influence of supplemental feeding of perennial peanut hay (*Arachis glabrata*) on growth performance, attainment of puberty, and fertility in replacement heifers. Over 2 yr, 120 heifers (60 heifers/yr) were allocated into pens (5 heifers/pen) and assigned to receive one of 3 supplement treatments during a 140 d development phase (DP) before initiation of the breeding season: 1) 1.23 kg DM/d of a mix of 80% cracked corn and 20% soybean meal, DM basis (CSBM); 2) 2.74 kg DM/d of perennial peanut hay (PPH); and, 3) no supplement (CON). Pen was the experimental unit. During the DP all heifers received ad libitum access to bermudagrass hay (*Cynodon dactylon*). After the DP, heifers were comingled for a 77-d breeding season. During the DP ADG was influenced ($P = 0.002$) by 28-d period. In addition, ADG of CSBM (0.48 ± 0.109 kg/hd/d) and PPH (0.46 ± 0.109 kg/hd/d) treatments tended ($P = 0.07$) to be greater than the CON (0.18 ± 0.109 kg/hd/d) treatment. There was a treatment × period interaction ($P = 0.06$) for mean BW with heifers in the CSBM and PPH treatments having a greater ($P < 0.05$) BW than the CON heifers during the periods from d 84 to 112 and d 112 to 140. Total DMI during the 140 d DP was greater ($P < 0.01$) for PPH (5.3 ± 0.25 kg/hd/d) than for CSBM (4.3 ± 0.25 kg/hd/d), which were greater ($P < 0.01$) than CON (3.4 ± 0.25 kg/hd/d). Treatment did not alter age ($P = 0.38$), BW ($P = 0.16$), or BCS ($P = 0.27$) at attainment of puberty or d on treatment before attainment of puberty. No differences existed in fetal age 30 d following the end of the breeding season ($P = 0.34$), however overall pregnancy rates differed ($P = 0.05$) by treatment with PPH (88 ± 6.7%) having greater pregnancy rates than CON (64 ± 6.7%), whereas CSBM (78 ± 6.7%) were intermediate. We conclude that attainment of puberty was not altered by treatment, although differences in DMI intake existed. However, pregnancy rates of heifers receiving PPH were greater than CON, indicating that PPH may be a suitable alternative for development of replacement beef heifers.

Key Words: perennial peanut, replacement heifer, heifer development

352 Effects of different sources of rumen-degradable protein supplementation on performance of cows and calves grazing limpograss stockpiled pastures in Florida. A. D. Aguiar*[1], J. M. B. Vendramini[1], J. D. Arthington[1], and L. E. Sollenberger[2], *[1]Range Cattle Research Education Center, Ona, FL, [2]University of Florida, Gainesville.*

Limpograss (*Hemarthria altissima* [Poir.] Stapf & C.E. Hubb.) is a warm-season grass used as a stockpiled forage during the winter for cow-calf production in South Florida, however, the usual decreased CP and RDP concentrations may affect animal performance. The objective of this study is to investigate the effect of supplements with different sources of RDP on performance of cow-calf pairs (*Bos* sp.) grazing stockpiled limpograss pastures. The experiment was conducted in Ona, FL from January to March 2011. Treatments were: 1) Cows receiving 1.3 kg/d of cottonseed meal (CSM) and 2) Cows receiving 0.13, 0.33, and 0.9 kg/d of urea, feather meal and corn meal respectively. Treatments were isonitrogenous (48% CP) with similar concentrations of RDP (62 kg RDP/kg CP). All treatments received additional 2.3 kg/d of sugarcane (*Saccharum officinarum* L.) molasses. Treatments were distributed in randomized complete block design with 4 replicates. Twenty 4 cow-calf pairs (420 ± 59 and 78 ± 12 kg, respectively) were randomly distributed in 8 limpograss pastures (experimental units; 1.0 ha/pasture; 3 cow-calf pairs/pasture). Cows BCS and cows and calves weights were recorded every 28 d to calculate ADG. Herbage mass (HM) and nutritive value was measured every 14 d. The data were analyzed using PROC GLMMIX with treatment and months as fixed effects, and replicates as random effects. There was no difference in HM ($P = 0.13$; mean = 5392 kg/ha; SE = 134), CP concentration ($P = 0.21$; mean = 14.9%; SE = 0.7), IVOMD ($P = 0.38$; mean = 46.7%; SE = 1.9) between treatments. There was no effect of the treatments on cow ADG ($P = 0.34$; mean = 0.0 kg/d; SE = 0.1), milk production ($P = 0.37$; mean = 6.5 kg/d; SE = 1.2), and blood urea nitrogen concentrations ($P = 0.83$, mean = 12.25 mg/dL; SE = 0.77), and calf ADG ($P = 0.78$; mean = 0.85 kg/d; SE = 0.04). However, there was an effect on final BCS for cows consuming CSM supplement compared with urea (5.2 vs. 4.7, $P = 0.039$), respectively. There was an increase in BCS of cows consuming CSM supplement, however performance of cows and calves were not improved.

Key Words: cow-calf pairs, limpograss, protein supplementation

353 Effects of three levels of rumen-undegradable protein supplementation on performance of early weaned calves receiving stargrass. J. M. B. Vendramini*[1], J. D. Arthington[1], and L. E. Sollenberger[2], *[1]University of Florida/IFAS Range Cattle Research and Education Center, Ona, [2]University of Florida, Department of Agronomy, Gainesville.*

Warm-season grasses have reduced concentrations of CP fractions A and B and microbial protein alone may be insufficient to meet the metabolizable protein requirements of young growing cattle. The objectives of this study was to evaluate the effects of increasing levels of rumen-undegradable protein supplementation on performance, forage intake, and total DM intake of early weaned calves receiving stargrass (*Cynodon nlemfuensis*). The experiments were conducted in Ona, FL from May to August 2007 and 2008. The treatments were 3 levels of rumen-undegradable protein supplementation, soybean meal (SBM, 35% RUP 65% RDP), a 50:50 mixture of SBM-Soyplus (modified expeller soybean meal with 60% RUP 40% RDP), or Soyplus, supplemented at 0.15% BW, and distributed in a randomized complete block design. The calves (*Bos* sp.) received additional 0.85% BW of soybean hulls daily. In experiment 1, 4 calves (initial BW = 217 ± 30 kg) were assigned to 8 experimental units (0.51-ha pastures, each divided into 2 paddocks for rotational stocking (14-d grazing and 14-d rest period). Calves were weighed every 28-d and average daily gain calculated. There was no difference ($P \geq 0.10$) in forage CP (11%), IVDOM (64%), herbage mass (2600 kg/ha), and herbage allowance (1.4 kg DM/kg BW) among treatments. Calves average daily gain and liveweight gain per ha did not differ among treatments ($P \geq 0.10$; 0.56 kg/d and 238 kg/ha, respectively). In experiment 2, 3 early weaned steers (160 ± 18 kg BW) were distributed in a 3 × 3 Latin square, 3 treatments (same treatments described for experiment 1) and 3 periods (10 d adaptation, and 7 d data collection). Ground stargrass hay (11% CP, 51% IVDOM) was offered daily and adjusted to allow 10% refusals. Daily offered forage and refusals were weighed, and subsampled for DM determination. Total feces production was collected. There was no difference ($P \geq 0.10$) in forage DM and total DM intake among treatments (2.0 and 2.9% BW, respectively). However, there was a linear increase in the diet apparent digestibility with increasing levels of Soyplus ($P = 0.08$; from 60 to 64%). Increasing levels of RUP did not improve performance of early-weaned calves grazing stargrass pastures.

Key Words: supplementation, RDP, stargrass

354 Ruminal availability of iron in forages.

Y. L. Huang*[1,2], K. E. Lloyd[1], C. L. Pickworth[1], and J. W. Spears[1], [1]*North Carolina State University, Raleigh,* [2]*Southwest University for Nationalities, Chengdu, Sichuan, China.*

Iron (Fe) is an essential trace element that is required for several important biological processes. However, excessive Fe can lead to the production of free radicals and expose sensitive tissues to oxidative stress. Many feedstuffs fed to ruminants are frequently high in Fe. Little is known regarding bioavailability of Fe naturally found in feedstuffs. A study was conducted to examine water solubility and ruminal availability of Fe from 4 forages (white clover, KY 31 tall fescue, Max-Q tall fescue, and orchardgrass) at 3 growth stages. Clipped forage samples were collected at 14-d intervals beginning in early April (vegetative stage) and continuing through early May (mid bloom stage). The Fe content of forages ranged from 24.4 to 315.4 mg/kg DM. The percentage of water-soluble Fe in forages varied considerably. Orchardgrass had the highest ($P < 0.05$) Fe water solubility at 50.9% ± 13.3%; compared with white clover (13.6% ± 0.4%), KY 31 tall fescue (12.2% ± 6.4%), and Max-Q tall fescue (18.2% ± 6.7%) which were similar. Release of Fe from forages in the rumen was measured using the Dacron bag technique. Dacron bags (10 × 20 cm with 4.0 g sample) were incubated in duplicate for 3, 12, or 24 h in 2 fistulated steers. Despite the greater percentage of water soluble Fe in orchardgrass, percent disappearance of Fe from Dacron bags was less ($P < 0.05$) for orchardgrass compared with the other forages after 3, 12, and 24 h of ruminal fermentation. Iron disappearance after 24 h of incubation was 83.8 ± 1.8, 73.1 ± 9.5, 71.6 ± 5.2, and 45.3 ± 14.2% for white clover, KY 31 tall fescue, Max-Q tall fescue, and orchardgrass, respectively. Disappearance of Fe was greater ($P < 0.05$) for white clover than the tall fescue varieties after 12 and 24 h. Increasing stage of maturity was associated with reduced ($P < 0.05$) Fe disappearance during ruminal fermentation for the grasses studied, but not for white clover. This study indicates that a large portion of the total Fe in most forages is released in a soluble form in the rumen within 24 h of ruminal digestion.

Key Words: iron availability, forage, ruminants

355 Nutritional profile of native warm season grass grown as a mono- or multi-species pasture.

B. S. Oloyede,* B. J. Rude, H. T. Boland, and B. S. Baldwin, *Mississippi State University, Starkville.*

The objective of this study was to evaluate the nutritional profile of mono- or multi-species pastures of native warm season grasses (NWSG). Twelve pastures were randomly assigned to one of 4 treatments: 1) Bermudagrass (BG; *Cynodon dactylon*); 2) Indiangrass (IG; *Sorghastrum nutans*); 3) MIX G (Indiangrass, little bluestem (*Schizachyrium scoparium*), big bluestem (*Andropogon gerardii*)) established at 9.0 kg/ha seeding rate; and 4) MIX NG the same as MIX G but established at 4.5 kg/ha seeding rate. The fourth treatment (MIX NG) was not intended to have cattle grazing to facilitate a congruent wildlife research project. One month before grazing was initiated (mid April) P, K, and lime was added per individual pasture recommendation. For IG, MIX G and MIX NG, N was applied at 38 kg/ha while BG was 67 kg/ha. Growing steers (n = 225, BW = 237 ± 1.5 kg, 2.7 steers/ha) were randomly assigned to one of 9 pastures. Animals were weighed on 2 consecutive days at initiation and termination of the experiment and once every 28 d during the experiment. Grass samples were taken from all pastures every 28 d during 4-mo period and were analyzed for DM, NDF, ADF, OM, EE, and IVDMD. Dry matter was greater ($P < 0.05$) for all NWSG (33.6, 30.7, and 29.5% for MIX G, IG, and MIX NG, respectively) compared with BG (27.5%). However, OM was similar ($P > 0.05$) for all treatments (between 91.2 and 92.61%). Neutral Detergent Fiber, ADF and hemicellulose were greater ($P < 0.05$) for all NWSG (66.9, 67.8, and 66.6% NDF, 34.6, 35, and 33.5% ADF, 32, 32.8, and 33.1% hemicellulose for IG, MIX G, and MIX NG, respectively) compared with BG (63.6% NDF, 32.9% ADF, and 30.6% hemicellulose). Fat was similar ($P > 0.05$) for all treatments (between 10.8 and 11.1%). Crude protein was less ($P < 0.05$) for NWSG (8.6, 8.2, and 8.6% for IG, MIX G, and MIX NG respectively) compared with BG (10.7%). Crude protein decreased ($P < 0.05$) with increased maturity (12.7% May to 6.6% September) while NDF, ADF, and hemicellulose increased ($P < 0.05$; NDF = 58.3% May to 70.2% Sept.; ADF = 30.4% May to 36.3% Sept.; hemicellulose = 27.8% May to 33.8% Sept.). More forage ($P < 0.05$) was available and consumed by steers on all NWSG pastures compared with BG. It appears that NWSG may offer a viable alternative to BG for grazing cattle during the summer.

Key Words: native grass, pasture, beef cattle

356 Using switchgrass to produce stocker cattle gain and bioenergy feedstock I: Production potential.

J. R. Blanton Jr.,* J. T. Biermacher, J. Mosali, and B. J. Cook, *The Samuel Roberts Noble Foundation, Ardmore, OK.*

Switchgrass (*Panicum virgatum* L.) has been identified as a potential feedstock for cellulosic bioenergy production. To mitigate the risk of establishing this crop for bio-fuel feedstock production only, producers are looking to incorporate switchgrass into early spring grazing systems. The objective of this study was to determine the effect of stocking density on measures of animal performance and end-of-season residual feedstock yield in an early spring stocker grazing system. Twelve, 0.81-ha paddocks were established in southern Oklahoma in 2007 and evaluated over 3 grazing seasons (2008 – 2010). Four stocking densities; control (0 steers ha^{-1}), low (2.5 steers ha^{-1}), med (4.9 steers ha^{-1}) and high (7.4 steers ha^{-1}) were utilized. Animal weights were collected following 16h shrink at start and end of grazing period. All residual feedstock was harvested following plant senescence. Animal performance and forage yield data were analyzed using random effects mixed ANOVA models. Average daily gain was 1.05, 1.04, and 0.83 kg hd^{-1} d^{-1} for the high, med and low stocking densities, respectively with no significant effect detected ($P = 0.12$). Stocking density also has no significant effect on total gain with 199, 215 and 167 kg ha^{-1} for the high, medium and low stocking densities, respectively ($P = 0.07$). Grazing days were significantly affected by stocking density with the low, med and high densities grazed for 81, 43, and 28d, respectively ($P < 0.01$). Non-grazed controls produced significantly more biomass than any grazed treatments ($P < 0.01$). On average, the control produced 15320 kg ha^{-1} of biomass, whereas the low, medium and high stocking densities produced 10539, 8110 and 7771 kg ha^{-1} of residual feedstock, respectively. Within stocking density, the low density produced significantly more biomass as compared with medium and high stocking densities ($P < 0.05$). Results from this study indicate that switchgrass has the production potential to be used for stocker cattle gain and the production of bioenergy feedstock; however, further analysis would be important to determine the economic potential of the dual-use crop.

Key Words: stocker cattle grazing, switchgrass, bioenergy

357 Using switchgrass to produce stocker cattle gain and bioenergy feedstock II: Economic potential.

J. T. Biermacher,* J. Mosali, B. Cook, and J. Blanton Jr., *The Samuel Roberts Noble Foundation Inc., Ardmore, OK.*

Switchgrass (*Panicum virgatum* L.) has been identified as a leading source of biomass feedstock for conversion into bioenergy products in the southern Great Plains. Currently, no large-scale refineries exist in the region; however, in anticipation of the development of a large-scale industry, producers are curious about the economic potential of integrating switchgrass into their present livestock production systems. The objectives of the study were to determine the effects that stocking density treatments have on feedstock yield, ADG and total gain, and to determine the most economical gain/feedstock production system. Data for steer performance and residual feedstock yield were collected from a 3-year (2008–2010) CRD grazing study in south-central Oklahoma. Stocking density treatments [0 (an un-grazed control), 2.5, 4.9, and 7.4 hd ha^{-1}] were randomly assigned to a total of 12, 0.81-ha, switchgrass pastures. Enterprise budgeting was used to compute expected values of economic net returns for 5 systems: graze only, no forage (G/NF); no graze, feedstock only (NG/F); lightly grazed plus feedstock (LG/F); moderately grazed plus feedstock (MG/F); and heavily grazed plus feedstock (HG/F). Net return for each system was calculated for feedstock prices ranging from \$0 to \$165 Mg^{-1}. The effects of system on yield, gain, and net return were analyzed using random-effects mixed ANOVA models. F-tests were used to determine differences in means between systems and LSD tests were used to rank the profitability of systems. At \$0 Mg^{-1}, the most profitable system was the MG/F system, which realized \$45 ha-1. At \$55 and \$83 Mg^{-1} net return was \$232 and \$524 ha^{-1}, respectively, when grazing lightly and by marketing 10.54 Mg ha^{-1} of residual feedstock. At prices greater than \$110 Mg^{-1}, producers would not graze switchgrass, they would only produce and market feedstock. Early adopters could generate breakeven profitability by grazing switchgrass while waiting on biorefinery development. Moreover, switchgrass will likely not be economically competitive with conventional grazing systems commonly used by producers in the region if the biorefinery's purchase price for feedstock is less than \$110 Mg^{-1}.

Key Words: bioenergy economics, stocker cattle grazing, switchgrass feedstock

358 Investigating the nutritive value of *Panicum maximum* leaves for ruminant animals.

A. H. Ekeocha,* *University of Ibadan, Ibadan, Oyo, Nigeria.*

The *Panicum maximum* leaf (Pml) is a perennial grass readily available to grazing livestock in south western Nigeria. The objective was to determine the proximate composition of Pml. The samples of Pml were collected from the teaching and research farm, university of Ibadan during the onset of the wet season and analyzed for dry matter (DM), crude protein (CP), crude fiber (CF), ether extract (EE), ash and gross energy (GE) using standard procedures. Ten samples of Pml were slashed at 6cm above ground from a grazing paddock and bulked together and a representative sample was collected for proximate analysis. The samples were at vegetative stage and replicated thrice. Average total height of the forage at harvest is 1m. The Pml (g/100gDM) Contained CP 7.95; CF 31.0; EE 4.0, ash 8.90; and GE 3.2 kcal/g. The CP content was 7.95% and this was compared with tropical grass species, which seldom exceed a CP level of 10% and whose protein content is satisfactory for animal production for only about 4 mo of the year. It is far lower than that of cassava leaf meal (16.67%), and far below the minimum protein requirement (10–12%) for ruminants. The CF level of 31.00% for Pml is low compared with that of tropical grass species which may be as high as 45 – 50% at more matured stages of growth. It is higher than the CF level of *Amaranthus* spp. (17.01%), Siam leaf meal (16.0%), Cassava leaf meal (15.63%), deep litter manure (16.60%) and guava leaf (16.10%). %). The ether extract content was low (4.00%). This value was lower than the values of 5.61% reported for *Vernonia amygdalina* leaf and far lower than the value of 8.14% reported for Siam weed but higher than the EE reported for *Tithonia diversifolia* (2.81%). The total ash content of 8.90% was low and this was far lower than the ash content reported for *Vernonia amygdalina* leaf (13.86%) and *Tithonia diversifolia* leaf (14.68%) but higher than the value of 8.28% reported for *Acacia albida* used as a browse plant for sheep in the semi-arid region of Nigeria and lower than the value of 11.00% reported for *Leucaena spp* to feed Yankassa sheep and 11.54% reported for Siam weed leaf meal. The Gross Energy (GE) value was 3200kcal/kg. This is comparable with the GE value of Groundnut cake (2600kcal/kg) and *Vernonia amygdalina* leaf (2720kcal/kg) but far higher than the GE of *Tithonia diversifolia* leaf (1900kcal/kg). The Nitrogen Free Extract level of 48.15% for Pml was comparable to that of Siam leaf meal (44.40%) and *Tithonia diversifolia* leaf (44.38%) both used to feed West African Dwarf Sheep but lower than the value of 33.85% reported for *Vernonia amygdalina* leaf. On the whole, gross chemical analysis indicates that Pml contained appreciable level of nutrients that could be utilized in the diets of ruminants.

Key Words: nutritive value, *Panicum maximum* leaves, ruminant animals

359 Evaluating the mineral composition of *Panicum maximum* leaves.

A. H. Ekeocha* and O. T. Bankole, *University of Ibadan, Ibadan, Oyo, Nigeria.*

The *Panicum maximum* is a perennial grass readily available to grazing livestock in south western Nigeria. The objective was to determine the mineral content of *P. maximum*. Ten samples of *P. maximum* were slashed at 6cm above ground from a grazing paddock and bulked together and a representative sample was collected for mineral analysis. The samples were at vegetative stage and replicated thrice. Average total height of the forage at harvest is 1m. The atomic absorption spectrophotometer was used to determine any of the minerals (except P) using appropriate lamps. The P was determined with vanadomolybdate using spectrophotometer at 425nm. The principal elements present in *P. maximum* are Ca, P, K, Na and Mg while the essential trace elements (macro nutrients) are, Mn, Cu and Zn. The *P. maximum* contained Ca 0.42%, P 0.31%, K 1.03%, Na 0.49%, Mg 0.32%, S 0.24%, Cu 10.00ppm, Zn 50.00ppm and Mn 20.00ppm. Normally, plant materials are not good sources of Ca and P but the levels reported in *P. maximum* would easily satisfy animal needs if they occur in a readily available form. It is often postulated that a mineral supply in excess of dietary requirements is capable of blocking the availability of another. The result of mineral analysis on *P. maximum* leaf showed that the leaf contains high level of micro and macro elements, which is an indication that the leaf can sustain the nutritional and physiological status of the animal.

Horse Species I

360 Influence of maternal plane of nutrition and arginine supplementation on mares and their foals: Determination of voluntary dry matter intake of mares during late pregnancy. K. N. Winsco*[1], J. A. Coverdale[1], T. A. Wickersham[1], C. J. Hammer[2,3], and J. L. Lucia[1], *[1]Department of Animal Science, Texas A&M University, College Station, [2]Department of Animal Sciences, North Dakota State University, Fargo, [3]Center for Nutrition and Pregnancy, North Dakota State University, Fargo.*

Thirty-two mares (468–668 kg BW; 3–19 yr) were blocked by expected foaling date and randomly assigned within block to treatments. Treatments were arranged as a 2 × 2 factorial with 2 planes of nutrition (Nutr), moderate (Mod; 0.5% BW AF grain/d) or high (High; 1% BW AF grain/d) and 2 levels of L-arginine supplementation, 0.21 g/kg/d (Arg) or no supplemental Arg (Con; L-alanine to maintain isonitrogenous diets). The objective was to evaluate the impact of altered plane of nutrition on voluntary forage dry matter intake (FDMI) and determine the ability of Arg to mitigate these effects. Treatments began 110 d before expected foaling date and terminated at parturition. Mares were housed by block and allowed ad libitum access to coastal bermudagrass (*C. dactylon*) hay, and fed commercial grain 2 × /d in individual stalls. To evaluate FDMI, a dual marker system was used at 9, 10, and 11 mo gestation. Titanium dioxide (TiO_2) was dosed at 10 g/d for 14 d by top dressing onto the grain meal. Fecal grab samples were obtained the last 4 d of TiO_2 supplementation 2 × /d via rectal palpation at 12 h intervals with times advancing 3 h each d to account for diurnal variation. Fecal samples were analyzed for TiO_2 using a colorimetric procedure (Titgmeyer et al., 2001). Fecal, grain, and hay samples were analyzed for ADIA using the ANKOM fiber system. Data were analyzed using the PROC MIXED procedure of SAS. There was no effect of Arg on FDMI ($P \geq 0.60$). Nutrition tended to influence FDMI ($P \leq 0.10$) with Mod mares consuming a greater percentage of their BW compared with High. Regardless of dietary treatment, month of gestation influenced FDMI ($P \leq 0.01$) with all mares consuming less during the 11th mo ($P \leq 0.05$). Upon calculation, grain contained 3.60 Mcal/kg DE and hay contained 1.98 Mcal/kg. Based on calculated FDMI, Mod mares consumed an average of 28.21 Mcal DE/d while High mares consumed 34.60 Mcal DE/d which exceed NRC (2007) requirements for late gestation. In summary, maternal plane of nutrition had a tendency to alter FDMI and FDMI was influenced by gestation.

Key Words: intake, arginine, broodmares

361 The effect of hay steaming on forage quality and intake by horses. J. E. Earing,* M. R. Hathaway, C. C. Shaeffer, J. C. Paulson, S. L. Privatsky, and K. L. Martinson, *University of Minnesota, St. Paul.*

Heaves is a common equine disease. Current management strategies include soaking or wetting hay before feeding. Hay steaming is gaining popularity in the US, however, little is known about its impact on forage quality or palatability. Therefore, the objectives were to determine the effect of steaming on forage quality and intake. Two alfalfa-orchardgrass hays were tested: a moderately moldy hay (MM) and a lower mold hay (LM). While nutrient composition was similar, the mold content differed (MM: 373,000 cfu/g; LM: 120,500 cfu/g; $P = 0.0003$). Six mature horses were used in a 10 d crossover design. Three horses were assigned to each hay type; treatments were switched on d 6. Each day, one bale of each hay was steamed for 90 min using a commercial hay steamer. Two flakes of steamed and 2 flakes of unsteamed hay (MM or LM) were weighed and offered simultaneously to each horse in individual hay nets. Hay nets were located on opposite walls of the stall; location of the steamed and unsteamed hay was switched daily. The amount of hay offered was in excess of ad libitum intake. Horses were allowed access to hay for 2 h starting at 15:00 h, then orts were collected and DMI calculated. For each hay, paired *t*-tests were used to compare steamed and unsteamed hay nutrient content and DMI. Prior to steaming, the DM of both hays was similar (90%); steaming significantly reduced DM to 81 and 77% for MM and LM, respectively. In both MM and LM, steaming reduced P content ($P < 0.007$). Steaming reduced WSC by 13% ($P = 0.001$) and ESC by 27% ($P = 0.003$) for MM, but had no effect on LM ($P > 0.05$). Similarly, steaming reduced mold levels in MM by 85% ($P = 0.009$), but did not affect levels in LM ($P > 0.05$). No other forage quality components were affected by steaming. DMI of MM was not affected by steaming ($P > 0.05$); intake averaged 1.34 kg of unsteamed and 1.21 kg of steamed hay. Intake of LM was affected by steaming; horses ingested 0.64 kg of unsteamed and 2.02 kg of steamed hay ($P < 0.0001$). In moderately moldy hay, steaming reduced mold levels, but did not improve intake. However, for hay with low mold levels, steaming appeared to increase the palatability of the hay, while exerting no effects on forage quality.

Key Words: DMI, equine, mold

362 High non-structural carbohydrate diet in ponies alters location and absorptive capacity of glucose, phosphorus and glutamine across the gastrointestinal tract. B. E. Aldridge*[1], A. D. Woodward[2], J. S. Radcliffe[1], R. J. Geor[3], L. J. McCutcheon[3], and N. L. Trottier[2], *[1]Purdue University, West Lafayette, IN, [2]Michigan State University, Department of Animal Science, East Lansing, [3]Michigan State University, Department of Large Animal Clinical Science, East Lansing.*

Sixteen ponies were used to test the hypothesis that exposure to a rich non-structural carbohydrate (NSC) containing diet decreases small intestinal (SI) glucose transport capacity, and affects large intestinal (LI) absorptive nutrient profile compared with a strict forage-based diet. Ponies (n = 16) of mature age (BW 270 ± 74.4 kg) were equally assigned and fed one of 2 diets (n = 8) containing 12% CP: a control diet (CON) composed of grass hay (2.3% BW) and balancer pellet (0.2% BW), and a high NSC diet (CHO) containing 42% NSC, and composed of sweet feed and oligofructose (1.5% BW), grass hay (0.95% BW) and balancer pellet (0.05% BW). Ponies were subjected to a 4-wk adaptation period to the CON diet, followed by individual feeding of test diets for 7 d and euthanasia by single injection of pentobarbital. Segments of jejunum (J), ileum (I), left ventral (LVC) and left dorsal colon (LDC) were immediately mounted in Ussing Chambers to measure capacity for active glucose, phosphorus (P), and glutamine (Gln) absorption, based on change in short circuit current (Isc, $\mu A/cm^2$). Feeding CHO decreased active glucose transport ($P < 0.001$) across J and I compared with CON. Glucose transport across LVC and LDC did not differ between diets. In ponies fed CON, glucose transport capacity increased ($P = 0.008$) across J and I compared with that of the LVC and LDC, but in ponies fed CHO, glucose transport capacity between small and large intestinal segments did not differ. Feeding CHO did not affect active transport capacity of Gln or P across J and I, and increased ($P = 0.048$) active transport capacity of Gln by 239 and 60% and of P by 52.7 and 30.7% across LVC and LDC, respectively. Carbachol-induced Cl ion secretion was 30% lower ($P = 0.048$) across intestinal sections in CHO-fed ponies. In conclusion, abrupt exposure to NSC decreased SI glucose active transport capacity, increased LI active transport capacity of P and Gln, and reduced Cl ion secretion. Results indicate that abrupt dietary intake of NSC reduces the absorption of glucose by the SI of equids.

Key Words: equine, carbohydrate, intestine

363 Exercise-induced suppression of lymphocyte function is unaffected by a higher level of dietary selenium.

J. Bobel,* L. K. Warren, and S. White, *University of Florida, Gainesville.*

The effect of dietary selenium (Se) concentration on lymphocyte function and viability following prolonged exercise was evaluated in 12 unconditioned Thoroughbred horses (mean ± SE, 11 ± 1 y, 565 ± 11 kg). Horses were randomly assigned to receive either 0.1 mg Se/kg DM (NRC-Se; n = 6) or 0.3 mg Se/kg DM (HIGH-Se; n = 6) for 36 d. Horses were individually fed 1.6% BW/d of coastal bermudagrass hay (0.02 mg Se/kg), 0.4% BW/d of whole oats (0.24 mg Se/kg) and a mineral/vitamin premix containing no Se. Sodium selenite was added to achieve either 0.1 or 0.3 mg Se/kg DM in the total diet. On d 35, horses underwent 2-h (26 km) of submaximal exercise in a free-stall exerciser (heart rate 135 ± 39 bpm). Blood samples were obtained on d 0 and 34 for determination of serum Se, and before exercise and at 6 and 24 h post-exercise for identification of leukocyte populations and isolation of peripheral blood mononuclear cells. Data were analyzed using the MIXED procedure of SAS (v. 9.2) with repeated measures. Serum Se remained unchanged in NRC-Se horses, but increased ($P < 0.01$) in HIGH-Se horses after 34 d of supplementation. Exercise resulted in an increase in circulating neutrophils ($P < 0.001$) and decreases in lymphocytes ($P < 0.001$) and eosinophils ($P < 0.001$), which persisted through 24 h post-exercise. Suppressed lymphoproliferative responses to concanavalin A ($P < 0.001$), phytohemagglutinin ($P < 0.01$) and pokeweed ($P < 0.01$) mitogens were noted at 6 h and 24 h post-exercise. Lymphocyte cell viability following in vitro hydrogen peroxide exposure was decreased ($P < 0.05$) at 24 h post-exercise. Level of dietary Se had no effect on leukocyte populations or lymphocyte proliferation or viability following exercise. These data indicate lymphocytes may be more vulnerable to oxidative damage and may not function properly during recovery from exercise, which could put horses at risk for infection. Feeding Se at 3 × the current NRC recommendation failed to mitigate exercise-induced suppression of lymphocyte viability and function.

Key Words: sodium selenite, prolonged exercise, immune function

364 Feeding graded amounts of lysine to yearling Thoroughbred colts does not activate the mTOR signaling pathway.

S. L. Tanner,* L. R. Good, E. A. DeLuca, R. J. Coleman, and K. L. Urschel, *University of Kentucky.*

Lysine (Lys) is known to be the first limiting amino acid (AA) in typical equine diets and therefore it is of prime interest when considering the nutrition of growing horses. AAs, as a group, have been shown to stimulate the mammalian target of rapamycin (mTOR) pathway and the activation of this pathway has been used as an indicator of protein synthesis at the tissue level, particularly in muscle. However, it is unknown whether Lys intake specifically can affect the activation of mTOR signaling factors. The objective of this study was to determine how feeding graded amounts of Lys affects mTOR signaling activation in growing horses. Six Thoroughbred colts (401 ± 5 d) were studied while receiving each of 6 levels of Lys intake: 80, 95, 110, 125, 135, and 145 mg/kg/d in a 6 × 6 Latin square. Diets consisted of a concentrate portion, which varied in Lys, and timothy hay cubes. Diets were isocaloric, isonitrogenous, and met or exceeded NRC recommendations for all nutrients except lysine. Each horse was fed each diet in random order for a period of 6 d. On d 6 a venipuncture sample and gluteal medius muscle biopsy were collected approximately 100 min post feeding of the morning meal. The ratio of phosphorylated to total protein was determined via Western blots quantified using ImageJ. Although plasma Lys concentrations increased in a dose-dependent manner with increasing dietary Lys intake ($P < 0.0001$), Lys intake did not affect eukaryotic initiation factor 4E binding protein 1 (4EBP1), ribosomal protein S6 (rps6), or protein kinase B (Akt) ($P > 0.1$) activation. Despite differences in Lys intake, the diets did provide the same amount of nitrogen and therefore these results suggest that Lys is not an independent activator of mTOR signaling. Alternatively, it is also possible that mTOR signaling was already maximized by the lowest intake of Lys provided and that subsequent increases in Lys intake did not result in any further increases in mTOR signaling. This project was supported by Agriculture and Food Research Initiative Competitive Grant no. 2010–65206–20638 from the USDA National Institute of Food and Agriculture.

Key Words: lysine, horse, mTOR signaling

365 Influence of oral glucosamine supplementation on young horses in training: Pharmacokinetics.

J. L. Lucia*[1], K. L. Gehl[1], J. A. Coverdale[1], C. E. Arnold[2], R. Dabareiner[2], and E. D. Lamprecht[3], [1]*Department of Animal Science, Texas A&M University, College Station*[2]*Large Animal Teaching Hospital, Texas A&M University, College Station,* [3]*Cargill Animal Nutrition, Elk River, MN.*

Twenty-one yearling Quarter horses (442 to 565 d of age and 351 to 470 kg) were utilized in a pilot trial to determine pharmacokinetic parameters of oral glucosamine derived from a non-GMO fungal biomass fermentation product. Horses were arranged in a randomized complete block design, and assigned 1 of 3 treatments via nasogastric intubation: control (CON; no glucosamine, 1000 mL saline), glucosamine HCl 15 mg/kg BW (GLU15; Activesure liquid; Cargill, Eddyville, IA), and glucosamine HCl 30 mg/kg BW (GLU30; Regenasure powder; Cargill). Horses were fasted for 12 h before nasogastric intubation. The GLU15 and GLU30 treatments were diluted in saline to reach a volume of 500 mL. Horses receiving GLU15 and GLU30 were given a saline flush of 500 mL post administration to ensure treatment was received in its entirety and reach a final volume of 1000 mL. Blood samples were obtained via jugular venipuncture at 0, 1.5, 3, and 12 h after treatments were administered. Plasma was harvested and stored at −20°C, before glucosamine analysis via HPLC. Data were analyzed using PROC MIX procedure of SAS. Plasma glucosamine concentrations increased as dosage of oral glucosamine increased ($P \leq 0.01$). Following intubation, plasma glucosamine values for GLU15 and GLU30 peaked at 3.0 h ($P \leq 0.05$) and 1.5 h ($P \leq 0.01$), respectively, and returned to baseline by 12 h. Additionally, there was a treatment by time interaction with GLU30 horses experiencing a sharp rise in plasma glucosamine concentration by 1.5 h post administration, resulting in a 6-fold increase compared with horses receiving GLU15 ($P \leq 0.01$). Both glucosamine products resulted in increased plasma glucosamine concentrations and the response was dose dependent. Further research will be conducted to determine the influence of oral glucosamine supplementation over time, including plasma and synovial fluid incorporation.

Key Words: equine, glucosamine, pharmacokinetics

366 Effects of prolonged exercise and citrulline supplementation on metabolic status in equine blood and skeletal muscle.

S. White,* L. K. Warren, S. E. Johnson, and B. Miller, *University of Florida, Gainesville.*

Metabolic gene expression in skeletal muscle, as well as indicators of oxidative stress, in response to prolonged exercise and citrulline supplementation were evaluated in 12 untrained Thoroughbred and Quarter Horse mares (mean ± SE 11 ± 0.7 y, 552 ± 9 kg). Horses were randomly assigned to one of 2 isonitrogenous supplements for 15 d: 86 mg citrulline malate/kg BW (CIT; n = 6) or 25 mg urea/kg BW (n = 6). Additionally, horses were individually fed a fortified commercial feed and Coastal bermudagrass hay. On d 15, horses underwent 2 h (27.5 km) submaximal exercise in a free-stall exerciser (mean heart rate 142 ± 2 bpm). Blood samples were obtained before exercise and 1 h post-exercise for analysis of serum creatine kinase (CK) activity and total plasma lipid hydroperoxides (LPO). Biopsies of the middle gluteal muscle were obtained before exercise and 1 h post-exercise and gene expression was determined by quantitative RT-PCR using 18S as a reference gene. Data were analyzed using the MIXED procedure of SAS (v. 9.2) with repeated measures. Muscle expression of *MT1B* increased ($P = 0.04$) nearly 2.5-fold from pre- to 1 h post-exercise, indicating the exercise was sufficient to elicit oxidative stress. Muscle expression of *PDK4* increased ($P = 0.002$) over 64-fold from pre- to 1 h post-exercise, whereas expression of *iNOS*, *GLUT4*, *PGC1α*, and *SLC7A* remained unchanged through 1 h post-exercise. Serum CK activity ($P = 0.009$) and plasma LPO ($P = 0.04$) increased from pre- to 1 h post-exercise. However, CIT supplementation had no effect on expression of *MT1B*, *PDK4*, *iNOS*, *GLUT4*, *PGC1α*, or *SLC7A* in muscle or on serum CK activity or plasma LPO following exercise. Prolonged exercise in untrained horses upregulates aerobic metabolism (via expression of *PDK4*) and also appears to result in measurable tissue damage and lipid peroxidation. However, short-term CIT supplementation at rates sufficient to decrease production of reactive oxygen species in human athletes had no effect on markers of oxidative stress in exercised horses.

Key Words: horse, skeletal muscle oxidative damage, skeletal muscle metabolism

367 Selenium supplementation and immune function.

M. Brummer,* S. Hayes, A. Betancourt, A. A. Adams, D. W. Horohov, and L. M. Lawrence, *University of Kentucky, Lexington.*

Some studies indicate an effect of Se status on immune function. This study investigated the effect of Se supplementation on Se status and immune response in mature horses. Twenty-eight horses, blocked by age and sex, were randomly allocated to one of 4 groups: LS, AS, SP and SS. For 35 wk LS, SP and SS received a low Se diet (0.07 ppm Se) and AS received an adequate Se diet (0.14 ppm Se). For the next 29 wks LS and AS were maintained on the same diet while SP received a high organic Se diet (0.3 ppm; Sel-Plex, Alltech, Nicholasville, KY) and SS received a high inorganic Se diet (0.3 ppm; sodium selenite). The basal diet consisted of low Se pasture, hay, cracked corn and a balancer pellet either low (LS, SP, SS) or adequate (AS) in Se. The SP and SS supplements were top dressed on the balancer pellet. Whole blood Se and glutathione peroxidase activity (GPx) were monitored monthly. Horses were vaccinated with 10 mg ovalbumin (OVA) at wk 22 and 25. Blood samples were taken for 7 wk following vaccination for serum separation and at pre-, 3 and 5 wk post initial vaccination for peripheral blood mononuclear cell (PBMC) isolation, and whole blood cytokine mRNA evaluation. Data were analyzed as ANOVA with repeated measures (SAS 9.2). An effect of treatment, time and treatment x time ($P < 0.05$) existed for both Se and GPx. At the start of the 29 wk period Se was lower for LS, SP, and SS compared with AS. At 22 wk Se was higher for SP and SS than AS ($P < 0.05$). Whole blood GPx had a similar but delayed response. At 27 wk GPx was higher for SP and SS than AS, suggesting that maximum GPx activity is not maintained by dietary Se intakes of 0.1 ppm. The response to OVA vaccination, evaluated as OVA specific IgG production, cytokine mRNA expression of PBMC stimulated with OVA in vitro, and lymphocyte proliferation was unaffected by Se status. However, PBMC stimulated with phorbol 12-myristate 13-acetate indicated lower mRNA expression of some cytokines for LS ($P < 0.05$). Whole blood mRNA expression of IL-10 was higher for SS compared with LS, AS and SP ($P < 0.05$). Although the OVA vaccination response was unaffected by Se status, other measures of immune function suggest that low Se status affects cell-mediated immunity.

Key Words: horse, glutathione peroxidase, ovalbumin

368 Effect of strenuous exercise on stallion sperm quality.

J. L. Rosenberg,* C. A. Cavinder, C. C. Love, M. M. Vogelsang, S. R. Teague, D. H. Sigler, D. D. Varner, and T. L. Blanchard, *Texas A&M University, College Station.*

Performance ability of an equine athlete is one of the major considerations when selecting a stallion for breeding, and thermal stress associated with training exercise may affect sperm quality and the future reproductive capability of the stallion. Previous investigators reported that a prolonged increase in testicular temperature (3–3.5°C) decreased percentages of progressive motility and morphologically normal sperm. A subsequent study found contrasting results with no effect on semen quality when stallions were subjected to moderate exercise (0.8°C increase in internal scrotal temperature). It remains unclear what level of exercise imparts a negative effect on sperm quality. The objectives of this study were to compare sperm quality of strenuously exercised (EX) and non-exercised (CN) stallions. Strenuous exercise was determined by maintaining a heart rate between 145 and 155 bpm during work bouts. Miniature stallions (n = 7) implanted with subdermal thermosensory devices in the subcutaneous neck and scrotal tissue were matched by age and sperm quality and assigned to treatment group. Stallions (EX; n = 3) were exercised 4 d/wk for 90 min for 12 wk. Semen was collected from stallions for 5 consecutive d every 4 wks to evaluate semen quality (raw, 24 h and 48 h cooled). Internal scrotal (ST), rectal (RT) and neck (NT) temperatures were recorded along with heart rate of the stallions. Spermatozoa data were normally distributed; therefore, they were subjected to parametric analysis by repeated measures (wk) using the PROC MIXED procedure (SAS v 9.1; SAS Inst. Inc., Cary, NC). Model included treatment (CN or EX), time (wk 0, 4, 8, or 12), and stallion as the subject of the repeated measures. Compared with the CN group, EX stallions had elevated body temperature (avg RT 39.0 vs 37.2°C, NT 40.9 vs 38.5°C, and ST 34.9 vs 33.4°C) but parameters of spermatozoa quality remained unaffected by treatment ($P > 0.05$). While previous studies have illustrated that prolonged insulation of the testes reduces semen quality, strenuously exercising stallions for up to 90 min under hot and humid ambient conditions may not be harmful to spermatogenesis.

Key Words: heat stress, sperm, stallion

Lactation Biology II

369 Milk fat synthesis in thyroid hormone responsive spot 14 null mice is acutely responsive to *trans*-10, *cis*-12 conjugated linoleic acid (CLA). K. J. Harvatine*[1], M. Tanino[2], Y. R. Boisclair[2], and D. E. Bauman[2], [1]*Penn State University, University Park,* [2]*Cornell University, Ithaca, NY.*

Trans-10, *cis*-12 conjugated linoleic acid (CLA) reduces milk fat concentration and markedly reduces mammary de novo lipogenesis in both cows and mice. Thyroid hormone responsive spot 14 (S14) is decreased in mammary tissue of both the cow and mouse during CLA treatment. We have previously reported a functional role of S14 in CLA-induced inhibition of fat synthesis using the S14 null mouse. Mammary de novo lipogenesis of S14 null dams is hyper-responsive to CLA treatment. After 5 d of CLA treatment milk fatty acids (FA) less than 16 carbons are reduced about 2-fold more in S14 null mice compared with wild-type (WT) mice. Three experiments were conducted to further characterize the response to CLA in S14 null mice. Dams were bred to males of the opposite genotype and fed a low fat chow diet (Teklad 8640). First, recovery after termination of CLA treatment was tested in S14 null mice in a randomized block design. Starting at 8 to 9 d of lactation S14 null received oral doses of water (control) or 18 mg/d of CLA for 3 d. Two pups were euthanized for collection of stomach milk clots and the remaining pups were euthanized 5 d after termination of CLA treatment. CLA decreased pup growth and milk FA less than 16 carbons by approximately 60%, but both responses recovered by 5 d after termination of CLA (CLA × Day interaction $P < 0.01$). Second, the short-term response to CLA was investigated using WT and S14 null mice in a randomized block design with a 2 × 2 factorial arrangement of treatments (genotype × CLA). Starting on 10–12 d of lactation, S14 null and WT dams received water (control) or 20 mg/d of CLA for 24 h. The effect of genotype, CLA, and genotype by CLA interaction was tested. CLA reduced pup weight gain and there was no genotype x CLA interaction. However, there was genotype x CLA interaction for milk FA less than 16 carbons ($P < 0.001$; WT −17% vs S14 null −67%). Lastly, the sensitivity to CLA was tested using a similar randomized block design with WT and S14 null dams. Starting on 6 to 8 d of lactation, S14 null and WT dams received water (control) or 3.5 mg/d of CLA for 5 d. Dose selected was half the lowest dose previously used in a WT dose titration experiment that partially reduced milk fat. There was a genotype x CLA interaction for milk concentration of FA less than 16 carbons with an 8.9% decrease in WT and a 28.7% decrease S14 null. Overall, results demonstrate that the absence of S14 increases the responsiveness of mammary de novo lipogenesis to CLA without affecting sensitivity.

Key Words: CLA, spot 14 (S14), lipogenesis

370 Increased milk production by Holstein cows consuming endophyte-infected fescue seed during the dry period. R. L. Baldwin VI*[1], A. V. Capuco[1], C. M. Evock-Clover[1], P. Grossi[2], R. K. Choudhary[3], T. H. Elsasser[1], G. Bertoni[2], E. Trevisi[2], D. L. Harmon[4], and K. R. McLeod[4], [1]*Bovine Functional Genomics Lab, USDA-ARS, Beltsville, MD,* [2]*Istituto di Zootecnica, Università Cattolica del Sacro Cuore, Piacenza, Italy,* [3]*Department of Animal and Avian Sciences, University of Maryland, College Park,* [4]*Department of Animal Sciences, University of Kentucky, Lexington.*

Ergot alkaloids in endophyte-infected grasses inhibit prolactin (PRL) secretion and may reduce milk production of cows consuming endophyte-infected grasses. We hypothesized that consumption of endophyte-infected fescue during the dry period inhibits mammary differentiation and subsequent milk production. Twenty-five multiparous Holstein cows were randomly assigned to 3 treatment groups. Starting at 90-d prepartum, cows were fed endophyte-free fescue seed (control, CON; n = 9), endophyte-free fescue seed and 3x/wk subcutaneous injections of bromocryptine (0.11 mg/kg BW; positive control, BROMO; n = 8), or endophyte-infected fescue seed as 10% of the as-fed diet (INF; n = 8). Although milk yield of groups did not differ at −90 d prepartum, at dry-off (−60 d) INF and BROMO cows produced less milk ($P < 0.05$) than CON (averaging 20, 11 and 14 kg/d for CON, INF and BROMO cows). Throughout the treatment period, concentrations of PRL in the circulation were lower in INF and BROMO cows than CON cows ($P < 0.05$). Basal concentrations of PRL in venous plasma averaged 25.3, 2.8 and 3.7 ng/ml for CON, INF and BROMO cows, respectively. Prepartum release of PRL was also reduced by ergot alkaloids, averaging 19.5, 9.2 and 1.1 µg PRL/ml*h (area under curve) for CON, INF and BROMO cows, respectively. At 10 d of lactation, when treatments were terminated, basal concentrations of PRL in plasma averaged 22.5, 1.6 and 1.4 ng/ml for CON, INF and BROMO cows, respectively. Three wk after the end of treatment, circulating concentrations of PRL were equivalent across groups ($P > 0.05$). Gestation length did not differ between groups. Although treatment 4 wk before dry-off reduced milk yield in INF and BROMO cows, milk production in the ensuing lactation was increased 8% and 9% in INF and BROMO cows relative to CON ($P < 0.05$). We reject our initial hypothesis, as data show that consumption of ergot alkaloids during the dry period increases milk production in the ensuing lactation. We propose that this effect is due to a reduction in PRL during the dry period, analogous to the production effect realized by exposing cows to reduced photoperiod (low PRL) during the dry period.

Key Words: endophyte-infected fescue, prolactin, milk production

371 Association between plasma insulin and progesterone concentrations and the composition of milk fatty acids and lipids. N. Argov-Argaman,* H. Malka, and R. Mesilati-Stahy, *Animal Science Department, Hebrew University, Rehovot, Israel.*

This study examined the association between plasma insulin and/or progesterone concentration and milk fatty acid and lipid composition. Holstein dairy cows, 60 DIM, were synchronized (estrus = d 0) and held as controls (n = 20) or drenched for 14 d (d −5 to d 11) with 500 mL/d liquid propylene glycol to increase plasma insulin level (treatment, n = 20). Milk and blood samples were collected on d −5, 1 and 8 of the cycle. Insulin and progesterone concentrations were determined in the plasma, and fatty acid, polar and neutral lipid compositions were determined in the milk. While not significant, plasma insulin concentration was higher in the treated vs. control group on d 1 (6.09 and 3.8 ng/mL, respectively) and on d 8 (6.2 and 4.5 ng/mL, respectively). In both groups, plasma progesterone concentration increased ($P < 0.001$) through the estrous cycle with an average concentration of 0.18 and 3.7 ng/mL on d 1 and 8, respectively. However, on d 8, peak progesterone level was higher ($P < 0.04$) in the treatment group than in the controls (4.33 vs. 3.09 ng/mL, respectively). Milk fat concentration tended ($P < 0.08$) to negatively interact with plasma insulin and positively interact ($P < 0.07$) with plasma progesterone concentrations. Milk fatty acid composition was associated primarily with the day of the cycle. For instance, saturated fatty acid concentration decreased from 65.8% on d 1 to 63.5% on d 8 ($P < 0.04$). Treatment was the major factor associated with long-chain saturated fatty acid content in the milk, with higher concentrations in the control vs. treatment groups on both d 1 ($P < 0.05$; 9.3 and 8.0%, respectively) and d 8 ($P < 0.009$; 10.3 and 8.4%, respectively). Treatment was also associated with stearoyl CoA desaturase activity, as reflected by a 15% increase on d 1 ($P < 0.03$) and 10% increase on d 8 ($P < 0.08$). The results suggest that milk fatty acid composition changes during the estrous cycle in association with plasma progesterone concentrations. Propylene glycol administration increased progesterone concentration and to some extent that of insulin, which in turn might affect fatty acid composition.

Key Words: lipids, estrous, propylene glycol

372 Ontogeny of nuclear and cytoplasmic myoepithelial cell markers in pre-weaning Holstein heifers. S. Safayi[1], N. Korn[1], A. DiMascio[2], R. M. Akers[3], A. V. Capuco[4], and S. Ellis*[1], [1]*Clemson University, Clemson, SC,* [2]*University of Georgia, Athens,* [3]*Virginia Polytechnic Institute and State University, Blacksburg,* [4]*USDA-ARS, Beltsville Agricultural Research Center, Beltsville, MD.*

Myoepithelial cells (MC) have roles in cell proliferation and differentiation and hence may affect mammary parenchymal morphogenesis. Because MC can limit parenchymal growth in other species, it is important to understand MC-related mechanisms involved in early bovine mammary development. We previously saw changes in expression of the nuclear marker transformation-related protein 63 (P63) and the cytoplasmic marker common acute lymphoblastic leukemia antigen (CD10), corresponding with changes in the pattern of MC development in prepubertal heifers between 40 and 160d of age. In this study, we investigated the ontogeny of MC development during the pre-weaning period by tracking P63 and CD10 expression with immunofluorescent staining. Holstein heifers (n = 4/age) were sacrificed and sampled at 0 (<12 h of birth), 7, 14, 21, 28, 35, and 42 d of age. The basal epithelium was traced and MC marker expression within the outlined region was quantified using multispectral imaging of stained paraffin sections from each parenchymal sample. Fluorescent intensity (FI) of the markers in traced regions on each slide was normalized against a reference sample and then evaluated statistically using Mixed procedures in SAS. Samples were also used for subjective histologic assessment of MC marker distribution. Our analysis showed increased FI of CD10 and P63 at d 42, relative to d 0 ($P \leq 0.02$). The ratio of CD10 to P63 remained constant ($P = 0.94$) from d 0 to d 42. The increased intensity but consistent ratio values could be explained by our observation that P63+ nuclei were more closely spaced in the older calves. These results highlight a need to analyze expression within individual nuclei rather than quantifying expression within the entire basal layer. Double positive (P63+/CD10+) and double negative (P63-/CD10-) cells and single positive cells expressing either marker (P63-/CD10+ or P63+/CD10-) were present in both basal and supra-basal layers. As a result, our data does not yet define a sequential progression of bovine mammary MC differentiation. Further studies with additional MC markers are therefore required to define the sequence of bovine MC ontogeny.

Key Words: myoepithelial, mammary development, heifer

373 Ultrasonographic monitoring of mammary parenchyma growth in preweaned Holstein heifers. K. M. Esselburn*[1], T. M. Hill[2], K. M. O'Diam[1], V. A. Swank[1], H. G. Bateman II[2], R. L. Schlotterbeck[2], and K. M. Daniels[1], [1]*Department of Animal Sciences, The Ohio State University, Ohio Agricultural Research and Development Center, Wooster,* [2]*Nurture Research Center, Provimi North America, Brookville, OH.*

Mammary parenchyma (PAR) is present at birth in negligible quantities and undergoes extensive postnatal growth. Researchers have long been interested in nutritional effects on the mammary gland. However, monitoring in vivo growth of PAR has historically been difficult, necessitating slaughter studies to measure PAR quantity. Advances in ultrasound (US) technology warrant revisiting its use as a non-invasive tool to monitor PAR growth in vivo. Holstein heifers (n = 24; 41 ± 1kg initial BW) from a single farm were randomly assigned to 1 of 3 milk replacers (MR) at 2–3 d of age. Heifers were fed MR at 660 g/d until weaning at 42 d. MR contained 27% CP and was formulated with 3 fat and fatty acid compositions. MR treatments were A) only lard, 17% fat, B) animal fat supplemented with 1.25% NeoTect4 (MR, Provimi North America, Brookville, OH), 17% fat, and C) milk fat, 33% fat. Starter (20%CP) and water were fed ad lib for 56d. A real time B-mode US with a 7.5-MHz convex probe was used to examine 2-dimensional (2D) PAR area in all 4 glands of heifers once weekly from 2 to 3 d of age to 52 d. Individual digital images of each gland were saved for further analysis. At 52 d of age, heifers were slaughtered to validate final US measurements. At slaughter, the left half of the mammary gland was removed and examined by US 24 h later. Also at that time, left front and left rear glands were bisected to produce a sagittal plane view of PAR for comparison to US images. In all cases 2D areas of PAR were determined using ImageJ software (NIH). Data were analyzed using mixed procedure of SAS. Additionally, 8wk paired data were analyzed using the correlation procedure. There were no differences in PAR area due to diet. Regardless of dietary treatment, PAR grew over time (0.049cm^2 initially; 0.420cm^2 at 52 d ante-mortem; SEM = 0.020), as expected. Positive correlations existed between all paired variables analyzed (PAR area of bisected sagittal plane view; PAR area ante-mortem from US; PAR area postmortem from US; all r >0.60). Methodology used here demonstrates that US is an effective tool for measuring weekly changes in PAR area in vivo.

Key Words: ultrasound, mammary, dairy calf

374 Proteomic analysis of the nuclear phosphorylated proteins in dairy cow mammary epithelial cells treated with prolactin. J.-G. Huang, X.-J. Gao,* Q.-Z. Li, L. Zhang, F. Zhao, N. Zhang, Y. Lin, and Z. Sun, *Key Lab of Dairy Science, Ministry of Education, Northeast Agriculture University, Harbin, Heilongjiang, China.*

Prolactin (PRL) is a versatile signaling molecule and regulates a variety of physiological processes, including mammary gland growth and differentiation and the synthesis of milk proteins. While PRL is known to be necessary for high levels of milk protein expression, the mechanism by which the synthesis of milk proteins is stimulated at the transcript level is less known. A major modification important in the transcript level is protein phosphorylation. To gain additional insights into the molecular mechanisms at the transcript level underlying PRL action on the dairy cow mammary epithelial cells (DCMECs), nuclear phosphoproteins whose expression distinguishes proliferating regulated by PRL in DCMECs were identified. A phosphoprotein-enriched fraction from nuclear proteins was obtained by affinity chromatography, and a 2-dimensional gel electrophoresis (2-DE) and matrix assisted laser desorption/ionization time of matrix-assisted laser desorption/ionization/time of flight mass spectrometry (MALDI-TOF MS) were used to identify the changes of nuclear phosphoproteins in DCMECs treated with prolactin. Results: Seven proteins displaying ≥ 2-fold difference in abundance upon PRL treatment in DCMECs were identified by MALDI-TOF MS. The protein–GARS (GlyRS), which belongs to the class-II aminoacyl-tRNA synthetase family, plays a global role in the milk protein synthesis. SERPINH1 (Heat shock protein 47), which is the first heat shock protein found to be a member of the serpin superfamily, regulates physiologic functions such as complement activation, programmed cell death, and inflammatory processes. PRDX3, which belongs to a family of antioxidant enzymes, plays an important role in scavenging intracellular reactive oxygen species (ROS). ACTR1A, belongs to the actin family, which is associated with transport of p53 to the nucleus. Annexin A2, a Ca^{2+}-dependent phospholipid-binding protein, maintains the viability and cell cycle regulation of DCMECs. PSMB2, PSMD10, which belong to ubiquitin-proteasome system, are involved in several cellular processes, including cell cycle control, cellular stress responses, intracellular signaling. This screening reveals that prolactin influences the levels of nuclear phospho-proteins in DCMECs. This result opens new avenues for the study of the molecular mechanisms linked to the synthesis of milk proteins.

Key Words: nuclear phosphorylated protein, prolactin, 2-DE

375 Analysis of differentially expressed miRNA in dairy cow mammary gland identifies HK2-regulating miRNAs.

Z. Li,* H. Y. Liu, and J. X. Liu, *Institute of Dairy Science, MOE Key Laboratory of Molecular Animal Nutrition, Zhejiang University, Hangzhou, China.*

MicroRNAs (miRNAs) are non-coding RNAs of about 22 nucleotides in length. Functional studies have demonstrated that miRNAs play critical roles in a wide series of biological processes including development and disease pathogenesis. To investigate the functional roles that miRNA play in the mammary gland (MG) of lactating cows, the bovine MG miRNA transcriptomes were profiled using microarray. A custom-designed microarray assay was performed to analyze miRNA expression patterns in the MG of lactating and nonlactating dairy cows. Compared with non-lactation MG, a total of 226 miRNAs in the lactating MG showed significant differences in expression ($P < 0.01$). There were 120 miRNAs including bta-miR-199b and bta-miR-125b downregulated, whereas 106 miRNAs such as bta-miR-133a and bta-miR-500 were upregulated. Meanwhile other 73 new miRNAs in bovine MG were detected. Target prediction and network construction speculated that 5 differentially expressed miRNAs (bta-miR-125b, bta-miR-199b, bta-miR-181a, bta-miR-484 and bta-miR-500) could contribute to the lactation by targeting the hexokinase 2 (HK2) gene, the key enzymes in glucose metabolism. The potential target sites for all these 5 miRNAs were identified in predicted bovine HK2 3′UTR. These miRNA mimics were introduced into MAC-T cells to evaluate their effects on the HK2 at the translation level. Of these miRNAs, bta-miR-484 and bta-miR-500 showed the most inhibitory effect on production of HK2 protein, while this was not the case for other 3 miRNAs. These results indicated that miR-484 and miR-500 may exert their effect on lactation function via targeting HK2. The present study provides a systematic transcriptome profiling differentially expressed between lactating and nonlactating bovine MG.

Key Words: bovine mammary gland, hexokinase 2, microRNAs

Meat Science and Muscle Biology Symposium: In Utero Factors that Influence Postnatal Muscle Growth, Carcass Composition, and Meat Quality

376 Fetal programming of skeletal muscle mitochondrial function and insulin sensitivity: Perspectives from non-human primates and mouse models. J. A. Houck[1], K. L. Grove[2], and C. E. McCurdy*[1], [1]*Department of Pediatrics, University of Colorado,* [2]*National Primate Research Center, Oregon Health and Sciences University.*

Maternal obesity is associated with an increased and earlier risk for the offspring to develop early onset-obesity. In skeletal muscle from either obese adults or lean adult offspring of mothers with type 2 diabetes, reduced mitochondrial density, increased muscle triglyceride accumulation and impaired oxidative function have all been observed and the traits have been linked to skeletal muscle insulin resistance. Accordingly, it has been suggested that the fetal environment may have a profound effect on programming of skeletal muscle metabolism and subsequently have a substantial effect on life-long muscle growth, muscle self-renewal/repair and substrate partitioning. This talk will focus on the influence of maternal diet and obesity on offspring mitochondrial function, fiber typing and insulin sensitivity from both mouse models and a non-human primate model of maternal obesity. Female Japanese Macaques were fed either a control (10% fat) or a high fat/calorie diet (35% fat; HFD) for 2–4 years. Skeletal muscles were collected from fetuses (F-CON or F-HFD) terminated early-3rd trimester. Mitochondrial biogenesis, electron transport activity, and gene expression were analyzed in whole muscle homogenates and isolated mitochondria. Insulin-stimulated 2-deoxyglucose uptake (2DG) was measured in isolated muscle strips from F-CON and F-HFD at sub-maximal [0.3 nM] and maximal [12 nM] doses. Similar studies were performed in mouse models of maternal obesity to investigate post-weaning skeletal muscle mitochondrial development, persistence of insulin resistance and muscle progenitor cell populations. Mitochondrial copy number and citrate synthase activity were significantly reduced in male, but not female, fetal skeletal muscle from F-HFD vs. F-CON. Additionally, key transcriptional regulators of mitochondrial biogenesis, PGC1α, PGC1β, tFAM and Mitofusin-2, were also significantly downregulated in F-HFD. Analysis of maximal mitochondrial complex activity showed significant increase in mitochondrial complex activities and increased ROS damage with maternal obesity. Ex vivo insulin-stimulated 2DG uptake at submaximal and maximal insulin doses was significantly reduced in both male and female rectus femoris and soleus of F-HFD, demonstrating impaired insulin sensitivity and responsiveness that persists at 1 year of age. Additionally in mouse models, we find that maternal obesity leads to a significant shift in the offspring skeletal muscle progenitor cell population favoring adipogenic/fibrogenic precursor cells. Our results demonstrate that the intrauterine environment has profound effects on mitochondrial function and insulin sensitivity in fetal skeletal muscle. Impairments in these 2 key skeletal muscle metabolic functions would undoubtedly predispose the offspring to metabolic complications and poor or impaired muscle growth. It will be essential to determine the extent to which these effects persist in postnatal life. This work was supported by NIH grant K12 HD057022 (CEM) and DK090964 (CEM, KLG).

377 Manipulating mesenchymal progenitor cell differentiation to optimize performance and carcass value of beef cattle. M. Du,* *Department of Animal Sciences, Washington State University, Pullman.*

Beef cattle are raised for their lean, and excessive fat accumulation accounts for large amounts of waste. On the other hand, intramuscular fat or marbling is essential for the palatability of beef. In addition, tender beef is demanded by consumers, and connective tissue contributes to its background toughness. Recent studies show that myocytes, adipocytes and fibroblasts are all derived from a common pool of progenitor cells during the embryonic stage. It appears that during the early developmental stage, multipotent mesenchymal stem cells (MSCs) first diverge into either myogenic or adipogenic/fibrogenic lineage; myogenic progenitor cells further develop into muscle fibers and satellite cells, while adipogenic/fibrogenic lineage cells develop into the stromal-vascular fraction of skeletal muscle, which contains adipocytes, fibroblasts and resident fibro/adipogenic progenitor cells. Strengthening myogenesis (formation of muscle cells) enhances lean growth, promoting intramuscular adipogenesis (formation of fat cells) elevates marbling, and reducing intramuscular fibrogenesis (formation of fibroblasts and synthesis of connective tissue) improves overall tenderness of beef. Nutritional, environmental and genetic factors affect MSC differentiation; however, up to now, our knowledge regarding mechanisms governing MSC differentiation remains rudimentary. Altering MSC differentiation through nutritional management of cows, or fetal programming, is a promising method to improve cattle performance and carcass value.

Key Words: stem cell, myogenesis, adipogenesis

378 In utero nutrition related to fetal development, postnatal growth, and pork quality. N. Oksbjerg,* *Aarhus University-Foulum, Dept. of Food Science, Tjele, Denmark.*

Sub-optimal in utero nutrition gives rise to small birth weights (IUGR) and may cause long lasting effects on postnatal performance and economical loss in meat production. The objectives are to summarize the most important results of our research in this area. Our results show that increased (ad lib) global maternal feed intake in various windows had no main effects on performance and meat quality of the offspring. However, muscle growth rate was reduced in small pigs when the sow was feed ad lib from d 25 to 50 of gestation. On the other hand, when sows were fed a diet containing 30% less protein, the daily gain of the offspring tended to decrease. The meat quality traits, pH_{45} and shear force as well as calpastatin level, were increased and decreased, respectively, in entire male pigs, but not in female pigs following a maternal low protein diet. Comparing small and heavy pigs selected at slaughter at the same age or at birth (IUGR) showed that the small pigs had lower daily gain, fewer muscle fibers, and mean fiber area and increased kg feed/kg gain. Estimated content of DNA/fiber was lowest in the small pigs. Also shear force and calpastatin were increased in pigs born small. When blood was drawn at d 110 of gestation from the umbilicus cord and subjected to NMR metabolomics analyses, it was shown that the smaller fetuses had a lower concentration of glucose and a higher concentration of inositols compared with the heaviest littermates. Proteomic analyses of muscle samples identified 5 proteins which were differentially expressed depending on sex. In conclusion, our results suggest that pigs which were born small had lower performance due to a lower muscle fiber number and satellite cell proliferation which were at least partly due to reduced nutrition. Dietary manipulation of the pregnant sows also programmed the meat quality of the offspring dependent on the sex.

Key Words: maternal nutrition, offspring performance, muscle fiber traits

379 Maternal nutrition on pasture mediates long-term consequences for offspring primarily through effects on growth early in life of beef cattle. P. L. Greenwood,* L. M. Cafe, and D. L. Robinson, *Australian Cooperative Research Centre for Beef Genetic Technologies, and NSW Department of Primary Industries, UNE, Armidale NSW, Australia.*

Long-term consequences for offspring due to dam nutrition, beyond those due to variation in early-life growth were studied. Hereford cows were mated in consecutive years to Piedmontese or Wagyu sires. When confirmed pregnant, cows (n = 513) entered low or high pasture quality and availability treatments until parturition and (or) weaning. At weaning (7 mo), offspring (n = 240) within steer and heifer cohorts were selected for further study into 4 early-life growth groups (Low-Low, Low-High, High-Low and High-High), resulting in multi-model distributions based on maternal nutrition and offspring growth to birth and to weaning. A stepwise regression procedure specified covariates including birth (B) and weaning (W) weight, age at measurement (A), and effects of nutrition during pregnancy (P) and lactation (L), calf sex (S), year (Y), sire breed (G), and first order interactions of factors and with covariates. B was affected by P, and W by L and by P over and above differences due to B. For feedlot entry (26 mo) and exit (30 mo) weights and for carcass weight (C), there were significant linear effects of B and W, and effects of G, S and Y, but no effects of P or L beyond those due to differences in B and W. Average differences of 6 kg in B of calves due to P and 55 kg in W due to L both translated into differences of ~20 kg in C, 11–12 kg in retail yield and 6 kg of fat trim, but did not affect beef tenderness. When adjusted to a constant C, heavier W cattle had more fat trim and less retail yield. There were few interactions however at the same C there was a significant G x W interaction for rib eye area: Piedmontese-sired, Low 95.7 vs. High 88.4 cm^2; Wagyu-sired, both groups 85.7 cm^2. Feedlot feed intake (n = 142) was affected by B and W but not when corrected for weight at start of intake test. FCR was affected by W and L, and whether dams were lactating in early pregnancy. Maternal nutrition did not affect RFI. Overall, there were few long-term influences of maternal nutrition on offspring beyond those related to early-life growth within our pasture-based system. Optimal maternal nutrition to maximize capacity to re-breed has greater economic impact than longer-term consequences for offspring.

Nonruminant Nutrition: Management/Metabolism

380 Diet form and by-product level affect growth performance and carcass characteristics of grow-finish pigs. R. S. Fry,* W. Hu, S. B. Williams, N. D. Paton, and D. R. Cook, *Provimi North America, Akey Nutrition and Research Center.*

Two experiments were conducted to determine the effect of diet form and by-product (BP) level on growth performance and carcass characteristics of grow-finish pigs. In experiment 1, 384 pigs (22.2 ± 0.27 kg BW; 12 pigs/pen) were randomly assigned to one of the following treatments in a 2 × 2 arrangement: 1) low BP (LBP) meal [30% dried distiller grains with solubles (DDGS) and 15% wheat middlings (WM)] or 2) high BP (HBP) meal (50% DDGS and 15% WM) with diets fed either in meal or pellet form. In experiment 2, 1008 pigs (23.7 ± 0.27 kg BW; 21 pigs/pen) were randomly assigned to one of the following treatments in a 2 × 3 arrangement: 1) corn-soybean meal (CSBM), 2) LBP meal (25% DDGS and 7.5% WM), or 3) HBP meal (50% DDGS and 15% WM) with diets fed either in meal or pellet form. In both experiments, complete blocks of pigs were marketed when each block reached approximately 130 kg BW. In experiment 1, ADG was greater ($P < 0.01$) for pigs fed pelleted vs. meal diets. Increasing by-products in meal diets reduced ADFI, but not in pelleted diets ($P < 0.05$; diet form × BP level). Increasing by-products in meal diets improved G:F, but this did not occur when pelleted diets were fed ($P < 0.05$; diet form × BP level). In experiment 2, G:F was improved ($P < 0.01$) when diets were fed as a pellet vs. meal. Increasing by-product level decreased ($P < 0.01$) G:F. As BP level increased in meal diets ADG decreased, while increasing BP level in pelleted diets decreased ADG to a lesser extent ($P < 0.05$; diet form × BP level). As BP level increased, ADFI tended to decrease when meal diets were fed but not when pelleted diets were fed ($P < 0.10$; diet form × BP level). Increasing BP level decreased ($P < 0.05$) carcass yield and backfat. Pelleting tended ($P < 0.10$) to increase carcass yield. These data suggest that pelleting high by-product diets improves performance, and pelleting lessens the negative effects of by-product level on pig performance.

Key Words: pigs, by-products, pellet

381 Influence of ingredient complexity, feed form, and length of feeding of the phase I diets on nutrient digestibility and productive performance of Iberian pigs. J. D. Berrocoso, B. Saldaña, L. Cámara, M. P. Serrano, M. A. Ibáñez, and G. G. Mateos,* *Universidad Politécnica de Madrid, Madrid, Spain.*

In total, 216 Iberian piglets weaned at 28 d of age were used in a 35 d trial to evaluate the influence of ingredient complexity, feed form, and the length of feeding of the phase I diets on growth performance and total tract apparent digestibility (TTAD) of nutrients. There were 12 treatments with 2 type of diets that differed in CP content (20.5 vs. 18.5%) and in the percentage of inclusion of high quality ingredients (heat processed corn, protein concentrate, fish meal, and dried whey; HQ: high quality and LQ: low quality), 2 feed forms (mash vs. pellets), and 3 lengths of feeding the phase I diets (7, 14, and 21 d). From 7, 14 or 21 d to 35 d on trial, all pigs were fed a common phase II mash diet based on wheat and soybean meal. Cumulatively (0 to 35 d on trial), pigs fed the LQ phase I diets had higher ADFI ($P < 0.01$) and ADG ($P < 0.05$) than pigs fed the HQ diets. Pelleting improved ($P < 0.01$) G:F but not ADFI or ADG. Feeding the phase I diets for 21 d reduced ADFI and ADG but improved G:F as compared with 7 or 14 d feeding ($P < 0.01$). The incidence of diarrhea (DI) was higher in pigs fed the phase I diets for 21 or 14 d than in pigs fed these diets for 7 d ($P < 0.01$). Pigs fed pellets had higher ($P < 0.01$) DI than pigs fed mash. From 0 to 21 d of trial, pigs fed the HQ diets had lower ($P < 0.05$) ADFI than piglets fed the LQ diets and pelleting improved ($P < 0.01$) G:F. Increasing the length of feeding of the phase I diets improved G:F ($P < 0.01$). Also, DI was higher ($P < 0.01$) in pigs fed pellets than pigs fed mash and higher in pigs fed the phase I diets for 21 or 14 d than in pigs fed these diets for 7 d ($P < 0.01$). TTAD of nutrients was higher for pigs fed pellets ($P < 0.01$) or the HQ phase I diets ($P < 0.05$) than in pigs fed mash or the LQ phase I diets. From 21 to 35 d on trial, pigs previously fed the LQ diet had higher ($P < 0.01$) ADG and ADFI than pigs fed the HQ diet. Based on these results the use of LQ feeds in pellet form for only 7 d after weaning is recommended in Iberian pigs.

Key Words: diet complexity and feed form, growth performance, total-tract apparent digestibility

382 Hepatic gene expression analysis of nursery pigs fed simple and complex starter diets. M. Rudar,* L. D. Skinner, and C. F. M. de Lange, *University of Guelph, Guelph, ON, Canada.*

Reduced use of complex animal proteins in pig diets can reduce both feed costs and growth performance during the starter phase. The long-term consequences of this practice are unclear, as it may induce compensatory growth and alter disease resistance during the grower-finisher phase. The objective of this study was to explore potential indicators of health status, immune function, and nutrient partitioning that predict the effect of diet stressors on subsequent growth performance. Starter pigs were fed either simple (plant protein, non-medicated, n = 12 pens) or complex (milk and plasma proteins, medicated, n = 12 pens) diets formulated to be otherwise equivalent for 6 weeks. Liver tissue was collected from 4 pigs per treatment at 2 weeks post-weaning when the growth rate of pigs fed simple diets was reduced (397 vs 459 g/d, $P < 0.05$). Total RNA was isolated from liver and aminoallyl-modified cRNA was hybridized to Agilent Porcine Gene Expression Microarray in a reference design. The gene expression data were normalized, filtered, and analyzed using a simple linear (ANOVA) model. A total of 182 genes were detected to be differently expressed between the diets ($P < 0.10$, Benjamini-Hochberg false discovery rate adjustment). Pigs fed simple diets had increased hepatic gene expression of urea cycle enzymes (arginase-1, $P < 0.06$; and carbamoyl phosphate synthase-1, $P < 0.06$) and antioxidant enzymes (glutathione peroxidase-1, $P < 0.06$; and glutathione peroxidase-3, $P < 0.06$). Pigs fed complex diets had increased hepatic expression of genes involved in endogenous antigen processing and presentation (swine leukocyte antigen [SLA]-2, $P < 0.10$; SLA-8, $P < 0.08$; antigen peptide transporter-1, $P < 0.06$; and antigen peptide transporter-2, $P < 0.07$), and in exogenous antigen processing and presentation (SLA-DMA, $P < 0.08$; SLA-DMB, $P < 0.06$; SLA-DQA, $P < 0.06$; SLA-DQB1, $P < 0.03$; SLA-DRA, $P < 0.08$; SLA-DRB1, $P < 0.06$; CD74 invariant chain, $P < 0.09$; and cathepsin S, $P < 0.06$). These results indicate increased disease resistance of starter pigs fed complex diets in the nursery that may persist as they grow.

Key Words: immunity, microarray, pigs

383 Development and evaluation of a model estimating nitrogen partitioning in lactating sows.

A. V. Hansen[1], A. B. Strathe[1], P. K. Theil[2], and E. Kebreab*[1], [1]*Department of Animal Science, University of California, Davis,* [2]*Department of Animal Science, Faculty of Science and Technology, Aarhus University, Tjele, Denmark.*

The impact of nitrogen excretion from swine operations on the environment is of growing concern. There are very few models that predict nutrient excretion from sows, therefore, our objective was to develop and evaluate a whole animal model that predicts the nitrogen partitioning by lactating sows and nutrient excretion. A factorial approach was taken to estimate requirements for maintenance, milk production and body deposition. It was assumed that the priority for nutrient partitioning was in the order of maintenance, milk production and body deposition with body tissue losses constrained within biological limits. The model inputs were dietary composition, potential litter size (LS), litter gain (LG), and BW of the sow. Nitrogen input (NI) was predicted and the other outputs from the model were nitrogen excretion in milk (NL), urine (NU) and feces (NF). The model also predicts the loss of body fat (dL) and protein (dP) during lactation. The model was evaluated using existing nitrogen balance data from the literature. The information on potential LS, LG, sow BW, dietary composition and feed intake from the literature was used as input to the model and the predicted values for the nitrogen balance was compared with the values given in the publications. The root mean squared prediction error (RMSPE) and concordance correlation coefficients (CCC) were used in the evaluation. The mean values for observed and predicted NI, NU, NF, and NL were 95.4, 34.6, 10.9, and 65.6 g/d and 94.8, 38.5, 10.9, and 64.5 g/d, respectively. The RMSPE for NI, NU, NF, and NL were 9.9, 9.8, 1.4 and 5.6 g/d, respectively. The CCC for NI, NU, NF, and NL were 0.97, 0.93, 0.95 and 0.80, respectively. The prediction of dL and dP was evaluated using publications with relevant information. The RMSPE was 5.2 and 1.9 kg for dL and dP, respectively. The CCC was 0.74 and 0.70 for dL and dP, respectively. In conclusion, the evaluation shows that the model can predict nitrogen partitioning, dL and dP in lactating sows, and it is a potential tool for assessing intervention methods such as dietary manipulation on nutrient loading in the environment.

Key Words: nitrogen, lactation, sow

384 Dynamics of nitrogen retention in entire male pigs immunized with Improvest.

L. Huber,* D. Wey, and C. de Lange, *University of Guelph, Guelph, ON, Canada.*

Immunization against gonadotropin-releasing hormone (GnRH) reduces the occurrence of boar taint compounds in male pigs, and is likely to alter growth performance and whole body protein deposition (Pd). The latter is an important determinant of dietary amino acid requirements. Thirty-six male PIC pigs were used to determine the effects of immunization against GnRH with Improvest (Pfizer Animal Health) on plasma levels of androstenone and skatole and Pd (N-retention × 6.25). Four treatments were used: [1] conventional, early castrates (EC), [2] entire males (EM), [3] entire male pigs immunized with Improvest (IM), and [4] entire male pigs surgically castrated at 25–40 kg body weight (late castrates; LC). Improvest was injected at 30 kg and 70 kg BW. Within each of 9 litters, 4 males were randomly assigned to one treatment. Pigs were fed corn and soybean meal based diets that were not limiting in essential nutrients for high Pd. Five consecutive N-balances were conducted on days: −9 to −4, 1 to 7, 9 to 16, 20 to 26 and 30 to 36, relative to the second injection at d 0; blood was sampled on days: −4, −1, 2, 5, 8, 11, 14, 19, 28 and 37. Plasma androstenone became not different from zero in IM ($P > 0.10$) and equal to EC and LC ($P > 0.10$) by d 8. Treatment had no effect on plasma skatole levels (overall mean: 0.32 ± 0.10 ng/g; $P > 0.10$). There was an interactive effect of treatment and time on Pd ($P < 0.001$). Across periods, Pd for EC and LC were similar (204.4 vs 207.5 g/d, $P > 0.10$), and lower than EM (244.8 g/d, $P < 0.001$). Pd in EM and IM was similar up to d 7 (239.5 vs 242.1 g/d, $P > 0.10$), tended to be higher for EM than IM during d 9 to 16 (239.7 vs 216.7 g/d, $P = 0.07$) and was higher for EM than IM after d 20 (252.7 vs 202.6 g/d, $P < 0.05$). Between d 9 and 36 IM Pd was similar to EC and LC ($P > 0.10$). Immunization with IMPROVEST was effective at reducing plasma androstenone. Between d 7 and 16 after the second injection, Pd in IM changed gradually from EM levels to EC and LC levels, which should be considered when developing feeding programs for IM.

Key Words: entire males, Improvest, nitrogen retention

385 Effects of dietary protein and lipid levels on growth and stress tolerance of juvenile tilapia (*Oreochromis niloticus*).

C. G. Hooley*[1], F. T. Barrows[3], J. A. Paterson[1], and W. M. Sealey[2], [1]*Montana State University, Bozeman,* [2]*United States Fish and Wildlife Service, Bozeman, MT,* [3]*US Department of Agriculture, Agriculture Research Service, Bozeman, MT.*

The objectives of this study were to determine optimal dietary protein and lipid levels in diets on rate and efficiency of growth and stress response of juvenile tilapia cultured in a high-intensity recirculating-water system. A 3 × 3 factorial arrangement of diets formulated to contain 3 levels of dietary protein (28, 32 and 36%) and 3 levels of dietary lipid (3, 6, and 9%) was employed. Juvenile tilapia (34.5 ± 0.4g) were randomly assigned to each of the tanks (30 fish/tank), with 3 replicate tanks for each treatment except for the 3% lipid level (2 replicates). Fish were fed 3 times per d to apparent satiation, 6 d per wk for 12wks. Fish were weighed every 3 wks and feed efficiency (G:F) was calculated. All data were subjected to a 2-way ANOVA to determine the effects of dietary protein and lipid and their interactions on fish growth, performance and body composition and blood chemistry following a simulated hauling trial. There was no protein by lipid interactions for either rate or efficiency of gain. Fish fed 36% CP had higher ($P < 0.05$) weight gains and lower ($P < 0.05$) G:F when compared with either 28% or 32% CP diets. Fish fed 3% crude lipid had higher ($P < 0.05$) G:F (1.56) when compared with diets containing 6% and 9% crude lipid (1.41 and 1.40 respectively). Tissue composition was significantly ($P < 0.05$) affected by diet, but fish fed 36% CP retained more ($P < 0.05$) whole body protein but less whole body lipid than fish fed diets with 32% or 28% CP. Feeding fish diets with 9% lipid increased ($P < 0.05$) whole body lipid concentrations as well as whole body gross energy. Following the completion of the growth trial, tilapia were subjected to a 24-h simulated live haul. Glucose, lactate, and cortisol measurements were determined at 0, 24, and 72 h. There were significant effects ($P < 0.01$) of protein level on initial blood lactate. Fish fed 32% CP had higher lactate levels than fish fed 36% CP. After 24 h fish fed 36% CP had higher lactate levels than fish fed 32% CP suggesting that fish fed higher protein levels were more stressed during the live haul. An interaction was measured for cortisol at 24 h ($P < 0.05$), with fish fed 28% CP and 6% crude lipid having higher levels than other dietary treatment. Diets containing, 36% protein and 3% lipid supported faster growth compared with diets with higher levels of protein and lipid.

Key Words: tilapia, protein by energy, stress

386 Comparison of the in vitro fermentation activity of fecal inocula from piglets and dogs.

S. Brambillasca,* C. Deluca, A. Britos, and C. Cajarville, *Departamento de Nutrición Animal, Facultad de Veterinaria, Universidad de la República, Montevideo, Uruguay.*

It is expected that gut microbiota from dogs and piglets are different in terms of number and species. This would be reflected in differences in the fermentative activity. So, the aim of this study was to compare the microbiota potential of dogs and piglets to ferment different feedstuffs. Nine substrates (0.5 g of either ryegrass, citrus pulp, apple pomace, piglet and dog food, soy hulls, corn, barley and inulin) were incubated in vitro with 10 mL of diluted feces (1:5 w/v with 9 g/L NaCl solution) from 3 piglets and 3 adult dogs fed a soybean-corn based diet and a commercial dog food respectively (3 flask/inoculum, plus 3 blanks, n = 60). Gas volume was recorded at 2, 4, 6, 8, 10, 12, 18, 24, 48 and 67 h after inoculation. Asymptotic gas production (a, mL/g OM), rate of gas production (K_d, h^{-1}) and lag time (L, h) were determined. Data were analyzed by PROC MIXED considering the substrate and inoculum effects and its interaction. If interaction substrate*inoculum was significant simple main effect of inoculum was analyzed by the SLICE option. Interactions between inoculum and substrate were observed for a ($P < 0.001$), kd ($P = 0.011$) and L ($P = 0.002$). Inoculum from piglets produced more gas for all substrates incubated, except for corn, where gas production was similar among inoculum sources. Despite the fermentation rate was similar between inoculum sources, inulin fermentation rate was higher for piglets than for dogs (0.155 vs 0.099, $P < 0.001$). Lag times recorded were lower for ryegrass, citrus pulp, apple pomace, soy hulls and inulin when inoculum from dogs was used. In conclusion, inocula behaved different and it seems that piglets presented a microbiota more active to ferment substrates than that from dogs.

Key Words: hindgut fermentation, canine, swine

387 Prediction of voluntary feed intake in weaner pigs using physicochemical properties of bulky diets.

S. P. Ndou,* M. Chimonyo, and R. M. Gous, *Animal and Poultry Science, University of KwaZulu-Natal, Scottsville, Pietermaritzburg, South Africa.*

Prediction of voluntary feed intake of growing pigs is crucial in the management and welfare of growing pigs; it facilitates the accurate formulation of feeds. The objective of the study was to predict maximum feed intake in weaner pigs using the physicochemical properties of bulky feeds. A total of 124 six-week-old pigs weighing 18.1 (SD 1.37) kg BW were given, ad libitum, diets containing 0, 80, 160, 240, 320 and 400 g/kg of either lucerne hay, maize cob, maize stover, saw dust, sunflower husks or grass hay. The basal feed contained 13.7 MJ digestible energy and 180 g of CP/kg DM. Each of the 31 diets was given to each of the 4 pigs, in individual cages, for 4 weeks. Properties of bulkiness measured were water holding capacity (WHC; g water/ g DM), bulk density (g DM/mL), neutral detergent fiber (NDF) and acid detergent fiber (ADF). Average daily feed intake was expressed per unit BW to determine scaled feed intake (SFI; g/kg/day) for each pig. Stepwise regression was used to identify significant physicochemical properties that affect SFI. Response surface regression was used to determine the relationship between SFI and each of the physicochemical properties of the bulky feeds. Water holding capacity, bulk density, NDF and ADF affected ($R^2 = 0.65$; $P < 0.01$) SFI. The SFI was quadratically related to WHC using the function $SFI = 19.1 (\pm 3.49) + 10.0 (\pm 1.61) WHC - 1.1 (\pm 0.17) WHC^2$ ($P < 0.01$). The SFI was also related ($P < 0.01$) to NDF and ADF by quadratic functions $SFI = 24.3 (\pm 3.55) + 0.1(\pm 0.23)NDF - 0.0001 (\pm 0.000036)NDF^2$ and $SFI = 30.2 (\pm 1.95) + 0.1 (\pm 0.02)ADF - 0.0003(\pm 0.000061)ADF^2$, respectively. Using differentiation, the gut capacity was attained when WHC = 4.76 g water/g DM, NDF = 367.12 g/kg DM and ADF = 138.50 g/kg DM, respectively. In conclusion, WHC, NDF and ADF contents are appropriate measures of bulkiness responsible for constraining intake of bulky feeds.

Key Words: bulky feeds, gut capacity, water holding capacity

Physiology and Endocrinology Symposium: The Current Status of Heat Shock in Early Embryonic Survival and Reproductive Efficiency

388 Influence of sire breed on heat stress tolerance of in vitro-produced bovine embryos. C. M. Barros* and R. A. Satrapa, *Department of Pharmacology, Institute of Biosciences, University of Sao Paulo State, Botucatu, Sao Paulo, Brazil.*

In bovine, hyperthermia reduces both quality and quantity of sperm in males and decreases fertility in females. The detrimental effects of heat stress on embryo development are critical during the first cleavage divisions, when most of the embryonic genome is inactive. However, as pregnancy advances the deleterious effects of heat stress on embryonic survival decrease. Several in vitro studies indicate that *Bos indicus* embryos are better able to survive heat stress at early stages of development and are more capable of originating pregnancies following heat stress than *Bos taurus* embryos. The evidence that embryonic genotype determines resistance to heat shock leads to the question as to whether embryos sired by *Bos indicus* breeds exhibit superior resistance to heat stress than those sired by *Bos taurus*. Contrary to previous reports, in one of our in vitro studies we found that Holstein oocytes fertilized with *Bos indicus* semen (Nelore breed) were more resistant to heat stress than those fertilized with *Bos taurus* (Angus) semen, suggesting that the sire breed influences embryo tolerance to heat stress. However, in this particular experiment, only 2 sires from each breed were used. Therefore, we suspected that the sire effect may have overshadowed the breed effect; that is, the better tolerance to heat shock was due to the bull itself and not to the breed of the bull. To minimize the bull effect, we repeated the same experiment using 6 sires from each breed. It was observed that sire breed did not influence embryo tolerance to heat stress. Overall these results indicate that the oocyte plays a more crucial role in the ability of the embryo to resist the effects of heat stress than the spermatozoa. Supported by FAPESP (Sao Paulo, Brazil).

Key Words: embryo, heat stress, IVF

389 Associations between heat shock protein 70 genetic polymorphisms and calving traits in crossbred Brahman cows. C. Rosenkrans Jr.*[1], M. Brown[2], H. Brown Jr.[1], and M. Looper[1], [1]*University of Arkansas, Fayetteville,* [2]*USDA-ARS, El Reno, OK.*

Stressors such as heat, cold, toxins, and oxygen deprivation are known to induce heat shock proteins. Genetic polymorphisms associated with heat shock protein genes have been associated with decreased male and female fertility. Our objectives were to 1) confirm single nucleotide polymorphisms (SNP) located in the promoter region of the bovine heat shock protein 70 (*Hsp*70) gene and 2) evaluate associations among *Hsp*70 SNP, breed, forage system, and lifetime calving rates of multiparous cows (n = 88). Angus (n = 22), Brahman (n = 30), and reciprocal crosses (n = 36) cows were assigned to and remained on their respective forage system for the duration of the experiment (8 years). Forage systems were endophyte-infected toxic tall fescue (E+) or common bermudagrass (CB). Genomic DNA was extracted from buffy coats of EDTA-treated whole blood. Primers HSP-Pro749F (GCCAGGAAACCAGAGACAGA) and HSP-Pro1268R (CCTACGCAGGAGTAGGTGGT) were used for PCR amplification of a 539-base segment of the bovine *Hsp*70 promoter (GenBank accession number M98823). Ten SNP were detected: 7 transitions (G1013A, n = 4; G1045A, n = 7; C1069T, n = 8; A1096G, n = 3; G1117A, n = 36; T1134C, n = 6; and T1204C, n = 65), 2 transversions (A1125C, n = 62; and G1128T, n = 34), and one insertion/deletion at base position 895 (C895D; n = 12). Minor alleles numerically were associated with Brahman cattle; however, G1117A was the only site associated ($P < 0.05$) with breed with minor allele frequencies of 11, 25, and 43% respectively for Angus, reciprocal crosses, and Brahman. Interaction ($P < 0.05$) between forage system and C895D genotype affected lifetime calving percentage (87, 86, 80, 85, and 20 for CC-CB, CD-CB, DD-CB, CC-E+, and DD-E+; respectively). A similar interaction ($P < 0.05$) was observed for G1117A and forage system. Homozygous guanine cows grazing E+ had lower ($P < 0.05$) lifetime calving rates when compared with GG cows grazing CB (76 vs. 90%). Our results demonstrate that Hsp70 promoter SNP will be useful in marker assisted management programs.

Key Words: cattle, *Hsp*70, tall fescue

390 Expression of heat shock protein genes and their splice variants in in vivo and in vitro bovine preimplantation embryos. H. Khatib,* *University of Wisconsin, Madison.*

Heat shock proteins (HSP) are among the first proteins produced during embryonic development and are essential to cell function. Their activities include folding, unfolding, transport, and localization of proteins and differentiation and regulation of the embryonic cell cycle. Although HSPs have been extensively studied in human and mouse, there is limited information on the roles of these genes in bovine embryos. As such, the objectives of this study were to profile the expression of HSP and their splice variants in bovine embryos (degenerates vs. blastocysts) and to carry out association analysis with fertility traits. Quantitative real time PCR analysis revealed significant differences in expression in degenerate embryos compared with blastocysts. Interestingly, all members of the HSP40 family were found to be upregulated in degenerates. Analysis of current bovine Ensembl data showed that 13 HSP genes have one transcript each, 2 genes have 2 transcripts each, and 2 have 3 transcripts each. The results indicate that some splice variants show differential expression between degenerates and blastocysts while others were not expressed at all in embryos, which implies different functions of these transcripts in embryonic development. In addition, the expression profiles of HSPs were compared between in vitro produced embryos and in vivo embryos. The most significant differentially-expressed genes were further investigated for association with fertility traits. Single nucleotide polymorphisms some HSP genes were found to be associated with blastocyst rate and fertilization rate. Collectively, results of the present study point to the important roles of HSPs in fertilization and early development of cattle embryos.

Key Words: heat shock protein, expression, alternative splicing

391 Consequences of heat shock on development of the preimplantation bovine embryo: Role of free radicals, antioxidants, apoptosis, and heat shock proteins. P. J. Hansen*[1] and M. Sakatani[2], [1]*University of Florida, Gainesville,* [2]*Kyushu-Okinawa Agricultural Research Center, National Agriculture and Food Research Organization, Kumamoto, Japan.*

The preimplantation embryo is one of the most sensitive of mammalian cells to hyperthermia. Exposure to temperatures as low as 40°C can reduce competence of the bovine embryo to continue development. Temperature sensitivity in at least some species (cow, sheep, pig) is

transient, however, and the embryo acquires resistance to elevated temperature (i.e., heat shock) as it advances through development. For the bovine embryo, there is little effect of heat shock on development after the 8-cell stage. Developmental acquisition of thermotolerance can be exploited to improve fertility in heat-stressed females through transfer of embryos at advanced stages of development. Experiments with the bovine indicate that developmental changes in embryonic sensitivity to heat shock are due to changes in several molecules and processes important for thermotolerance. Perhaps most important is the change in redox balance of the embryo. Heat shock can increase free radical production and the level of at least one antioxidant, glutathione, is lowest at early cleavage stages. Moreover, some antioxidants have been reported to increase embryonic resistance to heat shock in vitro. Apoptosis, if limited in extent, can be beneficial to embryonic survival after heat shock. Inhibition of apoptosis in embryos at d 4 or 5 of development increased the magnitude of heat shock effects on development. In this regard, it is instructive that the embryo does not gain the ability to undergo apoptosis in response to heat shock until about the 8–16 cell stage. The embryonic genome is also not fully activated until the 8–16 cell stage. The lack of transcription in early embryos may contribute to their thermal sensitivity because of the inability to produce proteins that stabilize cellular function. However, heat shock protein 70 (HSP70) is not likely to be a limiting protein in determining thermosensitivity. Levels of HSP70, as determined by immunofluorescence, are similar between 2-cell embryos and d 5 embryos. Heat shock can induce changes in HSP70 synthesis as early as the 2-cell stage. Moreover, steady-state mRNA for *HSP70* is higher for 1-cell and 2-cell embryos than for d 5 embryos. To date, a suitable treatment for increasing embryonic resistance to heat shock in the pregnant cow has not been identified but experiments with mice suggest that provision of a suitable antioxidant might enhance fertility of heat-stressed females.

Key Words: heat shock, embryo, bovine

Production, Management and the Environment: Beef Production

392 GPS/GIS technology in range cattle management. D. M. Anderson,* *USDA-ARS, Jornada Experimental Range, Las Cruces, NM.*

Animal-dominated landscapes are dynamic and not fully understood. Electronics were first employed in the mid-1970s to monitor free-ranging cattle behavior and its effect on forage utilization. By the mid-90s, satellite positioning systems were being used to monitor wildlife and had all but removed human observation from animal tracking. However, not until the end of the 90s did animal-borne satellite receivers catapult range cattle management into the world of microchip technology. This advent eliminated some challenges associated with terrestrial-based systems but added others, not the least of which has been how best to provide sustained power to animal-borne electronics. This question caused a conundrum for researchers deciding how to balance data collection rates with battery power drain because satellite-based systems have the potential to collect data in fractions of a second. To assist in interpreting the vast reservoirs of time-stamped positional data available, researchers began looking to biotic and abiotic information in the vicinity of the animal's geographical location to help explain the animal's behavior. Enter the Geographic Information System (GIS) with its origins in the late 50s and 60s. It provides hardware and software capable of capturing, storing, retrieving, manipulating, analyzing, and displaying geographically referenced data. By combining GIS and Global Positioning System (GPS) satellite data, researchers were given a robust way to accurately associate possible cause and effect relationships. Because of the complexity associated with electronically obtained data, it is mandatory that multifaceted teams be established from the onset not only to keep electronics operational but also to optimize the design, gathering, summarization, analyses, interpretation and application of data. Though electronics have replaced the drudgery and incompleteness of manual data gathering, electronics should never be used in an attempt to replace the art of human observation and discernment that ultimately provides the interpretation and application of field-based management.

Key Words: foraging, range animal ecology, animal tracking

393 Detection of pregnancy in Arizona range cattle using near infrared spectroscopy of feces. D. R. Tolleson* and D. W. Schafer, *University of Arizona, V Bar V Ranch, Rimrock.*

Near infrared spectroscopy (NIRS) of feces has been used to determine pregnancy in cattle but not in the southwestern US. Fecal constituents affected by pregnancy in amounts sufficient to affect near infrared spectra are yet to be identified. Crossbred beef cows (n ~375) were used to evaluate the ability of fecal NIRS to determine pregnancy under commercial ranch conditions in Arizona. All cows were synchronized using the 5-d CO-Synch+CIDR protocol in mid-June of 2011 and then turned out with bulls for 75 d. Fresh fecal samples from individually identified cows were collected off the ground in the pasture on the day of AI, 2 weeks later, and ~monthly thereafter until mid-October. Samples (n = 78) were frozen and later analyzed by NIRS. Pregnancy was determined by rectal palpation in mid-September and used to estimate day of pregnancy for each cow on the date feces were collected. Fecal spectra (1100 to 2500nm) were paired with the corresponding pregnancy values to create a discriminant calibration data set. Validation was accomplished with ~25% of the samples (n = 17) randomly selected and removed from the original 78. Previous research has identified 30 d of gestation as the minimum threshold for detection of pregnancy via fecal NIRS. Successful identification of cows greater than 30 d gestation was 4/5 (80%) and for cows not-pregnant, or pregnant less than 30 d was 8/12 (67%). Discrimination was also attempted for arbitrary groupings (A versus B) of the calibration set. This exercise yielded a validation success rate of 1/5 (20%) for group A and 7/12 (58%) for group B, respectively. The proportion of successful individual identifications for the biological (71%) versus arbitrary (47%) group validation was numerically greater ($X^2 = 1.94$, $P = 0.16$). A comparison between the observed and fecal NIRS predicted percent of the herd pregnant in late June, mid-July, mid-August, and mid-September was 0 versus 2, 34 versus 16, 63 versus 50, and 72 versus 79, respectively ($r^2 = 0.88$, $P = 0.06$). Herd pregnancy status of range beef cows was predicted well enough to inform forward planning for reproductive management.

Key Words: fecal, near infrared spectroscopy, pregnancy

394 Effect of beef heifer development system on ADG, reproduction, and feed efficiency during first pregnancy. A. F. Summers,* T. L. Meyer, S. P. Weber, and R. N. Funston, *University of Nebraska, West Central Research and Extension Center, North Platte.*

A 3-yr study was conducted to determine the effects of heifer development system on ADG, reproductive performance, and subsequent feed efficiency as a pregnant heifer. Crossbred Angus heifers (n = 299) were assigned by initial BW to graze corn residue (CR) or developed in a dry lot (DL). Corn residue heifers grazed native pasture 33 d before grazing CR 74 d. Corn residue heifers were then placed on dormant forage pastures 66 d and then with DL heifers for approximately 40 d for synchronization and AI. Heifers assigned to DL grazed dormant forage for 98 d and then placed in a DL for 112 d. The following winter a subset of pregnant CR and DL heifers (n = 114) were stratified by BW and development treatment, and placed in a Calan Broadbent individual feeding system for 84 d during late gestation. The remaining pregnant heifers were placed on CR. Prebreeding BW was greater ($P = 0.01$) for DL heifers compared with CR heifers (349 vs. 314 ± 9 kg). At pregnancy diagnosis BW remained greater ($P = 0.06$) for DL compared with CR heifers (422 vs. 403 ± 10 kg). Dry lot heifers had greater ($P = 0.01$) overall ADG during development compared with CR heifers. There was no difference ($P \geq 0.41$) in percent cycling (43 vs. 53 ± 15%), AI pregnancy (71 vs. 64 ± 6%), or final pregnancy rates (93 vs. 91 ± 3%) for CR and DL, respectively. However, CR heifers had greater ($P = 0.09$) ADG (0.77 vs. 0.64 ± 0.05 kg/d) from AI to pregnancy diagnosis compared with DL heifers. At the beginning of the second winter, DL heifers had greater ($P = 0.09$) BW compared with CR; however, pre-calving BW was similar ($P = 0.37$). Gestation length, calving date, and calf birth BW were similar ($P \geq 0.28$) between development treatments. During the individual feeding period, DL heifers had greater final BW compared with CR heifers (516 vs. 506 ± 9 kg). Dry matter intake and RFI were similar ($P \geq 0.39$) between treatments. Dry lot heifers had greater ($P \leq 0.05$) ADG (0.80 vs. 0.69 ± 0.14 kg/d) and G:F compared with CR. Heifers developed on CR had reduced BW through early pregnancy; however, reproductive performance was similar to DL developed heifers.

Key Words: beef cattle, feed efficiency, heifer development

395 Use of MTB-100, provided through a mineral mix, in a strategic supplementation plan to alleviate the effects of fescue toxicity when lactating beef cows graze endophyte-infected tall fescue.

M. E. Hoar,* D. K. Aaron, D. G. Ely, and M. M. Simpson, *University of Kentucky, Lexington, Ky, United States.*

Sixty-three, 3 to 5 yr-old, Angus crossbred cows and their calves were used in a 3-yr study to evaluate response to strategic supplementation with a nutritional supplement produced from a carbohydrate-based toxin adsorbent (MTB-100, Alltech, Inc., Nicholasville, KY). MTB-100 was mixed with a complete mineral so daily intake was projected to be 0 or 20 g/cow. The experimental period extended from May 5 to Oct 2 and was divided into 3 strategic periods: P1 = May 5 to Jul 5; P2 = Jul 5 to Aug 18; P3 = Aug 18 to Oct 2. Treatments were either 0 or 20 $g\cdot hd^{-1}\cdot d^{-1}$ MTB-100 within a period (Trt 1 = 0, 0, 0; Trt 2 = 20, 0, 20; Trt 3 = 0, 20, 0; Trt 4 = 20, 20, 0; and Trt 5 = 20, 20, 20). In P1, 10 to 14 cow/calf pairs were managed in each of 9, endophyte-infected (>90%) KY 31 tall fescue pastures (re-randomized annually). On Jul 5 each year, pre-designated pairs were allotted to 21 individual, 1.6-ha plots of equivalent pasture and supplemented with either 0 or 20 $g\cdot hd^{-1}\cdot d^{-1}$ MTB-100, depending on treatment, until Oct 4. There was no significant effect of treatment on total cow weight changes from May 5 to Oct 4 (34, 38, 30, 35 and 35 kg for Trt 1, 2, 3, 4 and 5, respectively). Corresponding BCS changes were not significant. Overall, differences ($P < 0.10$) were found for rectal temperature changes. Calf gains for Trt 1 and 5 were 54 and 60 in P1 ($P < 0.10$), 47 and 56 in P2 ($P < 0.05$), and 24 and 22 kg ($P < 0.05$) in P3. Overall, calves receiving no MTB-100 (Trt 1) gained less (125 vs. 138 kg; $P < 0.10$) than calves receiving continual supplementation (Trt 5). Gains of calves receiving strategic supplementation during the 150 d (Trt 2, 3 and 4) were intermediate to gains of calves in Trt 1 and 5. These results show strategically invoked MTB-100^{TM} consumption, through a mineral mix available ad libitum, can increase performance of cows and calves grazing endophyte-infected tall fescue forage.

Key Words: fescue, cow/calf pairs, MTB-100

396 Effects of anti-phospholipase A2 antibody (aPLA2) supplementation on DMI, feed efficiency and blood differentials of steers fed forage and grain-based diets.

V. R. G. Mercadante*[1], K. M. Bischoff[1], G. H. L. Marquezini[1], J. D. Arthington[2], N. DiLorenzo[1], and G. C. Lamb[1], [1]*North Florida Research and Education Center, University of Florida, Marianna,* [2]*Range Cattle Research and Education Center, University of Florida, Ona.*

We determined whether supplementation of anti-phospholipase A2 antibody (aPLA2; BIG BEEF, Aova Technologies, Madison, WI) would alter voluntary DMI, feed efficiency (FE) and blood differentials (BD) due to a change in diet from a forage-based to a grain-based diet. Individual daily DMI was measured on 80 cross-bred steers during a 141 d period using a GrowSafe system (GrowSafe Systems Ltd., Alberta, Canada) at the University of Florida NFREC Feed Efficiency Facility. On d 0, steers were blocked by BW and assigned to receive a basal diet (0.97 Mcal NEg/kg of DM and 16% CP) comprised of 69% concentrate, 31% bermudagrass hay, and a vitamin and mineral supplement containing the following treatments: 1) no additive (CON; n = 20); 2) 30 mg of monensin and 8.8 mg of tylosin per kg of diet DM (MT; n = 20); 3) same as CON, but including aPLA2 at 0.4% of the diet DM (BB0.4%; n = 20); 4) same as CON, but including aPLA2 at 0.2% of the diet DM (BB0.2%; n = 20). On d 60 all steers were transitioned into a 90% concentrate diet (74% cracked corn; 1.32 Mcal NEg/kg of DM, 11.4% CP) over a 21-d "step-up" period while continuing to receive their supplement treatments. On d 0, d 60, d 81 and d 141 BW was recorded. Blood samples were collected on d 60, 63, 65, 67, 70, 72, 74, 77, 79, 81 and 84, and BD was assessed using a hematology cell counter (IDEXX ProCyte Dx Hematology Analyzer, Westbrook, ME). No differences existed for BW on d 0 (212 ± 34 kg), BW on d 141 (388 ± 46 kg), overall ADG (1.24 ± 0.16 kg/d), DMI (8.00 ± 0.94 kg/d), and residual feed intake (RFI). However, steers receiving the CON (0.34 ± 0.15 kg/d) treatment had greater ($P < 0.05$) RFI than the BB0.2% (−0.13 ± 0.15) and BB0.4% (−0.25 ± 0.15 kg/d) treatments, whereas the MT (0.06 ± 0.15 kg/d) treatment was intermediate. During the grain-based diet period, the BB0.2% (−0.12 ± 0.21 kg/d), BB0.4% (0.38 ± 0.21 kg/d), and MT (0.09 ± 0.21) steers tended ($P = 0.07$) to have greater RFI than the CON (−0.39 ± 0.21 kg/d) steers. During the step-up period the CON (7.09 ± 0.23 k/μL) and BB0.2% (7.62 ± 0.23 k/μL) treatments had greater ($P < 0.05$) concentrations of lymphocytes than the MT (6.73 ± 0.23 k/μL) and BB0.4% (6.73 ± 0.23 k/μL) treatments, and tended ($P = 0.06$) to have greater white blood cell counts (12.87 ± 0.42; 13.61 ± 0.42; 12.16 ± 0.42; 12.37 ± 0.42 k/μL for CON, BB0.2%, BB0.4% and MT, respectively;). We conclude that aPLA2 supplementation improved FE of steers fed forage-based diets and tended to reduce blood leukocyte concentrations when exposed to a transition into grain-based diets.

Key Words: feed efficiency, blood differentials, residual feed intake

397 Effects of acclimation to human handling on temperament, physiological responses, and performance of beef steers during feedlot receiving.

C. L. Francisco*[1,2], R. F. Cooke[1], R. S. Marques[1], T. Leiva[1], F. Sanches[1], A. Bouck[1], F. N. T. Cooke[1], and D. W. Bohnert[1], [1]*Oregon State University, EOARC, Burns,* [2]*Universidade Estadual Paulista - FMVZ/DPA, Botucatu, SP, Brazil.*

The objective was to compare temperament, plasma concentrations of cortisol and acute-phase proteins, and performance during feedlot receiving of Angus × Hereford steers acclimated or not to human handling. Sixty steers were initially evaluated, within 30 d after weaning, for BW and temperament score (average chute score and exit velocity score; d −30). On d −28, steers were ranked BW and temperament score, and randomly assigned to receive or not (control) the acclimation treatment. During the acclimation phase (d −28 to 0), steers were maintained in 2 pastures according to treatment, and acclimated steers were exposed to a handling process twice weekly (Tuesdays and Thursdays). The acclimation treatment was applied individually to steers by processing them through a handling facility, whereas control steers remained undisturbed on pasture. On d 0, all steers were loaded into a commercial livestock trailer, transported for 24 h, and returned to the research facility (d 1). Upon arrival, steers were ranked by BW within treatment, and randomly assigned to 20 feedlot pens. Total DMI was evaluated daily from d 1 to d 28, and shrunk BW was collected on d −31, 1, and 29 for ADG calculation. Blood samples were collected on d −29, 0 (before loading), 1 (immediately upon arrival), 4, 7, 10, 14, 21, and 28 for determination of cortisol, ceruloplasmin, and haptoglobin. Steer temperament was assessed again on d 0 and 28. During the acclimation phase (d −28 to 0), no treatment effects were detected ($P = 0.14$) on steer ADG. Acclimated steers had reduced chute score compared with control on d 0 and 28 ($P \leq 0.01$). During feedlot receiving (d 1 to 28), acclimated steers had reduced ADG ($P < 0.01$), DMI ($P = 0.07$), and G:F ($P = 0.03$) compared with control. Acclimated steers had greater plasma cortisol on d 1 ($P = 0.06$), greater haptoglobin on d 4 ($P = 0.04$), and greater ceruloplasmin from d 0 to 10 ($P \leq 0.04$) compared with control. In conclusion, steers exposed to the acclimation process had greater stress-induced cortisol and acute-phase protein responses, resulting in decreased performance during feedlot receiving.

Key Words: steers, handling, feedlot

398 Effects of 24-h transport or 24-h nutrient restriction on acute-phase and performance responses of feeder cattle. R. S. Marques*[1], R. F. Cooke[1], C. L. Francisco[1,2], T. Leiva[1], F. Sanches[1], A. Bouck[1], F. N. T. Cooke[1], and D. W. Bohnert[1], [1]*Oregon State University, EOARC, Burns,* [2]*Universidade Estadual Paulista - FMVZ/DPA, Botucatu, SP, Brazil.*

The objective was to compare acute-phase and performance responses of weaned beef calves exposed to transport or nutrient restriction. Angus × Hereford steer (n = 30) and heifer (n = 15) calves were balanced by sex and BW, and randomly assigned to 15 pens on d −12 of the experiment. On d 0, pens were randomly assigned to 1 of 3 treatments: 1) transport for 24 h in a livestock trailer (TRANS); 2) no transport, but feed and water deprivation for 24 h (REST); or 3) no transport and full access to feed and water (CON). Treatments were concurrently applied from d 0 to 1. Total DMI was evaluated daily from d 1 to d 28. Full BW was recorded before treatment application and at the end of experiment. Blood samples were collected on d 0, 1, 4, 7, 10, 14, 21, and 28. Mean ADG was greater ($P < 0.01$) in CON vs. TRANS and REST calves, but similar ($P = 0.46$) between TRANS and REST calves. No treatment effects were detected on DMI, but CON had greater G:F vs. TRANS ($P < 0.01$) and REST calves ($P = 0.08$), whereas G:F was similar ($P = 0.21$) between TRANS and REST calves. Plasma cortisol concentrations were greater ($P \leq 0.05$) in REST vs. CON and TRANS calves on d 1, 4, 7, 14, 21, and 28, and tended to be greater ($P = 0.10$) in TRANS vs. CON calves on d 1. Serum NEFA was greater ($P < 0.01$) in REST and TRANS vs. CON calves on d 1, but also greater ($P < 0.01$) in REST vs. TRANS calves on d 1. Plasma ceruloplasmin peaked on d 4 for TRANS and REST calves (day effects; $P < 0.01$) but did not change ($P = 0.58$) for CON calves. Hence, CON calves had reduced mean plasma ceruloplasmin concentration vs. TRANS ($P = 0.07$) and REST ($P = 0.01$) calves. Plasma haptoglobin peaked on d 1 for TRANS and increased from d 1 to 14 in REST calves (day effects; $P < 0.01$) but did not change ($P = 0.65$) for CON calves. Hence, TRANS calves had greater plasma haptoglobin vs. CON and REST calves on d 1 ($P < 0.01$), whereas REST calves had greater ($P \leq 0.05$) plasma haptoglobin vs. TRANS and CON calves on d 7. In conclusion, 24-h transport and 24-h nutrient restriction elicited acute-phase protein reactions, and similarly reduced performance of feeder cattle.

Key Words: cattle, nutrient restriction, transport

Ruminant Nutrition: Beef Production II

399 Precision processing barley grain improves the feeding value of barley grain in beef cattle. W. Z. Yang*[1], M. Oba[2], and T. A. McAllister[1], *[1]Research Centre, Agriculture and Agri-Food Canada, Lethbridge, AB, Canada, [2]Department of Agricultural, Food and Nutritional Science, University of Alberta, Edmonton, AB, Canada.*

The objectives of this study were to determine the effects of barley grain quality and precision processing (processing based on kernel size and volume weight) on DMI, ruminal pH and fermentation, and apparent total tract digestibility in steers. Eight ruminally cannulated steers were used in a replicated 4 × 4 Latin square design with 21-d periods. The 4 treatments were: 1) light barley (LB); 2) heavy barley (HB), LB and HB processed optimally with processing index ranging 75 to 80%; 3) LB and HB precision processed and mixed in equal proportions (PP); and 4) LB and HB mixed in equal proportions then processed at a single roller setting (industry standard; CON). All diets consisted of 10% barley silage, 67% barley grain, 20% corn DDGS and 3% supplement (DM basis). DMI was greater ($P < 0.04$) for steers fed LB than for HB (13.2 vs. 12.2 kg/d) with greater ($P < 0.01$) NDF intake (4.0 vs. 2.8 kg/d) but less ($P < 0.01$) starch intake (4.7 vs. 5.8 kg/d). Intakes of DM, NDF and starch were greater ($P < 0.04$) for PP (13.0, 3.6 and 5.4 kg/d, respectively) than for CON (12.0, 3.3 and 5.0 kg/d, respectively). There were no differences in mean ruminal pH (5.82 to 5.89) or in the duration of pH < 5.8 (9.9 to 11.5 h) and pH < 5.5 (5.0 to 6.6 h) between LB and HB, or PP and CON. Ruminal NH3-N (9.5 to 10.3 mM) and total VFA concentrations (122 to 133 mM), and VFA profile were not affected by treatment. Digestibility of DM was lower ($P < 0.05$) for LB than HB (68 vs. 72%), whereas that of CP, NDF, ADF and starch was not different. Digestibility of DM, CP and ADF was greater ($P < 0.05$) for PP (74, 73 and 48%, respectively) than CON (70, 68 and 39%, respectively). These results suggest greater feed efficiency with HB than with LB due to less DMI and greater digestibility. This work demonstrates that precision processing can be used to improve the utilization of barley grain with variable kernel uniformity by beef cattle.

Key Words: feedlot cattle, precision processing, ruminal pH and fermentation

400 Effect of rumen degradable energy source on performance and forage intake of steers grazing stockpiled crested wheatgrass pasture. F. Anez*[1], J. J. McKinnon[1], H. A. Lardner[1,2], G. B. Penner[1], and P. G. Jefferson[1,2], *[1]University of Saskatchewan, Saskatoon, SK, Canada, [2]Western Beef Development Centre, Humboldt, SK, Canada.*

The objective of this experiment was to determine the effects of supplementing blended by-product pellets that differed in starch and degradable fiber content on performance of steers grazing mature crested wheatgrass (CWG). Forty-five yearling crossbreed steers (334 ± 3.5 kg) stratified by BW were randomly assigned to 1 of 9 CWG pastures (5 steers/pasture). Each pasture was randomly assigned (n = 3), in a completely randomized design, to 1 of 3 treatments: no supplement (Control); low-starch high-degradable fiber (LSHDF; 40.3% starch; 29.5% NDF on DM basis) pellet and high-starch low-degradable fiber (HSLDF; 48.6% starch; 22.8% NDF on DM basis) pellet, both fed daily at 0.6% BW. The grazing period lasted 70 d (from late-July to mid-October). Forage utilization and DMI were estimated using the double weigh (before and after grazing) technique. Forage samples were clipped every 2 wk and analyzed for DM, CP, ADF and NDF. Steers were weighed on 2 consecutive d at the beginning and end, and every 14 d throughout the trial. Ultrasound rib-fat thickness was also measured at the beginning and end of trial. Over the 70-d study, forage CP decreased from 9.9 ± 0.82 to 6.9 ± 0.59% of DM and digestible energy content decreased from 2.6 ± 0.04 to 2.2 ± 0.04 Mcal/kg DM. Treatment did not affect forage utilization ($P = 0.50$; 73.4 ± 3.15%) or DMI ($P = 0.90$; 9.0 ± 1.54 kg/d). Final BW and ADG were not different ($P > 0.05$) between LSHDF (435 ± 6.4 kg and 1.4 ± 0.10 kg/d) and HSLDF (439 ± 10.4 kg and 1.5 ± 0.14 kg/d). However, cattle fed pellets had higher ($P < 0.05$) final BW and ADG than the control cattle (402 ± 5.6 kg and 1.0 ± 0.09 kg/d). No effect of treatment ($P > 0.05$) was noted on rib fat. These results show that beef steers grazing mature CWG were limited in energy intake and that supplementation of metabolizable energy in the form of starch or degradable fiber equally improved performance.

Key Words: crested wheatgrass, by-products, grazing steers

401 Effects of sugarcane fiber digestibility and concentrate level on intake and growth of finishing Nellore bulls. B. S. Mesquita, D. O. Souza, J. F. Penso, M. H. A. Santana, J. B. S. Ferraz, and L. F. P. Silva,* *Universidade de São Paulo, Pirassununga, SP, Brazil.*

Sugarcane has low fiber digestibility, one of the main factors limiting beef cattle performance. The objective of this study was to evaluate the effects of sugarcane stalk fiber digestibility and of concentrate level on intake, growth and carcass fat of finishing Nellore bulls. Forty-eight Nellore bulls (319 ± 9.2 kg of BW) were blocked by BW and assigned to 4 treatments in a 2 × 2 factorial arrangement in a randomized complete block design. Treatments were as follows: sugarcane genotype IAC2480 (greater stalk NDF digestibility) as roughage source fed at 20 or 40% of total DM, or sugarcane genotype IAC2094 (lower stalk NDF digestibility), fed at 20 or 40% of total DM intake (n = 4 pens for each of the 4 treatments). Diets were formulated to provide daily gain (ADG) of 1.2 kg/d (40% sugarcane) or 1.4 kg/d (20% sugarcane), and contained freshly cut sugarcane as the sole forage. Sugarcane IAC2480 stalk contained 42% NDF with 15% 30h-NDF digestibility, and sugarcane IAC2094 stalk contained 41.5% NDF with 6.5% 30h-NDF digestibility. Animals were fed ad libitum maintaining a minimum of 10% orts in each pen. Dry matter intake was determined daily, and animals were weighed every 14 d after 16h of fasting. Main effects of sugarcane genotypes (CANE), of level of concentrate (CONC), and their interaction were tested by ANOVA. Feeding sugarcane with higher NDF digestibility increased dry matter intake as a percentage of BW (2.24 vs. 2.12 ± 0.08%, $P = 0.04$) and subcutaneous carcass fat (4.6 vs. 3.1 ± 0.4 mm, $P < 0.01$). There were no significant effects of level of concentrate or of CANE × CONC interaction on these variables. Regarding ADG, there was a CANE × CONC interaction ($P = 0.03$), where sugarcane with higher NDF digestibility increased ADG only when fed at 20% of DM (1.80 vs. 1.52 ± 0.09 kg/d, $P = 0.005$), and not when fed at 40% DM (1.57 vs. 1.59 ± 0.09 kg/d, $P = 0.87$). Feeding finishing bulls a diet containing sugarcane with greater stalk NDF digestibility increased DM intake and subcutaneous fat, regardless of concentrate level. Higher NDF digestibility also increased ADG, but only when fed at 20% of total DM.

Key Words: cattle, fiber digestibility, sugarcane

402 High dietary sulfur decreases apparent absorption of copper and manganese by steers. D. J. Pogge, M. E. Drewnoski,* and S. L. Hansen, *Iowa State University.*

The antagonism between S and Cu in ruminants is well established. However, the potential antagonism between high dietary S in concentrate-based diets and the divalent trace minerals Mn and Zn has not been extensively explored. Ruminal metabolism of sulfate can lead to the production of sulfide. Sulfide has the potential to bind divalent minerals and make them less available for absorption. To examine the effect of dietary S on apparent absorption and retention of Cu, Mn, and Zn, 16 steers (8 cannulated; 355 kg; and 8 unmodified; 386 kg) were used in a 2 × 2 factorial design with the 2 factors being modification status and dietary treatment. Dietary treatment consisted of a low sulfate (0.2% S; LS) wheat midd-based pellet or LS plus sodium sulfate added at 2% of DM to achieve a high sulfate (0.7% S; HS) pellet. Steers were blocked to pairs by modification status and BW and pair-fed between treatments. The HS steers were fed 110% of the previous day's intake of pellets and the LS steers were pair-fed 105% of their HS counterpart. All steers were fed chopped bromegrass hay at 5% of pellet intake. Steers were adapted to metabolism crates for 4 d, stepped up to a high concentrate diet for 7 d, and after an additional 7 d ad libitum intake period apparent mineral absorption and retention were determined over 5 d in which all urine, feces, and orts were collected. By design, DMI did not differ ($P = 0.55$) between treatments during the collection period (5.8 and 5.6 kg, for LS and HS, respectively). Apparent absorption of Cu was greater ($P < 0.05$) in LS (34.5%) compared with HS (17.9%). Apparent absorption of Mn was also greater ($P < 0.05$) in LS steers (20.4%) vs. HS steers (10.1%); however, apparent absorption of Zn did not differ ($P = 0.17$; 17.3 vs. 12.1% for LS and HS, respectively). These data suggest that high dietary S cannot only negatively affect absorption of Cu but also absorption of Mn, and because both of these minerals are essential to antioxidant enzymes long-term feeding of high S diets may increase the risk of oxidative stress in cattle.

Key Words: cattle, copper, manganese

403 Comparison of receiving strategies on feedlot performance in beef calves at weaning. K. L. Neuhold*[1], J. K. Ahola[1], C. W. Shonk[1,2], T. E. Engle[1], and J. J. Wagner[1,3], [1]*Colorado State University, Fort Collins,* [2]*Agriculture, Research, Development and Education Center, Wellington, CO,* [3]*Southeast Colorado Research Center, Lamar.*

One hundred twenty-four newly weaned Angus, Hereford, and Angus × Hereford bull and heifer calves (initial BW = 233 ± 14.9 kg) were utilized to evaluate the effects of 2 feedlot receiving management strategies at Colorado State University's Agriculture, Research, Development and Education Center in Wellington, CO on feedlot performance over the first 30 d upon arrival to the feedlot. Cattle were blocked by sex and stratified by weight, breed, and age, and assigned to one of 14 pens (8 - 10 head/pen). Pens were then assigned to one of 2 dietary treatments. Dietary treatments included: 1) dried distiller's grain-based total mixed ration (TMR) initiated upon arrival (DDG), or 2) long-stem grass hay followed by a TMR containing no DDG (HAY). Calves receiving the HAY treatment received only grass hay for the first d after arrival, long stem grass hay and TMR combination the following 2 d, and a grain-based TMR on d 4. Beginning on d 4, calves across all treatments were fed once a d and had access to iso-caloric and iso-nitrogenous diets. Calves were weighed on d 0 and 30, and DMI was determined daily. Initial BW was similar ($P = 0.99$) across treatments; however, d 30 BW was greater ($P < 0.001$) for DDG vs. HAY calves. As a result, ADG was greater ($P < 0.001$) for DDG vs. HAY calves (0.59 vs. 0.41 ± 0.042 kg/d, respectively). Gain-to-feed ratio was greater ($P < 0.05$) for DDG vs. HAY calves (0.22 vs. 0.17 ± 0.013, respectively), and feed-to-gain ratio tended ($P = 0.05$) to be greater in HAY vs. DDG calves. Daily DMI tended ($P = 0.06$) to be greater in DDG vs. HAY calves (2.70 vs. 2.35 ± 0.256 $kg \cdot hd^{-1} \cdot d^{-1}$, respectively). In summary, providing a DDG-based receiving ration to newly weaned calves upon arrival to the feedlot resulted in greater feed intake, gain, and feed efficiency over a 30 d period than traditional long-stemmed grass hay followed by a non-DDG TMR.

Key Words: feedlot performance, receiving diet, weaning

404 Determining the influence of dietary NDF concentration from bromegrass hay on performance of steers fed high sulfur diets. S. J. Morine,* M. E. Drewnoski, and S. L. Hansen, *Iowa State University, Ames.*

Feedlot cattle are often fed co-products from ethanol production that are rich in protein and energy but high in sulfur (S). Excess sulfate, when fed to ruminants, is reduced to sulfide by ruminal bacteria. Rumen sulfide can be converted to hydrogen sulfide (H_2S) in a pH dependent process. Elevated ruminal H_2S has been correlated to S toxicity. The objective of this study was to determine the effect of feeding 5 dietary concentrations of NDF from chopped bromegrass hay (66% NDF) on cattle performance, rumen pH, and H_2S concentration of steers fed a high S diet. One hundred fifty steers (359 ± 4.9 kg) were fed 1 of 5 diets that included 3.5, 5.7, 7.9, 10.1, or 11.4% added roughage NDF (rNDF) from bromegrass hay and contained 0.5% dietary S, from a combination of distillers grains and condensed corn solubles. In all diets hay was added at the expense of corn. Steers were blocked by weight into pens of 5 and then randomly assigned within block to 1 of the 5 treatments (n = 6 pens per treatment). Effective NDF was linearly increased ($P < 0.01$) with increased inclusion of rNDF. The addition of roughage did not appear to negatively affect cattle performance as ADG did not differ ($P = 0.55$) between treatments (2.01 ± 0.05 kg/d). Intake linearly increased ($P = 0.02$) with the increased inclusion of rNDF and gain to feed was linearly decreased ($P = 0.01$) with the increased inclusion of rNDF. At 6 h post-feeding ruminal H_2S concentrations were linearly decreased ($P < 0.01$; 7365, 6290, 5568, 5148, and 4528 ppm for 3.5, 5.7, 7.9, 10.1, and 11.4% rNDF, respectively) and pH was linearly increased ($P < 0.01$; 5.48, 5.64, 5.75, 5.75 and 5.79 for 3.5, 5.7, 7.9, 10.1, and 11.4% rNDF, respectively) by the increased inclusion of rNDF. Ruminal pH and H_2S data were negatively correlated ($R = -0.48$; $P < 0.01$). The results of this study suggest that inclusion of hay up to 11.4% rNDF will not decrease cattle gain and will manage the ruminal pH and decrease H_2S concentrations, thus reducing the risk of S toxicity.

Key Words: cattle, roughage, sulfur

405 Effects of method of forage finishing and cattle breed on growth performance, carcass characteristics, meat quality, and fatty acid composition. L. Shepherd*[1], R. Berthiaume[2], C. Lafreniere[3], C. Campbell[1], L. Pivotto[1], and I. Mandell[1], [1]*Department of Animal and Poultry Science, University of Guelph, Guelph, ON, Canada,* [2]*Agriculture & Agri-Food Canada, Sherbrooke, QC, Canada,* [3]*Agriculture & Agri-Food Canada, Kapuskasing, ON, Canada.*

Three methods of forage finishing (pasture, silage, hay) were used to evaluate growth performance, carcass traits, meat quality, and fatty acid composition relative to a grain finished product. 100 Angus (AN) and 100 Hereford (HE) steers were allocated to 2 research stations (each station feeding 50 head from each breed), with one location evaluating alfalfa (Alf) forages while the other station evaluated grass forages.

Regardless of location, growth performance (total gain, average daily gain, feed:gain) and carcass traits (hot carcass weight (HCW), backfat depth) were greater ($P < 0.03$) for cattle fed a high grain (HG) diet vs. forage finishing. Feeding the HG diet decreased ($P < 0.03$) lean yield vs. forage finishing. Within forage treatments, gains were greater ($P < 0.03$) for pasture vs. conserved forages due to poor nutritional quality for the hays at either location. Carcass traits were similar ($P > 0.40$) across method of forage finishing Alf, apart from lower ($P < 0.09$) HCW for conserved forages vs. pasture finishing. Carcass traits were similar ($P > 0.19$) between grass pasture- and grass silage-fed cattle, while no steers fed grass hay were slaughtered due to poor performance. A trained taste panel found HG beef to be more tender ($P < 0.09$) vs. cattle fed Alf and numerically more tender ($P > 0.12$) vs. cattle fed grass forages Forage finished beef (Alf or grass) had less beef flavor ($P < 0.02$) and increased off flavor ($P < 0.01$) vs. HG beef. Palatability traits were generally similar across method of forage finishing. Omega 3 fatty acids and PUFA were greater ($P < 0.001$) in forage finished vs. HG beef. Linolenic acid content was higher ($P < 0.013$) in grass and Alf finished beef vs. HG beef. Generally, no breed differences existed in palatability traits at either location. Linolenic acid levels were greater ($P < 0.001$) in beef from cattle fed conserved Alf vs. Alf pasture. While palatability traits may be similar regardless of method of forage finishing, differences in fatty acid levels across method of forage finishing may affect nutrient composition claims about grass-fed beef.

Key Words: beef cattle, forage finishing, palatability traits

406 Evaluation of weight gain pattern between 7 and 18 months of age of Hereford heifers and reproductive performance when mated at 18 months of age.

J. B. G. Costa Junior*[1], J. O. J. Barcellos[1], J. C. Whittier[2], I. D. P. S. Diaz[3], L. Canellas[1], V. Peripolli[1], J. K. Ahola[2], and R. K. Peel[2], [1]*Universidade Federal do Rio Grande do Sul, Porto Alegre, Rio Grande do Sul, Brazil,* [2]*Colorado State University, Fort Collins,* [3]*Universidade Estadual Paulista, Jaboticabal, Sao Paulo, Brazil.*

The objective of this study was to evaluate the average ADG, BW, rump fat thickness (RFT) and pregnancy rate in Hereford heifers at 18 mo of age originated from a commercial cattle herd at a facility in state Rio Grande do Sul, Brazil. Three different levels of ADG (high - H, moderate - M and low - L) with 3 different combinations (LHM; HLL; MMH) were considered. These ADG levels were applied between 7 to 12 mo (P12); 12 to 15 mo (P15) and 15 to 18 mo of age (P18). The heifers were mated by natural service without synchronization of estrus for 60 d. Used to the LHM, MMH, and HLL treatments 65, 58, and 60 heifers respectively. The overall pattern of gain during the study period was different for each treatment. The animals had the same initial (171 kg) and final (312 kg) BW. The heifers submitted to the HLL treatment presented higher gains than the rest ($P = 0.09$). These animals probably presented compensatory growth. The heifers in MMH treatment, which had the highest BW at 12 mo of age, also had higher pregnancy rate than the heifers in LHM treatment. At the beginning of mating BW was similar between both MMH and LHM treatments. The combination of the BW gain in the winter (19.5 kg during 148 d or ADG of 0.131 kg/d) allowed compensatory gain in the spring and high BW gain before mating which were the factors that determined the highest pregnancy rate (94.8%) in heifers of the MMH treatment. The MMH treatment also had the highest BW (315 kg) at the end of post-weaning period. At the beginning of the mating, the RFT was different among the treatments. The pregnancy percentage was higher for heifers the MMH treatment, which had higher RFT associated with the intermediary BW gain at the beginning of the experimental period P12. The RFT at the beginning of the mating did not differ among heifers in the MMH and LHM treatments (2.19 and 1.96mm, respectively) and heifers in the HLL treatment (1.53mm) it was low, ($P < 0.05$) indicating that the backfat thickness at the mating was accumulated lately during the rearing and the fat precociously deposited during P12 could be mobilized. Considering the observed results, the MMH sequence of body weight gain between the 7 and 18 mo of age increased the pregnancy rate and the RTF of heifers mated at the age of 18 mo.

Key Words: body weight, pregnancy rate, rump fat thickness

407 Evaluation of feed efficiency and feeding behavior traits in performance tested bulls.

J. G. Moreno*[1], G. E. Carstens[1], D. Crews Jr.[2], L. O. Tedeschi[1], L. R. McDonald[3], and S. Williams[3], [1]*Texas A&M University, College Station,* [2]*Colorado State University, Fort Collins,* [3]*Midland Bull Test, Columbus, MT.*

Objectives of this study were to characterize feed efficiency traits and examine phenotypic relationships with feeding behavior traits in bulls. Performance, feed intake and feeding behavior traits were measured in bulls (n = 5,073) representing 11 breeds (3,335 Angus). Intake and feeding behavior traits were measured for 70 d using a GrowSafe system while fed a corn silage based diet (ME = 2.42 Mcal/kg DM). BW was measured at 14-d intervals. Residual feed intake (RFI) was calculated as the difference between actual DMI and that expected from regression of DMI on mid-test $BW^{0.75}$ (MBW) and ADG, and residual gain (RG) as the difference between actual ADG and that expected from regression of ADG on MBW and DMI. Both models included fixed effects of trial (n = 12) and breed. A 2-population distribution model was fit to $\log_{10}$-transformed interval lengths between bunk visit events to estimate meal criterion, and compute meal traits. As expected, RFI was correlated with DMI ($r = 0.52$, $P < 0.0001$) but not MBW or ADG, whereas, RG was correlated with ADG ($r = 0.72$, $P < 0.0001$) but not MBW or DMI. RFI was positively correlated with F:G ($r = 0.35$, $P < 0.0001$) and negatively correlated with RG ($r = -0.44$, $P < 0.0001$). Initial BW was weakly correlated with F:G ($r = 0.15$, $P < 0.0001$) and RG ($r = -0.11$, $P < 0.0001$) but not RFI, indicating that lighter bulls were more efficient based on F:G and RG. Feeding bout (FB) frequency and duration were correlated with RFI ($r = 0.30, 0.26$; $P < 0.001$), but were not significant or weakly correlated ($r < 0.10$) with RG and F:G. Meal criterion and duration were both correlated ($r = -0.07, 0.18$; $P < 0.0001$) with RFI, but not with RG or F:G. Bulls with low RFI spent less time at the feed bunk (118 vs 133 ± 0.80 min/d) and had fewer FB events (75 vs 89 ± 0.6 events/d) then high-RFI bulls. Low-RFI bulls had longer ($P < 0.001$) meal criterion (11.3 vs 10.6 ± 0.2 min) indicating they took longer to initiate new meals, and had longer meal durations (216 vs 233 ± 1 min/d) than high-RFI bulls. Bulls have distinctive feeding behavior patterns that contribute to between-animal variation in RFI. However, feeding behavior traits were not associated with between-animal variance in F:G or RG.

Key Words: feeding behavior, residual feed intake, residual gain

408 Ergot alkaloids decrease rumen epithelial blood flow.

A. P. Foote*[1], N. B. Kristensen[2], J. L. Klotz[3], D. H. Kim[1], A. F. Koontz[1], K. R. McLeod[1], L. P. Bush[1], and D. L. Harmon[1], [1]*University of Kentucky, Lexington,* [2]*Syddansk Kvæg, Vojens, Denmark,* [3]*USDA-ARS, FAPRU, Lexington, KY.*

Ergot alkaloids induce vasoconstriction of peripheral and core body vasculature resulting in altered blood flow. An experiment was conducted to determine if ergot alkaloids affect blood flow to the absorptive surface of the rumen. Steers (n = 8) were pair-fed alfalfa cubes at 1.5 × NE_m and received ground endophyte-infected tall fescue seed (E+; 0.015 mg ergovaline·kg $BW^{-1}·d^{-1}$) or endophyte-free tall fescue seed (E-) via rumen cannula 2 × daily for 7 d at thermoneutral (TN; 21°C) and heat stress (HS; 32°C) conditions. On d 8 the rumen was emptied and rinsed with tap water and saline. Buffer containing VFA was incubated in the following sequence: control (CON), 0.015 mg ergovaline/kg BW (1 × EXT), and 0.045 mg ergovaline/kg BW (3 × EXT). Ergovaline in the buffer was supplied as a seed extract solubilized in methanol. For each buffer treatment there were 2 30-min incubations; a 30 min incubation of a treatment buffer with no sampling followed by removal of the buffer and incubation of an identical sampling buffer with the addition of Cr-EDTA and D_2O. Epithelial blood flow was estimated as ruminal clearance of D_2O corrected for influx of physiological water and liquid outflow. Feed intake data was analyzed as a CRD. Blood flow data was analyzed as a split plot with a whole plot factorial of seed and temperature and buffer treatment was the subplot factor using a mixed model. Feed intake decreased with dosing E+ at HS but not at TN ($P = 0.016$). Seed treatment did not affect rumen epithelial blood flow ($P = 0.73$). Inclusion of the seed extract in the buffer caused a 50% reduction in epithelial blood flow ($P < 0.0001$) but there was no difference between 1 × EXT and 3 × EXT ($P = 0.53$). The 3 × EXT tended to reduce blood flow more at TN than HS ($P = 0.11$). Chronic exposure to ergot alkaloids through dosing steers with E+ seed did not alter rumen epithelial blood flow. However acute exposure through inclusion of ergot alkaloids in the washed rumen buffer did decrease rumen epithelial blood flow indicating that gut vasculature responds to acute alkaloid exposure and nutrient absorption could be decreased.

Key Words: blood flow, washed reticulorumen

409 Feeding distillers grains as an energy source to gestating and lactating beef heifers: Effect on feedlot performance, carcass characteristics, and glucose tolerance of steer progeny.

P. J. Gunn*[1], G. A. Bridges[2], R. P. Lemenager[1], and J. P. Schoonmaker[1], *[1]Department of Animal Sciences, Purdue University, West Lafayette, IN, [2]North Central Research and Outreach Center, University of Minnesota, Grand Rapids.*

Angus-cross beef heifers pregnant to a single sire (n = 80) were used to assess the effects of feeding dried distiller′s grains with solubles (DDGS) as an energy source during late gestation and early lactation on feedlot performance, carcass characteristics, and glucose tolerance of male progeny. From 192 d of gestation through 118 ± 0.2 d of lactation, dams were fed either a control diet of corn silage and haylage (CON; 10% CP prepartum; 11.8% CP postpartum) or corn stover and DDGS (DG; DDGS at 1.2% BW per d; 15.7% CP) diet. Male progeny (n = 36) were weaned, commingled, and started on a step-up diet at 186 ± 0.2 d of age. At 210 ± 0.2 d of age, steers were placed in individual pens and fed a diet devoid of DDGS (12.7% CP, 1.36 kcal/kg NEg on DM basis) once daily for ad libitum consumption. Steer weights and back fat measurements via ultrasound were recorded on 21-d intervals. At 520 ± 38 kg, a subsample of 20 steers was selected for intravenous glucose tolerance testing (IVGTT). Steers were harvested at a common 12th rib fat depth of 1.41 ± 0.22 cm. Carcass characteristics were determined following a 72-h chill. Categorical and continuous data were analyzed with the GLIMMIX and MIXED procedures of SAS, respectively. Weaning wt, feedlot entry wt, slaughter wt, slaughter frame score, days on feed, and feedlot performance parameters including ADG, DMI, and G:F did not differ due to maternal diet ($P \geq 0.11$). Steer IVGTT parameters including fasted, average, and peak glucose and insulin concentrations, and area under the curve did not differ ($P \geq 0.24$) between treatments. Furthermore, HCW, back fat, LM area, KPH, yield grade, marbling score, quality grade, and proportion of Certified Angus Beef carcasses did not differ ($P \geq 0.18$) between treatments. Dressing percent, however, tended to be greater ($P = 0.08$) in DG (59.2%) than CON (58.5%) progeny. In summary, feeding DG at 1.2% of BW per d to first-parity heifers did not affect post-weaning performance, carcass characteristics or glucose tolerance of steer progeny.

Key Words: DDGS, developmental programming, steer

410 Effects of roughage concentration in dry-rolled corn-based diets containing wet distillers grains with solubles on performance and carcass characteristics of finishing beef steers.

K. E. Hales* and H. C. Freetly, *USDA, ARS, US Meat Animal Research Center, Clay Center, NE.*

Distillers grains and distillers solubles are by-products of grain fermentation used to produce ethanol and contain relatively high concentrations of NDF and ADF compared with other grains and concentrates it replaces in feedlot diets. Typical finishing diets in the US contain 8.3 and 9.0% roughage in the summer and winter months, respectively. Therefore, it is plausible that the dietary concentration of roughage can be altered when distillers grains are included in feedlot diets. The effects of roughage concentration in dry-rolled corn-based diets containing wet distillers grains with solubles (WDGS) were evaluated in MARC II steers (n = 128, initial BW = 339 ± 6.51 kg) using Calan gates. Diets consisted of 25% WDGS and the balance being dry-rolled corn and coarsely ground alfalfa hay (AH) replacing corn at 2 (AH-2), 6 (AH-6), 10 (AH-10), and 14% (AH-14) of dietary dry matter. Daily feed offered was recorded, feed refusals were measured weekly, and BW was measured on d 0, 1, 35, 70, 105, 140, 174, and 175. At harvest, camera data were collected. The data were analyzed using the Mixed procedure of SAS. The fixed effect of treatment was included in the model. Decreasing concentrations of AH in the finishing diet resulted in no differences in final BW ($P = 0.18$), but a tendency for ADG ($P = 0.06$) to be greater when steers were fed intermediate concentrations of AH (6 and 10%) than AH-2 and AH-14. Steers consuming AH-2 had a lower DMI ($P = 0.04$) than steers consuming AH-6, AH-10, or AH-14; whereas, G:F was greater for steers consuming AH-2, AH-6, and AH-10 than AH-14 ($P < 0.01$). Concentration of AH in the finishing diet did not affect HCW, LM area, marbling score, or the proportion of cattle grading USDA choice ($P \geq 0.32$); however, dressing percent was greater for steers fed AH-2 and AH-14 than AH-6 and AH-10 ($P = 0.04$). Results indicate that decreasing AH to 2% in a finishing diet based on dry-rolled corn with WDGS may not affect ADG, but does decrease DMI which results in an increased G:F. USDA is an equal opportunity provider and employer.

Key Words: cattle, distillers grains, roughage

Ruminant Nutrition: Dairy Production III

411 Impacts of feeding a citrus extract on measures of heat stress, as well as production, of high producing dairy cows during summer heat. J. M. Soderstrom*[1], P. H. Robinson[1], and J. M. Clauzel[2], [1]*Department of Animal Science, University of California-Davis, Davis,* [2]*Phodé Laboratoires, Terssac, France.*

High somatic cell counts (SCC) in milk result from degraded mammary health and negatively affect animal performance and milk quality. Citrus by-products are high in antioxidants (i.e., vitamin C) and essential oils (e.g., limonene), both of which have positive effects on animal health. We determined effects of feeding an orange extract (OE) to high producing dairy cows on measures of heat stress as well as milk production and composition, including SCC. A replicated 2 × 2 Latin square experiment was conducted with two 28-d periods on a dairy farm near Hanford (CA) in summer 2011 with 4 high group pens (i.e., cows which had cleared the fresh pen but not yet confirmed pregnant), each with ~310 early lactation multiparity cows. Total mixed rations (TMR; based on alfalfa hay, almond hulls, canola meal, distillers dried grains with solubles, corn silage, corn grain and cottonseed, with 17% crude protein (CP), 5.4% fat, 33.4% neutral detergent fiber (NDF) and 13.4% starch were identical except for inclusion of orange extract (Veo Premium, Phodé, Terssac, France) at 4 g/cow/d in the treatment TMR (OE). Due to seasonally mild ambient temperatures (i.e., highs 31–34°C; lows 16–17°C), cows showed only mild heat stress. Feeding OE had no effect on indicators of heat stress (i.e., respiration rate, panting score, rump temperature) at anytime (i.e., 02:45, 09:15, 17:30). However at 02:45 h, a higher ($P < 0.01$) proportion of OE cows were lying (vs. standing) vs. control cows (68.6 vs. 53.7%), a possible indicator of reduced heat stress. DM intake (avg. 25.3 kg/d) and whole tract digestibility of organic matter (71.9%), CP (70.3%) and NDF (51%) did not differ between treatments. Milk production (avg. 47.3 kg/d) and composition (avg. 3.54, 2.86, 4.78% fat, true protein, lactose) also did not differ, and changes in body condition and locomotion score were not affected. However, SCC for OE cows was lower ($P < 0.05$) than control (160,000 vs. 196,000). Feeding this OE to high producing California cows during moderately hot summer weather decreased SCC with no effect on other aspects of performance or indicators of heat stress.

Key Words: limonene, vitamin C, SCC

412 Meta-analysis of the effects of dietary sugar on intake and productivity of dairy cattle. C. F. Vargas*[1], C. D. Reinhardt[1], J. L. Firkins[2], and B. J. Bradford[1], [1]*Kansas State University, Manhattan,* [2]*Ohio State University, Columbus.*

A meta-analysis was performed to determine the possible effects of dietary sugar on feed intake and milk production in lactating dairy cattle. The database used in this analysis included 18 treatment comparisons from 10 studies reported between 1985 and 2011. Treatment comparisons were used only if 1) either sucrose (n = 9) or molasses (n = 9) replaced corn grain without adding fat, and 2) sugar added by treatment ranged from 2 to 5% of DM. In addition, 1 study was excluded because the SD for DMI response was more than twice the mean SD across studies. The meta-analysis included studies analyzed by both fixed effects and mixed effects statistical models. To account for the differences in SEM reported for treatment means by these approaches, studies with repeated measures that used a mixed effects model were re-analyzed to estimate fixed effects model SEM; this approach allowed for consistent weighting across studies. The meta-analysis was conducted using a random effects model. First, responses to sucrose and molasses were compared using Cochran's Q statistic, and no evidence for heterogeneity across sugar sources was found in either DMI ($P = 0.25$) or ECM ($P = 0.59$) responses. Therefore, different sugar sources were pooled for the remaining analyses. In the final data set, ECM and DMI responses to added sugar were moderately correlated (r = 0.68, $P < 0.001$). No evidence of publication bias was observed for DMI, although for ECM, the trim and fill method suggested that 2 additional studies with negative responses would be required to generate a normal response distribution. The combined data included in this analysis showed that the addition of sugar tended ($P = 0.07$) to increase DMI by 0.38 kg/d (95% confidence interval: −0.04 to +0.80 kg/d). On the other hand, no effect was detected for ECM ($P = 0.34$; 95% confidence interval: −0.29 to +0.85 kg/d). In summary, results of this analysis suggest that the addition of 2 to 5% dietary sugar may promote small increases in DMI, but do not consistently increase ECM in lactating dairy cattle.

Key Words: lactation, molasses, sucrose

413 Potential use of specific milk fatty acids to predict enteric methane emissions from lactating dairy cows. K. E. DeLand,* M. Hollmann, J. C. Ploetz, W. J. Powers, D. K. Beede, and A. L. Lock, *Michigan State University, East Lansing.*

The ability to accurately predict methane emissions is valuable for the quantitative monitoring of environmental and management impacts of livestock production. Biomarkers such as milk fatty acids (FA) may be a useful tool for the prediction of enteric methane emissions from lactating dairy cows. This study assessed if there was a relationship between the concentration or yield of specific milk FA and enteric methane emissions. Methane emissions (by gas flux in environmentally controlled rooms) and lactation performance were measured from individual lactating Holstein cows fed a TMR with 0.0% (control), 1.3, 2.7, or 3.3% coconut oil, DM basis. Compared with control, daily methane emissions declined 3.2, 37.3, and 45.5% with increased coconut oil, respectively. Milk samples were obtained from 4 milkings (d 26 and 28 of the 35-d experiment). We evaluated the relationship between the concentration (g/100 g FA) and yield (g/milking) of individual milk FA and methane emissions for the 24-h period preceding each milking. Multiple regression analysis using forward selection criteria identified significant FA that predicted methane emissions. On a FA concentration basis, the overall coefficient of determination (CD) for methane output ($R^2 = 0.86$, $P < 0.05$) was due primarily to C18:1 12*c* ($R^2 = 0.78$, $P < 0.0001$), C18:1 9*t* ($R^2 = 0.05$, $P < 0.001$), and C16:1 *iso* ($R^2 = 0.03$, $P < 0.01$). On a FA yield basis, the overall CD for methane output ($R^2 = 0.90$, $P < 0.05$) was due primarily to C13:0 *iso* ($R^2 = 0.65$, $P < 0.0001$), C18:1 12*c* ($R^2 = 0.07$, $P < 0.01$), C15:0 *iso* ($R^2 = 0.07$, $P < 0.001$), C18:1 9*t* ($R^2 = 0.05$, $P < 0.001$), and C20:5 ($R^2 = 0.02$, $P < 0.05$). Concentration of C18:2 12*c* and yield of C13:0 *iso* also were important in explaining 12-, 36-, and 48-h methane emissions, with similar CD as found for 24-h methane emissions. Results confirm a positive relationship between enteric methane emissions and C15:0 *iso*. Importantly, results suggest for the first time that C18:1 12*c* and C13:0 *iso* may be important milk FA for prediction of enteric methane emissions in lactating dairy cows.

Key Words: dairy cows, methane emissions, milk fatty acids

414 Nitrogen concentration and source alter products from fermentation of glucose by mixed ruminal microbes. M. B. Hall,* *U.S. Dairy Forage Research Center, USDA-ARS, Madison, WI.*

Effects of N source and concentration on microbial fermentation products formed over time were evaluated. Replicated in vitro fermentations with mixed ruminal microbes were performed with 3 treatments (Ntrt): LoN (Goering and Van Soest media with 12% less N by removal of enzymic digest of casein; 0.337 g N/L), and HiNU (urea added) and HiNT (enzymic digest of casein added) both with 0.385 g N/L. Glucose (Glc) at 3 g/L was the carbohydrate substrate. Fermentation vessels were destructively sampled at 0, 0.25, 0.5, 0.75, 1, 2, and 3 h of fermentation. Data were analyzed as a randomized complete block design with the factors Ntrt, hour of fermentation (HR), the interaction, and fermentation run (random variable) in the model. Disappearance of Glc did not differ by Ntrt (Ntrt: $P = 0.92$; Ntrt x HR: $P = 0.85$) with residual Glc at < 6% of initial Glc by 2 h. Microbial N accumulation (indicative of microbial growth) differed by Ntrt x HR ($P = 0.05$) with LoN smaller than HiNU and HiNT at 2 h (2.19, 2.52, and 2.48 mg N, respectively), and LoN and HiNT greater than HiNU at 3 h (2.80, 2.69, and 2.48 g N, respectively; SED: 0.136). Microbial glycogen peaked at 2 h, then declined. Maximum glycogen mg detected were LoN:11.0, HiNU:10.7, and HiNT:10.1 (SED = 0.108; $P = 0.03$) with HiNT differing from HiNU and LoN ($P < 0.04$). Organic acid production differed among Ntrt at 0.25 and 0.5 h; mean organic acid concentrations for these 2 time points showed LoN and HiNU greater than HiNT (4.42, 4.25, and 2.83 mM, respectively; SED = 0.254; Ntrt: $P = 0.02$, Ntrt x HR: $P = 0.10$). Molar percentages of acetate, propionate, and butyrate did not differ for Ntrt or Ntrt x HR in this same time span ($P > 0.20$), however, yield of carbon in organic acids per Glc carbon that disappeared from the media differed for Ntrt ($P = 0.01$; SED = 0.004) and Ntrt x HR ($P < 0.01$; SED = 0.005) with least squares means values averaging 0.083, 0.085, and 0.062 for LoN, HiNU, and HiNT, respectively. Ntrt did not differ in maximal lactate concentrations ($P = 0.99$; LoN: 1.28, HiNU: 1.28; HiNT: 1.36 mM; SED = 0.709). The effect of N source and amount on microbial products may have implications as factors that could alter nutrient supply to the cow.

Key Words: nonfiber carbohydrate, protein, rumen fermentation

415 Interactions in rumen pool characteristics by dairy cows fed two concentrations of a novel co-product from corn wet milling with different forage sources. D. M. Shepherd*[1], J. L. Firkins[1], and P. von Behren[2], [1]*Department of Animal Sciences, The Ohio State University, Columbus,* [2]*Cargill Corn Milling, Blaire, NE.*

Increasing particle length or decreasing fragility should increase the density of the rumen mat, rumination time, and the retention time of particles in the rumen in part by trapping smaller particles. We used a novel corn wet milling co-product, termed Dairy Protein Product (DPP, coarse particle size and approximately 70% DM, 27.1% CP, 27.5% NDF, and 23.9% NSC) in diets formulated to contain 19.0% forage NDF, 17.4% CP, 20.2% starch, and 3.7% sugar. Six primiparous, rumen-cannulated Jersey cows were assigned to a 6x6 Latin square design with a 2 × 3 factorial arrangement of treatments in 6 periods of 3 wk (last week for data collection). We hypothesized for an interaction between 20 and 30% DPP with forage source (corn silage, CS, 46% NDF; CS replaced with 10% alfalfa hay, AH, 45% NDF; or CS with 7% grass hay, GH, 63% NDF). We expected that forage source would have minimal effect on production or rumen mat characteristics (from 2 rumen evacuations) when DPP was included at 20% of dietary DM, but when DPP was increased to 30%, we expected that CS+ AH would increase rumen mat consistency and associated ruminal fluid weight more than would CS alone but potentially less than CS+GH. Means were compared by pre-planned contrasts. There were no effects on production of milk or milk components, but DMI tended ($P = 0.10$) to increase when 20% DPP was included with CS and with reciprocal effects on fat-corrected milk/DMI. For CS only, DMI (16.1 vs. 14.8 kg/d) decreased ($P < 0.05$) when DPP was increased from 20 to 30% DPP; in contrast, rumen DM pool increased ($P < 0.05$) from 8.04 to 8.65 kg/d. Grass hay increased ($P < 0.05$) total and liquid pool size of rumen contents compared with AH (by 3.2 and 3.0 kg). No effects of ruminal pH were noted (averaging 5.99). In diets containing low starch (with 4% corn grain), increasing DPP from 20 to 30% requires more attention to interactions among forages with respect to fill, digestion, and passage of fiber.

Key Words: corn co-product, forage source, rumen pool

416 Fates of medium-chain fatty acids fed to lactating dairy cows. M. Hollmann*[1], M. S. Allen[1], T. H. Herdt[2,3], J. S. Zyskowski[3], K. M. Lebbin[1], J. P. Steibel[1], and D. K. Beede[1], [1]*Department of Animal Science, Michigan State University, East Lansing,* [2]*Department of Large Animal Clinical Sciences, Michigan State University, East Lansing,* [3]*Diagnostic Center for Population and Animal Health, Michigan State University, East Lansing.*

We examined fates of dietary saturated medium-chain fatty acids (FA; C8 through C14). Eight lactating Holstein cows were fed a TMR with either coconut oil (CNO) or Energy Booster (EB) supplemented at 3.35% of diet DM for 28 d in a crossover design. Concentrations of FA in rations were 0.6 or 0.0% C8:0, 1.8 or 0.1% C10:0, 13.9 or 0.3% C12:0, and 6.8 or 1.4% C14:0, for CNO or EB, respectively (total FA basis). Cows were fed ad libitum once daily at 1000 h. Rumens were evacuated and contents sampled 4 h post-feeding (d 26) and 2 h pre-feeding (d 28). Blood samples were obtained (d 17 to 20) before feeding and hourly post-feeding for 6 h. Data were analyzed by ANOVA with repeated measures. CNO reduced DMI 17% ($P < 0.001$), but did not affect weight or volume of ruminal contents. CNO resulted in reduced total FA concentration in ruminal contents, increased plasma concentration of total FA, and depressed milk fat yield (d 22 to 25) compared with EB ($P < 0.01$). CNO vs. EB increased ruminal concentrations of C8:0 and C10:0 post-feeding ($P < 0.001$), but not pre-feeding. Although apparent total tract digestibilities of these FA were nearly complete (>98%), their respective yields in milk were reduced ($P < 0.001$) and plasma concentrations were minute in CNO-fed cows. Amounts of C12:0 and C14:0 in rumen contents were greater with CNO than with EB ($P < 0.01$). Ruminal turnover rates per h were > 100% for C8, 58% for C10, 5.8% for C12, and 4.8% for C14 in CNO-fed cows. CNO increased C12:0 and C14:0 concentrations in plasma and in milk fat compared with EB. Yet, milk fat yield of C14 decreased with CNO. Apparent transfer from diet (CNO) to milk was 57% for C12 and 187% for C14. Disappearance of C8 and C10 (not accounted for in ruminal contents, plasma, feces, or milk) suggests rapid absorption and oxidation. Ruminal turnover rate and apparent total tract digestibilities of FA decreased with increased chain length from C8 to C14. Increased conversion of C14 vs. C12 into milk FA and greater increase of C14 vs. C12 in plasma FA indicate reduced uptake of C14 by extra-mammary tissue. Results suggest large differences in fate among medium-chain FA fed to lactating cows.

Key Words: β-oxidation, digestibility, partitioning

417 The effect of rumen digesta inoculation on the time course of recovery from diet induced milk fat depression in dairy cows.

D. E. Rico,* Y. Ying, A. R. Clarke, and K. J. Harvatine, *Penn State University, University Park.*

The predominant pathway and rate of ruminal biohydrogenation is dependent on the rumen environment and microbial population. Ten ruminally cannulated cows were used in a crossover design that investigated the effect of rumen digesta inoculation from non-milk fat depressed cows on recovery from diet induced milk fat depression. Two additional cows fed a control diet (32% NDF, no supplemental PUFA) were used as rumen digesta donors. MFD was induced from d 1 to 10 of each period by a low fiber and high oil diet (27% NDF and 3.0% soybean oil). On d 11 all cows were switched to the control diet treatment (trt) was no inoculation and ruminal inoculation (Inoc) with 8 kg of donor cow digesta/d from d 11 to 16. Milk yield and composition were measured every 3 d from d 10 to 28. Data were analyzed using repeated measures. The model included period, sequence, and cow nested in sequence as random effects and trt, d on diet, trt × d, and a covariate (d10 value) as fixed effects. Day was the repeated variable and cow × period was the subject. Second, a random regression model that included the random effect of cow and period, and the fixed effect of trt and trt × d, and trt × d^2 interactions were used for analysis of the rate of recovery. Both milk fat concentration and yield increased progressively during the recovery phase and trt were not different at any time points. However, in the regression analysis, there was an effect of trt and trt × d and trt × d^2 interactions for fat concentration and an effect of trt and a trt × d interaction for fat yield (All $P < 0.01$). The best fit predictions for milk fat concentration for the Con and Inoc were $1.55 + 0.161 \times d+(-0.003) x d^2$ and $0.56+0.253 \times d+(-0.005) \times d^2$, respectively. The concentration of milk fatty acids less than 16 carbons increased progressively in both trt and was higher for Inoc than Con on d 16. In contrast, milk fat concentration of *trans*-10 C18:1 and *trans*-11 C18:1 decreased progressively and was not affected by trt. Under the conditions of the current experiment, ruminal inoculation from non-milk fat depressed cows modestly accelerated the rate of recovery from diet induced milk fat depression.

Key Words: milk fat depression, biohydrogenation, CLA

418 Effect of carbohydrate conformation in hulless barley (*Hordeum vulgare* L.) on in situ rumen and in vitro intestinal nutrient availability.

L. Yang*[1,3], J. McKinnon[1,3], D. Christensen[1,3], B. Rossnagel[2,3], A. Beattie[2,3], and P. Yu[1,3], [1]*Department of Animal and Poultry Science*, [2]*Crop Development Centre*, [3]*University of Saskatchewan, Saskatoon, SK, Canada.*

Hulless barley breeding lines varying in amylose (1 to 20% DM), amylopectin (34 to 51% DM), amylose to amylopectin ratio (Ay:Ap) (0.02 to 0.59) and β-glucan content (5 to 10% DM) have been developed at the Crop Development Centre, University of Saskatchewan. The objective of this study was to determine the effect of these new hulless barley lines (zero-amylose waxy, CDC Fibar; 5%-amylose waxy, CDC Rattan; normal-amylose, CDC McGwire and high-amylose, HB08302) on rumen degradation kinetics and in vitro intestinal nutrient digestion (CDC Copeland was included as a hulled control). Three dry Holstein cows fitted with rumen cannula were used for measuring rumen degradation of barley varieties. The estimation of intestinal digestion was determined by a modification of the 3-step in vitro procedure described by Calsamiglia and Stern with duplicate of each in situ residue. Among the hulless barley lines, HB08302 was greater ($P < 0.05$) in rumen bypass dry matter (BDM: 46.5 vs. 33.4% DM), rumen bypass starch (BST: 40.3 vs. 25.2% ST or 218 vs. 155g/kg DM) and reduced ($P < 0.05$) in effective degradability of dry matter (EDDM: 53.5 vs. 66.6% DM) and starch (EDST: 59.8 vs. 74.8% ST or 320 vs. 461 g/kg DM) compared with CDC Rattan. HB08302 was also greater ($P < 0.05$) in rumen bypass crude protein (BCP: 52.1% CP), effective degradability of neutral detergent fiber (EDNDF: 74 g/kg DM) and intestinal absorbable feed protein (IADP: 40.6% CP) but reduced ($P < 0.05$) in total digestible protein (TDP: 120 g/kg DM) than the other hulless barley lines. CDC Fibar showed greater ($P < 0.05$) effective degradability of crude protein (EDCP: 90 g/kg DM) while CDC McGwire showed reduced ($P < 0.05$) TDP (116 g/kg DM). Compared with hulless barley, the hulled CDC Copeland showed relatively greater ($P < 0.05$) BNDF (62.5% NDF or 98 g/kg DM), starch degradation rate (K_d: 17.4%/h) and EDST (75.9% ST) but reduced ($P < 0.05$) BCP (49 g/kg DM), rumen undegradable protein (RUP: 55 g/kg DM) and TDP (102 g/kg DM). In conclusion, hulless barley lines with altered carbohydrate traits have the potential to increase rumen and intestinal nutrient availability to ruminants.

Key Words: amylose to amylopectin ratio, hulless barley, rumen degradation and intestinal digestion

419 Palmitic acid increased milk yield and feed efficiency across production level of lactating cows.

P. Piantoni,* A. L. Lock, and M. S. Allen, *Michigan State University, East Lansing.*

The objective of this experiment was to evaluate the effects of palmitic acid supplementation on feed intake, digestibility, and metabolic and production responses of dairy cows with a wide range of milk production (35 to 66 kg/d) in a crossover design experiment with a covariate period. Thirty-two multiparous Holstein cows (151 ± 66 DIM) were assigned randomly within level of milk yield to treatment sequence. Treatments were diets supplemented (2% of diet DM) with palmitic acid (PALM, 99% C16:0) or control (CONT, soy hulls). Treatment periods were 21 d with the final 4 d used for data and sample collection. No interactions were detected between treatment and milk yield when all cows received a common diet during the covariate period for any response variable. Compared with CONT, the PALM treatment increased milk yield (46.0 vs. 44.9 kg/d, $P = 0.04$), milk fat concentration (3.4 vs. 3.3%, $P = 0.01$) and yield (1.53 vs. 1.45 kg/d, $P = 0.001$), and 3.5% fat-corrected milk (FCM, 44.63 vs. 42.89 kg/d, $P < 0.01$). Treatment did not affect dry matter intake (DMI, $P = 0.96$), yield and concentration of protein and lactose in milk ($P > 0.12$), or body weight ($P = 0.58$). The PALM treatment increased feed efficiency (3.5% FCM/DMI, 1.61 vs. 1.55, $P < 0.0001$) and tended to decrease body condition score (2.93 vs. 2.99, $P = 0.06$) compared with CONT. Compared with CONT, the PALM treatment increased total tract digestibility of NDF (38.7 vs. 35.4%, $P < 0.001$) and OM (67.3 vs. 66.0%, $P < 0.01$). The PALM treatment increased plasma concentration of NEFA (101.4 vs. 90.0 μEq/l, $P < 0.0001$) and the ratio of insulin to glucagon (0.092 vs. 0.083, $P = 0.05$), and tended to increase plasma concentration of insulin (11.4 vs. 10.3 μIU/ml, $P = 0.07$). Results show that palmitic acid has the potential to increase yields of milk and milk fat as well as the conversion of feed to milk, independent of production level without increasing body condition score or body weight.

Key Words: feed efficiency, milk fat, palmitic acid

420 Palmitic acid increased the yield of milk fat and improved feed efficiency across production level of cows compared with stearic acid.

J. E. Rico,* M. S. Allen, and A. L. Lock, *Michigan State University, East Lansing.*

The effects of dietary palmitic (C16:0) and stearic (C18:0) acids on feed intake, yield of milk and milk components, and feed efficiency of dairy cows with a wide range of milk production were evaluated in an experiment with a crossover arrangement of treatments and a covariate period. A wide range of milk production (38 to 65 kg/d) was used to determine if response to fat supplementation varied according to production level. Thirty-two Holstein cows (143 ± 61 DIM) were assigned randomly to treatment sequence within level of milk yield. Treatments were diets supplemented (2% of diet DM) with palmitic acid (PA; 99% C16:0) or stearic acid (SA; 98% C18:0). Treatment periods were 21 d with the final 4 d used for sample and data collection. The corn silage and alfalfa haylage based diets were formulated to contain 29% NDF, 17% CP, and 5.7% crude fat. The statistical model included the random effect of cow and the fixed effect of treatment and period. No interactions were detected between treatment and level of milk production when all cows received a common diet during the covariate period for any response variable. Compared with SA, the PA treatment increased milk fat concentration (3.55 vs. 3.66%, $P < 0.01$) and yield (1.59 vs. 1.68 kg/d, $P < 0.001$), and 3.5% fat-corrected milk yield (45.56 vs. 47.46 kg/d, $P < 0.001$). Treatment did not affect DMI, milk yield, milk protein yield, body weight, or body condition score (all $P > 0.10$). Milk protein concentration was lower for PA compared with SA treatment (3.24 vs. 3.29%, $P < 0.01$). The PA treatment increased feed efficiency (3.5% fat-corrected milk yield/DMI) compared with SA (1.48 vs. 1.40, $P < 0.001$). Results demonstrate that palmitic acid is more effective than stearic acid in improving milk fat concentration and yield as well as efficiency of feed conversion to milk. Responses were independent of production level and without change in body condition score or body weight. Further studies are required to test the consistency of these responses across different types of diets.

Key Words: milk fat, palmitic acid, stearic acid

421 Linseed oil reduces methane emissions from grazing dairy cows.

T. M. Boland*[1], K. M. Pierce[1], J. D. Rowntree[1], D. A. Kenny[2], and A. K. Kelly[1], *[1]University College Dublin, Lyons Research Farm, Newcastle, Co. Dublin, Ireland, [2]Animal Bioscience Centre, Teagasc, Grange, Dunsany, Co. Meath, Ireland.*

Enteric methane accounts for approximately 50% of the total greenhouse gas emissions from the average Irish dairy farm as well as representing an energy loss to the animal. Lipid supplementation of the diet is an accepted mitigation strategy; however, the efficacy of individual oils is linked to their individual fatty acid composition. The objective of this study was to assess the effect of oils rich in polyunsaturated fatty acid (PUFA) on methane output, milk performance and rumen parameters of grazing dairy cows. Forty 5 Holstein Friesian cows were blocked on parity and allocated to 1 of 3 (n = 15) treatments, balanced for days in milk (mean 143 d ± 22) and pre-experimental milk yield (mean 24.6 l ± 4.8) in a randomized block design study. All animals had a daily grass allocation of 17kg dry matter (DM) plus 4kg of concentrate DM containing either 160g/kg FW of stearic acid (CO), soy oil (SO) or linseed oil (LO). Individual methane emissions were measured using the SF6 technique at 17 (PI) and 44 (PII) days post dietary introduction. Individual rumen samples were collected on d 22 and 49 for volatile fatty acid (VFA) and ammonia (NH3) analysis. Data were analyzed using the least squares procedures using the MIXED procedure of SAS. The statistical model used included the fixed effects of treatment, period and parity and appropriate interactions. Pre-experimental milk yield and days in milk were included in the model as covariates. Supplementary LO reduced ($P < 0.001$) methane emissions per kg of milk and milk solids produced compared with the CO or SO diets. Dietary LO reduced methane emissions per kg of dry matter intake ($P < 0.01$) compared with the SO diet. Dietary LO and SO supplementation increased ($P < 0.001$) milk yield and milk protein yield and had no effect on milk fat yield ($P < 0.001$) compared with the CO diet. Dietary PUFA supplementation reduced total rumen VFA concentrations ($P < 0.001$), NH3 concentrations ($P < 0.001$) and molar proportion of butyrate ($P < 0.001$) in the rumen. Dietary LO supplementation has the capacity to substantially reduce enteric methane emissions from grazing dairy cows while maintaining or enhancing milk production and composition.

Key Words: dairy cows, linseed oil, methane

422 Effects of different protein supplements on AA availability in dairy cows.

G. Maxin,* D. R. Ouellet, and H. Lapierre, *Dairy and Swine Research and Development Center, Agriculture and Agri-Food Canada, Sherbrooke, QC, Canada.*

Canola meal (CM) or by-products of ethanol production (dried distillers grain, DDG) may offer an economical alternative to soybean meal (SBM) in North American dairy rations. Several studies have shown that these protein sources can effectively replace SBM, but few studies have focused on the AA availability. The objective of this study was to determine the effects of replacing SBM by either CM, high protein corn DDG with solubles (HPDDG) or wheat DDG with solubles (WDDG) on the availability of 3 AA: His, Lys and Met. Eight Holstein cows were used in a replicated 4 × 4 Latin square with 14-d periods. Cows were fed isoN (17.4%CP) diets formulated to slightly exceed energy and protein requirements (NRC, 2001) which contained 38% grass hay and 62% corn-based concentrate including either SBM, CM, HPDDG or WDDG as the protein source. The AA availability was estimated using the variation of whole body (WB) irreversible loss rate (ILR) of each AA, determined by the isotope dilution technique (Borucki Castro et al. 2008, Animal 2:224). A pulse dose of L-[$^{15}N_3$]His (0.18 g), L-[1-^{13}C]Met (0.12 g) and L-[α-^{15}N]Lys (0.55 g) was administered into one jugular vein. Blood samples were then collected from the other jugular vein at 1, 2, 3, 4, 5, 6, 7, 8, 9, 10, 13, 16, 19, 25 and 31 min after the bolus injection to determine AA enrichments. The procedure was repeated at the end of the main study following a 7-d continuous abomasal infusion of Lys (70g/d) and Met (20g/d) with cows fed the SBM diet. As required by this technique, DMI, milk and milk protein yields were not affected by treatments and averaged 23.7, 31.4 and 1.14 kg/d. Preliminary results showed no difference in the WB ILR of Met and His among the treatments (122.1 ± 7.6, 128.4 ± 6.2 g/d), suggesting a similar availability of these 2 AA across diets. WB ILR of Lys was numerically ($P = 0.20$) higher with CM (352 g/d) and lower with HPDDG (291 g/d) than with SBM and WDDG (325 and 319 g/d). In comparison with the SBM diet, Lys and Met infusions increased ($P < 0.05$) Lys and Met WB ILR by 62.2 ± 30.5 and 24.8 ± 14.5 g/d, respectively, indicating that the above method is reliable to determine changes in AA availability.

Key Words: amino acids, dairy cow, protein sources

Small Ruminant: Nutrition and Parasites

423 Nitrogen balance of growing West African Dwarf ewe fed Mexican sunflower leaf meal based diets. A. H. Ekeocha,* *University of Ibadan, Ibadan, Oyo, Nigeria.*

After a previous 84-d performance phase, a study was conducted using 16 West African Dwarf (WAD) ewes. Ewes (Initial BW 17.5 ± 0.19kg) were used in a completely randomized design to study the effects of increasing level of Mexican sunflower leaf meal (MSLM) on nitrogen balance. The experimental animals were assigned to 4 treatment groups A (O%MSLM), B(15%MSLM), C (30%MSLM) and D (45%MSLM) of 4 replicates each and were fed with grass (*Panicum maximum*) plus concentrate diet mixture of Mexican sunflower leaf meal (MSLM) and wheat bran (WB) such that 0%, 15%, 30% and 45% of WB was replaced by weight with MSLM gravimetrically. About 60% of the diet came from the concentrate while 40% came from grass. The experiment lasted for one week. Digestibility was determined using a 6-d total urine and fecal collection. Ewes were given ad libitum access to feed and water and routine vaccination and medication followed standard procedures. Parameters measured were nitrogen intake (NI), nitrogen balance (NB), nitrogen apparent digestibility (NAD) and nitrogen retention(NR). Data were analyzed using descriptive statistics and ANOVA. Concentrate DMI (CDMI) ranged from 181.8 g/d (45%MSLM) to 536.8 g/d (15%MSLM) and grass DMI (GDMI) ranged from 130.6 g/d (0%MSLM) to 215.9 g/d (30%MSLM) and this was significant ($P < 0.05$). Positive NB was observed for animals on all treatments. This suggested that the various diets were able to meet the protein need of the animals for maintenance and production. Urinary nitrogen g/d was greater ($P < 0.05$) with increasing inclusion of MSLM in the ration while protein retention increased from treatment A (0%MSLM) to treatment B (15%MSLM) (90.4 - 90.8%) and subsequently decreased from treatment B (15%MSLM) to D (45%MSLM) (90.8 - 85.0%). Data obtained for N- balance in this study ranged from 6.28 – 15.0 g/d. Animals on treatment B (15.01g/d) had the greater N-balance, and this was significantly ($P < 0.05$) greater compared with animals on treatment D (6.28g/d) but numerically more ($P > 0.05$) than observed values for animals on treatments C (9.05g/d) and A (9.32 g/d). This suggested that the fermentable OM in the WB apparently encouraged greater N digestibility and it is an indication that a favorable energy: N balance resulted from diet B. This trend was the same for nitrogen intake (7.39 – 16.5g/day) and absorbed (6.36 – 15.1 g/d). Nitrogen balance was positively related to DMI and N intake. The overall regressions were NB = 2.39 + 0.07 DMI; $R^2 = 0.93$, ($P = 0.37$) and NB = 0.72 +0.91 NI; $R^2 = 0.99$, ($P = 0.13$). This study showed that a greater level of NI and DMI improved ($P < 0.05$) N-balance. The low level of nitrogen balance in animals on treatment D could have been due to the level of feed intake. Mexican sunflower leaf meal incorporation in the diets of sheep improved nitrogen intake, balance and retention.

Key Words: nitrogen balance, West African dwarf ewe, Mexican sunflower leaf meal

424 Excess iodine intake by the ewe in late pregnancy programs on the lamb for reduced immunoglobulin G absorption. T. M. Boland,* *University College Dublin, Lyons Research Farm, Newcastle, Co. Dublin, Ireland.*

The lamb is born hypoimmunocompetent as the placenta prevents the in utero transfer of antibodies from mother to offspring. Therefore, the lamb is dependent on the postnatal absorption of antibodies from colostrum to confer disease resistance in early life. Several maternal and nutritional factors influence this transfer, but perhaps none so dramatically as high level iodine intake by the pregnant ewe in late gestation. Several studies were conducted over several years with the objective of determining the mechanisms involved in the reduced antibody transfer following high level iodine supplementation. This abstract represents a synthesis of these studies to better describe this phenomenon. The lamb's ability to absorb colostral immunoglobiulin G (IgG) is greatly impaired by high (11 to 40 mg/ewe/day) level iodine intake by the pregnant ewe during the last 6 weeks of pregnancy. While these levels of intake are in excess of requirements they do represent the voluntary iodine intake of ewes when offered free access mineral blocks. Vitamin E absorption from colostrums is affected in a similar manner. The response to this high level iodine intake is rapid with supplementation during the final 2 weeks of pregnancy sufficient to produce the response. A 2 week supplementation period earlier in pregnancy has no effect. This is a dose dependent response with greater reductions seen at higher levels of intake. The lamb is preprogrammed in utero for this effect and the quality or availability of colostral IgG is unaffected by iodine supplementation. In the small intestine, the primary site of IgG absorption there are alterations in mRNA expression of several genes, namely β2-microglobulin (B2M) and a lower expression of upstream stimulator factor 2 (USF2), interleukin-4 (Il-4) and thyroid hormone receptor β (THRβ) ($P < 0.05$) potentially mediated through alterations in thyroid hormone metabolism. These findings indicate the pathway involved in the observed reduction in IgG absorption and the need for a downward revision (to approximately 40% of current values) of the iodine toxicity levels for ewes during late pregnancy.

Key Words: iodine, IgG, lambs

425 Effects of different NFC/NDF ratios of TMR on ruminal pH and VFA in meat sheep. J. Liu,* Q. Y. Diao, Y. Tu, Y. G. Zhao, X. H. Gao, and L. H. Zhao, *Key Laboratory of Feed Biotechnology of Ministry of Agriculture/Feed Research Institute, Chinese Academy of Agricultural Sciences, Beijing, China.*

This study examined the effect of different NFC/NDF (nonfiber carbohydrates/NDF) ratios of TMR (total mixed ration) on ruminal pH and VFA in meat sheep. Twelve crossbred rams (Dorper♂ × Thin-tailed Han♀) fitted with ruminal cannulas and BW of 47.2 kg (±1.01 kg) at the start of trial were used in an incomplete 12 × 4 Latin square arrangement. Period length was 16 d, and the first 14 d of each experiment were for ration adaption, with sampling during d 15 to 16 of each period. The rams were fed rations with different NFC/NDF ratios, which the ratios were 0.25 (1), 0.34 (2), 0.36 (3), 0.52 (4), 0.60 (5), 0.80 (6), 0.87 (7), 1.13 (8), 1.30 (9), 1.58 (10), 2.17 (11), and 2.49 (12), respectively. Diets were fed as pelleted TMR once daily at 08:00. The amount of feed offered was restricted to 1.2 kg/d. Ruminal fluid was sampled from rams at 08:00, 14:00, and 20:00 on d 15 and at 02:00, 05:00, 11:00, 17:00, and 23:00 on d 16 of each period. Data were analyzed using the GLM procedure of SAS software. The results showed that, with increasing NFC/NDF ratios, ruminal pH decreased ($P < 0.01$), total VFA and butyrate percentage changed with cubic curve ($P < 0.05$), percentage of propionate, valerate and isovalerate in rumen increased ($P < 0.01$), while acetate percentage and A/P (acetate/propionate) ratio decreased ($P < 0.01$). It was concluded that NFC/NDF ratios of TMR had significant effect on ruminal pH and VFA. Increasing dietary NFC/NDF ratios decreased ruminal pH, acetate percentage and A/P ratio and increased percentage of propionate, valerate and isovalerate in rumen.

Key Words: NFC, rumen fermentation, sheep

426 Protein supplementation of low-quality forage: Effects of amount and frequency on intake and nutrient digestibility by lambs. M. L. Van Emon*[1,2], C. S. Schauer[2], and D. W. Bohnert[3], *[1]Department of Animal Sciences, North Dakota State University, Fargo[2]Hettinger Research Extension Center, North Dakota State University, Hettinger, [3]Eastern Oregon Agricultural Research Center, Oregon State University, Burns.*

The objectives of this research were to determine the effects of protein supplementation and frequency on intake and nutrient digestibility by lambs. Seven lambs were utilized in a 4 × 7 incomplete Latin square design. Dietary treatments were arranged in a 2 × 3 factorial design (2 levels of CP and 3 supplementation frequencies); CON = unsupplemented control; D = supplemented daily 0.28% of BW of soybean meal (SBM); 5D = supplemented 1.4% of BW of SBM once every 5 d; 10D = supplemented 2.8% of BW of SBM once every 10 d; 1/2 D = supplemented at 50% of D; 1/2 5D = supplemented at 50% of 5D; 1/2 10D = supplemented at 50% of 10D. Full CP refers to D, 5D, and 10D and half CP refers to 1/2 D, 1/2 5D, and 1/2 10D dietary treatments. Lambs were supplemented with SBM immediately before feeding of low-quality forage (Chewings fescue grass seed straw). Each experimental period was 30 d, with intake measured d 19 to 28. Feces, urine, and blood were collected d 21 to 30. Straw and SBM DMI, total DMI, straw OM intake, OM intake, ADF intake, and NDF intake were not different ($P \geq 0.26$) due to supplementation. Supplementation increased ($P \leq 0.02$) DM, OM, and NDF digestibility compared with the CON. The CON lambs had reduced ($P \leq 0.002$) N intake, urine N excretion, N balance, N digestibility, and digested N retained compared with supplemented lambs. Plasma urea N was increased in the supplemented lambs ($P = 0.004$) compared with the CON lambs as well as for full CP compared with half CP lambs ($P = 0.03$). Lambs supplemented with full CP had increased ($P \leq 0.03$) urine N excretion and N digestibility compared with the half CP lambs; however, digested N retained was not different ($P = 0.94$) due to supplementation amount. As supplementation frequency decreased, N digestibility was also reduced ($P = 0.01$). Both DM and OM digestibility increased ($P \leq 0.04$) as supplementation interval increased. These results suggest that increasing the supplementation interval may be utilized to maintain intake, digestibility, and reduce the labor costs associated with more frequent supplementation.

Key Words: lambs, nitrogen balance, supplementation frequency

427 Effect of feeding differently processed sweet sorghum (*Sorghum bicolor* L. Moench) bagasse based complete diet on nutrient utilization and microbial N supply in growing ram lambs. N. Nalini Kumari[1], Y. Ramana Reddy*[1], M. Blummel[2], T. Monika[1], B. V. S. Reddy[3], and Ch. Ravinder Reddy[3], *[1]S.V. Veterinary University, Tirupati, Andhra Pradesh, India, [2]International Livestock Research Institute (ILRI), Patancheru, Andhra Pradesh, India, [3]International Crops Research Institute for the Semi-Arid Tropics (ICRISAT), Patancheru, Andhra Pradesh, India.*

This study was carried out to identify appropriate processing method for efficient utilization of sweet sorghum bagasse (SSB), an agro-industrial by product of bio-ethanol industry after blending with concentrate in sheep. The SSB based complete diet with roughage to concentrate ratio of 50:50 was processed into mash (SSBM), expander extruded (SSBP) and chop form (SSBC) and evaluated in a growth- cum-metabolism trial using growing ram lambs in comparison to sorghum stover based complete diet (50:50) in mash form (SSM). Mash form of diet is prepared by grinding the roughage and concentrate portion of the ration after batching through hammer mill using 8mm sieve and mixing the grind material in a horizontal mixer. Expander extruded pellets are prepared by using expander extruder which combines the futures of expanding (application of moisture, pressure and pressure) and extruding (pressing the feed through constrictions under pressure). Twenty-four growing Nellore × Deccani ram lambs (10.6 ± 0.23 kg BW) were randomly divided into 4 groups of 6 animals each in a completely randomized design and the experimental complete diets were allotted at random to each group. A metabolism study was conducted at the end of the growth trial of 180 d to assess the nutrient utilization, and energy, nitrogen (N), calcium (Ca) and phosphorus (P) balance. The daily intestinal flow of microbial nitrogen (g/d) was calculated from total urinary purine derivatives (PD) (mmol/d). The average DMI (g/d or g/kg$^{0.75}$) was greater ($P < 0.01$) in lambs fed SSBP diet than those fed SSBC, SSBM and SSM diets. The lambs fed expander extruded (SSBP) diet could digest more ($P < 0.01$) DM, OM, CP ($P < 0.01$) than those fed SSBC, SSBM and SSM diets. Cellulose digestibility was greater ($P < 0.05$) in lambs fed SSBP diet than those fed SSM and SSBC diets. The intake of ME was more ($P < 0.01$) in lambs fed SSBP diet but comparable among SSM, SSBC and SSBM diets. The SSBP diet had greater ($P < 0.01$) DCP content compared with SSM, SSBC and SSBM diets, whereas the ME ($P < 0.05$) content was greater than SSBC and SSM diets. The DCP and ME values were comparable between SSBM and SSM diets. There was greater N, P ($P < 0.05$) and Ca ($P < 0.01$) balance in lambs fed SSBP diet compared with those fed the other 3 diets. Expander extrusion of SSB based complete diet resulted in improved ($P < 0.01$) efficiency of microbial protein synthesis. It is concluded from the results of the present study that, sweet sorghum bagasse is comparable with that of sorghum stover in nutritional value and processing SSB based complete diet into expander extruded pellets improved the nutrient utilization and microbial protein synthesis in growing sheep.

Key Words: sweet sorghum bagasse, processing, nutrient utilization

428 Effect of the dietary cation-anion difference on the lactation performances of dairy ewes at early-mid lactation. M. M. Youssef, G. Caja,* A. A. K. Salama, A. Ait-Saidi, and E. Albanell, *Grup de Recerca en Remugants (G2R), Universitat Autonoma de Barcelona, Bellaterra, Barcelona, Spain.*

Lactating ewes from 2 dairy breeds (Manchega, n = 20, Lacaune, n = 20) at 82 ± 3 DIM were used to study the lactational effects of diets varying in dietary cation-anion difference taking into account S (DCAD:S). Ewes were allocated in balanced groups of 5 ewes according to breed, BW and milk yield (Manchega, 68.3 ± 1.7 kg BW, 0.84 ± 0.05 L/d; Lacaune, 71.8 ± 2.1 kg BW, 1.46 ± 0.09 L/d), to which the dietary treatments were randomly assigned. Diets were fed for 8 wk and consisted of a total mixed ration (forage-to-concentrate ratio = 60:40) with 4 different DCAD:S values (22.5, 31.9, 45.9 and 64.9 mEq/100 g DM) formulated by adding anionic or cationic salts. Individual intake was calculated using polyethylene glycol 6000 as indigestible marker. Milk yield and milk composition were recorded weekly and biweekly, respectively. Blood and urine samples, for studying acid-base balance, were taken at wk 4 and 8, and wk 8 respectively. There were no effects of DCAD:S on feed intake, but milk yield showed a positive linear response to DCAD:S ($P < 0.001$). Effects of DCAD:S on milk composition differed by breed, showing a negative linear response in Lacaune ewes ($P < 0.01$) and no variation in Manchega. There was no DCAD:S effect on blood acid-base indicators (pH, HCO3—, pCO$_2$, AGap, BEx), indicating that ewes were in a neutral stage, but blood glucose and urea showed positive and negative linear effects of the treatments ($P < 0.001$), respectively. Blood fixed ions (Na$^+$, K$^+$, and Cl$^-$) did not vary and urine pH varied in a linear and positive manner by DCAD:S treatments ($P < 0.001$). Urinary urea and minerals showed different responses to

DCAD:S according to breed, with negative effects on urea, Ca and S ($P < 0.05$), and positive effects on Na ($P < 0.001$), which agreed with their respective intakes and with a metabolic stage of Ca mobilization. According to the obtained results, cationic diets (DCAD:S ~60 mEq/100 g DM) are recommended for lactating dairy sheep, which is markedly greater than previously reported in dairy cows and in dairy goats.

Key Words: dairy sheep, DCAD, electrolytic balance

429 Factors affecting dry matter intake of grazing goats in the Brazilian rangelands. M. A. D. Bomfim*[1,2], L. O. Tedeschi[2], and N. F. De Paula[3,2], [1]*Embrapa Goats and Sheep, Sobral, Ceara, Brazil,* [2]*Texas A&M University, College Station,* [3]*Universidade Federal de Viçosa, Viçosa, Minas Gerais, Brazil.*

Feed intake of grazing goats is a critical factor to determine their nutrient requirements. Research has shown that DMI varies with BW when diet DM digestibility (DMD) is lower than 66%, but other factors may affect DMI, such as pasture or environmental variables. A DMI database of grazing goats under the Brazilian rangeland conditions was built from 10 studies and had 61 data points. This database was used to determine key variables that could explain the variation in DMI. The recorded variables were age, BW, ADG (g/d), DMI (g/d), pasture area (AREA, ha), stocking rate (SR, goat/ha), pasture offer (PO, kg/goat/d), forage availability (FA, kg/ha), legume (LEG, % forage), pasture CP (PCP, %DM), pasture DM (PDMD) and OM digestibility (POMD), supplement CP (SCP, %DM) and ME (SME, Mcal/kg), supplement DMI (SDMI, g/d), minimum and maximum temperatures, and relative humidity (RH). The OM intake (OMI) was converted to DMI assuming an average of pasture ash content of 11.5% DM obtained from several publications. A stepwise regression was performed to identify the variables that explained the variation in the DMI. Then, a random coefficient model was used to obtain the fixed effect coefficients of the selected variables by assuming study as a random variable. The BW, FA, LEG, and their interactions explained more than 88% of the variation in the DMI. The study-variation free multiple regression was DMI (g/d) = $708.3 - 7.91 \times \mathrm{BW} - 0.172 \times \mathrm{AVAIL} + 0.00875 \times \mathrm{BW} \times \mathrm{AVAIL} - 6.8 \times \mathrm{LEG} + 0.304 \times \mathrm{BW} \times \mathrm{LEG}$ (n = 26, root of mean square error (RMSE) = 79.4 g/d, $R^2 = 0.883$). When only BW was used, approximately 75% of the variation in the DMI was explained and the study-variation free polynomial regression was DMI (g/d) = $368.9 - 6.56 \times \mathrm{BW} + 0.6 \times \mathrm{BW}^2$ (n = 61, RMSE = 104.5 g/d, $R^2 = 0.75$). Our results suggested that although BW was able to explain the majority of the variation in the DMI of these grazing goats, additional variation could be explained when forage availability and legume in the pasture were used. Although our database included most of the research carried out under these conditions, more studies are needed to confirm our findings.

Key Words: caatinga, caprine, ingestion

430 Effects of diet on carcass quality and consumer taste panel acceptance of intact or castrated hair lambs. J. D. Kohler*[1], W. W. Miller[1], J. L. Vest[1], J. M. Burke[2], M. A. Brown[3], K. R. Maddock Carlin[4], M. D. Hudson[1], and E. L. Walker[1], [1]*Missouri State University, Springfield,* [2]*Dale Bumpers Small Farms Research Center, Booneville, AR,* [3]*USDA ARS Grazinglands Research Laboratory, El Reno, OK,* [4]*North Dakota State University, Fargo.*

Forty hair-type lambs were examined in a 70-d study to determine the effects of gender (castrate; C vs. intact; I) and forage type on carcass traits and sensory acceptability. Lambs were procured from a single source in Missouri and one-half were randomly castrated. Lambs were randomly assigned to treatment and housed in individual pens. Equal number of each gender were assigned to 1 of 2 isonitrogenous dietary treatments: alfalfa (*Medicago sativa*; AL) or sericea lespedeza (*Lespedeza cuneata*; SL). Lambs were slaughtered and carcasses fabricated 48 h postmortem. Wholesale loins were split, vacuum packaged, and randomly assigned to an aging time of 48 h or 14 d before freezing. Minolta color scores were taken on the lateral surface of the loin after 15 min bloom time. A consumer taste panel was conducted using 64 untrained panelists. Approximately 13.5 cm of the loin was cooked to 71°C, cut into 12.7-mm x 12.7-mm pieces, and served at room temperature. Panelists scored samples for color, aroma, texture, aftertaste, juiciness, and overall appeal (1 = strongly disliked and 8 = highly desirable). Data were analyzed using Proc Mixed. The model included the fixed effects of gender, forage, panelist gender, and postmortem aging and all interactions. Non-significant interactions were removed. Initial BW was not different ($P = 0.89$). At slaughter, I lambs were 4.36 kg heavier and had greater HCW (18.8 vs. 16.6 kg; $P \leq 0.05$) than C lambs. Castrate lambs had greater ($P \leq 0.05$) a* and b* values than I lambs. Color was rated highest for C than I lambs (5.4 vs. 5.0; $P \leq 0.01$). Aging for 14 d had a positive effect on texture and aftertaste ($P \leq 0.05$) and there was a diet by lamb gender interaction on texture ($P \leq 0.01$). Female panelists preferred the aroma of AL vs. SL lambs (5.3 vs. 4.9; $P < 0.04$) and male panelists had a greater acceptance of aftertaste than females (5.2 vs. 4.8;$P = 0.017$). Castrate lambs fed AL were juicier and with a more desirable aftertaste (5.3 vs. 4.9; $P = 0.07$). Overall, male panelists preferred lamb more than females (5.4 vs. 4.9; $P = 0.002$). Consumer acceptance of lamb is influenced by diet, gender, and aging of lamb.

Key Words: lambs, carcass quality, consumer panel

431 Exploring the combined effects of dietary tannins and saponins on sheep infected with *Haemonchus contortus*. G. Copani[1], H. Hall[2], J. Miller[3], A. Priolo[1], and J. Villalba*[2], [1]*University of Catania, Catania, Sicily, Italy,* [2]*Utah State University, Logan,* [3]*Louisiana State University, Baton Rouge.*

The feeding behavior of lambs and the anthelmintic properties of tannins and saponins when offered in single rations or as a choice between rations were determined. Thirty 5 lambs were randomly assigned to 5 groups (7 lambs/group) and fed for 12 d: beet pulp (Group BP); BP + 8% quebracho tannins (Group CT); BP + 1.5% quillaja saponins (Group SAP), or a choice between BP + 8% quebracho tannins and BP + 1.5% quillaja saponins (groups CH-P parasitized and CH-NP non-parasitized). After this period, lambs in all groups, except those in CH-NP, were dosed with 5,000 and 27 d later with 8,000 infective larvae of *Haemonchus contortus*. After 23 d, all lambs were exposed to their respective diets for 12 d. Feed intake and fecal egg counts (FEC) were analyzed as a split-plot design with lambs (random factor) nested within group and day as the repeated measure. Lambs in BP, CH-P and CH-NP ate more feed than lambs offered just tannins (CT) or saponins (SAP) in single rations ($P < 0.05$). Groups offered choices (CH-P and CH-NP) did not differ in food intake ($P > 0.05$) and preferred the saponin- over the tannin-containing ration ($P < 0.05$). Before exposure to the experimental diets, groups had similar FEC ($P > 0.05$). In contrast, after being exposed to the experimental diets for 12 d, lambs in CT and SAP showed lower FEC than lambs in BP and in CH-P ($P < 0.05$). Thus, even when lambs exposed to a choice of rations containing tannins and saponins consumed more total feed than animals exposed to single rations, the effect at reducing FEC was less effective, suggesting that a combination of saponins and tannins have synergistic effects on food intake but antagonistic effects on parasitic loads.

Key Words: plant secondary compounds, food choice, endoparasites

432 Effect of feeding sericea lespedeza pellets on *Haemonchus contortus* in goats. D. S. Kommuru*[1], T. H. Terrill[1], N. C. Whitley[2], J. E. Miller[3], and J. M. Burke[4], [1]*Fort Valley State University, Fort Valley, GA,* [2]*North Carolina A&T State University, Greensboro,* [3]*Louisiana State University, Baton Rouge,* [4]*USDA/ARS/DBSFRC, Booneville, AR.*

Due to increased prevalence of anthelmintic resistance in sheep and goat gastrointestinal nematodes (GIN), there is a critical need for alternative control methods. Sericea lespedeza (SL; *Lespedeza cuneata*) has been shown to have activity against small ruminant GIN, but the mechanism of action has not been determined. Three experiments (Exp) with Spanish or Boer crossbred goats were designed to study the effect of feeding SL leaf meal pellets fed for 10% orts in confinement on *Haemonchus contortus* larvae during establishment (Exp 1; 75% SL; mature bucks group fed; n = 8/treatment) and after establishment (Exp 2; 75% SL; mixed sex kids individually fed; n = 18/treatment) or fed at 0.9 kg/head/day while grazing (Exp 3; 75 and 95% SL; young bucks; n = 10/treatment). Control animals in each study were given commercial forage-based pellets. A total of 5 adult female *H. contortus* recovered from the abomasum of 2 animals from each treatment group in each experiment were examined for evidence of surface damage using scanning electron microscopy. There was no evidence of damage on worms processed from Exp 1, indicating little effect of feeding SL pellets on establishment of *H. contortus* larvae in mature goats. There were constricted folds and a disheveled cuticular surface on 2 worms (40%) and damage on the cuticular surface on one worm (20%) from the 75% SL leaf meal pellet treatment group in Exp 2, with no damage observed on control worms. In Exp 3, all 5 worms (100%) observed from both the 75% and 95% SL leaf meal pellet treatment goats (but not control goats) showed a disheveled surface. As previously reported, fecundity of worms in Exp 2 and 3 was reduced ($P < 0.05$) by SL, and total adult worm numbers were reduced ($P < 0.05$) by SL in Exp 3. Together, this work suggests that SL may have a direct effect on the cuticle of female *H. contortus*.

Key Words: goats, *Haemonchus contortus*, sericea lespedeza

ADSA-ASAS Northeast Section Symposium: The Future of Animal Agriculture Programs in the Northeast in the Face of Reducing Animal Holdings on Campus

433 The challenges associated with sustaining livestock farms for undergraduate teaching programs. T. Etherton,* *The Pennsylvania State University, University Park.*

It is extraordinarily important to provide animal science majors access to dynamic hands-on learning experiences with animals used in animal agriculture. This is particularly important as the proportion of students enrolling in animal science degree programs from urban/suburban areas grows. This shift in student demographics is occurring in the Northeast in an era where budget cuts have reduced or eliminated livestock farms at many universities. Consequently, we are navigating an era where regionally (and nationally) the number of universities that provide students learning opportunities in a “full-service” manner (i.e., maintaining farms that house beef, dairy, horses, poultry, sheep, and swine) has dramatically decreased. This reality raises many questions, including how will Colleges that elect to sustain dynamic full-service educational, research and extension programs continue to fund farms? This presentation will address strategies that universities need to use to continue to meet the funding needs (which are rapidly increasing) associated with providing full-service learning programs involving farms. In addition, an important part of the presentation will be directed to the matter of providing, and funding, a robust learning experience for the growing cohort of animal science students who wish to pursue important career interests that focus on other animal species including cats and dogs.

Key Words: farms, funding, undergraduate education

434 Budgeting for teaching programs in animal science with shrinking resources. M. G. Hogberg,* *Iowa State University, Ames.*

The cost of operating teaching programs in animal science programs have always been higher than our sister departments in colleges of agriculture. This has been due to many of our courses being laboratory intensive and the cost of maintaining university farms as teaching laboratories. As budget resources shrink, the cost of operating farms draws attention of college administrators. Departments are increasingly being asked to justify the cost of teaching farms. In this paper there will be a discussion on increasing the student educational experience as one means to justify the use of the farms as well as how to increase the funding through course fees and per diems to help pay for the cost of operations.

Key Words: teaching costs, university farms

435 Who are the animal science customers of the future? An industry perspective. D. E. Putnam,* *Balchem Corporation, New Hampton, NY.*

The future of animal science programs, particular the future of having animal holdings on campus is uncertain. There is a lack of connectivity with the largest source of funding for most institutions, which is state level, and the customers that benefit from the activities, which are national and global. Indeed, from an industry perspective regarding a university, the state or regional boundary has little meaning. What are most relevant are core competencies, how well these relate to market needs and other sources for similar information or services. This is ultimately true whether the entity is an animal producer or one of the associated industries such as animal health. Thus, while historically, a state or regional industry segment, including its students and recipients of research and extension information, was the primary customer for a given university animal science program, this has changed. A significant consolidation of all industry segments has occurred, significantly altering the number of potential customers for a given university animal science program. Yet the ease of global transfer of information has eroded the natural barriers to competition for a university, making the best programs increasingly relevant and the pressure on others to be relevant more intense. The endpoint of these changes is an overcapacity of animal science programs relative to the needs of a smaller customer base. Therefore, costs must be aligned with the value created. This problem creates an opportunity and need for interstate, multi-institutional collaboration and perhaps, consolidation. This should be done with strategic intent, choosing carefully what core competencies will be created, which customers will be targeted to serve and how this program will withstand competitive forces. Strong programs focused on clear research and educational core competencies will appeal to students and industry customers alike, all the while being enabled to maintain and enhance basic research and overall scholarly endeavors. These customers will be drawn from a larger geography yet will be well poised to extract the value from a high quality animal science program, in turn ensuring future growth for successful programs.

Key Words: animal science, customers, students

Animal Health IV

436 I. Demographic trends in livestock inventory and number of operations in the United States. G. M. Schuenemann* and W. P. Shulaw, *Department of Veterinary Preventive Medicine, The Ohio State University, Columbus.*

Food animal veterinary services are important to support rural communities in the US; however, the veterinary supply (shortage) has recently been a source of debate in the academia and representative organizations. The objective of the present study was to estimate the trends of livestock inventory (dairy, beef, sheep, and swine) and the number of operations from 1982 to 2010 in the US. The livestock inventory and the number of operations are the main source of income that supports food animal veterinary practices in rural areas. Over time they provide a description of industry trends and serve as data points or baseline for comparisons for service providers (e.g., veterinarians), input suppliers, producers, and government among others. Historical data collected by the National Agriculture Statistical Services (NASS) were used in the present study. Livestock inventory (millions of heads) by county and the numbers of operations by group size (≤99, 100–499, and ≥500 head) were estimated for 1982 and 2010. The data collected at each point in time was compared to assess the changes (%) between 1982 and 2010 in inventory and the numbers of operations. A reduction in inventory was observed for beef (18.4%), dairy, (15.1%) and sheep (58.4%) while the inventory for swine increased (56%) from 1982 to 2010. Regardless of group size, the overall numbers of operations was reduced for beef (10.4%), dairy (40.2%), sheep (30.7%), and swine (33.6%). The livestock industry has lost about 50% (21–66% range) of small (≤99 head) beef, dairy, sheep and swine operations from 1982 to 2010. For the same period, the proportion of operations with ≥500 head has steadily increased for dairy (250% up) and beef (600% up) herds. Fewer producers of larger size characterized the US livestock industry in 2010 as compared with 1982. The effect of the livestock industry consolidation on the designated food animal veterinary shortage situations in rural areas needs further investigation.

Key Words: livestock inventory, food animal veterinary practice, rural area

437 II. Effect of trends in livestock inventory and number of operations on food animal veterinary practices in the United States. G. M. Schuenemann* and W. P. Shulaw, *Department of Veterinary Preventive Medicine, The Ohio State University, Columbus.*

The number livestock operations and inventory are the main source of income for food animal veterinary practices across rural areas in the US. The objective of the present study was to compare the trends of livestock (dairy, beef, sheep, and swine) inventory (head) and the number of operations by group size (≤99, 100–499, and ≥500 head) from 1982 to 2010 with the designated areas of food animal veterinary shortage for 2010 in the US. Historical data collected by the National Agriculture Statistical Services (NASS) and the Veterinary Medicine Loan Repayment Program (VMLRP; USDA-AFRI, Animal Health) were used in the present study. The VMLRP reported the state-designated veterinary shortage situations by county for 2010 in the US. Type I (Private practice, food animal medicine with at least 80% time) and type II shortage situations (Private practice, rural areas, food animal medicine with at least 30% time) were considered. According to the VMLRP, an estimated 187 shortage areas (628 counties) were reported in 2010. According to the NASS, the inventory and number of operations (≤99 head) has steadily declined from 1982 to 2010 for cattle and sheep, but has increased for swine (56% up). Fewer producers with larger size of operations characterized the US livestock industry in 2010. When data for 2010 from the NASS and the VMLRP were compared, about 30% (Type I) and 52% (Type II) of the counties with veterinary shortage situations had ≤12,000 head of livestock (all cattle, sheep, and swine combined) to support food animal veterinary practices. In 1982, about 3% (Type I) and 13% (Type II) of the counties with shortage situations in 2010 had ≤ 12,000 head of livestock to support food animal veterinary practices. Both livestock inventory and number of operations are vital to support food animal veterinary practices. The livestock industry consolidation (steadily decline in livestock inventory and in the number of operations with ≤ 99 head) may contribute, at least in part, to those designated food animal veterinary shortage situations. The livestock industry consolidation and the food animal veterinary shortage situations warrant further investigation.

Key Words: livestock inventory, food animal veterinary practice, rural areas

438 Estimation of genetic parameters for hoof lesions in Canadian Holstein cows. N. Chapinal*[1,2], A. Koeck[3], S. Mason[4], A. Sewalem[5,6], D. Kelton[1], and F. Miglior[5,6], *[1]Department of Population Medicine, University of Guelph, Guelph, ON, Canada, [2]Animal Welfare Program, University of British Columbia, Vancouver, BC, Canada, [3]Centre for Genetic Improvement of Livestock, Department of Animal & Poultry Science, University of Guelph, Guelph, ON, Canada, [4]Alberta Milk, Edmonton, AB, Canada, [5]Guelph Food Research Centre, Agriculture and Agri-Food Canada, Guelph, ON, Canada, [6]Canadian Dairy Network, Guelph, ON, Canada.*

Impaired hoof health is one the most important welfare and economic problems in modern dairy herds. No direct genetic selection for resistance to hoof lesions has been done so far. The objective of this study was to estimate the genetic parameters of hoof lesions for Holstein cows from Alberta, British Columbia, and Ontario (Canada). Hoof lesions were routinely recorded by 18 different hoof trimmers in 365 different herds from 2004 to 2011. A total of 35,059 records from 27,267 cows were used in this study. Lesions were divided into infection (dermatitis, heel erosion and foot rot), horn lesions (ulcers, hemorrhages and white line disease) and other lesions (e.g., interdigital hyperplasia, fissures). One-trait (any lesion in any hoof), 2-trait (any lesion in the front and rear hooves), and 4-trait (front and rear infection, and front and rear horn lesions) linear animal model were used. For the analyses, the statistical model included the fixed effects of parity (1 to 6), hoof trimmer, and stage of lactation, and the random effects of herd-year-season, permanent environment, animal and random error. Variance components were estimated with REML procedure using a DMU software package. The heritability estimates were: a) 0.06 for the occurrence of any lesion, b) 0.02 and 0.07 for the occurrence of any front and rear lesion, respectively, and c) 0.02, 0.01, 0.08 and 0.05 for the occurrence of front infection, front horn lesion, rear infection and rear horn lesion, respectively. The genetic correlation between the occurrence of any lesion in the front and rear hooves was 0.53. The genetic correlations between the occurrence of front and rear infection and the occurrence of front and rear horn lesion were 0.78 and 0.58, respectively. In conclusion, hoof lesions traits showed genetic variation that needs to be included in routine genetic evaluation for lameness resistance. Standardized hoof health data collection by hoof trimmers should be encouraged. Further analysis using additional hoof health data and conformation traits is in progress.

Key Words: dermatitis, sole ulcer, lameness

439 An international overview of the recording and use of functional traits in dairy cattle breeding and management.

J. B. Cole*[1], K. F. Stock[2], J. Pryce[3], A. Bradley[4], N. Gengler[5], L. Andrews[6], and C. Egger-Danner[7], *[1]Animal Improvement Programs Laboratory, ARS, USDA, Beltsville, MD, [2]Vereinigte Informationssysteme Tierhaltung w.V. (vit), Verden, Germany, [3]Department of Primary Industries, Victorian AgriBiosciences Centre, Bundoora, Victoria, Australia, [4]Quality Milk Management Services Ltd., Westbury-sub-Mendip, United Kingdom, [5]University of Liège, Gembloux Agro-Bio Tech (GxABT), Animal Science, Gembloux, Belgium, [6]Holstein UK, Rickmansworth, United Kingdom, [7]ZuchtData EDV-Dienstleistungen GmbH, Vienna, Austria.*

An important component in the development of sustainable dairy production systems is the maintenance of cow health and functionality. Genetic selection has resulted in substantial increases in cow productivity over the past 50 years, but health and fertility are increasingly important determinants of individual profitability. Breeding goals and selection programs are changing worldwide to reflect this shift toward greater functionality. Standardized trait definitions, recording practices and data analyses are needed to ensure that data and genetic evaluations are comparable across countries, but such efforts have proven to be difficult in practice. The International Committee for Animal Recording's Functional Traits Working Group (FTWG) has worked for several years to develop a standard defining best practices for the recording, evaluation, and genetic improvement of functional traits in dairy cattle. A review of past, current, and planned activities in many countries allowed the FTWG to identify key areas in which standards were needed. In addition to indicator traits like somatic cell score for mastitis, direct measures of health and disease will provide valuable information for genetic evaluations. Other traits, such as feed intake, may be developed and used to improve cow functionality. Guidelines for new traits must account for new sources of information and the needs of parties involved in data recording. Technical developments should be reviewed regularly to ensure that data represent the entire population, collection costs to producers and recording bodies are reasonable, and high-quality records suitable for use by management systems and genetic evaluation programs are obtained. A network of experts is needed to support the FTWG's efforts in compiling and updating the guidelines, exchanging information and experiences, and meeting the future needs of the dairy industry. A survey to assess current practices relating to the collection and evaluation of functional data has been distributed internationally.

Key Words: health traits, dairy management, data recording

440 Effect of intrauterine dextrose therapy on reproductive performance of lactating dairy cows with clinical endometritis.

M. G. Maquivar*[1], G. M. Schuenemann[1], S. Bas[1], and T. A. Brick[2], *[1]Department of Veterinary Preventive Medicine, The Ohio State University, Columbus, [2]Large Animal Medicine and Surgery Academic Program, St. George's University, Grenada, West Indies.*

The objective was to assess the effect an intrauterine infusion of 50% dextrose in water (DEX) on clinical cure and reproductive performance of lactating dairy cows diagnosed with clinical endometritis (CE) compared with untreated control cows (CON). Cows (n = 1122) from 2 herds were screened using vaginoscopy for CE at 26 ± 3 DIM and scored using a 0—3 scale. Cows scored as 2 or 3 were stratified by parity and randomly allocated into 1 of 2 treatment groups: 1) CON (n = 159) or 2) 200 mL DEX (n = 154). Fourteen days post-therapy (at 40 ± 3 DIM), treated cows were re-examined to assess treatment responses (cure). All cows were presynchronized with 2 injections of PGF2α given 14 d apart (starting at 26 ± 3 DIM) followed by Ovsynch (OV; GnRH-7 d-PGF2α-56 h-GnRH 16 h-timed-AI; TAI) or Cosynch (GnRH-7d-PGF2α-72 h-GnRH^{+}TAI) 12 d later. Cows displaying signs of standing estrus any time during the OV protocol received AI, while the remaining cows were subjected to TAI-16 h after second GnRH of OV. Body condition scores (BCS) were recorded at calving, 26 ± 3 and 40 ± 3 DIM. Pregnancy diagnosis was performed via ultrasonography at 39 ± 3 d post-AI. The proportion of cows that cured (GLIMMIX) and pregnancy up to 250 DIM (PHREG) were assessed. DIM at first service, milk yield at first service, BCS at treatment, rectal temperature at treatment were not different between groups. Cows with CE had greater cervical diameters at the time of treatment compared with cows without CE (n = 809). The proportions of cows that cured (vaginoscopy score of 0) was greater for DEX (48.4%) compared with CON cows (29%; $P < 0.05$). The probability of pregnancy was greater for DEX (HR = 0.74) compared with CON cows (HR = 0.60; $P < 0.05$). The median time to pregnancy was shorter for cows without CE (89 d), or DEX (117 d) compared with CON cows (135 d). The use of intrauterine DEX alone or as an adjunct of antibiotic therapy for the treatment of cows diagnosed with CE or metritis needs further investigation.

Key Words: endometritis, intrauterine dextrose, pregnancy

441 Efficacy of two herbal remedies as alternatives to antibiotic dry cow therapy: Preliminary microbiology results.

K. A. E. Mullen,* R. L. Lyman, S. P. Washburn, and K. L. Anderson, *North Carolina State University, Raleigh.*

Mastitis is a costly disease for the dairy industry. It is normally treated using antibiotics either for clinical cases of mastitis or for prevention in nonlactating cows. The aim of dry period preventive therapy is to eliminate existing infections and to prevent new infections from occurring pre-calving. This study evaluated the effectiveness of 2 herbal remedies as dry period treatments: Phyto-Mast (Penn Dutch Cow Care, Narvon, PA) and Cinnatube (New AgriTech Enterprises, Locke, NY). If proven effective, those treatments could potentially reduce antibiotic usage on all dairy farms. Data were taken from 3 private and one research herd over 2 years. Five intramammary dry treatments were assessed: 1) Phyto-Mast; 2) Cinnatube; 3) Phyto-Mast plus Cinnatube; 4) no treatment; 5) Penicillin dihydrostreptomycin plus teat sealant (Conventional). Milk samples were aseptically collected from each functional quarter of each cow (n = 264) before treatment and once within 3 to 10 d post-calving. Microbiological content was assessed using methods consistent with those of the National Mastitis Council. A mixed linear model was used to obtain least squares means and comparisons between treatments were obtained using the Tukey-Kramer adjustment. A cure was defined as the absence of a microbiological species that was present pre-treatment. The scope of the analysis is limited by the positive fact that 130 cows had no infection present pre-treatment and no infection post-calving. Results are given as least squares means ± se. There were no differences among treatments for percentage of quarters per cow with new infections: Conventional 2.8 ± 2.0%, Cinnatube 12.1 ± 4.4%, no treatment 16.0 ± 5.4%, Phyto-Mast plus Cinnatube 16.8 ± 5.7%, Phyto-Mast 17.2 ± 5.8%. For percentage of quarters per cow cured, analyzed from the subset of cows with infections pre-calving (n = 134), there were no differences among treatments: Phyto-Mast 23.4 ± 8.9%, Phyto-Mast plus Cinnatube 21.0 ± 7.9%, no treatment 18.8 ± 7.8%, Cinnatube 15.6 ± 6.7%, Conventional 15.0 ± 12.6%. Though no dry cow treatment was significantly more effective in this trial, the proportion of non-infected cows was encouraging.

Key Words: mastitis, organic, dairy

442 Comparison of low versus high calcium "anionic" diets for prevention of hypocalcemia and milk fever. J. P. Goff*[1] and R. L. Horst[2], [1]*Iowa State University, Ames,* [2]*Heartland Assays, Ames, IA.*

Three questions were addressed with this study. 1) Is it necessary to increase diet Ca when using anions to reduce DCAD to prevent periparturient hypocalcemia? 2) Can adding anions to a "low" Ca diet further reduce hypocalcemia around calving? 3) Are anions effective even if urine pH is not reduced all the way to the target pH of 6.2–6.8? Sixty Holstein cows entering their 2nd or greater lactation were assigned to 1 of 3 treatments. A high wheat straw-corn silage, 1.46 Mcal NEl/kg diet was utilized that was 1.44% K, 0.11% Na and 0.25% P. A high Mg, low Ca, No anion, a high Mg, low Ca, Anion, or a moderate Mg, high Ca, Anion supplement was added to the basal diet to create diets (see Table 1). Diets were fed for at least 2 weeks before calving and plasma Ca was determined weekly and within 7 h after calving and again at 24 ± 7 h after calving. Dry matter intake before calving was similar across all treatments with cows averaging 13.4 kg/d from 14 to 3 d before calving. The pH of urine collected during the wk before calving and blood Ca concentrations (mg/dl) (Mean + SEM) close to calving (Time 0 and 24 h) are presented (see Table). Plasma Ca was significantly improved (ANOVA, $P < 0.05$) at calving by both Low and Hi Ca anion supplementation – despite the fact that anions were not added in high enough quantity to decrease urine pH to the "target pH." Use of anions to prevent hypocalcemia does not require addition of Ca to the diet. The effectiveness of a "low calcium" diet to prevent hypocalcemia can be improved by adding anions.

Table 1. Diet composition; urine pH and plasma Ca observed

Treatment	% Ca	% Mg	% Cl	DCAD (mEq/kg)	Urine pH	Plasma Ca Time 0	Plasma Ca at 24 h
Lo Ca, No Anion	0.46	0.65	0.44	+162	8.20 ± 0.06	7.17 ± 0.31	7.44 ± 0.34
Lo Ca, Anion	0.46	0.66	1.24	−61	7.07 ± 0.17	7.95 ± 0.24	8.09 ± 0.24
Hi Ca, Anion	0.78	0.48	1.26	−68	7.41 ± 0.17	8.05 ± 0.27	7.98 ± 0.35

Key Words: milk fever, DCAD, hypocalcemia

443 Variation in metabolic, hematologic, and innate immunologic parameters in early postpartum dairy cows is not largely influenced by dairy, days in milk, or parity. M. D. Sellers,* A. R. Pepper-Yowell, D. L. Hanson, C. R. Nightingale, C. J. Cobb, B. S. Obeidat, and M. A. Ballou, *Department of Animal and Food Sciences, Texas Tech University, Lubbock.*

The objective was to partition total variation in metabolic, hematologic, and immune variables in early postpartum dairy cows among dairy, days in milk (DIM), and parity (LACT). Two hundred forty Holstein cows, 2–8 DIM and 2nd-8th LACT, from 8 dairies were sampled across 5 d (BLK; n = 6 cows/dairy/day). Metabolic measurements included plasma nonesterified fatty acids, β-hydroxybutyrate, glucose, and urea nitrogen concentrations. Hematologic measurements included total leukocytes and differentials, and immunologic measurements included neutrophil oxidative burst capacity to an *Escherichia coli*, neutrophil L-selectin expression, plasma haptoglobin concentration, rectal temperature, as well as tumor necrosis factor-α and interferon-γ concentrations in stimulated whole blood cultures with lipopolysaccharide and phytohemagglutinin, respectively. Type III sums of squares were estimated using PROC Mixed with the fixed effects of DIM, LACT, and the random effects of dairy and BLK. No differences were observed in regard to DIM ($P > 0.22$) or LACT ($P > 0.14$). Data are reported as η^2, representing the proportion of the total sums of squares for each effect. For metabolic parameters, DIM accounted for an average of 2.2% of total variation, LACT an average of 2.9%, and dairy an average of 4.3%, with residual variation accounting for an average of 75.1%. For hematologic parameters, DIM accounted for an average of 3.4% of total variation, LACT an average of 2.8%, and dairy an average of 4.2%, with residual variation accounting for an average of 85% of total variation. For immune parameters, DIM accounted for an average of 3.1% of total variation, LACT an average of 2.7%, and dairy an average of 9.8%, with residual variation accounting for an average of 78.1% of total variation. Differences among dairy, DIM, and LACT did not explain a large portion of the total variation across each class of variables; whereas residual effects likely associated with genetics, metabolic status, and health status contributed to the majority of the total variation.

Key Words: immune, metabolic, transition cow

444 Production and metabolic response of lactating dairy cows supplemented with a dietary antioxidant to intramammary infusion of lipopolysaccharide during thermoneutral and heat stress conditions. A. L. Kenny*[1], Y. M. Yang[2], N. M. Barkley[1], R. R. Rodrigues[1], G. I. Zanton[2], and M. R. Waldron[1], [1]*University of Missouri, Columbia,* [2]*Novus International Inc., St. Charles, MO.*

The response to intramammary lipopolysaccharide (LPS) infusion during heat stress in 24 lactating dairy cows fed the antioxidant Agrado Ultra (dry blend of ethoxyquin and propyl gallate) was investigated. Holstein cows (153 ± 5 d in milk) were randomly assigned (complete block design) to 1 of 2 treatments: Control (soy hulls 6.1 g/cow/day; n = 12) or AOX (AGRADO Ultra 6.1 g/cow/day; n = 12). Cows were housed in a free stall barn until d 14 of treatment and then housed in environmentally controlled rooms for 7 d at thermoneutral temperature (TN; d 15 to 21; Constant 20°C) and then 14 d of programmed 12-h cyclical heat stress (HS; d 22 to 35; Mean THI range 72.5 ± 0.1 to 81.3 ± 0.5). On d 20 (TN) systemic plasma and quarter milk was sampled and sterile saline (10 mL) infused into the right front quarter of the mammary gland and LPS (100 ng/10 mL saline) into the right rear quarter. Rectal temperature, respiration rate were measured, and systemic plasma and milk from the 2 quarters were sampled 1, 2, 3, 4, 6 and 12 h after infusion. This process was repeated on d 34 (HS) using the left quarters. Data were analyzed using SAS by mixed model ANOVA with repeated measures. Data collected at 0 h were used as covariates if found to be significant. Rectal temperature and respiration rate increased during HS ($P < 0.01$) and somatic cell count was greater in the LPS quarter than the saline quarter ($P < 0.01$). All milk components changed over time ($P < 0.01$) and between TN and HS ($P < 0.01$); however, these responses were similar for both saline and LPS quarters. The saline quarter of control cows had a greater percent of milk lactose ($P = 0.03$) and a tendency ($P = 0.08$) for fewer somatic cells than the saline quarter of AOX cows. All other responses of milk components and metabolites to LPS infusion were similar between control and AOX ($P > 0.05$). The addition of antioxidant to the diet of lactating dairy cows did not alter the response of plasma metabolites or milk components to intramammary infusion of LPS.

Key Words: dairy, antioxidant, lipopolysaccharide

445 Potential risk of western juniper-induced abortion in beef cattle.

C. T. Parsons*[1], D. R. Gardner[2], K. D. Welch[2], D. Cook[2], J. A. Pfister[2], and K. E. Panter[2], [1]*Oregon State University, Corvallis,* [2]*USDA Agricultural Research Service, Poisonous Plant Research Laboratory, Logan, UT.*

Ponderosa pine needles are known to induce late term abortions in cattle. Labdane acids including isocupressic acid (ICA) and agathic acid are the compounds responsible for initiating the abortions. Current research results suggest that an ICA concentration of 0.5% is required for pine needles to be a risk for inducing abortions, while pine needles that contain >1% ICA pose a significant risk. However, stage of pregnancy, amount consumed, snow cover, temperature and other issues contribute to the overall risk. Research on ponderosa pine needles has demonstrated large variation in the concentrations of the abortifacient compounds, both geographically and seasonally. Concentrations vary from location to location as well as seasonal fluctuations in some areas throughout the year. This variability results in differential potential for pine needle-induced abortions to occur depending upon the location and the time of the year. Several other trees, including many species of pine, juniper, cypress and cedar contain either isocupressic acid or agathic acid at concentrations sufficient to be a risk for causing abortions in late term pregnant cattle. In this study, we present data that western juniper (*Juniperus occidentalis*) trees contain compounds known to be abortifacient in cattle and that consumption of large amounts of bark in the third trimester of gestation can induce abortions. We also examined the geographical variation in the labdane acid content of western juniper trees by measuring the labdane acid content of bark, needles, and berries from western juniper trees from 6 different locations in Baker County, Oregon. The berries had a higher concentration of labdane acids than needles ($P < 0.001$) and bark ($P < 0.001$). Interestingly, bark had a higher concentration of labdane acids than needles ($P < 0.001$). However, there was no difference in the concentrations of labdane acids from location to location for berries ($P = 0.33$), needles ($P = 0.13$), or bark ($P = 0.15$). These results indicate that there is a similar risk for western juniper trees to cause late term abortions in cattle across Baker County, Oregon.

Key Words: juniper-induced abortion, western juniper, abortifacient

446 Assessment of daily milk fat and protein composition and the milk fat-protein ratio early postpartum as a predictor for subclinical ketosis in dairy cows.

F. S. Lima*[1], C. A. Risco[1], R. V. K. Pereira[2], K. N. Galvão[1], and J. E. P. Santos[1], [1]*University of Florida, Gainesville,* [2]*Cornell University, Ithaca, NY.*

Objectives were to determine milk fat percentage (%), milk protein % and fat-protein ratio cut-off values (Cv) to predict subclinical ketosis (SCK) during early lactation. A total of 209 cows were enrolled in the study. Daily milk samples were analyzed using AfiLab milk analyzer from Afikim milk system and the daily average % of fat and protein in milk, and the milk fat-protein ratio were calculated for the first 12 d in milk (DIM). Blood samples were collected at 4, 7 and 12 DIM to evaluate the concentration of β-hydroxybutyrate (BHBA). Concentration of BHBA > 1.2 mM was the criterion to determine SCK. The receiver-operating characteristics analysis using MedCalc software was deployed to calculate Cv of milk fat %, milk protein %, and fat-protein ratio for each day before and on the same day when BHBA was measured. A Cv was selected based on the best-combined sensitivity (Se, %) and specificity (Sp, %). Milk fat % at 3 DIM predicted SCK at 4 DIM (Cv > 4.96%, Se = 65.3 and Sp = 69.2). Likewise, milk fat % at 4 (Cv > 4.57%, Se = 78.6 and Sp = 52.2), 7 (Cv > 4.68%, Se = 74.6 and Sp = 60.5) and 12 (Cv = 4.35%, Se = 63.0 and Sp = 76.6) DIM predicted subclinical at 4, 7 and 12 DIM, respectively. Milk fat protein at 7 DIM predicted subclinical ketosis at 7 DIM (Cv < 3.47%, Se = 65.3 and Sp = 69.2). Milk fat-protein ratio on d3 postpartum predicted subclinical ketosis at 4 DIM (Cv > 1.36, Se = 50.0 and Sp = 78.0). Moreover, milk fat-protein ratio at 4 (Cv > 1.31, Se = 69.1 and Sp = 61.6), 7 (Cv > 1.40 Se = 68.7 and Sp = 77.4) and 12 (Cv > 1.56, Se = 40.8 and Sp = 93.7) DIM predicted SCK at 4, 7 and 12 DIM, respectively. Milk composition in the first 12 DIM can be used to predict SCK; however, the Se and Sp of cut-off values were moderate. Thus, because of limited Se or Sp, milk composition in the first 2 weeks postpartum can aid on the diagnosis, but should be used concurrent with other methods to identify cows with SCK.

Key Words: subclinical ketosis, milk composition, dairy cows

Breeding and Genetics: Advances in Genomic Methodology

447 Iterative combination of national phenotype, genotype, pedigree, and foreign information. P. M. VanRaden,* *Animal Improvement Programs Laboratory, ARS, USDA, Beltsville, MD.*

Single step methods can combine all sources of information into accurate rankings for animals with and without genotypes. Equations that require inverting the genomic relationship matrix G work well with limited numbers of animals, but equivalent models without inversion are needed as numbers increase. An equivalent model that includes extra equations to solve for the added contribution of genomic information was applied to national Jersey data. The extra equations solved for $G\gamma = u$ and $A_{22}\phi = -u$, where A_{22} contains pedigree relationships for genotyped animals and u contains genomic estimated breeding values (GEBV) from the previous iteration. Solutions for γ and ϕ were then added when solving for u. Multi-trait across country evaluations (MACE) were deregressed and inserted as extra records containing foreign information. The methods were tested on US Jersey yield data containing 4.4 million lactation records, 4.1 million animals in the pedigree, 16,852 genotyped animals, and 7,072 bulls with foreign MACE records. Heritability was reduced from 0.35 in official evaluations to 0.23 to mimic the effect of cow adjustments. For genotyped young bulls, single-step evaluations were correlated by 0.966 to multi-step evaluations. Both had the same reliability when tested using 4 year truncated data to predict deregressed proofs from the last 4 years, but regressions for single-step evaluations were closer to expected values. The weight on ϕ was reduced to 0.8 in the single step method and polygenic variance was increased to 20% in the multi-step method, both to improve the regressions. Convergence was much slower when the same algorithm was applied to Holstein data, and correlations were poor even after thousands of iterations. The number of Holstein genotypes was 135,724, with 65 million lactation records and 50 million animals in the pedigree. Second order Jacobi iteration was used in this study, but preconditioned conjugate gradient algorithm should be faster. More efficient strategies are needed because algorithms that work well on small or medium-sized data sets may not handle very large populations.

Key Words: single step methods, genomic evaluation, mixed model equations

448 Adaptation of BGF90 package for genomic computations. I. Misztal*[1], A. Aguilar[3], S. Tsuruta[1], and A. Legarra[3], *[1]University of Georgia, Athens, [2]INIA, Las Brujas, Canelones, Uruguay, [3]INRA, UR631 Station d'Amélioration Génétique des Animaux (SAGA), Castanet-Tolosan, France.*

The BGF90 package is a tool for mixed model analyses. The original package contains programs for renumbering, BLUP, variance components estimation, accuracy approximation and visualization. A renumbering program (RENUMF90) prepares data files for application programs, prunes pedigrees and can support national data sets. BLUP programs are for equations in memory (BLUPF90) and iteration on data (BLUP90IOD). Parameter estimation is via REML (REMLF90 and AIREMLF90) or Bayesian methods (GIBBS*F90), which are able to support large number of traits (20+). Samples from GIBBS* programs can be analyzed by POSTGIBBSF90, and accuracies of predictions can be approximated by ACCF90. Specific programs are available for threshold-linear models. Nearly all programs were updated to support the genomic information and several new programs were added. Program PreGSF90 analyzes the SNP information, provides basic quality control, creates a genomic relationship matrix using a large variety of options, and combines pedigree and genomic relationship matrices for a single-step methodology. Computations with PreGSF90 are optimized for parallel processing; preparing matrices for 30k animals with 50k SNP takes about 1 h. PreGSF90 can be run separately or as part of application programs. PostGSF90 converts GEBV to SNP effects, displays Manhattan plots possibly using moving averages, and estimates variances of SNP effects. Program PredF90 predicts GEBV based only on estimates of SNP effects obtained from PostGSF90. Most of the programs are available online at nce.ads.uga.edu. The package can be used for genomic predictions (including national data sets), parameter estimation (including GBLUP and G-REML), and GWAS. Unequal variances for SNP effects similar to those in BayesA and subsequently "Manhattan" plots can be obtained by iterating on postGSF90 and possibly one of BLUP programs; no deregression is required and complex models may be used. Classical GWAS can be carried out with BLUPF90 fitting one SNP at a time as fixed regression and an animal effect with a genomic (or combined) a relationship matrix. The package has been used for genomic analyzes of models with up to 10 million animals, 18 traits, 40k genotypes and 400k SNP. The updated package simplifies genomic analyses in breeding applications.

Key Words: genomic selection, genome wide association, software

449 Methods to include foreign information in national evaluations. P. M. VanRaden and M. E. Tooker,* *Animal Improvement Programs Laboratory, ARS, USDA, Beltsville, MD.*

Genomic evaluations (GEBV) with higher reliability often result from including genotypes and phenotypes from foreign bulls in the reference population. Multi-step methods evaluate domestic phenotypes first using only pedigree relationships (EBV), then add foreign data available from multi-trait across country evaluations (MACE), then compute GEBV for genotyped animals, and finally propagate information from GEBV to EBV of non-genotyped relatives. An alternative is to include domestic and foreign phenotypes together so that GEBV and EBV for all animals can be computed in a single step. The MACE EBV could be treated as a correlated trait, but previous research indicates that including these as the same trait with their lower reliability (REL) is sufficient. To include foreign data, the bull's deregressed proof (DRP) was obtained from the MACE EBV as: DRP = PA + (EBV - PA)/REL, where PA is the parent average from MACE. For bulls with both domestic and foreign daughters, domestic EBV was used instead of PA to compute DRP, and domestic daughter equivalents (DE) were subtracted from the total. Remaining DE were added to diagonals of the mixed model equations and were used to compute REL. This strategy included 1 extra record per bull and differed from previous methods that included 1 record for each foreign daughter. For multi-trait models, diagonal matrix D contained the DE for each trait of a bull. The vector of DRP was premultiplied by $D^{.5}T^{-1}D^{.5}$, where T is the genetic covariance matrix among traits, and $D^{.5}T^{-1}D^{.5}$ was added to the mixed model equations. A mean for the DRP was included in the model because the base is not fixed during iteration, only after convergence. The methods were tested using national Holstein data for 25 million cows, MACE data for 88,000 bulls, and a pedigree file of 52 million animals. For bulls with only foreign daughters, correlations between MACE EBV and national EBV after including the foreign data were 0.991 to 0.994 for yield traits, 0.986 for somatic cell score, 0.973 for single-trait productive life, and 0.974 for daughter pregnancy rate. This simple approach is reasonably accurate for including foreign data in national evaluations.

Key Words: MACE, foreign daughters, genomic evaluation

450 Characteristics and use of the Illumina BovineLD BeadChip. G. R. Wiggans*[1], P. M. VanRaden[1], T. A. Cooper[1], C. P. Van Tassell[2], T. Sonstegard[2], and B. Simpson[3], [1]*Animal Improvement Programs Laboratory, ARS, USDA, Beltsville, MD,* [2]*Bovine Functional Genomics Laboratory, ARS, USDA, Beltsville, MD,* [3]*GeneSeek, Lincoln, NE*

Genotypic information from the 6,909-SNP Illumina BovineLD (LD) Genotyping BeadChip, which replaced the Illumina GoldenGate Bovine3K (3K) Genotyping BeadChip, have been included in US genomic evaluations since November 2011. Of 73 LD single nucleotide polymorphisms (SNP) not used in genomic evaluation, 35 were from the Illumina BovineSNP50 (SNP50) Genotyping BeadChip, and 38 (13 mitochondrial, 9 Y-chromosome, and 16 X-chromosome SNP to improve genome coverage) were from the Illumina BovineHD (HD) Genotyping BeadChip. As of February 2012, the USDA national genotype database for dairy cattle included LD genotypes for 19,515 animals (550 males). Call rate for LD SNP used in genomic evaluation was 99.4%. The 9 Y SNP were highly effective in sex validation (call rate of 98% for males and 0.5% for females). Rate of parent-progeny conflicts on a SNP basis was similar to that for SNP50 SNP. Imputation accuracy averaged 98.9% for Holsteins, 98.3% for Jerseys, and 97.9% for Brown Swiss for LD genotypes compared with 95.9, 94.6, and 93.9% for 3K genotypes. To calculate reliability of genomic evaluations, the fraction of correctly imputed SNP was estimated as a function of the number of low-density SNP that were not missing and the number of animals with SNP50 genotypes. Reliabilities for LD genotypes were about 5 percentage points higher than for 3K genotypes. Using the add-on capability of the LD chip, the GeneSeek Genomic Profiler (GGP) for Dairy Cattle BeadChip was developed with 8,655 SNP. The additional SNP were for proprietary single-gene tests, detection of haplotypes that affect fertility, imputation of microsatellite alleles to facilitate parentage validation, and improved imputation by including more 3K SNP. The GeneSeek Genomic Profiler 80K (GGP-80) also was developed with around 80,000 SNP. The added SNP were SNP50 and HD SNP with the largest effects on primarily the net merit index. Consideration also was given to spacing as well as maintaining around 30,000 SNP50 SNP for imputation accuracy. The GGP and GGP-80 genotypes are expected to further improve accuracy of imputation and genomic evaluation because of the additional SNP.

Key Words: genomic evaluation, beadchip, SNP

451 Partitioning genetic (co)variances leading to alternative derivation of single-step type genomic prediction equations allowing joint estimation of GEBV and SNP effects. N. Gengler*[1], G. Nieuwhof[2], K. Konstantinov[2], and M. Goddard[3,4], [1]*ULg - Gembloux Agro-Bio Tech, Gembloux, Belgium,* [2]*ADHIS, Bundoora, Australia,* [3]*DPI, Bundoora, Australia,* [4]*University of Melbourne, Melbourne, Australia.*

Interest in single-step type procedures to do genomic prediction is growing because of its numerous advantages especially its robustness and its simplicity. Current derivations of single-step equations modify relationships among animals replacing for genotyped animals on an inverted scale, pedigree based by modified, partially genomic based, relationships. From an theoretical standpoint these methods are all based on assumptions and use a hidden underlying hypothesis that modified relationships are obtained as linear combination of strictly genomic and pedigree based relationships, therefore implicitly "weighting" SNP and polygenic effects. Alternative equations were recently proposed de-absorbing the genomic relationships out of the equations. This derivation did not change basic assumptions, but was derived using a matrix of relationship differences. This presentation will show a new and alternative derivation of single-step type genomic prediction equations allowing joint estimation of GEBV and SNP effects based on the partitioning of genetic (co)variances. The method was derived from a random mixed inheritance model where SNP and residual polygenic effects are jointly modeled. The derived equations were modified to allow non-genotyped animals and to estimate directly and jointly GEBV and SNP effects. Equations resemble recently proposed alternative single-step equations but were derived differently and are based on completely different assumptions and avoid certain issues in de-absorbing derivation linked to the matrix of relationship differences by using (co)variances. Several other advantages of the new equations are that weighting of SNP and polygenic effects becomes explicitly and that SNP effects are also estimated. This method makes better use of High-Density SNP panels and can be easily modified to accommodate other genetic effects as major gene effects or copy-number variant based effects. Finally these alternative equations combine advantages of single-step and of explicit SNP effect estimation based methods. Additional research is required to test and validate the proposed method.

Key Words: genomic prediction, single-step method, alternative equations

452 Use of canonical discriminant analysis for detecting selection signatures in cattle. R. Steri, C. Dimauro, S. Sorbolini, G. Marras, M. Cellesi, G. Gaspa, and N. P. P. Macciotta,* *Dipoartimento di AGRARIA, Università di Sassari, Sassari, Italia.*

The development of high throughput SNP platforms for several livestock species allows to study genetic variability both within and between breeds. Several techniques have been used to exploit information derived by these new tools, including principal component analysis (PCA). However, results are not easy to interpret in terms of markers, or genomic regions, linked to phenotypic traits. To explain the biological meaning of multivariate approach, canonical discriminant analysis (CDA) could be proposed. CDA is based on PCA applied on within-between (co)variance ratio matrix of predefined groups instead the (co)variance matrix. The new orthogonal variables maximize the differences among groups on the basis of variances within each groups. The biological meaning of canonical variables (CANi) can be inferred by the canonical coefficients (loadings) that represents the correlations between CAN and the original variables. In the present work, CDA was used to analyze a total of 2,627 bulls of Italian Holstein (IH; 1000), Italian Brown (IB; 755), Italian Simmental (IS; 493) and Piemontese (IP; 379). Thus CDA was used to study genetic differences between 2 dairy, one beef and one dual-purpose cattle breeds. Animals were genotyped with the 50k SNP panel. The analysis was carried out separately for the 29 autosomes. The separation among breeds was always clear. On average, the CAN1 explained about 50% of the total variability and was able to discriminate between IH and all the other breeds. This result, probably, underline the high selection pressure exerted on this population. CAN2 and CAN3, explaining on average 25% each, usually separated dairy breeds (IH and IB) from the IP, whereas the IS tended to be located in an intermediate position. Structure of the new variables shows genomic regions associated with extreme loadings value. Considering only values exceeding the 0.99 quantile as an empirical threshold, we found 743 SNPs across the whole genome that can be considered involved in differences among breeds. Interesting clustered signals were found near ABCG2 for CAN1, MSTN, LEPR and MC1R for CAN2 and LEP and KIT for CAN3.

Key Words: SNP, canonical discriminant analysis, selection signatures

453 Genome-wide association mapping including phenotypes from relatives without genotypes. H. Wang*[1], I. Misztal[1], I. Aguilar[2], A. Legarra[3], and W. Muir[4], *[1]Department of Animal and Dairy Science, University of Georgia, Athens, [2]Instituto Nacional de Investigación Agropecuaria, INIA Las Brujas, Canelones, Uruguay, [3]INRA, UR631 Station d'Amélioration Génétique des Animaux (SAGA), Castanet-Tolosan, France, [4]Department of Animal Science, Purdue University, West Lafayette, IN.*

The purpose of this study was to extend single-step GBLUP (ssGBLUP) to genome wide association analysis (GWAS). The ssGBLUP is a procedure that calculates breeding values (GEBVs) based on combined pedigree, genomic and phenotypic information. The procedure achieves these goals by blending traditional pedigree relationships with those derived from genetic markers. In this study, GEBVs were converted to marker (SNP) effects. Unequal variances for markers were incorporated by deriving weights from SNP solutions, and incorporating the calculated weights into a new genomic relationship matrix. Improvements on the SNP weights were obtained iteratively either by recomputing the SNP effects only or also by recomputing the GEBVs. Efficiency of the method was examined using simulations for 10 replications with 15,800 subjects across 6 generations, of which 1500 were genotyped with 3000 SNP markers evenly distributed on 2 chromosomes. Heritability was assumed 0.5 all due to 30 QTL effects that were simulated based on Gamma distribution across genome. Comparisons included accuracy of breeding values and cluster of SNP effects of ssGBLUP and BayesB with several options for each procedure. For genomic evaluation, an accuracy of prediction of 0.89 (0.01) was obtained by ssGBLUP after only one iteration, which was slightly higher than BayesB of 0.88 (0.02), but required only a small fraction of time. Power and precision for GWAS applications was evaluated by correlation between true QTL effects and the sum of m adjacent SNP effects, where m varied from 1 to 40. The highest correlations were achieved with m = 8 and were 0.82 (0.02) for ssGBLUP, and 0.83 (0.07) for BayesB with m = 16 according to marker density and extent of linkage disequilibrium in simulated population. Computing time for ssGBLUP took about 2 min while BayesB took about 5 h. Therefore, ssGBLUP with marker weights is 2 orders of magnitude faster than the next best procedure, accurate, and easy to implement for GWAS applications. In particular, ssGBLUP is applicable to GWAS with complex models including multitrait, maternal and random regression.

Key Words: genomic evaluation, genome-wide association mapping, single step procedure

454 Genotyping by sequencing (GBS): A novel, efficient and cost-effective genotyping method in cattle. M. De Donato*[1,2], S. O. Peters[1,3], S. E. Mitchell[4], T. Hussain[1,5], and I. G. Imumorin[1], *[1]Department of Animal Science, Cornell University, Ithaca, NY, [2]IIBCA, Universidad de Oriente, Cumana, Venezuela, [3]Department of Animal Breeding and Genetics, University of Agriculture, Abeokuta, Nigeria, [4]Institute for Genomic Diversity, Cornell University, Ithaca, NY, [5]Institute of Biochemistry and Biotechnology, University of Veterinary and Animal Sciences, Lahore, Pakistan.*

High-throughput genotyping methods have increased the analytical power to study complex traits by increasing the resolution and ultimately identifying the changes responsible for phenotypic differences in economic traits. However, high cost has prevented large scale use for animal improvement. In this study, we applied a recently published method for genotyping plants to 7 taurine and indicine breeds of cattle from the US and Africa, to determine the efficiency and feasibility of this method in cattle. Genomic DNA from each animal was individually digested with *Ape*KI and *Pst*I. Each sample was then ligated to adaptors containing one of 96 unique bar codes. Samples were then pooled and sequenced in a single lane on the Illumina HiSeq 2000. *Ape*KI GBS libraries produced more than 1.37 million unique reads, but had low number of SNPs, low call rate and too many reads with multiple locations in the genome, so this data was not analyzed any further. *Pst*I libraries produced about 500,000 unique reads, 93.9% of which were tags with at least 64 bases with no "Ns," with a significantly lower number of non-unique reads. On average, 1.14 million reads were produced per animal. A total of 62,295 SNPs were detected throughout all autosomes with an average distance of 39.9 kb, as well as 1,402 SNPs on the X chromosome at an average distance of 106.1 kb. The average marker density per autosome was highly correlated with size (CC = 0.797, $r^2 = 0.635$) with more markers per Mb in smaller chromosomes. Average SNP call rate in the genotyped individuals was higher than 0.70 in 81.5% of all loci, and the average minor allele frequency was 0.223 ± 0.001. Average observed heterozygosity per individual ranged from 0.046 to 0.294, with 0.064 as the lowest found in the Nigerian Sokoto Gudali breed (indicine) and the highest of 0.197 in Brangus (indicine × taurine). This technique has shown to be a novel, flexible, cost effective and sufficiently high-throughput, yet requiring no previous knowledge of the population, genome structure or diversity and can provide different levels of marker density depending on the resolution or cost desired.

Key Words: cattle, genotyping, NGS

455 Models' predictive ability of breeding values for a small data set of genotyped animals. F. M. Rezende*[1], J. B. S. Ferraz[1], F. V. Meirelles[1], J. P. Eler[1], and N. Ibañéz-Escriche[2], *[1]Faculdade de Zootecnia e Engenharia de Alimentos-Universidade de São Paulo, Pirassununga, São Paulo, Brazil, [2]Genètica i Millora Animal-IRTA, Lleida, Cataluña, Spain.*

The aim of this study was to compare the breeding values' predictive ability of 3 different models for a small data set composed by 3,149 animals genotyped for 106 SNP markers, for which adjusted phenotype and pedigree information were available. The 106 SNP are causal mutations or are located in transcript or promoter regions of *Bos taurus* genes. A data set composed by 83,404 Nellore beef cattle animals measured for production traits and their pedigree, contained a total of 116,652 animals, were used to estimate fixed and random effects solutions on single traits analysis by MTDFREML software, under animal model. The direct additive effects estimated from that analysis were assumed to be the "true" breeding values for those animals. The individual records for all traits were adjusted for fixed and random effects solutions, except for the direct additive effect. The adjusted phenotypes, composed by the direct additive and residual portions of raw phenotype, were used as dependent variables in tested models. Model 1 included only polygenic effects, model 2 included only markers effects and model 3 included both polygenic and markers effects. These analyses were performed by TM software. The models' predictive ability was verified by Spearman rank correlation coefficient, estimated by PROC CORR from SAS, between the animals' rank based on breeding values estimated on models 1, 2 and 3 and the rank based on "true" breeding value. The correlation coefficients estimated for models 1, 2 and 3 were 0.47, 0.22 and 0.66 for weaning weight, 0.53, 0.36 and 0.83 for post weaning gain, 0.57, 0.31

and 0.94 for scrotal circumference and 0.57, 0.29 and 0.84 for muscle score, respectively. The estimates of rank correlation coefficients lead to the same inferences for all analyzed traits. The reduced number of genetic markers available was not enough to retain a large proportion of additive effects contained in the adjusted phenotypes, as indicated by the lower values of rank correlation for model 2. The outcomes for model 3 suggested that for a small data set and a reduced set of genetic markers, the additive effects were better estimated when markers and polygenic effects were considered together, what suggests that marker assisted selection can be useful for Nellore populations.

456 Improving efficiency of inferring genetic architecture parameters in whole genome prediction models. W. Yang* and R. J. Tempelman, *Michigan State University, East Lansing.*

The reliability of whole genome prediction models (WGP) based on using high density single nucleotide polymorphism (SNP) panels critically depends on knowledge and/or reliable estimation of key hyperparameters that partly specify genetic architecture for the traits of interest. These hyperparameters include π, the proportion of SNP not associated with the trait as well as df and s^2. These latter 2 are, respectively, the degrees of freedom and scale parameter for the Student t density, often used to characterize the distribution of SNP effects in BayesB ($\pi > 0$) and BayesA ($\pi = 0$) models. Estimation schemes, however, based on the use of Markov Chain Monte Carlo (MCMC) methods have been plagued by poor mixing, in part because of the high correlation between df and s^2 in current univariate (UNI) sampling approaches. We consider 2 alternative approaches based on Metropolis-Hastings sampling schemes; one based on univariate draws from each of df and scale (UNIMH) and the other based on bivariate draws of the 2 parameters (BIVMH). We tested these 3 sampling methods on 6 replicated data sets, each analyzed at 3 different SNP marker densities with average pairwise LD levels of r^2 = 0.17, 0.25 and 0.32 . The BIVMH and UNIMH methods had significantly higher computational efficiencies for estimating df and scale compared with UNI ($P < 0.001$) in BayesA and BayesB implementations at all LD levels with the BIVMH outperforming UNIMH for s^2 in BayesA only. For BayesA, these efficiencies were 3–7 times greater in BIVMH and UNIMH relative to UNI whereas they were 5–35 times greater in BayesB with the largest gains being attained at higher LD levels. One ominous result is that the effective number of independent samples (ESS) from MCMC on estimating df and s^2decreases substantially with increasing marker densities such that reliable inference from higher density SNP marker panels require not only greater computing time per MCMC cycle but also greater total number of cycles as well. We also demonstrate how sensitive the accuracy of WGP is to misspecification of these key hyperparameters.

Key Words: genomic prediction, Bayesian inference, genetic architecture

457 A multi-compartment model for genomic selection in admixture populations. E. Hay,* S. Smith, and R. Rekaya, *University of Georgia, Athens.*

Currently, genome wide association studies and genomic selection (GS) are often conducted using purebred populations. Estimation and often validation of SNP are carried out using a select elite set of purebred animals (i.e., proven sires). This process was successful when estimated SNP effects were used to predict genomic breeding values on animals of the same breed. But it fails at different degrees when these SNP estimates are used for genomic prediction in other breeds or crossbred animals. Current approaches for dealing with admixed and crossbred populations in GS rely on using different groups of pooled animals in training and validation sets, hence are data dependent and often lead to reduction in accuracies for animals in pure breed populations. In admixture populations or in presence of crossbred animals, pooled databased methods assume SNP effects are the same across breeds or sub-populations. This assumption is seldom true due to several parameters such as minor allele frequency, strength of LD between markers and QTLs, and linkage phase between marker and QTL alleles change across sub-populations. To deal with this problem, we proposed a multi-compartment model where the effect of a SNP could be different between breeds and parameterized as a function of its effect on one of the breeds in pooled population through a one to one mapping function. An admixture population consisting of 2 lines (A and B) of birds was used to test our proposed method. It consisted on 2807 birds (1989 for A and 818 for B) genotyped for around 57 k SNPs. Three analyses were conducted: 1) each line analyzed separately (M1); 2) pooled data (M2); 3) pooled data using our multi-compartment model (M3). For M1, accuracy (correlation between EBVs and GEBVs) was 0.69 and 0.68 for line A and line B, respectively when training and validation were conducted within the same line. These accuracies dropped to 0.15 and 0.21 when training and validation were conducted in different lines. Using M2 (training and validation on pooled data), the accuracy decreased to 0.53. Using our method (M3), the accuracy was 0.59 or 11% increase compared with M2.

Key Words: genomic selection, admixture, SNP

458 Bayesian integration of external information into the single step approach for genomically enhanced prediction of breeding values. J. Vandenplas*[1,2], I. Misztal[3], P. Faux[1], and N. Gengler[1], [1]*University of Liege - Gembloux Agro-Bio Tech, Gembloux, Belgium,* [2]*National Fund for Scientific Research, Brussels, Belgium,* [3]*University of Georgia, Animal and Dairy Science Department, Athens.*

An assumption to compute unbiased estimated breeding values (EBV) is that all information, i.e., genomic, pedigree and phenotypic information, has to be considered simultaneously. However, current developments of genomic selection will bias evaluations because only records related to selected animals will be available. The single step genomic evaluation (ssGBLUP) could reduce pre-selection bias by the combination of genomic, pedigree and phenotypic information which are internal for the ssGBLUP. But, in opposition to multi-step methods, external information, i.e., information from outside ssGBLUP, like EBV and associated reliabilities from Multiple Across Country Evaluation which represent a priori known phenotypic information, are not yet integrated into the ssGBLUP. To avoid multi-step methods, the aim of the study was to assess the potential of a Bayesian procedure to integrate a priori known external information into a ssGBLUP by considering simplifications of computational burden, a correct propagation of external information and no multiple considerations of contributions due to relationships. To test the procedure, 2 dairy cattle populations (referenced by “internal” and “external”) were simulated as well as milk production for the first lactation of each female in both populations. Internal females were randomly mated with internal and 50 external males. Genotypes of 3000 single-nucleotide polymorphisms for the 50 males were simulated. A ssGBLUP was applied as the internal evaluation. The external evaluation was based on phenotypic and pedigree external information. External information integrated into the ssGBLUP consisted to external EBV and associated reliabilities of the 50 males. Results showed that rank correlations among Bayesian EBV and EBV based on the joint use of external and internal data and genomic information were higher than 0.99 for the 50 males and internal animals. The respective correlations for the internal evaluation were equal to 0.50 and 0.90. Thereby, the Bayesian procedure can integrate external information into ssGBLUP.

Key Words: Bayesian, genomic, single step

459 Conceptual comparison between standard multiple-trait and structural equation models in animal breeding applications.

B. D. Valente,* G. J. M. Rosa, X.-L. Wu, D. Gianola, and K. A. Weigel, *University of Wisconsisn, Madison.*

Structural equation models (SEM) are multivariate specifications capable of conveying causal relationships among traits. Although these models offer insights into how phenotypic traits relate to each other, it is unclear how SEM can improve multiple trait selection. This is a major issue, ultimately defining how SEM can serve animal breeding. Here, we explored concepts involved in SEM, seeking for benefits it could bring to breeding programs, relative to the standard multi-trait models (MTM) commonly used in practice. Genetic effects pertaining to SEM and MTM have distinct meanings. In SEM, these represent genetic effects acting directly on each trait, without mediation by any other instances of the multiple-trait set under study; in MTM they represent overall genetic effects on each trait. Hence, by using a SEM, it is possible to disentangle the overall genetic components into direct and indirect effects. However, in breeding programs one is interested in selecting candidates that produce offspring with best phenotypes, regardless of how traits are causally associated, and overall additive genetic effects are predictive of offspring phenotypes. So, there is no loss of information by using MTM based predictions, even if there are causal associations among traits. Conversely, the extra knowledge provided by causal information may give the ability of predicting effects of external interventions. One may be interested in selecting for a scenario where interventions are performed, e.g., artificially defining the value of a trait, blocking causal associations, or modifying their magnitudes. By knowing SEM genetic effects and mirroring interventions on the causal structure of the model, predictions for these scenarios are possible from data recorded without the interventions. MTM, on the other hand, do not provide information for such predictions. As livestock production involves many interventions, SEM may be then advantageous in many settings.

Key Words: multiple-trait models, selection, structural equation models

Breeding and Genetics: Beef Cattle Breeding I–Production Traits

460 Incorporation of external EBV into the American Gelbvieh Association carcass national cattle evaluation.

S. E. Speidel*[1], R. M. Enns[1], and S. Willmon[2], [1]*Colorado State University, Fort Collins,* [2]*American Gelbvieh Association, Westminster, CO.*

The goal of this project was to incorporate prior genetic knowledge on Angus and Red Angus sires whose progeny are being registered in the American Gelbvieh Association (AGA) to better account for selection on these sires and to improve carcass EBV prediction for their crossbred progeny. External EBV (EEBV) for carcass weight (CWT), rib eye area (REA) and marbling score (MARB) were obtained from the American Angus Association (n = 5,472) and Red Angus Association of America (n = 3,482). EEBV for CWT and REA were added to the AGA model containing actual CWT, REA, and ultrasound REA (UREA). EEBV for MARB were added to the AGA model containing actual MARB and percent intramuscular fat (IMF). Prior to their inclusion, EEBV were deregressed for accuracy. Models currently used by the AGA for the prediction of carcass EPD were preserved. Heritability of the EEBV and genetic correlations between the EEBV and traits in the existing models were the only parameters estimated. A simple mean was the sole EEBV fixed effect included. Heritability estimates for the EEBV were found to be 0.23 ± 0.01, 0.28 ± 0.01 and 0.18 ± 0.01 for CWT, REA and MARB, respectively. Genetic correlations between external CWT EBV and actual CWT, external REA EBV and actual REA, external REA EBV and UREA, external MARB EBV and actual MARB, external MARB EBV and IMF were found to be 0.35 ± 0.15, 0.33 ± 0.15, 0.39 ± 0.06, 0.53 ± 0.15 and 0.49 ± 0.05, respectively. Angus animal EPD correlations between models with EEBV and those without were 0.94, 0.95 and 0.78; Gelbvieh EPD correlations were 0.98, 0.996 and 0.98; EPD correlations for all animals were 0.95, 0.98 and 0.90 for CWT, REA and MARB, respectively. Inclusion of the EEBV resulted in an increased EPD spread for the suite of AGA carcass EPD. For Angus animals and their progeny, this spread was increased by 43%, 25% and 101%; EPD spread increase for all animals was 6.3%, 3.4% and 44.8% for CWT, REA and MARB, respectively. This procedure resulted in positive and moderately high genetic correlations between the EEBV and corresponding traits in the current evaluation. This procedure resulted in the models more appropriately evaluating external Angus sires in the AGA carcass evaluation.

Key Words: beef cattle, genetic evaluation

461 Across-population estimation of heritability of carcass traits in beef cattle: Meta- vs. mega-analyses.

H. Okut*[1,3], X.-L. Wu[1], D. Gianola[1], G. J. M. Rosa[1], S. Bauck[2], and B. W. Woodward[2], [1]*University of Wisconsin, Madison,* [2]*Merial Limited, Duluth, GA,* [3]*University of Yuzuncu Yil, Van, Turkey.*

Across-population estimation of genetic parameters is a challenge because populations are heterogeneous and the distribution of individual estimates over populations may be multi-modal. Two types of statistical methods can be used to combine estimates from many populations. Meta-analysis combines summary results from populations, whereas mega-analysis pools data from multiple populations into a single data set. We compared these approaches in estimation of heritability of 6 carcass traits [marbling score (MBS), back fat thickness (BFAT) at 12th rib, hot carcass weight (HCW), ribeye area (REA), yield grade (YG) and Warner-Bratzler shear force (WBSF)] using 15,016 cattle (2,964 phenotyped) from 4 populations sired by Angus, Hereford, Limousin or Simmental. We fitted fixed-effects (FMA) and random-effects (RMA) meta-analytical models in a frequentist framework. FMA viewed populations as homogeneous for any of the traits; RMA postulated a normal distribution of heritability values across populations. Further, a Bayesian non-parametric model with a Dirichlet process prior (DPP) was fitted, to avoid the normality assumption implied in RMA. In the mega-analysis, heritability was estimated with an animal model, pooling data over the 4 populations. Heritability was 0.42 (MBS), 0.24 (BFAT), 0.35 (HCW), 0.28 (REA), 0.29 (YG), and 0.12 (WBSF) using mega-analysis, and 0.31 to 0.39 (MBS), 0.21 to 0.34 (BFAT), 0.33 to 0.39 (HCW), 0.27 to 0.41 (REA), 0.31 (YG), and 0.17 to 0.20 (WBSF) with the meta-analysis models. In general, heritability estimates from RMA and DPP models agreed, but differed slightly from those obtained with FMA for all traits, except YG. When population heterogeneity is evident, meta-analysis using FMA (possibly mega-analysis too) appears suboptimal, whereas RMA and DPP can potentially capture the distribution of heritability estimates over populations.

Key Words: heritability, mega-analysis, meta-analysis

462 Accuracies with different genomic models for traits with maternal effects.

D. A. L. Lourenco*[1], I. Misztal[1], H. Wang[1], I. Aguilar[2], and S. Tsuruta[1], [1]*University of Georgia, Athens,* [2]*Instituto Nacional de Investigación Agropecuaria INIA, Las Brujas, Canelones, Uruguay.*

Several methods were compared for the accuracy of evaluation using phenotypic, pedigree and genomic information for a trait influenced by a maternal effect. A simulated population included 15,800 animals in 5 generations. Genotypes from 3k SNP were available for 1500 animals in the last 3 generations. All animals except 300 in the last generation had phenotypes. Simulations were by an animal model with direct (heritability 0.32) and maternal (heritability 0.13) effects, mimicking weaning weight in beef cattle. Models of analysis were regular BLUP, single-step GBLUP (ssGBLUP), BayesC with deregressed proofs (BayesC-D) and BayesC using phenotypes and ignoring the maternal effects (BayesC-ph). For all animals, the accuracies with ssGBLUP were 0.01 (0.04) higher than with BLUP. For genotyped animals, the direct (maternal) accuracies for males were 0.71 (0.43) for BLUP, 0.79 (0.60) for ssGBLUP, 0.70 (0.48) for BayesC-D, and 0.63 for BayesC-ph. For females, the same accuracies were 0.68 (0.54) for BLUP, 0.76 (0.65) for ssGBLUP, 0.69 (0.56) for BayesC-D, and 0.65 for BayesC-ph. For genotyped animals in the last generation, the direct (maternal) accuracies were similar for males and females and were 0.50 (0.38) for BLUP, 0.69 (0.58) for ssGBLUP, 0.62 (0.48) for BayesC-D, and 0.54 for BayesC-ph. Accuracies by BayesC-D were lower than those by ssGBLUP because of approximations involved in deregressions, lack of accounting for parental average that is done automatically by ssGBLUP, and by sequential rather than simultaneous fitting of genomic and nongenomic information. Low direct accuracies by BayesC-ph were additionally due to ignoring phenotypes on ungenotyped animals and ignoring the maternal effect. Highest accuracy of prediction with the genomic information occurs when the information on all ungenotyped but related individuals is included and when all sources of information (phenotypic, pedigree and genomic) are considered jointly. The accuracy with a procedure that uses simplified models and ignores information from ungenotyped animals can be lower than that by BLUP.

Key Words: beef cattle, genomic selection, single-step procedure

463 Cumulative discounted gene expression for economically relevant traits for terminal and maternal purpose in cattle production system. X. Zeng,* B. W. Brigham, S. E. Speidel, D. H. Crews, and R. M. Enns, *Colorado State University, Fort Collins.*

The objective of the study was to estimate the cumulative discounted gene expressions (CDGE) for birth, slaughter, annual and end-of-cow-life traits in terminal and maternal purpose Angus cattle. CDEG were not calculated to annual and end-of-cow-life traits for terminal sire. The overarching goal of the project is to develop prototype producer-specific selection indexes based on production characteristics in the intermountain region of the US. The discounted gene-flow principle was used to estimate CDGEs. The parameters used in equations to calculate the CDGEs were estimated from 10,007 individual records and 27,165 pedigree records from the Angus herd at the John E. Rouse Beef Improvement Center of Colorado State University. There were 313 sires with generation interval of 3.30 years involved in the study, as well as 2,160 dams with generation interval of 5.32 years. The planning horizon, cull age of cow and discount rate were set as 20 years, 12 years old and 0.03 as the base situation to estimate CDGE. The result contained 14 CDGEs for 4 kinds of animals, each of which included different categorical traits. n the base situation, the CDGE of annual cow traits were 4.29, 6.93 and 29.01 for terminal female, self-replace female and sire breeding replacement females. The range of CDEG for slaughter traits is 20.39 to 35.00 from terminal sire to sire breeding replacement females, while 1.90 to 4.72 from terminal female to self-replacing female. For self-replacing female, the CDEGs of traits expressed at different time and frequency were 6.93, 6.15, 1.35 and 4.72 for annul, birth, end-of cow-life and slaughter traits, with a range of 1.35 to 6.93. Sensitivity analysis was adapted to test the effect of different levels of discount factors from 0 to 2.0. Results of the study indicated that different purpose of calves lead to large differences in gene expression. Thus, when adjustments are made to economic values, the relative economic importance may change for the economically relevant traits in a breeding objective.

Key Words: cumulative discounted gene expression, discounted gene-flow, economic value

464 Cluster and meta analyses of genetic parameters for feed intake traits in beef cattle. I. D. P. S. Diaz[1], D. H. Crews Jr.*[2], and R. M. Enns[2], *[1]Universidade Estadual Paulista, Jaboticabal, Sao Paulo, Brazil, [2]Colorado State University, Fort Collins.*

A lot of studies have been estimated genetics parameters for different measures of feed efficiency so it has becoming important to summarize all the different parameters found on publication and to get an average of these results. In this study feed efficiency data from 62 studies were used to estimate the pooled heritability and the pooled genetic correlation estimates among average daily gain (ADG); residual feed intake (RFI); metabolic body weight (MBW); feed conversion ratio (FCR) and dry matter intake (DMI) of beef cattle. A meta-analysis approach was applied following a cluster analysis of the heritability estimates. The total data sample had 177 heritability estimates and 149 genetic correlation estimates collected from studies published from 1961 to 2011. The cluster analysis was conducted using the Ward method within trait. Pooled heritability estimates were calculated for each cluster within each trait and for all the clusters together. For all traits 2 clusters were obtained, however for each trait the key variable that separated the groups was different. With this approach, the homogeneity between the studies could be evaluated and if present, a random model was chosen to calculate the variance between studies. In this study the variance was calculated using restricted maximum likelihood. Heterogeneity was found among the studies for all traits. Pooled heritability estimates for ADG, DMI, RFI, MBW and FCR were 0.32 ± 0.04; 0.39 ± 0.03; 0.31 ± 0.02; 0.31 ± 0.03 and 0.26 ± 0.03, respectively. Pooled genetic correlation estimates ranged from −0.15 to 0.67 among these traits. These pooled genetic parameter estimates could be used to solve genetic prediction equations in populations where data are insufficient for variance components estimation.

Key Words: feed efficiency, multivariate analysis

465 Marbling change patterns of rib eye area by slaughter age using random regression sire model. K. Kato,* Y. Nakahashi, and K. Kuchida, *Obihiro University of Agriculture & Veterinary Medicine, Obihiro, Japan.*

Japanese Black cattle (Wagyu) are the predominant beef breed due to high marbling. Degree of intramuscular marbling is measured at the 6th to 7th rib section, and graded according to the beef marbling standard (BMS, 1 to 12) in Japan. Currently the slaughter age of this breed is about 29 mo on average. However, it is required to shorten the length of fattening because of increasing the feeding costs. The objectives of this study were to investigate sire differences in marbling change patterns of rib eye area by slaughter age in Japanese Black cattle using regression within sire, and to find the appropriate slaughter age. Data were 18,350 carcass records (steer: 13,218, heifer: 5,132) collected between April in 2000 and December in 2010 in Hokkaido, Japan. Statistical analysis was performed using AI-REML procedure. The random regression model included year, month, sex and farm as fixed effects, slaughter age (linear and quadratic) as fixed regression, and random sire effects was fitted with a k-th ($k = 0, 1, 2$) order Legendre polynomials of slaughter age. The breeding value of sire for each age was predicted by BLUP of random regression coefficients. Estimated sires were totally 753. Estimated breeding value (EBV) of BMS increased with the age until the peak, and then decreased. The different regression curves and the peaks among sires were shown. For top 5 sires in service number, EBV of BMS ranged 1.0~1.4, 1.0~2.1, 1.0~1.2, 0.9~1.2 and 0.5~1.3, respectively Therefore, it is thought that fattening farmer can decide the slaughter age appropriately and carcasses can show their ability maximally.

Key Words: marbling, slaughter age, random regression

466 Estimation of heterotic effects on stayability in beef cattle. E. M. Huff*[1], B. W. Brigham[1], S. Willmon[2], and R. M. Enns[1], *[1]Department of Animal Science, University of Colorado, Fort Collins, [2]American Gelbvieh Association, Westminster, CO.*

Stayability in beef cattle is defined as the probability that a cow remains in the herd until age 6 given that she has calved as a heifer. In some breeds with total herd reporting, those cows are required to calve every year. Profitability of the herd is affected by stayability by decreasing the need for replacements by increasing the number of cows that reach the typical breakeven age of 6. Stayability is a binary trait on the observed scale and is considered a lowly heritable trait. General consensus is that lowly heritable traits should be subject to higher levels of heterosis in crossbreeding programs and has shown to have a large effect on cow longevity. Therefore, heterosis should have a positive effect on the cows' ability to remain in the herd until age 6. The objective was to estimate maternal and individual heterosis values for stayability. Data obtained from the American Gelbvieh Association and included a total of 103,022 animals, with 20,173 being purebred Angus, 6,223 purebred Red Angus, 47,549 purebred Gelbvieh, and the rest being a combination of crossbred animals. Variance components and fixed heterosis effects were estimated from an animal model using a probit threshold link function. The model included contemporary group as a fixed effect and breed percentage as a linear covariate. Contemporary groups were required to have variation within the group and to have at least 5 observations. After initial analysis Red Angus and Angus cattle were combined due to there not being a significant difference between the 2 breeds. Two models were run with different backcross covariates, model one included only individual backcross and model 2 included individual and maternal backcross. Heterosis was estimated to be 35.78% for the individual with the first model. For the second model individual heterosis was estimated to be 31.77% and 11.85% was the estimate for maternal heterosis. The results from this experiment indicate that stayability is affected by heterosis and that these effects should be accounted for in cattle evaluation using pure and crossbred data.

Key Words: heterosis, stayability, beef cattle

467 Comparison of single breed and admixed reference populations for across-breed prediction of direct genomic breeding values in Red Angus beef cattle. M. Saatchi*[1], R. D. Schnabel[2], J. F. Taylor[2], and D. J. Garrick[1,3], [1]*Department of Animal Science, Iowa State University, Ames,* [2]*Division of Animal Science, University of Missouri, Columbia,* [3]*Institute of Veterinary, Animal and Biomedical Sciences, Massey University, Palmerston North, New Zealand.*

The objective of this study was to derive and evaluate the accuracy of direct genomic breeding values (DGV) for Red Angus beef cattle using single breed and admixed reference populations. Seven traits (birth, weaning and yearling weights; calving ease direct and maternal; marbling; rib eye area) were evaluated using 2,359 Black Angus, 891 Hereford and 1,655 Limousin genotyped individuals as a reference population, separately and admixed. Genotyping used the Illumina BovineSNP50 assay. Deregressed estimated breeding values (DEBV) were used as observations in a weighted Bayesian analysis to estimate marker effects used in DGV calculation. Accuracy of DGV was the correlation between DEBV and DGV in a sample of 90 Red Angus sires. The single breed reference populations accuracies of DGV were, in general, higher for marker effects predicted in Black Angus, followed by Hereford, and finally Limousin, reflecting the genetic distances between the breeds. The use of admixed reference populations produced more accurate DGV (average accuracies over all traits were 0.24, 0.19, 0.13 and 0.06 when marker effects were predicted in admixed, Black Angus, Hereford and Limousin, respectively). Incorporating 86 additional Red Angus (different animals from validation individuals) and 102 Simmental individuals into the admixed training population dramatically increased the accuracies of DGV, averaging 0.43 over all studied traits. These DGV show promise for routine use by Red Angus breeders to predict the genetic merit of their animals at a young age. Red Angus breeders will benefit most from the use of an admixed reference population which includes Red Angus.

Key Words: admixed reference population, genomic breeding values, Red Angus

468 Adipose and muscle tissue expression of two genes (*NCAPG* and *LCORL*) located in a chromosomal region associated with cattle feed intake and gain. A. K. Lindholm-Perry,* A. K. Sexten, L. A. Kuehn, L. A. Rempel, J. R. Miles, R. A. Cushman, and H. C. Freetly, *USDA, ARS, U.S. Meat Animal Research Center, Clay Center, NE.*

A region on bovine chromosome 6 has been implicated in cattle birth weight, growth, and length. Non-SMC conodensin I complex subunit G (*NCAPG*) and ligand dependent nuclear receptor corepressor-like protein (*LCORL*) are positional candidate genes within this region. We previously identified genetic markers in both genes that were associated with average daily gain and feed intake in a crossbred population of beef steers. Two markers within *LCORL* were validated in a second, unrelated population of steers. We also detected associations between these markers and hot carcass weight, adjusted fat thickness and ribeye area suggesting that one or both of these genes play a role in lean muscle growth and reduced fat deposition. The purpose of this study was to determine whether the transcript abundance of either of these genes in adipose and muscle tissues was associated with variation in beef cattle feed intake, residual feed intake and average daily gain phenotypes. Transcript abundance for *NCAPG* and *LCORL* in adipose and muscle tissue was measured by quantitative PCR from heifers (adipose only, n = 88), cows (n = 85 muscle, n = 18 adipose) and steers (n = 12). Phenotypic correlations among expression levels and measures of growth, feed intake, and efficiency were derived and tested for significance. The levels of *NCAPG* and *LCORL* gene expression in adipose tissue were not correlated to gain, feed intake or residual feed intake in steers, heifers or cows. However, transcript abundance of *NCAPG* in the muscle tissue of cows was correlated to BW gain ($r = 0.31$; $P = 0.004$) while muscle gene expression levels of *LCORL* were correlated with dry matter intake in steers ($r = -0.57$; $P = 0.03$). These data corroborate the genetic associations with gain and feed intake within this region and represent biological activity of these genes in the muscle tissue of cattle. The data also suggests that sex, age and/or nutrition-specific interactions may affect the expression of *NCAPG* and *LCORL* in beef cattle. USDA is an equal opportunity provider and employee.

Key Words: beef cattle, gene expression

469 Identification of single nucleotide polymorphisms for feed efficiency and performance in crossbred beef cattle. M. K. Abo-Ismail*[1], G. Vander Voort[1], E. J. Squires[1], K. C. Swanson[1,2], J. Thomson[3], B. Karisa[3], G. Plastow[3], S. Moore[3], and S. P. Miller[1,3], [1]*Centre for Genetic Improvement of Livestock, University of Guelph, Guelph, ON, Canada,* [2]*Animal Sciences Department, North Dakota State University, Fargo,* [3]*Faculty of Agricultural, Life and Environmental Sciences, University of Alberta, Edmonton, AB, Canada.*

Novel genomics approaches offer opportunities to select for efficient cattle to reduce feed costs. The objectives of this study were to: (1) identify new SNPs for residual feed intake (RFI) and performance traits within the candidate genes identified in a genome wide association study (GWAS); (2) estimate the proportion of variation in feed efficiency traits explained by the detected SNPs; (3) estimate the effect of detected SNPs on carcass traits to avoid undesirable correlated effects on other economically important traits when selecting for feed efficiency; and (4) map the corresponding genes to biological mechanisms and pathways. A total number of 339 SNPs corresponding to 180 genes were tested for association with phenotypes using a single locus regression (SLRM) and genotypic model on 726 and 990 crossbred animals for feed efficiency and carcass traits, respectively. Strong evidence of associations for RFI were located on chromosomes 8, 15, 16, 18, 19, 21, and 28. The strongest association with RFI ($P = 0.0017$) was found with a newly discovered SNP located on BTA 8 within the ELP3 gene. In addition, SNPs rs41820824 and rs41821600 on BTA 16 within the gene HMCN1 showed strong evidence of association with RFI ($P = 0.0064$ and $P = 0.0033$, respectively). A newly identified SNP located on BTA 18 within the ZNF423 gene provided strong evidence for association with RFI ($P = 0.0028$). Several SNPs provided strong evidence of association with other feed efficiency, performance, and carcass traits using the SLRM and genotypic model. Genomic estimated breeding values (GEBV) from 98 significant SNPs were moderately correlated (0.47) to the estimated breeding values (EBVs) from a mixed animal model. The significant SNPs (98) explained 18.06% of the phenotypic variance of RFI. Functional analysis for the corresponding genes to significant SNP for feed efficiency traits suggested 35 and 39 biological processes and pathways respectively with majority in ion and cation transport, phosphorus metabolic process, and regulation of transcription. The newly discovered SNPs should be validated in another population before incorporation in a DNA testing panel to evaluate the genetic merit of beef cattle for feed efficiency industry-wide.

471 Genetic and environmental influences on movement patterns of beef cattle grazing foothill rangeland.

D. Bailey*[1], D. Jensen[2], M. Thomas[3], D. Boss[2], and R. Welling[4], *[1]New Mexico State University, Las Cruces, [2]Montana State University, Havre, [3]Colorado State University, Fort Collins, [4]CashCattleBiz.com, Vaughn, MT.*

A study was conducted in foothill rangelands of Montana to evaluate the effects of genotype and environment (or early learning) on grazing distribution. Based on 5 years of observations, 5 of 180 cows that used the highest and steepest terrain (hill climbers) and 5 cows that used the most gentle terrain near water (bottom dwellers) were used as donor-dams for embryo transfer. A single unrelated Simmental sire was used in these matings. Recipient cows were classified as hill climbers (HC) and bottom dwellers (BD) based on 4 years of observation from a separate herd of 98 cows. This resulted in 2x2 factorial study with donor and recipient as factors and HC and BD as levels within each factor. During the summer of 2011, 18 of these cows (6 to 8 years of age) were tracked at 10-min intervals by global positioning system technologies in a 336 ha pasture. Distance to water, elevation, slope and a normalized average of these terrain attributes from recorded cow locations were averaged and evaluated using a statistical model that included donor, recipient and the donor*recipient interaction. A separate analysis compared breed groups irrespective of the donor and recipient classifications. We were unable to detect any differences between HC and BD recipients for any measure of grazing distribution. We observed a tendency ($P = 0.08$) for cows from HC donors (490 ± 13 m) to be farther from water than those from BD donors (456 ± 11 m), but we did not detect any differences ($P > 0.10$) between HC and BD donors for other measures of distribution. No interactions between donors and recipients were detected ($P > 0.10$). Tarentaise maternally influenced cows walked farther per day ($P = 0.03$) and were farther from water ($P = 0.01$) than Hereford maternally influenced cows. Grazing use of foothill rangeland appears to be affected to some degree by genetic factors, but the mechanism of this influence requires further study.

Key Words: genotype, early learning, behavior

Cell Biology Symposium: Molecular Basis for Feed Efficiency

472 Unique roles for agouti proteins and melanocortin signaling in lower vertebrates. C. Zhang[1,2], P. M. Forlano[3], and R. D. Cone*[1], *[1]Department of Molecular Physiology and Biophysics, Vanderbilt University School of Medicine, Nashville, TN, [2]Department of Cell and Developmental Biology, Oregon Health Science University, Portland, [3]Department of Biology and The Aquatic Research and Environmental Assessment Center, Brooklyn College of The City University of New York, Brooklyn.*

The agouti proteins and the central melanocortin circuits have been identified in all vertebrate species studied, from the most primitive fish to humans. These circuits regulate energy storage in adipose depots and somatic growth from fish to humans as well. However, deletion of the MC4R has only modest effects on somatic growth and reproduction in mammals, but large effects on larval teleosts, suggesting a fundamental difference in the neuroendocrine function of central melanocortin signaling in lower vertebrates. We have shown in a teleost that the hypothalamic proopiomelanocortin and AgRP neurons are hypophysiotropic, projecting to the pituitary to coordinately regulate multiple pituitary hormones. Indeed, AgRP-mediated suppression of MC4R appears essential for early larval growth. This identifies the mechanism by which the central melanocortin system coordinately regulates growth and reproduction in teleosts, and suggests it is an important anatomical substrate for evolutionary adaptation. Plasticity in growth and reproductive behavior is found in many vertebrate species, but is common in male teleost fish. Typically, "bourgeois" males are considerably larger and defend breeding territories while "parasitic" variants are small and use opportunistic breeding strategies. The P locus mediates this phenotypic variation in *Xipophorus* and encodes variant alleles of the melanocortin-4 receptor (MC4R), also explained mechanistically by our findings. These data also suggest potential commercial applications in lower vertebrates for the regulation of growth, and potentially feed efficiency as well, since inhibition of MC4R significantly stimulates early growth.

473 The physiological basis defining feed efficiency differences in pigs selected on residual feed intake. N. K. Gabler,* J. K. Grubbs, A. Harris, S. M. Cruzen, E. Huff-Lonergan, J. F. Patience, J. C. M. Dekkers, and S. M. Lonergan, *Iowa State University, Ames.*

In recent years, much attention has been given to feed efficiency in livestock production due to the rising costs of feed and other inputs. However, compared with growth and development, our understanding of the molecular biology and physiology regulating feed efficiency (FE) in swine is relatively limited. Residual feed intake (RFI) is a unique way to measure FE computed as the difference between the amount of feed a pig actually consumes and what it is expected to consume, based on its rate of growth and backfat. Therefore, selecting pigs for lower RFI results in animals that require less feed for a given rate of growth. The main biological factors that contribute to differences in RFI may include physical activity, feed intake patterns and behavior, stress, nutrient digestibility and efficiency of utilization, composition of gain and metabolism. In other words, both the maintenance and growth components of nutrient and energy utilization may be involved. In particular, the contributions of protein turnover, mitochondrial leakage and ion pump activity (i.e., Na^+, K+-ATPase) may provide the primary basis for divergence FE. Results from our lines of pigs that have been selected for high versus low RFI show that changes in body composition may help explain some of the variation observed in RFI divergence. Our data also suggests that a significant part of RFI variation may also be related to the level of protein turnover and degradation rates. These differences could be linked to mitochondrial function and oxidative stress in muscle and liver tissues. Furthermore, increased ion pump activity may contribute to reduced FE in pigs selected for high RFI, as maintaining high ion pump activity and membrane potentials are energetically expensive processes in metabolism. Altogether, this paper will discuss the molecular and physiological explanations for the observed phenotype in response for selection based on RFI. This project was supported by USDA-AFRI Competitive Grant #2010–65206–20670 and the Iowa Pork Producers Association.

Key Words: pig, feed efficiency, residual feed intake

474 Genetics of feed efficiency in dairy and beef cattle. D. P. Berry*[1] and J. J. Crowley[2], *[1]Teagasc, Moorepark Dairy Production Research Center, Fermoy, Co. Cork, Ireland, [2]Department of Agricultural, Food and Nutritional Science, University of Alberta, Edmonton, AB, Canada.*

Increasing food production for the growing human population off a decreasing land-base will require greater efficiency of production. Feed efficiency in cattle can contribute to this, and breeding, which is cumulative and permanent, is one likely vehicle to achieving efficiency gains within animal. A meta-analysis of up to 25 studies in growing cattle clearly showed that genetic variation in feed efficiency exists with a pooled heritability for residual feed intake and feed conversion efficiency of 0.34 ± 0.01 (range of 0.14 to 0.62) and 0.25 ± 0.01 (range of 0.06 to 0.46), respectively. However, what is not clear from the literature is what is the best breeding strategy to ensure food security, long-term—a conflict exists between focusing on improving feed efficiency per day or efficiency of an entire sector. Also, the studies to-date that highlight the importance of feed efficiency in breeding programs seem to ignore selection index theory that most of the variation in feed intake can actually be accounted for by other performance traits. Selection index calculations on a genetic covariance matrix between feed intake, liveweight and average daily gain generated from a meta-analysis of up to 12 studies showed that 84% of the genetic variation in feed intake could be explained by these traits. Therefore the marginal benefit of collecting feed intake data appears to be low. There is now sufficient information available to develop a roadmap on how best to direct research to ensure long-term food security for a growing human population.

Key Words: cattle, genetic, efficiency

475 Feed efficiency: Mitochondrial function to global gene expression. W. G. Bottje* and B.-W. Kong, *Department of Poultry Science, Center of Excellence for Poultry Science, University of Arkansas, Fayetteville.*

There is evidence that links mitochondrial function and biochemistry with the phenotypic expression of feed efficiency (FE, gain:feed). Consistent findings observed in low FE in several tissues were evidence of increased protein oxidation or oxidative stress that probably resulted from increased mitochondrial reactive oxygen species (ROS) generation. As ROS are well known to act as second messengers, gene expression in the low FE phenotype could be hypothesized to be due to inherent gene expression that is modulated by increased mitochondrial ROS production. Studies have been conducted to assess global gene expression in breast muscle associated with the phenotypic expression

of FE. In these studies, RNA samples were obtained from broilers that exhibited either high FE (0.65 ± 0.01) or low FE (0.46 ± 0.01) (n = 6 per group). Global RNA expression was investigated using a 44K chicken oligo microarray that was validated by comparison to values obtained by qRT-PCR for 33 different genes. A 1.3 fold cutoff value for expression resulted in over 750 genes that were differentially expressed in muscle between the high and low FE phenotypes. An online software program (Ingenuity Pathway Analysis) was used to group genes by function, gene networks and into established biochemical (canonical) pathways to facilitate data interpretation. The results indicate that animals exhibiting a high FE phenotype had increased expression of genes associated with anabolic activities and signal transduction-cascade mechanisms that would appear to favor cell growth, development and differentiation. AMP kinase (AMPK) that senses coordinates energy production to meet cell energy needs was also upregulated in the high FE phenotype. In contrast, animals exhibiting a low FE phenotype exhibited upregulation of many genes associated with actin-myosin filaments that would be involved in cytoskeletal architecture and/or muscle development. Several stress-related or stress responsive genes (e.g., heat shock proteins, superoxide dismutase) were also upregulated that might be attributed to higher ROS production. Although these studies are limited mRNA expression in muscle, the results provide additional information to help in understanding the cellular basis of feed efficiency.

Key Words: feed efficiency, bioenergetics, gene expression

Companion Animals Symposium: Impact of Anthropomorphism on Companion and Captive Animal Husbandry

476 Capitalizing on human health trends to improve feline health and wellbeing. M. R. Lappin,* *Department of Clinical Sciences, Colorado State University, Fort Collins.*

For some pet owners, their cat(s) is(are) treated like other 2-legged family members. In these situations, the veterinarian can be as vital a member of the family as the pediatrician or family practitioner who guide human health decisions. These owners tend to be well read and are easy influenced by electronic and other media. In my opinion, human health trends generally improve feline health and wellbeing. However, information derived from the human health care system can also hamper feline health care. In this lecture, a case-based approach will be used to provide examples of both potential outcomes. For example, in an attempt to provide cats the safest possible environment, many owners restrict the cat's access to the outdoors. This housing trend combined with over-feeding has led to an epidemic of feline obesity and related problems such as diabetes mellitus. Increased recognition of the human obesity problem by pet owners in North America has led to an increase in recognition of the problem in cats and makes directing the cat owner toward providing a more positive lifestyle for their cat much easier. The widespread use of supplements such as glycosaminoglycans to enhance the wellbeing of humans has also lead to improvement in feline health. For example, degenerative joint disease is more common in cats than is commonly believed. The resultant discomfort decreases activity levels and can potentiate the feline obesity problem. The increased recognition of the benefits of glycosaminoglycans in humans has made it much easier to convince owners to complete diagnostic evaluations of cats exhibiting inactivity and to appropriately manage degenerative joint disease. Last, due to a perceived increased risk of autism in vaccinated children and injection site sarcoma in cats, some cat owners are now fearful of vaccines of all types for cats. This problem dramatically lessens numbers of feline veterinary visits, which provide many benefits other than just vaccination.

477 Effect of anthropomorphism on companion and captive animal husbandry. T. M. Edling,* *Petco Animal Supplies Inc., San Diego, CA.*

The objective of this presentation is to demonstrate how anthropomorphism affects companion and captive animals, specifically those within the pet industry. Anthropomorphism is a double-edged sword. From the point of view of the veterinarian, the pet product manufacturer, service providers and retailers, we all embrace the fact that pet owners actively anthropomorphize their animals. We love that most people in the United States consider their pets to be part of their families and consider themselves to be "pet parents." In fact, we promote that pet owners place human attributes on their animals and we play to the emotions that relationship elicits to encourage owners to purchase products and services. The other edge of the sword cuts backward as we consider animals that are treated like human children. Those animals are fed inadequate diets of "people food," kept in habitats that are designed to fit fashionably into a home but are dysfunctional and inappropriate for the animal and placed in social situations where a human would be comfortable but are not ideal for an animal. It is vitally important that those of us who understand the husbandry needs of companion and captive animals educate the public as well as the marketing and merchandising leaders in the pet industry. With the proper influence, we can help ensure the products and services available to pet owners will provide the best possible outcome and anthropomorphism is kept in check.

Key Words: anthropomorphism, animal husbandry, companion and captive animals

478 Companion animal and captive animal husbandry: The balance between what animals need and what people think they need. M. S. Edwards,* *California Polytechnic State University, San Luis Obispo.*

Air, food, water, and shelter are described as fundamental animal needs. Species-specific adaptations enable animals to satisfy their unique needs. Those unable to meet their needs are removed, along with their genetics, from populations through natural selection. Animals maintained in human managed environments are dependent upon their caregivers for these needs, in appropriate type, quantity and quality. Selections made by human caregivers are not always consistent with species, or individual, requirements and may result in clinical or subclinical disease, reduced longevity and/or productivity. When considering appropriate nutrition (i.e., food, water), requirements are defined as the lowest nutrient intake that maintains a defined level of nourishment for a specific adequacy indicator (Jones and Varady, 2007). It is the exception that species are offered the identical compliment of foods consumed by their native range counterparts. Regardless of environment, species require nutrients contained within consumed foods, not the foods themselves. Nutrients, including those catabolized for energy, may be effectively delivered using multiple methods. Polar bears feed primarily on ringed and bearded seals, but seasonally shift to alternative nutrient sources, including caribou, arctic charr, several berry species, and human garbage (Dyck and Kebreab, 2009). In managed environments, nutrients supporting polar bears are effectively delivered using available ingredients, nearly all of which are not consumed by the species in its native range. The apparent disconnect between animal requirements and what human caregivers perceive as needed is best demonstrated by the current incidence of companion animal obesity. In the United States, 53% of adult dogs, 55% of cats, and 32% of horses are overweight or obese (APOP, 2012; Thatcher et al., 2008). These are animals whose needs are dependent on a human population, 68% of which are overweight or obese (Flegal et al., 2010). Wildlife species maintained in human managed environments are also susceptible to these trends, although objective population data has not been compiled. An effort to educate animal caregivers regarding species needs, and how they distinctly differ from their own, should be an objective of responsible animal management.

Key Words: requirements, husbandry, obesity

479 Antimicrobial cathelicidin peptides: What are they and how do they help protect the dog? T. Melgarejo* and F. Blecha, *Kansas State University, Manhattan.*

Cathelicidins, a group of cationic peptides found mainly in leukocytes and epithelial cells, play a central role in the innate immune defense against infection. These host defense peptides (HDPs) have been reported in several animal species; however, our team was the first to identify a HDP in the neutrophil granules of the domestic dog. This finding recently led to the patent of a canine cathelicidin (K9CATH) peptide and its functional analogs. The mature K9CATH peptide exhibits broad antimicrobial activity against gram-negative and gram-positive bacteria, fungi as well as certain intra-cellular parasites. Through computational optimization we have moreover succeeded in further enhancing the biological activity and stability of the synthetic K9CATH peptide. The potency and broad antimicrobial activity of K9CATH support that this peptide acts as a key player in the innate immune response of the dog. In light of increasing antibiotic resistance it is important to identify natural compounds that may serve as model molecules for the development of novel antimicrobials with application against clinically relevant infections in veterinary medicine. We are currently investigating the use of K9CATH analogs as potential therapeutic agents for common pathologies in dogs, such as urinary tract infections, yeast and bacterial dermatitis, and chronic otitis.

Key Words: dog, canine, antimicrobial

480 New findings in the obligate carnivore-omnivore debate: Regulation of macronutrient intake in cats and dogs. A. K. Hewson-Hughes*[1], V. L. Hewson-Hughes[1], A. Colyer[1], A. T. Miller[1], S. M. McGrane[1], S. R. Hall[1], R. F. Butterwick[1], S. J. Simpson[2], and D. Raubenheimer[3], *[1]Waltham Centre for Pet Nutrition, Waltham-on-the-Wolds, Leicestershire, UK, [2]University of Sydney, Sydney, Australia, [3]Massey University, Auckland, New Zealand.*

Animals in the wild are faced with a variety of food sources that differ in nutritional content (quality) and availability from which they must compose a diet to meet their nutrient requirements. While many herbivores and omnivores have been shown to balance their intake of macronutrients [protein (P), fat (F) and carbohydrate (C)] when faced with nutritionally variable foods, study of this ability has been relatively neglected in predators, largely on the assumption that prey are less variable in nutrient composition than the foods of herbivores and omnivores and such mechanisms therefore unnecessary. The mammalian order Carnivora is of particular interest for the study of macronutrient regulation since it includes our major companion animals, cats and dogs which have predator heritage but today are largely provided with food by their owners. We carried out studies in adult domestic cats and adult dogs representing 5 breeds from toy to giant to determine whether these ′domestic predators′ regulate macronutrient intake. Cats and dogs were provided with a choice of 3 different foods (each in a separate bowl and each food containing different amounts of P, F and C) from which they could self-select the amount of each food they consumed to compose a diet. Each of the foods was offered in excess of energy requirements and if any animal consumed all of one or more foods the amount offered was increased to ensure that the diet composed was not influenced by food availability. From the amount of each food consumed we calculated the overall amount of energy consumed from each macronutrient and expressed this as a proportion of the total energy intake. Cats composed a diet from the 3 foods offered of ~52% of energy from protein (95% confidence interval (CI) 47.7, 56.1%), 36% from fat (33.0, 37.6%) and 12% from carbohydrate (7.5, 18.2%). The different breeds of dogs regulated intake to a remarkably similar %P:F:C balance of ~30% (CI 27.3, 30.9):63% (62.0, 64.6%):7% (6.4, 7.9) suggesting that the mechanisms regulating food intake have been strongly conserved in these dogs despite rapid (artificially selected) changes in other phenotypic traits such as size. These studies indicate that domesticated mammalian carnivores are able to regulate food selection and intake and so balance their macronutrient intake to specific intake targets.

Key Words: macronutrient regulation, companion animals, carnivore nutrition

Dairy Foods Symposium: Bioactive Components in Milk and Dairy Products: Recent international perspectives and progresses in different dairy species

481 Bioactive components in cow milk and products. H. J. Korhonen,* *MTT Agrifood Research Finland, Jokioinen, Finland.*

Milk is considered a nutritionally perfect food for newborn mammals. Furthermore, scientific evidence is continuously accumulating on the health-promoting effects of different milk components. These components encompass proteins, peptides, carbohydrates and lipids, glycolipids and other minor biomolecules. Their biological properties and functions are already reasonably well established and this knowledge has laid the basis for use of bioactive cow milk components as ingredients for functional foods. Industrial or semi-industrial scale processing techniques are available for fractionation and isolation of such components from colostrum and milk. Biomining and marketing of native dairy-derived functional ingredients is now emerging as a new lucrative business sector for the dairy industry and specialized bio-industries. A few milk protein and peptide-based products as well as growth factors have already been commercialized. It can be envisaged that more similar products will be launched on worldwide markets in coming years. Such products could be targeted to specific target groups so as to maintain good health status, improve performance, or prevent diet-related metabolic diseases.

Key Words: milk, bioactives, ingredients

482 Bioactive components in buffalo milk and products. M. Guo,* *University of Vermont, Burlington.*

Buffalo are the second largest source of milk supply in the world; world production of buffalo milk exceeds 75 million metric tons per year and is increasing steadily at about 3 percent per year. Because buffalo milk has higher total solids compared with bovine milk, it accounts for about twice the food contribution implied by the volume of buffalo milk produced yearly. Buffalo milk may contain almost all the bioactive compounds found in bovine milk, e.g., proteins, peptides, fatty acids, vitamins, and other bioactive compounds. Buffalo milk has higher levels of total protein, medium chain fatty acids, CLA, and contents of retinol and tocopherols than those in bovine milk. Some components may only be present in buffalo milk such as gangliosides. Because of the differences in compositional and physiochemical properties between buffalo and bovine milk, processing technology and equipment designed for cow's milk may not be suitable for buffalo milk processing. However, it has been approved that buffalo milk can be utilized for manufacture of a wide variety of functional dairy products with limited modifications in processing technology.

Key Words: bioactive, components, buffalo

483 Bioactive components in goat milk and products. Y. W. Park,* *Fort Valley State University, Fort Valley, GA.*

Milk contains a wide variety of heterogeneous mixture of chemical and bioactive compounds, which play integral roles in human health and nutrition. Once these components are liberated from milk and dairy products, they exhibit various physiological effects in the body, including gastrointestinal, cardiovascular, endocrine, immune, and nervous systems. Functionalities of bioactive peptides include antimicrobial, antihypertensive, antithrombotic, antioxidative, hypocholesterolemic, antiappetizing, immunomodulatory and mineral binding activities. Bioactive compounds in caprine milk have not been well explored compared with human and bovine milk. Quantification of bioactive components in different species milk has been difficult, due to their biochemical complexities, the small concentrations, the need to develop special methods to quantify, the compartmentalization of some of the agents, and the dynamic effects of maternal factors on the concentrations. A myriad of milk-derived bioactive peptides have been reported. Immunomodulatory peptides, as one example, include αs1-CN f194–199 (αs1-immunocasokinin) and β-CN f193–202, f63–68, f191–193 (immunopeptides), that are synthesized by hydrolysis with pepsin-chymosin. Casein fractions of goat milk proteins, such as α-, β- and k-CN, are sources of bioactive components, which contain the peptides Tyr-Gln-Glu-Pro, Val-Pro-Lys-Val-Lys, and Tyr-Gln-Glu-Pro-Val-Leu-Gly-Pro-* from β-CN, as well as Arg-Pro-Lys and Arg-Pro-Lys-His-Pro-Ile-Lys-His-* from αs1-CN, that exhibit ACE-inhibitory activity. Goat milk has therapeutic, hypoallergenic and nutritional advantages over cow milk due to its specific bioactive protein, fatty acids and mineral compositions. The short and medium chain fatty acids (MCT) in goat milk have several bioactive functionalities in digestion, metabolism, treatment of lipid malabsorption syndromes. Other bioactive components in goat milk include CLA, gangliosides, glycolipids, glycosphingolipids and cerebrosides, alkylglycerol, phospholipids, growth factors, hormones, immunoglobulins, oligosaccharides, lactose-derivatives, lactoferrin, lysozyme, nucleosides, nucleotides, minerals, and vitamins.

Key Words: goat milk, products, bioactive components

484 Bioactive components in sheep milk and products. M. A. de la Fuente* and M. Juarez, *Instituto de Investigacion en Ciencias de la Alimentacion, Madrid, Spain.*

Although in quantitative terms the production of sheep milk is of marginal importance compared with cow milk, it is of particular interest in certain areas of the world and has special relevance for arid and semi-arid regions. Most sheep milk produced in the world is processed into dairy products, mainly cheese. The specific composition of milk of sheep makes it especially valuable nutritionally and for consumer health since it generally contains higher total solids and major nutrient contents than goat and cow milk. Sheep milk is an excellent source of high-quality protein, calcium and lipids. It also became apparent during the last years, that some milk compounds possess biological properties beyond their nutritional significance that can be utilized as ingredients for health-promoting functional foods or as nutraceuticals. Milk lipids contain several components that have demonstrated healthy properties. The most important is the rumenic acid, an isomer of the conjugated linoleic acid (CLA). Data from in vitro studies and animal models suggest that rumenic acid is responsible for CLA anticarcinogenic and antiatherogenic properties, as well as a multiplicity of potentially beneficial effects on human health. Enzymatic hydrolysis of milk proteins during gastrointestinal digestion and/or milk processing can release fragments, known as bioactive peptides, able to exert specific biological activities, such as antihypertensive, antimicrobial, opioid, antioxidant, immunomodulatory, or mineral binding. With the research tools available nowadays, the presence of these components with biological activity has been demonstrated in cow but less is known about ovine milk. This presentation will discuss current knowledge of the main natural bioactive substances contained in sheep dairy products mostly linked to the lipid and protein fractions. Emphasis will be put on fatty acids as CLA and bioactive peptides, which can favorably contribute to human nutrition.

Key Words: sheep milk, dairy, conjugated linoleic acid

485 Biosynthesis and secretion of bioactive compounds in milk in relation to genetic, molecular, and endocrine mechanisms. R. M. Akers,* *Virginia Tech, Blacksburg.*

Research and general interest in bioactive components in milk and milk products has exploded in the past decade. A simple PubMed search of primary scientific journal articles using the key word bioactive shows returns of 714, 1524, and 2,751 for the years 2000, 2005, and 2010, respectively. In this review, I explore the sources of bioactive components in mammary secretions and pathways which allow for synthesis, secretion and/or transport of bioactive materials into milk and mammary secretions. In the past decade understanding of regulatory processes that affect secretion of lipids and proteins in multiple cell types has also increased. Some of these proposed mechanisms have also been examined in mammary secretory cells. A prime driver of alterations in the composition of mammary secretions e.g., the change from colostrum-like to mature milk is the state of biochemical and structural differentiation of the mammary alveolar cells. Thus understanding factors which initiate and maintain the differentiated state of these cells directly correlates with the composition of milk and therefore the presence of various bioactive components. Gene profiling, proteomic measurements and other molecular tools have made it clear that the various cells within the mammary gland (ductal and alveolar epithelial cells, myoepithelial cells, endothelial cells, fibroblasts, adipocytes, macrophages, plasma cells etc.) are capable of producing a variety of bioactive agents including hormones, growth factors, and derivatives unimagined until recently. It is important to remember that milk and mammary secretions are first and foremost biological fluids. The lactocrine hypothesis to explain how the mammary gland and its secretions can act to control neonatal development is gaining much support. It is rather ironic that while we have long appreciated the nutrient value of mammary secretions, a nearly perfect food, we are seemingly only now beginning to appreciate the rich diversity of the bioactive agents in milk and milk products.

Key Words: bioactive, mammary, milk

Forages and Pastures II

486 Corn hybrid and plant density effects on corn silage quality and yield.

D. B. Burken,* J. L. Harding, T. C. Hoegemeyer, G. E. Erickson, and T. J. Klopfenstein, *University of Nebraska-Lincoln, Lincoln.*

The objective of this study was to evaluate corn hybrid, plant density, and harvest time effects on corn silage quality and yield. Five moderately early maturity corn hybrids (MEM; Hoegemeyer Hybrids) and 5 moderately late maturity corn hybrids (MLM; 1, Pioneer; 4, Hoegemeyer Hybrids) were planted at 4 populations (49,421, 64,247, 79,073, and 93,900 plants/ha) in a split plot design with 3 replications per hybrid × population combination. Five competitive corn plants were cut 15 cm above ground level and collected at 2 harvest dates (September 1, EH; September 15, LH). Grain, husk, and cob fractions were compiled. The remaining tissues (stalk, leaf, and shank) were chopped through a wood chipper, weighed, mixed, and subsampled at time of collection. There were interactions ($P \leq 0.001$) between hybrid, plant density, and harvest time for grain yield, grain percentage of total DM yield, and NDF concentration of the chopped subsample. Mean and standard deviation of grain yield was 12.0 ± 1.6 Mg/ha (range of 8.5 to 15.9 Mg/ha) for MEM hybrids and 12.5 ± 1.7 Mg/ha (range of 8.1 to 15.6 Mg/ha) for MLM hybrids. Grain yield as a percentage of total DM yield was 52.8 ± 3.3% (range of 42.1 to 59.2%) for the MEM hybrids and 50.6 ± 2.8% (range of 42.3 to 55.8%) for the MLM hybrids. Neutral detergent fiber concentration of the chopped subsample was 59.6 ± 5.1% (range of 50.4 to 70.7%) for the MEM hybrids and 61.7 ± 5.0% (range of 50.7 to 74.1%) for the MLM hybrids. Grain yield for corn planted at 49,421, 64,247, 79,073, and 93,900 plants/ha was 10.4, 12.5, 12.8, and 13.3 Mg/ha, respectively. Grain yield as a percentage of total DM yield was 49.7, 52.0, 52.8, and 52.4% for plant densities of 49,421, 64,247, 79,073, and 93,900 plants/ha, respectively. Chopped subsample NDF concentration was 57.3, 59.1, 62.7, and 63.4% for plant densities of 49,421, 64,247, 79,073, and 93,900 plants/ha, respectively. Grain yield as a percentage of total DM yield was 51.2 and 52.2% for EH and LH, respectively. Chopped subsample NDF concentration was 62.5% for EH and 58.8% for LH. Data from this study illustrate that corn hybrid, plant density, and harvest time affect corn silage yield and fiber characteristics.

Key Words: corn, corn silage, plant density

487 Characterization of aerobic deterioration of corn silage treated with stabilizers.

C. Merrill,* A. P. T. P. Roth, M. A. Santos, M. C. Der Bedrosian, and L. Kung Jr., *University of Delaware, Newark.*

We determined how spoilage alters the nutritive value of corn silage and evaluated the ability of TMR-mate (TMR-M, containing a blend of antifungal organic acids, 0.3% wet weight basis) and a feed additive, Omnigen-WYC, (O-WYC, containing potassium sorbate and other ingredients, 0.176% wet weight basis) to slow this process. Five replicated 20 L buckets with 5 cm diameter holes drilled throughout the bucket were prepared for each treatment, and filled with 6 kg of untreated or treated silage with one of the 2 additives. Bucket silos were exposed to air at 22°C. Samples from each bucket were taken at time 0 and every 24 h for 5 d. Core temperatures were measured every 15 min and aerobic stability was calculated as the number of h before the silage mass increased 2°C above baseline. Data were analyzed as a 3 × 6 factorial arrangement of treatments with the main effects of additive and time of sampling and their interaction. In general, the chemical composition and numbers of yeasts remained constant for all treatments through 2 d of exposure. The general tendencies observed relative to time of exposure were an increase ($P < 0.01$) in pH, ammonia-N, numbers of yeasts, DM, CP, and NDF. Decreases ($P < 0.01$) in concentrations of lactic and acetic acids, ethanol, water-soluble carbohydrates, and soluble protein occurred with time. Concentrations of lactic and acetic acids decreased ($P < 0.01$) by more than 80% of initial values after 3 and 5 d, respectively. Loss of DM did not differ among treatments but averaged 11.2% after 3 d and 27.5% after 5 d. At 3 d of exposure, the number of yeasts was 6.42 $\log_{10}$ cfu/g in untreated silage but less ($P < 0.01$) in treated silages (average of 4.91 $\log_{10}$ cfu/g). Similarly, silage pH was higher (5.75, $P < 0.01$) in untreated silage than in treated silage (average of 4.75). Treatment with O-AF and TMR-M improved ($P < 0.01$) aerobic stability (average 53 h) compared with untreated silage (44 h). The extent and duration of heating was lower for silage treated with O-AF than TMR-M. The additives in this study moderately improved the aerobic stability of corn silage.

Key Words: aerobic stability, silage

488 Exogenous fibrolytic enzyme effects on preingestive fiber hydrolysis and release of sugars and phenolics from bermudagrass haylage.

J. J. Romero*[1], K. G. Arriola[1], M. A. Zarate[1], C. R. Staples[1], C. F. Gonzalez[2], W. Vermerris[3], and A. T. Adesogan[1], [1]*Department of Animal Sciences, IFAS, University of Florida, Gainesville,* [2]*Department of Microbiology and Cell Science, IFAS, University of Florida, Gainesville,* [3]*Department of Agronomy, IFAS, University of Florida, Gainesville.*

The objective was to examine the effects of 12 exogenous fibrolytic enzyme (EFE) on hydrolysis of the fiber in a 4-wk regrowth of Tifton 85 bermudagrass haylage. The endoglucanase (EN) and xylanase (XY) activities (μmol/min/g) of the enzymes ranged from 9 to 3624, and 86 to 29301, respectively. The EFE were diluted in citrate–phosphate buffer (pH 6) containing sodium azide (0.02% w/v) antimicrobial agent and applied in quadruplicate to ground bermudagrass haylage (67.3, 33.5, 3.4 and 18.7% NDF, ADF, ADL, and CP, respectively) at manufacturer–recommended rates. The suspensions were incubated at 25°C for 24 h before addition of 30 mL of water, shaking for 1 h, and filtration of contents through Whatman 451 paper. The model included the fixed effect of enzyme. Compared with the Control (buffer and substrate alone), 10 EFE released more water-soluble carbohydrates (WSC, %; 3.69 ± 1.12 vs. 2.28 ± 0.04; $P < 0.01$), 10 released more ferulic acid (FER, μg/g; 263 ± 64 vs. 198 ± 2.3; $P < 0.01$), 8 released more *p*-coumaric acid (μg/g; 178 ± 13 vs. 162 ± 1.3; $P < 0.05$), and 3 solubilized more DM (%; 24.1 ± 0.5 vs. 22.0 ± 0.5; $P < 0.05$). Furthermore, compared with the control, 4 EFE-treated substrates had lower NDF (%; 64.0 ± 1.1 vs. 67.3 ± 0.6; $P < 0.05$), 5 had lower hemicellulose (31.4 ± 1.2 vs. 33.8 ± 0.45; $P < 0.01$), 1 had lower ADF (31.9 ± 0.4 vs. 33.5 ± 0.4; $P < 0.01$) and 1 had lower cellulose (28.6 ± 0.4 vs. 30.1 ± 0.4; $P < 0.01$). Prediction equations with independent variables including enzyme protein content (PR, mg) and EN, exoglucanase (EX), β-glucosidase, (BG), XY and ferulic acid esterase activities applied explained ($P < 0.01$) 64, 72, 99 and 93% of variation in NDF, HEM, WSC (%), and FER (μg/g), respectively. The greatest ($P < 0.01$) contributors to the R^2 for predicting NDF, WSC, and FER were EN (0.34) and BG (0.15), EN (0.65) and PR (0.14), and EN (0.17) and XY (0.71), respectively. Several promising EFE candidates that can hydrolyze bermudagrass fiber before ruminal degradation were identified as well as the critical enzyme activities responsible for such hydrolysis.

Key Words: forage, enzyme, fiber

489 Indigestible NDF in predictions of grass and red clover silage digestibility.

S. J. Krizsan*[1], H. M. Alamouti[2], and P. Huhtanen[1], [1]*Swedish University of Agricultural Sciences, Department of Agricultural Research for Northern Sweden, Umeå, Sweden,* [2]*Zanjan University, Department of Animal Science, Zanjan, Iran.*

The objective of this study was to correct indigestible NDF (iNDF) for the loss of lignin to improve predictions of forage OM digestibility. Samples of silages, iNDF and feces were analyzed for acid detergent lignin (ADL). Feed and fecal samples were from grass and red clover silages with in vivo digestibility determined in sheep fed at maintenance level using the total fecal collection method. Silages were harvested at different maturities from primary growth (n = 12) or secondary growth (n = 14) of timothy-meadow fescue (n = 15) or red clover (n = 11) swards. Indigestible NDF was recovered from 288-h in situ incubation in the rumen of 3 lactating dairy cows. Acid detergent lignin was determined in all samples by solubilization of cellulose in sulfuric acid after extraction with acid detergent. Indigestibility of ADL was determined by the Lucas test, where indigestible ADL was calculated from the concentrations of ADL in feces or iNDF. Hypothesis testing was conducted based on the parameters 95% confidence intervals. The slopes of the Lucas test for grass and red clover silages, and for first and second cut silages based on fecal samples did not differ ($P > 0.05$), and indigestibility of ADL (0.97 ± 0.069) was not different from 1 across all silages ($P < 0.05$). Indigestibility of ADL recovered in iNDF was different for grass and red clover silages (0.55 vs. 0.81; $P < 0.05$). Further, intercepts of the regression lines based on recovery of ADL in iNDF were not different from 0 ($P \geq 0.06$) and slopes were smaller than 1 ($P < 0.05$). Correcting individual samples for the loss of ADL in predictions of OM digestibility from iNDF lowered root mean square error (RMSE) from 0.0194 to 0.0179. With a general correction based on an indigestibility of 0.55 or 0.81 for grass and red clover silages RMSE increased to 0.0223. It is concluded that despite the losses of ADL in iNDF determination it is not practical to correct iNDF concentration on an individual sample level.

Key Words: acid detergent lignin, digestibility, indigestible neutral detergent fiber

490 The effect of inoculants containing *Lactobacillus buchneri* on the fermentation of alfalfa silage harvested at two dry matters.

M. C. Der Bedrosian,* B. G. Case, M. C. Santos, J. Lim, and L. Kung Jr., *University of Delaware, Newark.*

The objective of this study was to evaluate the effects of microbial inoculants with *Lactobacilllus buchneri* on the fermentation of alfalfa silage. Alfalfa was wilted to 33 (low) and 50% (high) DM. Forage was chopped and treated in piles (4 each) with nothing (C), *L. buchneri* 40788, application rate of 4×10^5 cfu/g of wet forage (LB; Lallemand Animal Nutrition, Milwaukee, WI), LB and *Pediococcus pentosaceus* 12455 (1×10^5 cfu/g; LBP), or LB and *L. plantarum* MTD1 (1×10^5 cfu/g, Ecosyl Products Ltd., Stokesly, UK; LPLB). Forages were packed and stored in lab silos at 22°C for 3, 7, 14 and 90 d. Data were analyzed in a factorial arrangement of treatments with main effects of treatment and time and their interactions. Significance was declared when $P < 0.05$. At both DM, after 3 d of ensiling, the pH declined markedly ($P < 0.01$) and to the same extent for LBP and LPLB, and to a lesser extent for LB compared with C. The drop in pH was more marked ($P < 0.01$) in low vs. high DM silages. After 90 d, LB had lower ($P < 0.01$) concentrations of lactic acid when compared with C. Inoculation of high DM alfalfa did not affect the concentration of lactic acid at d 90. Regardless of DM, inoculation did not statistically increase acetic acid. In particular, treatment with LBC resulted in greater concentrations ($P < 0.04$) of this compound relative to C in both DM. Treatment with LB and LPLB resulted in greater concentrations ($P < 0.01$) of propionic acid when compared with C but only in low DM silages. Inoculation resulted in silages with lower concentrations ($P < 0.01$) of ethanol when compared with C in low DM silages. In high DM silage, only LPLB decreased ethanol relative to C. Treatment with *L. buchneri* altered silage fermentation but the changes were dependent on what organism it was combined with and the DM content of forage.

Key Words: silage, alfalfa

491 Alfalfa/grass mixtures yield more DM, CP, NDF, and dNDF than alfalfa in monocultures.

J. Paulson,* D. Holen, and P. Peterson, *University of Minnesota, St. Paul.*

Alfalfa and alfalfa/grass mixture trials were seeded in 1x7 M replicated plots near Hutchinson, MN on 25 August 2008, and near Underwood, MN on 29 August 2008 to compare agronomic and nutrient differences. Treatments included binary mixtures of alfalfa (ALF) with 9 different perennial grasses, and alfalfa seeded alone. Three different ALF varieties were tested alone and in binary mixtures with 2 varieties of each of the 9 grass species. Four harvests cut to a 10 cm residual were obtained in 2011 (third production year) at both locations. At each harvest, subsamples of chopped herbage of selected treatments were oven-dried, ground, and analyzed for forage quality via NIRS Consortium equations at the UW Forage Testing Lab. Parameters measured included CP, NDF, 48-h NDF digestibility, ADF, and ADL. Values for RFQ, RFV, milk per ton, milk per acre, and digestible fiber yield were also calculated. At Underwood, binary mixtures of alfalfa/tall fescue or alfalfa/orchardgrass produced significantly higher amounts of NDF and dNDF compared with monocultures of alfalfa. Alfalfa/tall fescue mixtures also produced significantly greater amounts of DM and numerically greater amounts of CP. At Hutchinson, binary mixtures of alfalfa/orchardgrass produced significantly greater amounts of DM, NDF and dNDF when compared with alfalfa alone. Binary mixtures of alfalfa/tall fescue also produced significantly greater amounts of DM and numerically greater amounts of NDF and dNDF compared with alfalfa alone. Yield of CP was similar across treatments at Hutchinson. Alfalfa/grass mixtures offer agronomic and nutrient advantages compared with alfalfa monocultures.

Table 1. 2011 total-season DM, CP, NDF and dNDF-yields of alfalfa/grass mixtures at Hutchinson (H) and Underwood (U), Minnesota

	DM Yld	CP Yld	NDF Yld	dNDF Yld
Mixture	Tons DM/ a	lb CP/a	lb NDF/a	lb dNDF/a
Alf/Tall Fescue - U	**5.87**	**5.87**	**5530**	**2670**
Alf/Orchardgrass - U	5.41	2330	**5070**	**2490**
Alf/Orchardgrass -H	**4.03**	1670	**4530**	**2430**

492 Effect of land clearing and tillage methods on weed incidence under maize-cassava inter-cropping system.

A. H. Ekeocha,* *University of Ibadan, Ibadan, Oyo, Nigeria.*

Agricultural activities have been identified as the most common causes of land transformation. Such transformation results in changes in ecological features, such as weed flora succession. It is in view of this that this work was carried out to evaluate the effect of land clearing and tillage methods on weed incidence under maize-cassava intercropping system. The experiment was carried out at the International Board for Soil Research and Management experimental site, Epemakinde, Nigeria. (40 45° E, 60 45° N) after 3 cropping years. The treatments consist of 3 land clearing methods thus, given a split plot fitted into randomized complete block design. The 3 land clearing methods: slash and burn (SB), bulldozed not windrowed (BNW) and bulldozed windrowed (BW) are the main treatments while the 4 tillage methods namely (zero, conventional, traditional, and minimum tillage) constituted the sub-treatments. Data were collected on weed incidence at 6 and 16 weeks after planting (WAP). The result indicates that weed coverage at WAP were not different ($P > 0.05$) among the land clearing treatments, although SB had the least weed coverage (55.5%) ($P > 0.05$) on the average representing 9.2% and 8.9% lower than those of BW (60.63%) and BNW (60.46%). Zero tillage and traditional practices had the highest weed coverage of 86.11% and 82.17% respectively, representing 207.5% and 193.5% increase over conventional tillage (28.00%). In conclusion, slash and burn under minimum tillage and conventional tillage treatments, which gave a reduced weed problem, appears a better option.

Key Words: land clearing, tillage methods, weed incidence

493 Agronomic characteristics of pearl millet genotypes for forage production in southwestern Nigeria.

B. Ogunlolu,* A. Jolaosho, O. Onifade, B. Oduguwa, and P. Dele, *Department of Pasture and Range Management, University of Agriculture, Abeokuta, Ogun State, Nigeria.*

This study was conducted to evaluate 10 selected *Pennisetum glaucum* (L.) R. Br. genotypes for forage production in Abeokuta, South - Western Nigeria. The experiment was laid out on the field in a randomized block design. The land area of 555m ^{2} was divided into 30 plots of 3m by 2.5m each with spacing of 1m between plots. Ten genotypes of pearl millet were randomly planted at a spacing of 75 × 25 cm into 10 plots per block and replicated 3 times. Weekly observations were taken on the tiller number, number of leaves on main and secondary tillers, crown spread and leaf area from the 2nd week after planting (WAP) and plant height was taken up to 22 WAP. There were significant differences in the plant height, number of tillers and leaves, leaf area and crown spread on the pearl millet genotypes. Bunkure, Mokwa, Maiwa UI 25–2, Maiwa UI 28–1, Maiwa UI 94–2 and Dauro reached their maximum heights of 275.00 cm to 417.30 cm at 22WAP with Bunkure having the highest plant height of 417cm. Dauro and Mokwa had the highest ($P < 0.05$) leaf area at 7WAP. Dauro, Maiwa UI 94–2, Maiwa UI 25–2 and Mokwa had the highest ($P < 0.05$) number of leaves on primary and secondary tillers from 8WAP to 10WAP. Bunkure had highest number of leaves on secondary tillers, though produced fewer primary leaves. It can be concluded that Bunkure, Mokwa, Dauro, Maiwa UI 25–2 and Maiwa UI 94–2 pearl millet genotypes planted between May and October which exhibited late maturity and had the highest number of leaves, are the most desirable for forage production in Abeokuta, southwestern Nigeria.

Key Words: pearl millet, genotypes, forage

494 Influence of sample preparation technique on masticate fiber content collected from esophageally fistulated cattle.

K. L. Gillespie,* J. A. Musgrave, L. A. Stalker, T. J. Klopfenstein, and S. K. Pruitt, *University of Nebraska, Lincoln.*

Diet samples collected using esophageally fistulated cattle are representative of nutrients consumed by grazing cattle. However, preparation methods may alter the nutrient composition of the masticate sample. Meadow, hay, and upland range diet samples collected using esophageally fistulated cows were used to determine the effect of squeezing masticate samples on NDF content. In study 1, nine 1-ha Sandhills upland range paddocks were each sampled twice throughout the grazing season using 3 esophageally fistulated cows each collection day. Samples were collected at 12-d intervals from May 18 to June 11 and at 28-d intervals from June 12 to August 26. In study 2, 12 esophageally fistulated cows were offered 428 g (DM) vegetative grass harvested immediately before presentation from a subirrigated meadow, and, after collection of the masticate, they were offered 1,032-g (DM) hay harvested the previous summer from a subirrigated meadow. In all studies, esophageal plugs were removed, cows were fitted with screen bottom bags and allowed to graze, and following collection, masticate samples were divided and left unsqueezed (UNSQZ) or hand squeezed until no saliva could be extracted (SQZ). Samples were frozen, lyophilized, ground to pass a 1-mm screen, and analyzed for NDF. Representative samples of the clipped meadow and hay offered in study 2 were collected, ground through a 1-mm screen, and analyzed. In study 1, squeezing increased ($P < 0.01$) NDF content from 65.9% (UNSQZ) to 69.7% (SQZ). In study 2, squeezing increased ($P < 0.01$) NDF content of clipped meadow from 43.9% (UNSQZ) to 52.0% (SQZ), and hay from 67.3% (UNSQZ) to 71.2% (SQZ). Fresh, vegetative masticate samples were affected most by squeezing. There was no significant difference ($P = 0.27$) between NDF content of hay offered at 66.2% and UNSQZ masticate sample collected at 67.3%. However, meadow sample NDF significantly increased ($P < 0.01$) under both methods, from 40.0% originally to 43.9% UNSQZ and to 52.0% SQZ. Cell solubles may be lost with saliva through screen bottom bags and further losses occur with squeezing. Squeezing masticate samples markedly increases NDF content of samples collected with esophageal fistulated animals.

Key Words: NDF, forage diet sample, fistulation

495 Influence of pre-collection diet and squeezing on crude protein content of masticate collected from fistulated cattle.

J. A. Musgrave,* K. L. Gillespie, S. K. Pruitt, L. A. Stalker, and T. J. Klopfenstein, *University of Nebraska, Lincoln.*

In study 1, 12 esophageally fistulated cattle were maintained on 2 pre-collection diets: HI (24% CP, n = 6) or LO (7.7% CP, n = 6) for 8 d. On d 9, the esophageal plug was removed, screen bottom bags were attached and all cattle were presented with 428 g (DM) vegetative grass (VEG; 24% CP, 40% NDF) which had been harvested from subirrigated meadow immediately before presentation. Following VEG collection, all cows were presented with 1032 g (DM) hay (HAY; 7.7% CP, 66% NDF) harvested from subirrigated meadow the previous summer. Blood samples were collected via coccygeal venipuncture and analyzed for BUN content. In study 2, 3 esophageally fistulated cows sampled Sandhills upland range 12 times from May 21 to August 18. In study 3, 5 ruminally fistulated steers were fed vegetative smooth bromegrass harvested immediately before presentation. In all 3 studies, masticate samples were divided and each was either squeezed by hand until no more saliva could be removed (SQZ), or un-squeezed (UNSQZ). All masticate samples were immediately frozen and stored until lyophilized and analyzed for CP content. In study 1, pre-collection diet did not affect ($P = 0.49$) CP content of masticate. Type of forage offered (VEG vs. HAY) interacted ($P = 0.01$) with preparation technique, where CP was lost when VEG samples were squeezed (20.0 vs. 21.5% CP for SQZ vs. UNSQZ, respectively; $P < 0.05$) but not when HAY samples were squeezed (7.6 vs. 7.6% CP for SQZ vs. UNSQZ, respectively; $P > 0.05$). BUN levels tended to be higher for HI cows (27.6 ± 4.0 vs. 23.5 ± 3.2 mL/dL; HI vs. LO, respectively; $P = 0.08$). In this case, total amount of salivary contamination may not have been enough to influence CP content of the masticate. In study 2, there was no difference in CP between SQZ and UNSQZ (9.5 and 9.6%; $P = 0.66$) samples. In study 3, the difference in CP between SQZ and UNSQZ (18.6 and 20.1%) samples was not statistically separable ($P = 0.16$). Previous diet did not affect CP level of masticate and squeezing affected CP levels of high quality forage but had little effect on lower quality forage.

Key Words: grazed diet, diet collection, sample preparation

496 Variability and implications of indigestible neutral detergent fiber in C3 and C4 forages.

E. Raffrenato*[1,4], D. M. McNeill[2], D. G. Barber[3], M. N. Callow[3], and D. P. Poppi[1], [1]*School of Agriculture and Food Sciences, The University of Queensland, Gatton, Queensland, Australia,* [2]*School of Veterinary Science, The University of Queensland, Gatton, Queensland, Australia,* [3]*Agri-Science Queensland, Department of Employment, Economic Development and Innovation, Lawes, Queensland, Australia,* [4]*Department of Animal and Wildlife Sciences, University of Pretoria, Pretoria, Gauteng, South Africa.*

Rates of NDF digestion are used within models such as the CNCPS and CPM Dairy to determine optimal rations for dairy cows. These models multiply ADL by 2.4 to estimate the indigestible NDF (iNDF). The resulting iNDF can be used to estimate the rate of digestion for the potentially digestible NDF (kd, pdNDF). However, recent work in C3 forages has found considerable variability in the ratio iNDF/ADL, resulting in profound effects on the calculated pdNDF, kds and the supply of energy and microbial protein. The objectives of this work were to further characterize the variability of this ratio in C3 and C4 species grown in Queensland, Australia, and to suggest better equations to predict iNDF. One hundred and 40 forages or forage mixtures were selected out of 240 sampled across Queensland during winter 2011 to represent a wide spread of NDF content, forage groups and species. Samples were analyzed for ADL, NDF and iNDF, and results were grouped for single species. Long-term in vitro fermentations were conducted for 240 h to reach the maximum extent of digestion to determine iNDF. Within and across forage groups, the iNDF/ADL ratio ranged from 1 to 9.6, with lower values ($P < 0.05$) for C3 species (3.05 ± 1.47) compared with C4 ones (5.01 ± 1.75). Only for ryegrass, iNDF appeared similar (2.53 ± 0.76, $P = 0.33$) to that estimated using the 2.4 ratio, with, however, 75% of the samples having ratios numerically lower than 2.4 and therefore lower actual iNDF and kd. The attempt to predict iNDF within species based on the relationship between ADL/NDF and the ratio, through exponential equations, resulted in R^2 values between 0.15 and 0.85. This suggests that the 2.4 ratio when applied indiscriminately has potentially large errors and simply using C3 and C4 classification will not solve this issue, but possibly a grouping tht is species-specific may be more appropriate. A wider data set across species, agronomic and environmental conditions is needed to see if generalized equations with more acceptable error terms can be devised. The project was partially funded by Dairy Australia.

Key Words: indigestible NDF, fiber, rate of digestion

497 Fecal NIRS relationship with intake and diet digestibility of grazed Bahiagrass by cows determined by n-alkanes.

S. W. Coleman*[1], C. C. Chase Jr.[2], and D. G. Riley[3], [1]*USDA ARS, El Reno, OK,* [2]*USDA ARS, Clay Center, NE,* [3]*Texas Agrilife, College Station.*

The objective of this study was to determine if fecal analysis by NIRS could be used to calibrate for intake determined by the alkane ratio technique in grazing cows. Dry matter intake (DMI; g/kg BW) and diet digestibility (D) was estimated in cows of various breeds in 7 trials over 7 years during different seasons. Nine to 12 cows were used in each trial and on d-1, each received a bolus that delivered a prescribed amount daily of both C_{32} and C_{36} n-alkanes as external markers. The bolus was designed to deliver 300 mg of marker each day over about 21 d. In 4 of the trials, actual payout was determined by collecting feces until dosed marker was not detected. Fecal samples were collected daily from the ground as marked cows defecated in presence of an observer, lyophilized, scanned by NIRS (400–2500 nm), and analyzed for n-alkane concentration following ethanolic KOH extraction and cleanup. Diet D was estimated by the ratio of naturally occurring plant cuticular wax n-alkanes (odd-chain C_{27}-C_{37}) in the forage and feces. Intake was estimated by the ratio of daily dose of external marker and fecal marker concentration corrected for forage C_{32} or C_{36}. Bahiagrass contained sufficient C_{31}, C_{33}, and C_{35} for use as markers and concentration in feces varied both within trial and across trials providing variation in D. Calibration equations were developed by PLS regression of DMI and D on fecal spectra. The equations were then used to predict values on the same spectra to determine if structural bias occurred within the data set among trials and breeds within trial. Differences between alkane estimated DMI (31.6 ± 13.6) and D (65.2 ± 7.0) and NIRS estimated DMI (31.1 ± 8.3) and D (65.5 ± 4.7) were significant ($P < 0.001$) among trials but not different due to breed within trial. When alkane estimated D was regressed on NIRS predicted D, slopes differed among trials ($P < 0.0001$) and breed within trial ($P < 0.01$). However, slopes for DMI differed among trials ($P < 0.001$) but not breed ($P = 0.60$). We suggest that NIRS can be used as a double sampling technique with n-alkanes for estimating DMI and diet D on large numbers of animals.

Key Words: grazing intake, diet digestibility, fecal NIRS

498 Dry season nutrient availability of vegetation species selected by the African elephant (*Loxodanta africana*) in the Pongola Game Reserve, South Africa.

E. Cuthbert,* P. Yu, and D. A. Christensen, *University of Saskatchewan, Saskatoon, SK, Canada.*

African elephants were reintroduced to the Pongola Game Reserve (PGR), South Africa, in 1997, via translocation. Fourteen elephants established the original population and it has since grown to over 50 individuals. Elephant conservation and management has continued to increase in importance throughout the southern African countries, and along with efforts of Space for Elephants, the PGR currently monitors herd health and behavior, but information on herd nutritional status is lacking. The purpose of this research was to collect samples of plant species consumed by the elephants and analyze the chemical composition and adequacy of the general diet using horse nutrient requirements. Body condition score was assessed to determine if animals were losing condition due to lack of nutrition. Collection of plant samples occurred during the dry season in July 2011. Nutrient analyses included DM, ash, crude protein, EE, ADF, NDF, ADICP, NDICP, hemi-cellulose, CHO content, macro and micro minerals; DE was estimated using horse energy calculations; GE, ME, TDN, and estimated digestibility were calculated using NRC Beef 2000. Fecal samples were also collected and analyzed for fiber and mineral content. Estimated DE averaged 1.63 Mcal/kg for grasses, 3.01 Mcal/kg for *Aloe marlothi*, and 2.18 Mcal/kg for tree species. Grasses averaged 2.98% CP, 47.0% ADF, and 76.8% NDF, on a dry matter basis. Aloe averages 16.0% CP, 19.7% ADF, and 25.5% NDF. Tree species averaged 8.8% CP, 37.0% ADF, and 52.7% NDF. Results of this study suggest that crude protein and phosphorus (average 0.11% of DM) are available in marginal amounts and lactating female elephants and the bulls with the highest energy requirements are at risk of losing body condition. Therefore, further population control methods or herd size reduction may be required to sustain the population and avoid detrimental environmental damage from over-exploitation.

Key Words: African elephant, nutrition, chemical composition

Horse Species II

499 Estimation of ideal body weight in horses and ponies using morphometric measurements. K. Martinson*[1], R. Coleman[2], J. Earing[1], A. Rendahl[1], and M. McCue[1], [1]*University of Minnesota, St. Paul,* [2]*University of Kentucky, Lexington.*

As the incidence of equine metabolic syndrome and obesity become more prevalent in the equine population, owners, veterinarians, and professionals need information to more effectively manage equine body weight. Body condition score (BCS) is used to measure body fat or adiposity in specific areas of the body, however, ideal body weight for equines is currently unknown. The objective of this study was to determine if ideal equine body weight could be derived based on body measurements unaffected by adiposity. Six hundred and 40 non-pregnant adult equines, ≥ 3 years of age, and ≥ 112 cm in height were measured and weighed at 2 non-breed specific equine shows in September 2011 in MN. For all equines, 2 personnel assessed BCS on a scale of 1 (poor) to 9 (extremely fat), one person measured wither height at the third thoracic vertebra, and 2 personnel measured body length from the point of buttock to the point of the shoulder. Girth and neck circumference, age, sex, and breed were also recorded, and equines were weighed on a portable livestock scale. Equines had a BSC range of 2 to 8 (mean = 5.6), mean age of 12 years, and the dominant breed and sex were Quarter Horses (n = 345) and geldings (n = 345), respectively. Of the 640 equines, 253 and 236 were given a BSC of 5 and 6, respectively, and were used to predict ideal weight. A linear regression for ideal weight was fit using body length and height as predictors. Neck ($P < 0.001$) and girth ($P < 0.001$) circumference affected model fit, however, these measurements are biased by adiposity and were removed from the model. Age ($P = 0.734$) and sex ($P = 0.337$) did not affect model fit. Body length ($P < 0.001$) and wither height ($P < 0.001$) accurately predicted ideal body weight ($R^2 = 0.86$). Breed ($P < 0.001$) affected the model, however, including that factor resulted in a minimum improvement in model fit ($R^2 = 0.88$). Morphometric measurements can be used to predict ideal equine body weight resulting in useful information for health and nutritional management of equines.

Key Words: body condition score, body length, height

500 Influence of maternal plane of nutrition and arginine supplementation on mares and their foals: Glucose and insulin dynamics. A. E. Hanson*[1], K. N. Winsco[1], J. A. Coverdale[1], C. J. Hammer[2], and A. N. Wolford[1], [1]*Texas A&M University, College Station,* [2]*North Dakota State University, Fargo.*

The objective was to determine if supplemental dietary arginine can mitigate the effect of maternal over-nutrition on mare and foal glucose and insulin dynamics. Thirty-two mares (468 to 668 kg BW; 3 to 19 yr) were blocked by expected foaling date and randomly assigned to treatments. Treatments were arranged as a 2 × 2 factorial with 2 planes of nutrition, moderate (Mod; 0.5% BW AF grain/d) or high (High; 1% BW AF grain/d) and 2 levels of L-arginine supplementation, 0.21 g/kg/d (Arg) or no supplemental Arg (Con; L-alanine to maintain isonitrogenous diets). Treatments began 110 d before expected foaling and terminated at parturition. Mares were housed by block, allowed ad libitum access to water and coastal bermudagrass (*Cynodon dactylon*) hay, and fed commercial grain 2 × /d in individual stalls. A modified frequent sampling i.v. glucose tolerance test (FSIGT) was performed on mares at 11 mo gestation and foals at 5 and 30 d of age. After a baseline plasma sample, a glucose bolus of 0.3 g/kg BW was administered, and then, an insulin bolus of 30 mU/kg BW after 20 min. Blood samples were harvested at 1, 2, 3, 4, 5, 6, 7, 8, 10, 12, 14, 16, 19, 22, 23, 24, 25, 27, 30, 35, 40, 50, 60, 70, 80, 90, 100, 120, 150, and 180 min. Glucose concentrations were analyzed using a colorimetric assay and insulin using a RIA kit. Data were analyzed using PROC MIXED of SAS with effects of plane of nutrition (Nutr), amino acid (AA), time, and their interactions. There was no influence of diet on mare glucose area under the curve (AUC) or peak glucose (PG) and peak insulin (PI) concentrations. Mare insulin AUC tended to be influenced by diet ($P \leq 0.06$) with HighCon mares having greater AUC than ModCon ($P \leq 0.05$), and HighCon having greater AUC than HighArg ($P \leq 0.05$). Foal glucose AUC, PG, insulin AUC, and PI were not influenced by maternal diet. Mare AA tended to influence foal PG with foals from Con having higher concentrations than Arg ($P \leq 0.09$). Foal age influenced glucose and insulin AUC with glucose greater at 5 d compared with 30 d ($P \leq 0.003$), and insulin tending to be greater at 30 d than 5 d ($P \leq 0.08$). Data suggest maternal nutrition and arginine supplementation can alter mare and foal glucose and insulin dynamics.

Key Words: glucose, insulin, arginine

501 Prevalence of internal parasites and anthelmintic efficacy in horses in relation to age, season and housing system. E. R. Share,* J. M. Reddish, C. Dyer, K. Koke, K. Barnhart, P. Sparks, and K. Cole, *The Ohio State University, Columbus.*

The effective control of internal parasites is important in maintaining horse health. The objective of this study was to determine the prevalence of internal parasites and anthelmintic efficacy in horses in relation to age, season and housing system. Fecal samples were collected from 65 horses, ranging in age from 1 to 22 years, on a farm in central Ohio between July 2011 and January 2012. Fecal egg count data were collected before treatment with pyrantel pamoate at the recommended dosage and 14 d post-treatment. Fecal samples were analyzed by the fecal float method, with the number of internal parasites recorded as eggs per gram (EPG) of feces. Fecal egg count (FEC) reduction was calculated as (pre-treatment EPG minus post-treatment EPG)/pre-treatment EPG. Data were analyzed using the PROC GLM procedure of SAS. A P value of ≤0.05 was considered statistically significant. Treatment with pyrantel pamoate was considered effective if FEC reduction was ≥90% by d 14 post-treatment. Strongyle, ascarid, hookworm, pinworm, whipworm and tapeworm eggs were identified in this study; however, strongyle, ascarid and tapeworm eggs were the most prevalent. Young horses (<3 yr) had greater FEC compared with mature horses (464.35 ± 239 EPG vs. 198.89 ± 234 EPG, $P < 0.05$). FEC were similar during summer months compared with winter months. Horses maintained on pastures had greater FEC than horses kept in stalls (280.4 ± 261 EPG vs. 72.6 ± 100 EPG; $P < 0.05$). Resistance to pyrantel pamoate was evident regardless of the age of the horses, season or housing system. In this study, treatment with pyrantel pamoate was more effective at reducing total FEC in mature horses (27.8%) compared with young horses (14.3%). Pyrantel pamoate was also found to be more effective at reducing total FEC in the summer months (15%) as compared with the winter months (0%). Horses maintained on pastures were less resistant (21.4%) to treatment with pyrantel pamoate compared with stalled horses (16.7%). Although pyrantel pamoate was not considered effective in reducing the total FEC of horses on this farm, it may still be a useful product if used in combination other anthelmintics.

Key Words: horse, internal parasites, pyrantel pamoate

502 Antibiotic therapy disrupts equine fecal microflora.

B. E. Davis*[1], L. M. Lawrence[1], M. D. Flythe[2,1], S. H. Hayes[1], G. L. Gellin[2], L. A. Strasinger[1], M. Brummer[1], and A. L. Fowler[1], *[1]University of Kentucky, Lexington, [2]United States Department of Agriculture, Agricultural Research Service, Forage-Animal Production Research Unit, Lexington, KY.*

Antibiotic associated diarrhea (AAD) is a side effect of antibiotic therapy in horses. AAD is attributed to the disruption of the normal microflora of the hindgut allowing colonization of pathogenic bacteria. However, there is little information on the effect of antibiotics on specific microflora. Therefore, we evaluated the effects of 2 common antibiotics on the equine hindgut microflora. Horses ranging from 2 to 14 y, were blocked by age and sex into 6 blocks of 3 horses. Within block, horses were randomly assigned to 1 of 3 treatments: CO (no antibiotic; $n = 6$), ST (trimethoprim-sulfadiazine, oral, 30 mg/kg; $n = 6$) and CF (ceftiofur sodium, IM, 2.2 mg/kg; $n = 6$). Each block consisted of a 21-d adaptation, a 7-d treatment and a 7-d withdrawal period. Fecal samples were collected during each block and were used to enumerate typical AAD pathogens (*Clostridium difficile*, *Clostridium perfringens* and *Salmonella* spp.) and selected normal microflora (lactobacilli and cellulolytics). Data were log-transformed, averaged within period, and analyzed by repeated measures ANOVA using the mixed procedure and the ttest procedure of SAS version 9.2. There were treatment x period interactions for cellulolytics ($P < 0.0001$) and lactobacilli ($P = 0.0504$) in that they decreased in response to CF and ST. No significant effects of period were found in the CO horses ($P > 0.05$). *C. difficile* was not detected during adaptation or in any CO horse throughout the study. However, there was a treatment by period interaction ($P < 0.0001$) where horses treated with antibiotics had an increase in *C. difficile* during the treatment and withdrawal periods. Antibiotics also increased *Salmonella* spp. prevalence ($P = 0.0024$). When comparing horses with and without detectable levels of *C. difficile*, horses with *C. difficile* had lower levels of lactobacilli ($P < 0.0001$) and cellulolytics ($P < 0.0001$). No effects of antibiotic treatment were observed for *C. perfringens* ($P > 0.05$). These results indicate that antibiotic therapy has negative effects on equine hindgut microflora, even when AAD does not occur.

Key Words: *Clostridia*, *Salmonella*, diarrhea

503 Influence of probiotics on microflora in the gastrointestinal and reproductive tracts of horses.

K. Barnhart*[1], J. M. Reddish[1], C. Dyer[1], J. Saul[1], M. A. Coutinho da Silva[2], and K. Cole[1], *[1]Department of Animal Sciences, The Ohio State University, Columbus, [2]Department of Veterinary Clinical Sciences, The Ohio State University, Columbus.*

Current scientific literature is limited on what microorganisms are present in the equine gastrointestinal and reproductive tracts. Microbial populations in these environments can be easily disrupted and probiotics have been utilized in other species to re-establish homeostasis and inhibit the growth of pathogenic bacteria. The objective of this study was to determine whether probiotics could influence the microflora in the gastrointestinal and reproductive tracts of mature horses. Eight Quarter Horse mares (10 ± 2 yrs of age) were randomly assigned to 1 of 2 treatment groups (probiotic or control) for a period of 56 d. All horses received 0.5% BW of a 12% CP pelleted concentrate, with water and mixed grass hay ad libitum. Horses in the probiotic treatment group were fed a supplement containing L. acidophilus at a target dose of 10^9 cfu/45 kg of BW per day. Fecal samples and vaginal swabs were collected weekly to measure pH and evaluate changes in microflora. Uterine swabs were collected when possible during periods of estrus. Mean pH values were analyzed using the PROC MIXED procedure of SAS. A P value of ≤ 0.05 was considered statistically significant. There were no changes in fecal, vaginal or uterine pH due to probiotic supplementation. Microbial diversity was investigated using PCR with universal primers specific to 16S rRNA gene sequences and subsequent denaturing gradient gel electrophoresis (DGGE) analyses. Images were captured and analyzed with Bionumerics software to compare microbial diversity. PCR using universal primers was successful in amplifying the 200 bp region of interest in all samples. DGGE analysis of fecal and vaginal samples revealed that the control horses had a more diverse microflora compared with the horses given the probiotic. However, DGGE analysis of uterine samples revealed no differences in microbial populations due to the probiotic. The ability of a probiotic to colonize the host may be species and/or environment specific. Further analysis with Lactobacillus specific primers is needed to determine the influence of the probiotic on microbial diversity within the gastrointestinal and reproductive tracts.

Key Words: horse, probiotic, reproductive tract

504 Effects of weight distribution on movement of mature riding horses.

H. Roberts,* J. M. Reddish, and K. Cole, *The Ohio State University, Columbus.*

Several studies have shown that a rider's weight can affect the horse's movement. However, horses often carry riders with different skill levels who may or may not distribute their weight evenly. The objective of this study was to determine the effects of even and uneven weight distribution on the movement of mature riding horses ($n = 15$) at the walk and trot. Every 15 d for a period of 15 wk, each horse was fitted with a surcingle and increasing amounts of weight (13.6 kg evenly distributed, 27.2 kg evenly distributed, and 27.2 kg unevenly distributed), then videotaped in hand at the walk and trot tracking to the right and left on a flat surface. All horses carried each weight each time they were videotaped and the weight was always added in the same order. The camera was positioned at a height of 3.0 m and 8.6 m away from and perpendicular to the line of travel. Videos were analyzed using OnTrack Equine software for stride length, maximum knee angle and maximum hock angle at the walk and trot. The horses were unshod and their hooves were trimmed every 30 d to minimize changes in hoof shape due to normal hoof growth that may affect their movement. Data were analyzed using the PROC GLM procedure of SAS. A P value of ≤ 0.05 was considered statistically significant. Average stride length at the walk and trot for horses fitted with the surcingle only was 2.19 m and 2.21 m, respectively. There were no differences in average stride length at the walk for horses carrying 13.6 kg or 27.2 kg evenly distributed across their back compared with horses carrying no additional weight. However, a shorter stride length at the walk was observed for horses carrying 27.2 kg unevenly distributed across their back ($P < 0.01$). At the trot, average stride length and hock angle decreased in response to increasing amounts of additional weight and uneven distribution of that weight ($P < 0.01$). Average knee angle at the trot decreased in response to uneven weight distribution but not due to increasing amounts of weight. Overall, the results of this study indicate that additional weight placed on a horse's back and the distribution of that weight can influence the movement of the horse at both the walk and trot.

Key Words: horse, movement, weight distribution

Nonruminant Nutrition: Feed Ingredients

505 Energy, phosphorus, and amino acid digestibility in Lemna protein concentrate, fish meal, and soybean meal fed to weanling pigs. O. J. Rojas* and H. H. Stein, *University of Illinois, Urbana.*

Lemna protein concentrate (LPC; 68% CP) may be used in diets fed to pigs, but no data on the nutritional value to pigs of LPC have been published. Three experiments were, therefore, conducted to determine the concentration of ME, the standardized total tract digestibility (STTD) of P, and the standardized ileal digestibility (SID) of AA in LPC and to compare these values to values for fish meal (FM) and soybean meal (SBM). Experiment 1 was conducted to determine the ME of LPC, FM, and SBM. Thirty-two barrows (initial BW: 16.8 ± 2.8 kg) were placed in metabolism cages and allotted to a randomized complete block design with 4 diets and 8 replicate pigs per diet. A corn-based diet and 3 diets that contained corn and LPC, FM, or SBM were formulated. Feces and urine were collected for 5 d after a 5-d adaptation period and all samples were analyzed for GE. Results indicated that the concentration of ME was not different among the 3 ingredients. In Exp. 2, 24 barrows (initial BW: 10.5 ± 2.5 kg) were allotted to a randomized complete block design with 3 diets and 8 replicate pigs per diet and used to determine the STTD of LPC, FM, and SBM. Three diets that each contained 1 of the 3 test ingredients as the sole source of P were formulated. Pigs were placed in metabolism cages and feces were collected for 5 d after a 5-d adaptation period. The STTD of P in LPC (72.8%), FM (65.6%), and SBM (62.8%) was not different among ingredients. The SID of AA in LPC, FM, and SBM was determined in Exp. 3. Eight barrows (initial BW: 21.4 ± 4.0 kg) were equipped with a T-cannula in the distal ileum and randomly allotted to a replicated 4 × 4 Latin square design. An N-free diet and 3 cornstarch-based diets in which SBM or SBM and LPC or SBM and FM were the only sources of AA were formulated. The SID of most indispensable AA was greater ($P \leq 0.01$) in SBM than in LPC and FM. In conclusion, the concentration of ME and the STTD of P is not different among LPC, FM, and SBM, but SID of most indispensable AA is greater in SBM than in FM and LPC.

Key Words: Lemna protein concentrate, nutrient digestibility, pigs

506 Amino acid digestibility in camelina seeds and camelina expellers fed to growing pigs. F. N. Almeida*[1], J. K. Htoo[2], J. Thomson[3], and H. H. Stein[1], [1]*University of Illinois, Urbana,* [2]*Evonik Industries AG, Hanau, Germany,* [3]*Evonik Degussa Corporation, Kennesaw, GA.*

The nutritional value of camelina seeds (*Camelina sativa*) and camelina expellers fed to pigs has not been reported. Therefore, an experiment was conducted to determine the standardized ileal digestibility (SID) of CP and AA in camelina seeds and camelina expellers and to compare these values with SID values of CP and AA in canola meal fed to pigs. Two sources of camelina seeds (average of 27.9% CP, 39.4% acid hydrolyzed ether extract (AEE), and 27.6% NDF, as-fed basis), 3 sources of camelina expellers (average of 33.1% CP, 15.8% AEE, and 24.9% NDF, as-fed basis), and 1 source of canola meal (36.4% CP, 3.7% AEE, and 34.8% NDF, as-fed basis) were procured from companies located in the United States. Seven pigs (initial BW = 43.5 ± 3.5 kg) were allotted to a 7 × 7 Latin square design with 7 diets and 7 periods. Two diets contained camelina seeds (CS-1 and CS-2), 3 diets contained camelina expellers (CE-1, CE-2, and CE-3, respectively), and 1 diet contained canola meal as the sole source of CP and AA. Each test ingredient was included at 40% in the diets. A N-free diet was used to determine basal endogenous losses of CP and AA. Data were analyzed by the Mixed Procedure with diet as the main effect, and pig and period as random effects. Results indicate that the SID of AA in camelina seeds is less ($P < 0.05$) than in camelina expellers and canola meal (Table 1), which limits the use of camelina seeds in swine diets, but the SID of AA in camelina expellers is mostly comparable to that of canola meal. Camelina expellers may, therefore, be used as an alternative feed ingredient in diets fed to pigs.

Table 1. Standardized ileal digestibility (%) of AA in camelina seeds (CS), camelina expellers (CE), and canola meal

Item	CS-1	CS-2	CE-1	CE-2	CE-3	Canola meal	SEM	*P*-value

507 Withdrawal patterns of DDGS on performance, belly firmness, and fatty acids in pigs—A cooperative study. G. L. Cromwell,* M. J. Azain, O. Adeola, S. K. Baidoo, S. D. Carter, T. D. Crenshaw, G. M. Hill, P. S. Miller, J. F. Patience, M. C. Shannon, and H. H. Stein, *NCCC-42 Committee on Swine Nutrition, University of Kentucky, Lexington.*

An experiment involving 580 pigs (20 reps of 4 to 8 pigs/pen) was conducted at 10 stations to assess the effect of various DDGS withdrawal patterns to pigs from 29 to 123 kg BW. Corn-soybean meal diets with 0 to 33.5% DDGS were fed in 3 phases. A single source of DDGS containing 8.8% fat, 26.4% CP, and 1.07% Lys was used at each station. Diets were formulated to contain 0.91, 0.73, and 0.58% SID Lys during the 3 phases with changes at 58 and 91 kg BW. Levels of DDGS in the 3 phases were Trt 1, 0–0–0%; Trt 2, 33.5–33.5–33.5%; Trt 3, 33.5–33.5–0%; Trt 4, 33.5–20–11%; and Trt 5, 20–20–20%. Levels of DDGS in Trt 3, 4, and 5 were such that total DDGS consumed during the experiment was nearly identical (55.3, 55.2, and 55.1 kg/pig, respectively). At each station, 2 pigs from each pen in 2 reps were killed and a backfat sample was obtained for fatty acid (FA) analysis and iodine value (IV). In most cases, there were differences among stations ($P < 0.05$), but station x treatment interactions were few. The ADG and ADFI of the 5 groups did not differ (957, 925, 922, 938, 927 g/d; 2.67, 2.73, 2.79, 2.76, 2.68 kg/d), but pigs fed the control diet with 0% DDGS were more efficient (0.360, 0.341, 0.331, 0.341, 0.348 G:F; $P < 0.05$). Hot carcass yield tended to be less (76.1, 75.4, 75.8, 75.9, 75.5%; $P = 0.06$), and calculated fat-free lean was greater for Trt 2 (52.4, 53.7, 52.5, 52.3, 52.9%; $P < 0.05$). Bellies were softer ($P < 0.01$) in pigs fed DDGS based on lateral (16.0, 11.6, 14.4, 14.9, 14.9 cm) and vertical flex scores (22.6, 27.2, 24.9, 24.4, 24.0 cm). Feeding the high level of DDGS throughout resulted in less saturated and monounsaturated FA in the backfat (39.3, 34.9, 37.9, 38.6, 37.2%, and 46.6, 41.6, 43.7, 43.8, 43.3% of total FA; $P < 0.001$)

and more polyunsaturated FA (13.5, 22.8, 17.8, 17.1, 19.0%; $P < 0.001$). The IV for outer fat layers were 67.9, 79.4, 73.2, 72.0, 74.3, and for inner fat layers were 60.4, 72.8, 65.0, 63.8, 67.2 ($P < 0.001$). Gilts had higher IV than barrows in outer (74.8 vs. 72.2) and inner (67.5 vs. 64.6) fat ($P < 0.001$). Withdrawal of DDGS in phase 3 or feeding less DDGS produced FA and IV levels that reverted toward those of control pigs.

Key Words: pigs, DDGS, fatty acids

508 Wheat-DDGS pig finishing diet reduces feed cost but does not improve net profit of production. G. A. Mastromano,* M. R. Ashby, R. C. Roberson, J. M. Scheffler, and J. Escobar, *Virginia Tech University, Blacksburg.*

Corn prices are increasing due, in part, to ethanol production, resulting in increased feed costs for swine producers. The objective of this experiment was to determine if a wheat-dried distiller's grains with solubles (DDGS) based diet (WD) would reduce cost efficiency of gain compared with a corn-SBM (CS) based diet. Fifty pigs (24 gilts and 26 barrows) were segregated by sex and housed 2–3 pigs/pen with free access to feed and water over a 53-d study. One-half of pigs were fed CS diet (85.92% corn, 12.50%SBM, 1.58% others) and the remainder were fed WD diet (50.50% wheat, 40% corn DDGS, 7.00% SBM, 2.5% others). Feed disappearance was monitored daily and pigs were weighed every 14 d. At the end of the study, pigs were transported about 6 h to a commercial slaughter facility. Initial BW was not different ($P = 0.83$) between CS (68.5 ± 1.7 kg) and WD (68.0 ± 1.7 kg) treatments. Overall ADG, ADFI, and G:F was not different ($P = 0.48$ to 0.67) between CS (1.17 ± 0.03 kg/d, 3.80 ± 0.09 kg/d, 0.32 ± 0.01, respectively) and WD (1.14 ± 0.03 kg/d, 3.85 ± 0.08 kg/d, 0.31 ± 0.01, respectively). Final BW was not different ($P = 0.23$) between CS (131.3 ± 1.8 kg) and WD (128.2 ± 1.7 kg) treatments, but hot carcass weight (HCW) was reduced ($P = 0.009$) 5.6% in WD compared with CS pigs. Dietary treatment had no effect on ham weight ($P = 0.41$); however, pigs eating WD had lower picnic ($P = 0.008$), boneless loin ($P = 0.03$), belly ($P = 0.06$), and butt ($P = 0.10$) weights compared with controls. Ultrasound measurements of last rib backfat (BF) and longissimus dorsi eye area (LEA) were recorded before transportation. BF was reduced ($P < 0.001$) in WD (1.30 ± 0.03 cm) compared with CS (1.52 ± 0.03 cm) pigs; however, treatment had no effect on LEA (42.1 ± 0.4 cm for CS vs. 41.5 ± 0.4 cm for WD). Feed cost (¢ per kg) was 9.45% lower ($P < 0.001$) in WD (37.97 ± 0.33) compared with CS (41.94 ± 0.33). Even though feed cost was reduced using the WD treatment, there was no difference in profit due to lower HCW in WD pigs. Further investigation in lengthening the trial period may be necessary to increase profit when feeding the WD diet.

Key Words: DDGS, swine growth, wheat

509 The effects of corn- or sorghum-based diets with or without sorghum dried distillers grains and solubles on lactating sow and litter performance. K. M. Sotak,* R. D. Goodband, M. D. Tokach, J. M. DeRouchey, S. S. Dritz, and J. L. Nelssen, *Kansas State University, Manhattan.*

A total of 140 sows (PIC 1050) and their litters were used to determine the effects of corn- or sorghum-based diets with or without 20% sorghum dried distiller's grains with solubles (DDGS; 31.1% CP and 9.2% crude fat) on lactating sow and litter performance. Sows were allotted to 1 of 4 dietary treatments 3 d before farrowing in a RCBD. There were 2 and 1 sows removed from the study for the sorghum and sorghum-DDGS treatments because of initial feed refusal with all others removed due to illness. Weaning age was 21 d. Treatments were arranged in a 2 × 2 factorial with main effects of grain source (corn vs. sorghum) and sorghum DDGS (0 vs. 20%). All diets were formulated to 0.97% standardized ileal digestible Lys but were not balanced for energy. Overall (d 0 to 21), ADFI increased in corn-based diets when DDGS were added, but decreased in sorghum-based diets resulting in a tendency ($P < 0.08$) for a DDGS × grain source interaction. Sows fed the sorghum-based diets had decreased ($P < 0.04$) lactation weight loss compared with those fed corn-based diets. Pig weights at weaning were lower ($P < 0.06$) for sows fed the diets containing DDGS compared with those fed the diets without DDGS. Overall, feeding sows corn- vs. sorghum-based (without DDGS) diets in lactation did not affect litter performance; however, the 4% decrease in litter weaning weight of sows fed sorghum with 20% sorghum DDGS needs to be taken into account in ingredient selection for lactating sows.

Table 1. Effects of corn- or sorghum-based diets with or without 20% sorghum dried distillers grains with solubles (DDGS)

	Corn DDGS		Sorghum DDGS			Probability, P <		
						DDGS × Grain source	Control vs. DDGS[1]	Corn vs. sorghum

510 Amino acid digestibility in blood products fed to weanling pigs. F. N. Almeida*[1], J. K. Htoo[2], J. Thomson[3], and H. H. Stein[1], *[1]University of Illinois, Urbana, [2]Evonik Industries AG, Hanau, Germany, [3]Evonik Degussa Corp., Kennesaw, GA.*

Blood products are commonly used in diets for nursery pigs, but different processing techniques may result in differences in AA digestibility among these ingredients. Thus, the objective of this experiment was to compare values for the standardized ileal digestibility (SID) of AA in spray-dried animal blood (SDAB; 89.4% CP), spray-dried blood cells (SDBC; 92.6% CP), spray-dried plasma protein (SDPP; 77.7% CP), roller dried avian blood meal (ABM, 88.4% CP), and roller dried porcine blood meal (PBM, 94.6% CP), when fed to weanling pigs. Seven weanling barrows (initial BW: 11.5 ± 1.1 kg) were equipped with a T-cannula in the distal ileum and allotted to a 7 × 7 Latin square design with 7 diets and 7 periods in each square. One of the diets was based on casein, and 5 diets were based on a mixture of casein and each source of blood product. A N-free diet that was used to measure basal endogenous losses of AA and protein was also formulated. The SID of AA in each blood product was calculated by the difference procedure. The Mixed procedure of SAS was used to analyze the data. The model included diet as the main effect whereas pig and period were random effects. Results indicate that the SID of AA in SDAB, SDBC, and in SDPP is close to 100% and not different from casein. The SID of AA in ABM and PBM is less ($P < 0.05$) than those calculated for the 3 spray dried blood products, which indicates that the drying procedure used to prepare these products may have reduced the SID of AA.

Table 1. Standardized ileal digestibility (%) of AA

Item	SDAB	SDBC	SDPP	ABM	PBM	Casein	SEM	*P*-value

Key Words: amino acid digestibility, blood products, pigs

511 Amino acid digestibility in hydrolyzed feather meal fed to pigs. F. N. Almeida*[1], L. I. Chiba[2], S. D. Brotzge[2], R. L. Payne[3], and H. H. Stein[1], *[1]University of Illinois, Urbana, [2]Auburn University, Auburn, AL, [3]Evonik-Degussa Corp., Kennesaw, GA.*

An experiment was conducted to determine the standardized ileal digestibility (SID) of AA in hydrolyzed feather meal (FM) products without or with blood addition when fed to pigs. Eight FM products were obtained from 4 sources with each source providing FM without and with added blood. Ten pigs (initial BW: 23.8 ± 1.3 kg) were allotted to a 10 × 10 Latin square design with 10 diets and 10 periods. One diet contained 36% soybean meal, and the 8 FM diets contained 12% soybean meal and 25% of 1 of the 8 FM products. Soybean meal and FM were the only ingredients contributing AA in these 9 diets. The 10th diet was a N-free diet that was used to determine the basal endogenous losses of AA. Pigs were fed experimental diets for 7 d with ileal digesta being collected during the last 2 d. Values for the SID of AA were calculated for each diet using the direct procedure, and the difference procedure was used to calculate the SID of AA in each FM product. Data were analyzed as a 2 × 4 factorial, with blood addition, FM source, and the interaction between blood addition and FM source as main effects. Differences ($P < 0.01$) in the SID of all indispensable AA were observed among the 4 sources of FM (Table 1). There were also effects ($P < 0.01$) of blood addition on the SID of Ile, Leu, Lys, Phe, and Val, but there was an interaction ($P < 0.05$) between FM source and blood addition, indicating that addition of blood did not have a consistent effect on the SID of AA in the 4 sources of FM. In conclusion, the SID of AA in FM varies among sources, and addition of blood to FM may affect the SID of AA.

Table 1. Standardized ileal digestibility (%) of AA in feather meal

Item	FM-1	FM-1	FM-2	FM-2	FM-3	FM-3	FM-4	FM-4	SEM

512 Nutritive value and relationship between nutrient content and protein quality of soybean meals according to origin. G. G. Mateos*[1], M. P. Serrano[1], M. González[2], S. Sueiro[2], M. Hermida[2], R. Lázaro[1], and P. G. Rebollar[1], *[1]Universidad Politécnica de Madrid, Madrid, Spain, [2]Laboratorio de Mouriscade, Pontevedra, Spain.*

Soybean meal (SBM) is the main protein source in pig and poultry feeds. United States (USA), Brazil (BRA), and Argentine (ARG) are the major SBM exporter countries. According to agronomic and processing conditions of the beans, the nutritive value of SBM varies among countries. This research studied the chemical composition and correlations between chemical analyses and protein quality of SBM by origin (USA, BRA, and ARG). Samples (n = 412) were collected during a 5-yr period and analyzed for major chemical components including amino acids (AA) and protein quality. On DM bases, USA meals (n = 164) had more CP (53.8 vs. 53.0 vs. 51.6%; $P < 0.001$) and sucrose (8.2 vs. 7.6 vs. 6.5%; $P < 0.001$) but less NDF (8.9 vs. 10.6 vs. 12.0%; $P < 0.001$) than ARG (n = 131) and BRA meals (n = 117). Stachyose content was higher and raffinose lower for USA than for ARG and BRA meals (6.47 vs. 5.56 vs. 5.29%; and 1.11 vs. 1.33 vs. 1.59%, respectively; $P < 0.001$). The USA meals had more P (0.79 vs. 0.69 vs. 0.75%; $P < 0.001$) than the BRA with ARG meals being intermediate. The CP content was negatively related with sucrose (−0.70, $P < 0.001$) for USA and with NDF (−0.64 and −0.46, $P < 0.001$) for ARG and BRA meals. The trypsin inhibitor activity (TIA) was higher (3.86 vs. 2.97 vs. 2.97 mg/g; $P < 0.001$) for USA meals than for ARG or BRA SBM. Protein dispersibility index and KOH were higher for USA than for ARG and BRA meals (19.7 vs. 16.8 vs. 15.3 and 86.8 vs. 82.1 vs. 83.3, $P < 0.001$), and were positively related with TIA of the meals (+0.70 and 0.73, $P < 0.001$ for USA; +0.62 and +0.65, $P < 0.001$ for ARG; +0.27 and +0.44, $P < 0.05$ for BRA, respectively). On CP bases, Lysine was higher (6.16 vs. 6.09 vs 6.05, $P < 0.001$) for USA than for ARG and BRA meals. The Lysine content was negatively related with CP content (−0.48, $P < 0.001$) for USA, but positively (+0.34, $P < 0.001$) for BRA SBM. Heat Damage Index (Aminored) was (−0.90, −0.87 and −0.90, $P < 0.001$) related with percentage of Lysine (%CP) for all origins. Nutrient values and the relationship between chemical composition and protein quality of the meal varied widely among origins. Thus, SBM origin should be considered in the evaluation of the nutritive value of the meal.

Key Words: chemical composition, origin, soybean meal

513 Influence of soybean meal source and micronization (fine grinding) of soybean meal on productive performance and digestive traits of Iberian pigs from 30 to 51 days of age. J. D. Berrocoso,* M. P. Serrano, L. Camara, P. G. Rebollar, A. Lopez, R. Abad, and G. G. Mateos, *Universidad Politecnica de Madrid, Madrid, Spain.*

In total, 216 Iberian piglets weaned at 30 d were used in a 21 d experiment to evaluate the effects of the inclusion of different sources of SBM on growth performance, nutrient digestibility (TTAD and AID), and morphological characteristics of the ileum. There was a positive control diet that included 10% soy protein concentrate (65% CP; SPC), a negative control diet with 14.8% regular SBM (44% CP; R-SBM), and 4 extra diets arranged factorially that included 13.3% of high protein SBM (USA vs. Argentina origin) with 49% CP (HP-SBM) at 2 different particle size (ground, 990 μm vs. micronized, 60 μm). Each of the 6 treatments was replicated 6 times (6 pigs per pen). The experiment design was completely randomized. The following orthogonal contrasts conducted: 1) SPC vs. all SBM diets, 2) micronized HP-SBM vs. ground HP-SBM, 3) HP-SBM of ARG origin vs. HP-SBM of USA origin, and 4) R-SBM vs. HP-SBM diets. Type of soy product had no effect on growth performance but the incidence of diarrhea (DI) was higher (*P*

≤ 0.01) for pigs fed R-SBM than for pigs fed HP-SBM. At 15 d of the experiment, the TTAD and AID of nutrients were higher ($P < 0.05$) for the HP-SBM than for the R-SBM diets. The inclusion of SPC in the diet had no effect on TTAD of nutrients except for CP that tended ($P = 0.06$) to be higher. The TTAD of DM ($P = 0.07$) and GE ($P = 0.05$) tended to be higher with micronized than with ground HP-SBM. Source of HP-SBM did not affect TTAD, except for GE that tended ($P = 0.05$) to be higher for the USA meal than for the Argentinean meal. At 15 d of experiment, pigs fed HP-SBM showed higher villi height:crypt depth ratio ($P < 0.05$) than pigs fed R-SBM. It is concluded that the inclusion of SPC in the diet improved TTAD of CP and reduced the DI but did not affect growth performance of the pigs. The inclusion in the diet of HP-SBM in substitution of R-SBM increased TTAD and AID of all nutrients, reduced the DI, and improved the morphological characteristics of the ileum but did not affect growth performance of the pigs.

Key Words: iberian pig, nutrient digestibility, soybean meal

514 Net portal absorption of amino acids in Iberian pigs fed with acorn.

J. M. Rodriguez-Lopez, M. Lachica, L. Gonzalez-Valero, and I. Fernandez-Figares,* *CSIC (Spanish National Research Council), Granada, Spain.*

Iberian pigs are reared indoors fed concentrate feeds until the final fattening period at the *dehesa* (Mediterranean woodland) where they are fed acorns and grass. The acorn is rich in carbohydrates and lipids but it has low protein content with unbalanced AA profile. This is a very abrupt nutritional challenge. There are no studies of how this nutritional challenge affect AA metabolism in the portal-drained viscera and consequently AA supply to peripheral tissues. For that reason, 6 pure Iberian pigs (26 kg BW) were fitted with chronic catheters, in carotid artery, portal vein and mesenteric vein and trained to consume 25 and 75% of their daily ration at 9.00 and 15.00, respectively. An equilibrated diet (140 g/kg CP and 14–14.5 MJ ME/kg DM) based on barley and soybean meal, at 85% ad libitum was consumed until surgery recovery (32 kg BW) in metabolic cages. The day before sampling, pigs were offered 2.4 kg of acorns (85% ad libitum: 1.405 kg DMI, 23.27 MJ MEI, 71.0 g CP intake) following the same feeding schedule. The first set of blood samples was taken the following day, after pigs were fed 600 g of acorns, every 30 min for 4 h and then hourly until 6 h after feeding,. Pigs were then fed acorns for 7 d and a second set of blood samples was taken following the same protocol as in the first set. Net portal AA absorption was calculated by multiplying porto-arterial plasma AA concentration difference by portal vein plasma flow rate, estimated by infusing p-aminohippuric acid into the mesenteric vein. Repeated measures analyses were carried out using the mixed procedure of SAS. Overall, net portal AAs absorption of sum of all AAs, sum of NEAA, Tyr, Ala, Asn, Pro, Hypro and His was greater when the pigs were adapted to acorn consumption. Furthermore, Phe, Leu and Gly also tended to increase. The peak of portal absorption of AAs in pigs fed acorns appeared at 0.5 h postprandial. In conclusion, after one week adaptation to acorns feeding, net portal absorption of AAs increased in Iberian pigs. Changes in microflora may be responsible of the improved utilization of AAs from acorn.

Key Words: pig, amino acids, portal drained viscera

515 Gas production, in vitro organic matter disappearance, volatile fatty acid concentrations and physicochemical characteristics of fibrous sources for pigs.

M. Chimonyo* and S. P. Ndou, *Animal and Poultry Science, Pietermaritzburg, South Africa.*

Although dietary fiber enhances gut health, satiety and improves welfare of pigs, knowledge of physical and fermentation characteristics of bulky feeds is essential to understand the effects of dietary fiber on feed intake, digestibility and growth performance of pigs. The objective of the study was to characterize physicochemical properties and fermentation characteristics of common fibrous feed ingredients with a huge potential use formulating pig diets in Southern Africa. Crude fiber, neutral detergent fiber (NDF), acid detergent fiber (ADF), bulk density, water holding capacity (WHC), gas production parameters, in vitro organic matter disappearance (IVOMD) and volatile fatty acid (VFA) concentrations were assayed in groundnut haulms (GH), lucerne hay (LC), maize cobs (MC), maize stover (MS), rice bran (RB), saw dust (SD), sunflower husks (SH) and veld grass (VG). Fermentation was conducted over 24 h, using pig fecal inocula collected by rectal palpation from pigs (85.0 ± 5.49 BW) that had received a diet containing 12.6 MJ DE, 160 g CP/ kg DM and 80 g CF/ kg DM. Rice bran and maize cobs had the highest total VFA concentrations (6.5 ± 0.18 and 4.7 ± 0.18 μM, respectively). None of the fiber sources produced propionic acid, with acetic acid being the predominant acid. Surprisingly, maize cobs produced twice ($P < 0.01$) the amount of acetic acid (4.0 μM) than either groundnut haulms (2.2 ± 0.16 μM) or lucerne hay (2.0 ± 0.16 μM). Total gas production was 432, 485, 461, 428, 614, 210, 382 and 266 (s.e. = 12.2) ml g-1 OM for GH, LC, MC, MS, RB, SD, SH and VG, respectively. Total gas production and partitioning factor were reliable predictors of IVOMD and VFA concentrations ($P < 0.01$). Rice bran, maize cob, groundnut haulms were the most fermentable fibrous feed ingredients. The possibility of incorporating maize cob meal in pig diets, widely available in many countries where maize is a staple crop, should be explored. The influence of these physicochemical properties on voluntary feed intake is necessary to develop appropriate fiber-based feeding strategies for pigs.

Key Words: acetic acid, physical properties, rate of gas production

Physiology and Endocrinology: Pregnancy

516 Membrane progesterone receptors (α, β, and γ) in early pregnancy. R. L. Ashley,* S. M. Stanbrough, K. E. Quinn, J. D. Lindsey, and A. K. Ashley, *New Mexico State University, Las Cruces.*

Progesterone (P4) is required for maintenance of pregnancy and elicits physiological effects via binding to a nuclear receptor in various target tissues. Additionally, P4 can function through non-canonical membrane progesterone receptors (MPR) and numerous isoforms have been identified, including MPR α (MPRA), β (MPRB) and gamma (MPRG). P4 signaling through the MPRs has not been investigated in early pregnancy, and could effect initial maternal/fetal interactions. The objective of this study was to assess gene expression of MPRs in maternal and fetal ovine tissues during early pregnancy via real-time quantitative PCR (qPCR). Hypothalamus (HYP), pituitary (PIT), and caruncle (CAR) were collected from non-pregnant (NP) ewes on D10 of the estrous cycle, and from pregnant ewes on D20, 25, and 30 of gestation. Fetal placental tissue (FET) was also collected from pregnant ewes. RNA was isolated, cDNA synthesized and subjected to qPCR. Expression levels were normalized by standard methods, and subjected to ANOVA with Newman-Keuls post hoc test to determine significant differences ($P < 0.05$). Among the MPR isoforms in HYP, MPRA was highly expressed, while MPRG levels were the greatest in PIT. Both MPRA and MPRG were high in CAR, and MPRB were the most elevated in FET. In HYP, no gestation-induced alterations in any MPRs were observed. All 3 MPRs decreased with advancing pregnancy compared with NP in the PIT. MPRA decreased at early placentation (D20) and once attachment was established (D30) in CAR, whereas MPRG increased at early and mid-placentation (D25), but returned to basal levels by D30. MPRB decreased during mid-placentation in FET, with D20 and D30 expressing similar levels. MPRA and MPRG expression was similar across all times assessed in FET. During early gestation, P4 levels rise and are maintained in concert with critical fetal-maternal interactions for proper implantation and placentation. Our data indicate gestational status and stage effect MPR expression in numerous reproductive tissues, suggesting these proteins may be pivotal in P4-mediated establishment and maintenance of pregnancy. USDA-NIFA-AFRI 2009–65203–05717.

Key Words: implantation, placenta, membrane progesterone receptor

517 Expression of PRSS, the plasminogen activator system and its activity in the ovine placentome during stage 2 of parturition. A. K. McNeel,* R. A. Cushman, and J. L. Vallet, *USDA, ARS US Meat Animal Research Center, Clay Center, NE.*

The molecular mechanisms responsible for placenta separation are not completely understood. We know placentomes from cases of retained placenta possess limited matrix-metalloprotease (MMP) activity and retained placenta occurs at a greater incidence during induced parturition. The plasminogen activator (PA) system is a family of serine endoproteases capable of activating MMP. Two new serine proteases (PRSS) have been recently documented in multiple species, and in mice appear to be involved in follicular development and ovulation. We hypothesized that 1) the expression of PRSS and PA systems and PA activity increase as parturition approaches with maximal expression and activity during parturition, and 2) that both are reduced during induced parturition. To test these hypotheses, placentomes were collected at 17 and 10 d before projected parturition and during spontaneous and dexamethasone-induced parturition in ewes. Placentomes were separated into fetal and maternal tissues manually, snap frozen in liquid nitrogen, and stored at −80°C until protein and RNA extraction. Tissue replicates were homogenized and RNA and protein were extracted. Relative quantification for genes of interest was performed via RT-qPCR on purified RNA using the ΔΔCt method with GAPDH serving as the reference gene. Expression data were analyzed with the MIXED procedure of SAS with treatment as a fixed effect. Plasminogen-casein zymography was performed on protein isolates. There were no differences in expression of urokinase-type plasminogen activator (PLAU), SERPINB2, SERPINE1, or PRSS23 ($P \geq 0.05$). We were unable to detect expression of plasminogen, tissue-type plasminogen activator, or PRSS35. Plasminogen activator activity in placentomes was not detected using zymography. These data demonstrate that in the ewe, neither the PA nor PRSS systems change during Stage 2 of parturition compared with late gestation or induced parturition. USDA is an equal opportunity provider and employer.

Key Words: placental separation, proteolysis, ruminant

518 Physiological responses to repeated transportation of gestating Brahman cows. D. M. Price*[1], A. W. Lewis[1], D. A. Neuendorff[1], J. A. Carroll[2], T. H. Welsh Jr.[3], R. C. Vann[4], and R. D. Randel[1], *[1]Texas Agrilife Research, Texas A&M University System, Overton, [2]USDA-ARS, Livestock Issues Research Unit, Lubbock, TX, [3]Texas Agrilife Research, Texas A&M System, College Station, [4]MAFES, Mississippi State University, Raymond.*

The transportation process acts as a stressor with adverse effects on animal health and performance. The purpose of this study was to examine physiological responses to repeated transportation of gestating Brahman cows; previously classified as mature cows into temperament groups of Calm, Intermediate, or Temperamental. Brahman cows (n = 48) were subjected to 2 h of transport (T) on d 60, 80, 100, 120, and 140 of gestation. Blood serum collected before and after each T was assayed for glucose and nonesterified fatty acid (NEFA) concentrations. Indwelling vaginal temperature (VT) monitoring devices were inserted before each T and VT were recorded before and every 5 min through 30 min after T. Statistical analysis of data used multivariate repeated measures and area under the curve methods. VT and serum glucose concentrations decreased in all temperaments ($P < 0.01$) with repeated T. Peak VT were greater ($P < 0.001$) in all cows regardless of temperament on d 60 of T, compared with all other T days. During T Temperamental cows tended ($P < 0.09$) to have higher peak VT (39.86 ± 0.15°C) compared with Calm (39.41 ± 0.16°C) and Intermediate cows (39.55 ± 0.08°C). Area under the VT curve decreased ($P < 0\ 0.003$) by d 140 as the cows habituated to T. On d 60 post T, Calm cows had numerically lower VT (39.18 ± 0.18°C), compared with Intermediate and Temperamental cows (39.39 ± 0.10°C and 39.53 ± 0.17°C, respectively). Pre-T glucose concentrations on d 60 were greater ($P < 0.03$) for Temperamental cows (68.13 ± 4.31μg/dl) compared with Intermediate (53.42 ± 2.78 μg/dl) and Calm cows (52.76 ± 4.60 μg/dl). All cows had numerically increased NEFA concentrations post T, with temperamental cows showing the least numerical change due to T. However, NEFA concentrations did not increase with repeated T ($P > 0.10$). Glucose concentrations were affected ($P < 0.02$) by a time by temperament interaction with Temperamental cows having greater changes in serum glucose concentrations. These results reflect the partial acclimation of cows to a stressor over time, and demonstrate that both temperament and the T process influence physiological responses to stress in gestating cows.

Key Words: metabolites, transportation, vaginal temperature

519 Reduced fertility in female progeny from beef heifers on dietary restriction during development. S. E. Echternkamp,* D. R. Eborn, and R. A. Cushman, *USDA, ARS, U.S. Meat Animal Research Center, Clay Center, NE.*

Developing replacement heifers on lower energy diets does not affect fertility but may impart epigenetic effects on their progeny. Objective was to determine whether ovarian development or fertility is impeded in female progeny of replacement beef heifers developed on a lower energy diet. At 8 mo of age, Angus (n = 40) or composite MARC II (n = 40) heifers were assigned by BW and genetic line to be fed either a high (HE) or low (LE) energy diet for 180 d plus the first 22 d of the 47-d breeding period to achieve an ADG of either 0.45 or 0.9 kg/d or 55 vs. 65% of mature BW. Heifers within a line were mated to the same bulls. After breeding, treatment groups were combined and managed on pasture. Female progeny were developed on a standard heifer management protocol and bred at 14 mo of age. Total number of antral follicles (AFC), length and height of both ovaries, and uterine diameter were measured by transrectal ultrasonography in treated heifers (n = 72), and subsequently in female progeny (n = 32), at first breeding; pregnancy was diagnosed at about 75 d of gestation. Data were analyzed by ANOVA with diet and line as independent variables and their 2-way interaction. At 14 mo of age, LE heifers were lighter ($P < 0.01$) than HE heifers (344.8 vs. 429.4 ± 7.1 kg). Progeny birth weight (36.4 kg) was not affected by diet or line but Angus progeny were lighter ($P < 0.01$) at breeding (362.1 ± 7.2 vs. 387.2 ± 5.6 kg). Progeny of LE dams had fewer antral follicles than HE progeny (19.0 ± 1.9 vs. 26.0 ± 1.7; $P < 0.01$), whereas AFC (22.5 ± 2.8) did not differ between LE and HE dams. Ovarian size (length x height) was not affected by diet but was greater ($P < 0.05$) for MARC II vs. Angus heifers in both generations (dams, 301.3 vs. 351.9 ± 3.5 mm^2; progeny, 454.4 ± 31.8 vs. 586.3 ± 26.3 mm^2, respectively). Uterine diameter (12.1 mm) was not influenced by diet. Pregnancy rate was less ($P < 0.05$) for progeny from LE vs. HE dams (42.6 ± 15.3 vs. 80.3 ± 10.1%) and for Angus vs. MARC II progeny (39.3 ± 14.3 vs. 80.2 ± 12.1%). Results indicated that environmental effects imposed during early embryonic development in first-parity heifers may affect embryonic gametogenesis and fertility of progeny. USDA is an equal opportunity provider and employer.

Key Words: diet, progeny, fertility

520 The impact of cow nutrient status during the second and third trimester on development of the reproductive axis and fertility of daughters. R. A. Cushman,* A. K. McNeel, and H. C. Freetly, *USDA, ARS, U.S. Meat Animal Research Center, Clay Center, NE.*

Fluctuating feed resources to beef cows across the production cycle is a proven method for decreasing input costs; however, altering nutrients during gestation can decrease ovarian follicle numbers in female offspring. We hypothesized that limiting nutrients to mature (≥3 years) crossbred beef cows during the second and third trimester would result in daughters with decreased follicle numbers detectable by ultrasonography as yearlings. Over 4 breeding seasons, pregnant beef cows (n = 397) were assigned to Low (L), Moderate (M) or High (H) nutrient intake during the second and third trimesters to make 4 dietary treatment groups (L-H, L-L, M-H, and M-M). Heifers (n = 416) born to these cows were weighed at weaning and moved to a dry lot where they were monitored for behavioral estrus. Two weeks before their first breeding season, heifers were submitted for ultrasonographic examination of their ovaries to determine antral follicle numbers. Heifers were placed with bulls for 60 d and pregnancy status was determined 45 d after the bulls were removed. Growth and reproductive traits were analyzed using the MIXED Procedure of SAS with maternal diet, year, and the interaction as the independent variables and dam as a random effect. Maternal dietary intake did not affect heifer growth rates, age at puberty, or antral follicle counts ($P \geq 0.14$). However, heifers born to dams fed a high nutrient level during the third trimester (L-H or M-H) had a decreased number of days to calving ($P = 0.04$). From this we conclude that limiting nutrient intake during late gestation in mature (≥3 years) beef cows does not influence the ovarian reserve or maturation of the reproductive axis in daughters. However, high maternal nutrient levels during the third trimester improve the first service conception rates of their daughters when they go to their first breeding season. USDA is an equal opportunity provider and employer.

Key Words: beef heifers, puberty, antral follicle count

521 Feeding distillers grains as an energy source to gestating and lactating beef heifers: Impact on growth, puberty attainment and reproductive processes in female progeny. P. J. Gunn*[1], J. P. Schoonmaker[1], R. P. Lemenager[1], and G. A. Bridges[2], [1]*Department of Animal Sciences, Purdue University, West Lafayette, IN,* [2]*North Central Research and Outreach Center, University of Minnesota, Grand Rapids.*

Angus-cross beef heifers pregnant to a single sire (n = 80) were used to assess the effects of feeding dried distillers grains with solubles (DDGS) as an energy source during late gestation and early lactation on female progeny growth, puberty attainment and reproductive processes. From 192 d of gestation through 118 ± 0.2 d of lactation, dams were fed either a control diet of corn silage and haylage (CON; 10% CP prepartum; 11.8% CP postpartum) or corn stover and DDGS (DG; DDGS at 1.2% BW per d; 15.7% CP). Heifer progeny (n = 33) were weaned and commingled at 18 ± 0.4 d of age. Heifers were managed similarly for the remainder of the project. Heifer wt and blood samples for progesterone were collected weekly to assess wt and age at puberty. At 242 ± 0.4 d of age, 1 follicular wave was mapped via ultrasonography in 10 prepubertal heifers per treatment. Prepubertal antral follicle count and ovarian size were determined at 240 and 330 ± 0.4 d of age. Hip ht was recorded at 213, 297, and 436 ± 0.4 d of age. Estrous synchronization and AI was initiated at 447 ± 0.4 d of age. Categorical and continuous data were analyzed with the GLIMMIX and MIXED procedures of SAS, respectively. The DG progeny were heavier than CON ($P = 0.03$) at weaning (241 ± 5 kg vs. 223 ± 6 kg), but not at breeding (416 ± 7 vs. 401 ± 7 kg). Also, DG progeny had a greater ($P < 0.01$) frame score than CON throughout the developmental period. Ovarian size, antral follicle count, and follicular growth parameters did not differ between treatments. Age at puberty did not differ between CON (303 ± 10 d) and DG (320 ± 10 d) treatments; however, wt at puberty was heavier ($P = 0.01$) for DG (326 ± 7 kg) than CON (298 ± 8 kg) progeny. In addition, DG progeny (70.6%) had greater ($P = 0.05$) AI pregnancy rates than CON (33.3%). However, overall breeding season pregnancy rate did not differ. In summary, feeding DDGS at 1.2% of BW per d to first-parity heifers resulted in female progeny with greater skeletal growth that were heavier at onset of puberty, but had increased AI pregnancy rates.

Key Words: beef heifer, DDGS, developmental programming

522 Chronic uterine infusion of melatonin or melatonin receptor antagonist alters ovine placental efficiency and fetal blood flow during mid-gestation. C. O. Lemley,* L. E. Camacho, and K. A. Vonnahme, *North Dakota State University, Fargo.*

Objectives of the current experiment were to determine fetal descending aorta blood flow (BF), umbilical artery BF, and placental and fetal development following a 4 week uterine infusion of melatonin (MEL; n

= 5), melatonin receptor antagonist, luzindole (LUZ; n = 5), or vehicle (CON; n = 4). Multiparous singleton pregnant ewes were surgically implanted with mini osmotic pumps (2.5 µl/hr infusion of 1 mg/mL MEL or LUZ) on d 62 of gestation. Pumps and catheters were sutured under the perimetrium and catheters were advanced to the gravid uterine vascular network of the mesometrial region. On d 90 of gestation fetal BF was determined via Doppler ultrasonography followed by euthanasia. Data were analyzed using the mixed procedure of SAS. The model statement included infusion treatment and fetal sex. Placentome weight, cotyledon weight, and placentome number were not different ($P > 0.10$) among treatments. Caruncle weight was decreased ($P < 0.05$) in MEL and LUZ vs. CON treated ewes. Placental efficiency (fetal weight: placentome weight ratio) was increased ($P = 0.05$) in MEL vs. LUZ treated ewes with CON being intermediate. Fetal weight, biparietal distance, ponderal index, and crown rump length were not different ($P > 0.10$) among treatments, while thoracic girth was increased ($P < 0.02$) in MEL vs. LUZ treated ewes with CON being intermediate. Umbilical artery BF and umbilical artery BF relative to placentome weight were increased ($P < 0.05$) in MEL vs. CON and LUZ treated ewes. Fetal descending aorta BF was increased ($P < 0.05$) in MEL vs. LUZ treated ewes, while fetal descending aorta BF relative to fetal weight was increased ($P < 0.005$) in MEL vs. CON and LUZ treated ewes. The ratio of fetal descending aorta BF to umbilical artery BF was not different ($P > 0.95$) among treatment groups. The increase in umbilical artery BF due to chronic uterine melatonin infusion is potentiated by an increased fetal cardiac output through the descending aorta. Moreover, melatonin receptor antagonism did not alter umbilical artery blood flow compared with CON ewes. Therefore, mechanisms apart from melatonin receptor activation may mediate the observed increase in fetal BF following melatonin treatment.

Key Words: fetal blood flow, melatonin, placental efficiency

523 Influence of metabolizable protein supplementation during late gestation on vasoreactivity of maternal placental arteries in sheep. L. A. Lekatz*[1], A. Reyaz[1], M. S. Sane[2], F. Yao[2], S. T. O'Rourke[2], C. Schwartz[1], M. L. Van Emon[3], C. S. Schauer[3], K. M. Carlin[1], C. O. Lemley[1], and K. A. Vonnahme[1], *[1]Center for Nutrition and Pregnancy, Department of Animal Sciences, North Dakota State University, Fargo, [2]Department of Pharmaceutical Sciences, North Dakota State University, Fargo, [3]Hettinger Research Extension Center, North Dakota State University, Hettinger.*

To examine the effects of metabolizable protein (MP) intake during late gestation on the vasoreactivity of placental arteries, 18 pregnant ewes received isocaloric diets containing 60% (MP60), 100% (MP100), or 140% (MP140) of MP requirements from d 100 to 130 of gestation. On d 130, several caruncular (CAR) arteries from placentomes of similar size and in close proximity to the umbilicus were selected for vasoreactivity studies using wire myography. Arterial rings (n = 4/ewe) were suspended in organ chambers with a wire myograph filled with 5 mL of physiological salt solution aerated with a mixture of 95% O_2 and 5% CO_2 and kept at 38.6°C. Optimal tension was found by progressively stretching the rings until the contractile response to KCl (20 mM) was maximal. The presence or absence of endothelium was verified by testing the ability of bradykinin (BK; 10^{-7} M) to produce endothelium-dependent relaxation during contraction evoked by norepinephrine (10^{-6} M). Each ring underwent a dose response curve (DRC) to BK in the presence or absence of an inhibitor. Rings were contracted with either U46619 (10^{-6} M) or 5-HT (10^{-6} M), and the DRC to BK in the absence of an inhibitor was obtained. In addition, BK DRC were obtained for rings which were incubated for 30 min with one of the following inhibitors: iberiotoxin (IBTx; an inhibitor of Ca^{2+}-activated K^+ channels; 10^{-7} M), indomethacin (INDO; a cyclooxygenase inhibitor; 10^{-5} M), or *N*(omega)-L-arginine methyl ester (NLA; a nitric oxide synthase inhibitor; 10^{-5} M) before the BK DRC was obtained. There was no difference ($P = 0.97$) in the response to BK among the 3 groups. While there was no difference ($P = 0.67$) in relaxation due to BK in the presence of IBTX, there was a treatment by dose interaction ($P = 0.02$) when arteries were incubated with NLA where pattern of relaxation differing slightly among treatments. The response to BK is inhibited similarly by IBTx and NLA in across all treatments indicating vasorelaxation being partially dependent on NO and BKCa channels. In MP140, inhibition of cyclooxygenase by INDO enhances the response to BK ($P = 0.09$) compared with MP100 and MP60. This could suggest that contractile arachidonic acid metabolites are produced in MP140 CAR arteries.

Key Words: bradykinin, placental vasoreactivity, sheep

524 Transgenerational effects of n-3 and n-6 supplementation under the control of transcription factors related to lipid metabolism. C. B. Jacometo[1], S. Halfen[1], F. T. da Rosa[1], A. Schneider[1], C. C. Brauner[1], F. A. B. Del Pino[1], J. J. Loor[2], N. J. L. Dionello[1], L. F. M. Pfeifer[3], E. Schmitt*[1], and M. N. Corrêa[1], *[1]Federal University of Pelotas, Pelotas, Rio Grande do Sul, Brazil, [2]University of Illinois, Urbana, [3]Embrapa Rondônia, Porto Velho, RO, Brazil.*

Our objective was to determinate the influence of omega-3 and omega-6 consumption throughout generations under transcription factors expression related to lipid metabolism. Wistar rats females, 8 week old, (G0, n = 18/group) were divided in: diet containing flaxseed oil (G3) and diet containing soybean oil (G6). The diets were elaborated in accordance with AIN-93G recommendations (AIN-93G). After 30 d of acclimatizing the rats were mated for 3 d in 1:3 male:female ratio. The Males received only the control diet. The F1 female were selected at weaning (n = 16/group) and was divided into 3 groups: females from G3 group that continued receiving diet containing flaxseed oil (G3–3); females from G3 group that began to receive diet containing soybean oil (G3–6); and females from G6 group that continued to receive diet containing soybean oil (G6–6). These animals were mated with 60 d old as described above (G0). The F2 (n = 16/group) was selected like F1 and the diet groups were maintained: G3–3-3; G3–6-6 and; G6–6-6. The F2 was mated like the F1. Prepartum euthanasia (19 ± 1 d) was conducted in each generation (n = 4/group) to collect liver samples. The Real-Time quantitative PCR was performed to evaluate the peroxisome proliferator-activated receptor α (PPARα), retinoid X receptor α (RXRα), liver X receptor α (LXRα), sterol regulatory element binding protein 1c (SREBP-1c), carbohydrate regulatory element binding protein (ChREBP) and nuclear corepressor receptor 1 (NCoR1) expression. Actin β (ACTB), Glyceraldehyde-3-phosphate (GAPDH) and 18S subunit ribosomal RNA (18S) were used as internal control. NCor1 and ChREBP did not differ between groups and so throughout generations, indicating a PUFA independent control. Differences between groups were not observed in G0 generation. In the F1, the PPARα were higher expressed in the G6–6 group than the G3–6 group ($P = 0.03$) and LXRα were lower in the G3–6 group than the G3–3 group ($P < 0.01$) and G6–6 group ($P < 0.05$). In the F2 generation LXRα had a lower expression in the G3–3-3 group compared with the G3–6-6 ($P < 0.01$) and G6–6-6 ($P < 0.01$). There were cumulative effects throughout generations in all groups with crescent RXRα (G0-F2:$P < 0.01$ and F1-F2:$P < 0.02$) and LXRα expression (G0-F2: $P < 0.01$ and F1-F2:$P < 0.01$) along generations. In the F2 generation the G3–3-3 group had a higher PPARα expression and a lower LXRα expression indicating lipolytic and anti-lipogenic effect. Our results indicate that the PUFAs effect on the control of lipolysis and lipogenesis is cumulative throughout generations.

Key Words: lipid metabolism, epigenetic, nutriphysiogenomics

Production, Management and the Environment: Dairy

525 Use of electrical conductivity for the detection of subclinical mastitis in dairy cows in Saudi Arabia. A. Alyemni[1,2], R. Aljummah[2], M. Ayadi[2], M. Hussein[2], and M. Alshaikh*[2], [1]*Arasco, Riyadh, Saudi Arabia,* [2]*King Saud University, Riyadh, Saudi Arabia.*

The objective of this study was to evaluate the use of milk electrical conductivity (EC) for predicting subclinical mastitis in high-producing dairy cows under Saudi Arabian conditions. Three hundred and 60 lactating Holstein cows were randomly selected and divided into 2 herds of 180 cows each, based on parity and days in milk (DIM). A total of 11350 quarter milk samples were collected weekly from the animals during the morning milking. Both EC and somatic cell count (SCC) were used as indirect measures of udder health. Milk fat, protein, lactose, and solids non-fat (SNF) were measured weekly. The effect of seasonal variation during summer and winter months was taken into account. Data were analyzed using a mixed model. The average milk EC and SCC values of cows were 4.68 mS/cm and 181,900 cells/ml, respectively. The highest EC value for healthy quarters was 5.27 mS/cm. Milk EC values were lower ($P < 0.01$) in summer (4.62 mS/cm) than winter (4.73 mS/cm) months. Using inter-quarter ratio (IQR), 232 cases were diagnosed as subclinical mastitis at different periods of time. Our results indicated that low or high basic levels affect the sensitivity and specificity of EC test, while using (IQR) improved the results. There was a significant correlation between milk EC, SNF and lactose content. A significant positive correlation ($r = 0.36$; $P < 0.01$) between EC and SCC was also observed, which increased the percent sensitivity and specificity of the results and the certainty of the diagnosis for cows with subclinical mastitis. The significant effects of stage of lactation on milk EC and milk components varied significantly with different stages of milking. Hence, it was not possible to conclude that milk EC can be used as an effective means for detecting early signs of subclinical mastitis and predicting clinical cases before symptoms arise, unless it is used in combination with other methods.

Key Words: milk electrical conductivity, dairy cows, mastitis

526 Effect of feeding duration on growth, health, and economics of group-fed dairy calves in an organic production system. B. J. Heins* and E. A. Bjorklund, *University of Minnesota, West Central Research and Outreach Center, Morris.*

Heifer calves (n = 67) were used to evaluate the effect of early life feeding duration in an organic group management system on growth, health, and economics of organic dairy calves. Calves were assigned to replicate feeding groups of 10 in super hutches by birth order, and were born at the University of Minnesota West Central Research and Outreach Center, Morris, Minnesota from March to June 2011. Breed groups of calves were: Holsteins (n = 11) selected for high production (HO), Holsteins (n = 10) maintained at 1964 breed average level (H64), crossbreds (n = 28) including combinations HO, Montbéliarde, and Swedish Red selected for high production (HMS), and crossbreds (n = 18) including combinations of HO, Jersey, and Swedish Red selected for durability (HJS). Calves were weaned at 30 (EW), 60 (MW), or 90 (LW) days of age, and groups were fed 1.5% of birth weight of 13% total solids organic milk once daily and then weaned when the group consumption averaged 0.91 kg starter/calf/day. Body weight and hip height were recorded at birth, once per week, and at weaning. Analysis was with PROC GLM of SAS, and independent variables for statistical analysis were the fixed effects of weaning group and breed group. Weaning group performance was weaning age (days), EW (44.2), MW (61.3). LW (91.5) ($P < 0.01$); gain per day (kg), EW (0.52), MW (0.68), LW (0.75) ($P < 0.01$); weaning weight (kg), EW (61.7), MW (79.6) LW (106.8), ($P < 0.01$); and weaning hip height (cm), EW (88.3), MW (91.4), LW (97.0) ($P < 0.01$). The HO (0.72; 89.0), H64 (0.61; 80.5), HMS (0.67; 84.5), and HJS (0.60; 76.6) calves were not significantly different for gain per day (kg) or weaning weight (kg), respectively. Total costs (grain and organic milk) to weaning per calf were $108.81 for EW, $167.68 for MW, and $275.79 for LW groups; however, the cost per pound of gain was significantly higher ($P < 0.01$) for the EW ($4.83) group than the MW ($4.18) or LW ($4.06) groups. In summary, late weaned calves had higher daily gains than early weaned calves; however, the optimum time for weaning of organic dairy calves may be between 30 and 90 d.

Key Words: organic, calf growth, crossbreeding

527 Survey of lameness, body condition score, hygiene, and hock lesions of Colorado dairy cows housed in outdoor dirt lots or free stalls with outdoor access. R. Woiwode,* T. Grandin, and I. Roman-Muniz, *Colorado State University, Fort Collins.*

The objective of this study was to conduct a survey of the conditions of dairy cattle in Colorado. Dairies were visited between July and December 2011. Data were collected on locomotion score, body condition score (BCS), hygiene, and hock lesions. Cattle were observed on 10 dairies ranging in size from 400 to 3800 cows. An average of 12% of the lactating herd was scored on each dairy for lameness and hock lesions. Lactating cows observed were housed either in free stalls with outdoor access available (80%) or in dirt lots (20%). Lactating cows were gait scored using the Zinpro Locomotion Score, a 5 point numerical rating system, with 1 and 2 classified as non-lame and ≥ 3 classified as lame. An average of 3.2% (±2.5) of all cattle observed were classified as lame. Severe hock lesions were negligible, with only 0.1% (±0.04) of lactating cows exhibiting hock swelling ≥ baseball size. Lameness was much lower than the estimated national average of 20–25% (Cook, 2003; Espejo et al., 2006), possibly due to a combination of factors, including cows housed in free stalls having access to outdoor dirt lots, and other management practices. Body condition was scored on all lactating cows using a 5 point numerical rating system, with ≤ 2 classified as too low. The average BCS of lactating cows classified as too low was 2.4% (±1.7). Hygiene was scored using a 4 point numerical rating system, with 4 classified as unacceptable. Lactating and nonlactating cow hygiene was observed to be very good with an average of 2.4% (±3.2) cows classified as having unacceptable hygiene. Cow hygiene was observed to be better than calf hygiene, as an average of 7.8% of calves were observed to have unacceptable hygiene. Additional dairies and data will be included at the time of presentation.

Key Words: dairy, lameness, hygiene

528 Economics of using sheath protectors at the time of AI in dairy cows. S. Bas*[1], K. N. Galvão[2], and G. M. Schuenemann[1], [1]*Department of Veterinary Preventive Medicine, The Ohio State University, Columbus,* [2]*Department of Large Animal Clinical Sciences, University of Florida, Gainesville.*

The use of disposable sheath protectors (SP) to minimize contamination of the AI catheter at the time of AI improved conception risk (CR; 5

percentage points) of lactating dairy cows. The objective was to assess the effect of 5 percentage points increase in CR (from 32% to 37%) on dairy herd economics using an individual cow-based stochastic model. For the simulation, lactating dairy cows were enrolled in a Presynch-Ovsynch for first AI followed by estrus detection (ED) and resynchronization of cows diagnosed open 32 d after AI using Ovsynch. Herd size was maintained at 1,000 cows. Mortality was set at 6% and abortions at 13%. Cows not AI after 365 DIM and open cows were culled after 450 DIM. Culled cows were immediately replaced. The dry and VWP were set to 60 d. Compliance to each injection of the synchronization program was 95% and estrus detection (ED) was set to 60% with an accuracy of 95%. Simulation was performed at 32% for 3,000 d until steady-state was reached, then the model was set at 37% CR for the subsequent 2000 d to calculate the new economic values ($/cow/d). Average values from 10 runs were used. Net daily value was calculated by subtracting the costs of replacements ($1,800/heifer), feeding costs ($0.25/kg of lactating cow diet; $0.25/kg of dry cow diet), breeding costs ($0.1/cow/d for ED; $2.5/dose PF2α ; $3.0/dose GnRH; $0.17/injection administration, and other costs ($3.5/d) from the daily income [milk sales ($0.31/kg milk), cow sales ($0.75/kg live weight), and calf sales ($200/calf)]. According to the model, the use of SP provided an additional $4.8 cow/yr (or $4,800/yr for a 1,000-cow herd) for each point increase in CR (from 32% to 37%). Use of SP can increase farm profitability by increasing CR at a minimal cost.

Key Words: sheath protector, pregnancy, economics

529 Effect of AI technicians on reproductive performance and economics of lactating dairy cows.

G. M. Schuenemann*[1], S. Bas[1], and K. A. Galvão[2], [1]*Department of Veterinary Preventive Medicine, The Ohio State University, Columbus,* [2]*Department of Large Animal Clinical Sciences, University of Florida, Gainesville.*

It is common to observe large within-herd variation in AI technician conception risk (CR). The objective was to assess the effect of AI technicians on reproductive performance and economics using a stochastic dynamic model. CR from 3 distinct AI technicians (A = 38%, B = 32%, and C = 26%) were assessed. For the simulation, lactating dairy cows were enrolled in a Presynch-Ovsynch for first AI followed by estrus detection (ED) and resynchronization of cows diagnosed open 32 d after AI using Ovsynch. Cows were not AI after 365 DIM and open cows were culled after 450 DIM. Culled cows were immediately replaced. Herd was maintained at 1000 cows. Death losses were set at 6% and abortion at 11.3%. Dry period of 60 d. Net daily value was calculated by subtracting the costs with replacement heifers ($1,800/heifer), feeding costs ($0.25/Kg of lactating cow diet; $0.25/Kg of dry cow diet), breeding costs ($0.1/cow/d for ED; $2.5/dose PGF; $3.0/dose GnRH; $0.17/injection administration), and other costs ($3.5/d) from the daily income with milk sales ($0.31/Kg milk), cow sales ($0.75/Kg live weight), and calf sales ($200/calf). CR from AI technician A (38%), B (32%), and C (26%) was compared. Simulation was performed until steady-state was reached (3000 d), then average daily values for the subsequent 2000 d was used to calculate profit/cow/yr. ED was set to 60%. Accuracy of ED and compliance with each injection were set at 95%. Inaccurate ED resulted in 0% CR. Missing a Presynch injection resulted in loss of 50% of the benefit (40% increase to first AI), and missing an Ovsynch injection resulted in decrease in CR by 70%. The breeding costs/cow/yr for AI technician A, B, and C were $88, $96, $106, respectively. The profit/cow/yr for AI technician A, B, and C were $179, $139, and $82, respectively. Assuming that the herd remains constant, each point increases in CR (from 26% to 38%) represented $6 per cow/yr or $6,000/yr for a 1000-cow dairy. Compliance with the AI procedure (semen handling, accuracy of ED, hygiene, site of semen deposition) affects the bottom line of dairy herds and should not be compromised for convenience. Investing in educational training for professional AI technicians should be a top priority.

Key Words: AI technician, economics, dairy cow

530 The effect of reproductive performance on the herd value assessed by integrating a daily dynamic programming with a daily Markov chain model.

A. S. Kalantari* and V. E. Cabrera, *Department of Dairy Science, University of Wisconsin-Madison, Madison.*

The objective of this study was to determine the effect of reproductive performance on the herd value. The herd value was defined as the herd's average retention payoff (RPO) which is the expected profit from keeping the cow compared with immediate replacement. First, a daily dynamic programming model was developed to calculate the RPO of all cow states in a herd. Second, a daily Markov chain model was applied to estimate the herd demographics. Then, herd value was calculated by aggregating the RPO of all cows in the herd. Cow states were described by 5 milk classes (MC1 = lowest to MC5 = highest), 9 lactations, 750 d in milk (DIM) and 282 d in pregnancy. Five different reproductive programs were studied (RP1 to RP5). The RP1 used 100% timed artificial insemination (TAI) (42% conception rate (CR) for 1st TAI and 30% for 2nd and later services) and the other programs combined TAI with estrous detection (ED). The proportion of cows receiving AI after ED ranged from 30 to 80%, with CR of 25, 30, and 35%. These 5 reproductive programs were categorized according to their 21 d pregnancy rate (21 d PR), which is an indication of the rate the eligible cows become pregnant every 21 d. The 21 d PR was 17% for RP1, 14% for RP2, 16% for RP3, 18% for RP4, and 20% for RP5. Results showed a positive relationship between 21 d PR and the herd value. The most extreme herd value difference ($/cow per year) between 2 RP was $77 for MC3 (RP5 – RP2); $13 for MC1 (RP5 – RP1); and $160 for MC5 (RP5 – RP2). Reproductive programs were ranked based on their calculated herd value. With exception of the best reproductive program (RP5), all other programs showed some level of ranking change with MC. The most dramatic ranking change was observed in RP1, which moved from being the worst ranked for MC1 to the second best ranked for MC5. Supported by AFRI Competitive Grant no. 2010–85122–20612

Key Words: retention pay-off, economics, dairy cattle

531 Regression meta-models to predict the value of pregnancy in dairy cows.

A. De Vries,* *University of Florida, Gainesville.*

The value of a new pregnancy can be calculated with a complex dynamic programming model (DairyVIP) for a variety of input parameters, but the model needs to be installed on a computer and each calculation takes time. The objective of this study was to predict the values of pregnancy for 9 important input parameters using a regression meta-model. Meta-models provide instant predictions of the value of pregnancy for the fitted inputs and can be used in web-based dashboard tools for easy access by interested users. Nine input parameters were randomly varied over reasonable ranges using 265 design points. The value of pregnancy and profit per cow per year were calculated for each design point with DairyVIP. Mean ± SD of the 265 values of pregnancy was $246 ± $131. Values of pregnancy increased with greater replacement costs and lower pregnancy rates. The procedure Glmselect in SAS was used to fit the meta-model. The Glmselect procedure included learning (n = 150 design points), validation (n = 50) and testing (n = 65). The 9 main effects included the prices of replacement heifers, milk, feed, cull cows, and calves, as well as the probabilities of insemination, conception, culling, and the level of milk yield. The main effects, logs of the main effects, and all 2-way interactions were fitted. At most 10 effects were selected for the regression model. Stepwise selection with the Press criteria was used to select the best fitting meta-model. Statistics for the final meta-model were $R^2 = 0.987$ and AIC = 990. Mean ± SD of the prediction error was \$0 ± \$15 (range -\$30 to \$41). Prediction errors were independent of the profit per cow per year. In conclusion, regression meta-models were able to accurately predict the value of pregnancy in most cases. Meta-modeling may be a useful approach to make results from complex computer models widely available.

Key Words: regression, meta-model, value of pregnancy

532 Effect of heat stress during the dry period on immune function and growth performance of the offspring fed standardized pooled colostrum.

A. P. A. Monteiro,* S. Tao, I. M. Thompson, and G. E. Dahl, *University of Florida, Gainesville.*

Calves born and fed with colostrum from dairy cows exposed to heat stress during the dry period have compromised passive immunity and cell-mediated immune function compared with calves born to cows under cooling. However, it is unknown if this compromised immune response is caused by calf or colostrum intrinsic factors. Our objective was to evaluate the effect of maternal heat stress during the dry period on calf specific factors related to immune response and growth performance of the offspring. Cows were dried off 46 d before expected calving and randomly assigned to a cooling (CL, n = 18) or heat stress (HT, n = 18) environment. Cows of the CL group were housed with sprinklers, fans and shade, whereas cows of HT group had only shade. Colostrum from cows exposed to neutral environmental conditions during the dry period was pooled and stored frozen (−20°C). Within the first 4 h of birth, 3.78 L of pooled colostrum was fed to calves from both treatment groups. All the calves were exposed to the same management and were weaned at 50 d of age. The day of birth was considered study d 0. Blood samples were collected before colostrum feeding, 24 h after birth and twice weekly up to d 32. Total plasma protein and IgG concentrations were determined. Body weight was recorded at birth and at d 15, 30, 45 and 60. HT calves were lighter ($P < 0.01$) at birth than CL calves (38.3 vs. 43.1 kg), and no differences ($P = 0.36$) in weight gain were observed up to d 60 (31.9 vs. 34.2 kg gain). Additionally, HT calves had lower ($P < 0.05$) apparent efficiency of IgG absorption (26.04 vs. 30.24%), but no differences were observed for total plasma protein (5.42 vs. 5.50 g/dL; $P = 0.34$) and serum IgG concentration (2.09 vs. 2.15 g/dL; $P = 0.57$). Calves born from cows exposed to heat stress during the dry period had lower birth weight and lower apparent efficiency of IgG absorption. Thus, heat stress during the last 6 wks of gestation negatively affects the ability of the calf to acquire passive immunity regardless of colostrum source.

Key Words: calves, dry period, heat stress

533 Accuracy of the AfiLab real time milk analyzer to predict DHIA fat, DHIA protein and lactose.

K. Kanyiamattam,* K. D. Gay, E. J. Diepersloot, D. R. Bray, C. R. Staples, and A. De Vries, *University of Florida, Gainesville.*

Objective of this study was to quantify the agreement between the AfiLab real time milk analyzer based on light scattering and test day DHIA fat, DHIA protein and lactose, all based on the Bentley 2000 analyzer (BA). AfiLab data were collected twice daily at 12h intervals from the double 12 parlor at the University of Florida Dairy Unit in Hague, FL, from January 2010 to December 2011. Alternating AM/PM BA data for the 24 test days in 2010 and 2011 were also obtained. Approximately 450 cows were tested each month. AfiLab data were matched with DHIA fat and protein (n = 10,273; 23 test days) and lactose (n = 6,741; 16 test days). Means and SD of BA fat, protein and lactose were 3.76 ± 0.80%, 3.08 ± 0.37% and 4.72 ± 0.30% respectively. Mean and SD of average AfiLab minus BA observations of the test day milking were −0.077 ± 0.116% for fat (n = 23), 0.024 ± 0.107% for protein (n = 23) and −0.024 ± 0.083% for lactose (n = 16). Mean and SD of within test day SD of AfiLab minus BA observations of the test day milking were 0.659 ± 0.110% for fat, 0.274 ± 0.031% for protein and 0.262 ± 0.025% for lactose. Mean and SD of the corresponding correlations were 0.59 ± 0.09 for fat, 0.74 ± 0.03 for protein and 0.46 ± 0.08 for lactose. The accuracy of various combinations of AfiLab observations from up to 6 milkings before and after the test day milking was also evaluated. The accuracy of fat predictions was not improved. The average of the 13 protein observations improved the average difference to 0.011 ± 0.095% and SD of the difference to 0.227 ± 0.029%. The correlation increased to 0.78 ± 0.04. The average of 13 lactose observations improved the SD of the difference to 0.229 ± 0.021% but the mean of the difference was −0.031 ± 0.089%. The correlation increased to 0.55 ± 0.05. In conclusion, the accuracy of protein prediction was better than the accuracy of lactose and fat prediction. Combination of AfiLab observations from various milkings may improve the accuracy of prediction.

Key Words: accuracy, agreement, fat, protein, lactose

534 Potential utility of a parlor-based individual quarter milking system.

A. E. Sterrett,* C. L. Wood, K. J. McQuerry, and J. M. Bewley, *University of Kentucky.*

Overmilking may lead to teat end hyperkeratosis (HK). The objective of this study, conducted at the University of Kentucky Coldstream Dairy, was to examine changes in teat end HK in a herd transitioning from a standard pulsation system to an individual quarter pulsation milking system. Teat end HK was evaluated immediately after cluster removal using the scoring system outlined by Mein et al. (2001) where N signifies no ring; S signifies a smooth, raised ring; R signifies a rough ring; and VR signifies a very rough ring. Scorings were classified for 69 cows (48 Holstein, 12 Crossbred, and 9 Jersey) relative to installation (April 28, 2011) of the Milpro P4CTM (Milkline, Gariga di Podenzano, Italy) system as follows: PRE1-April 7; PRE2-April 21; POST1-May 12; POST2-May 26; POST3-June 9. The Milpro P4CTM system stops milking individual quarters using a unique individual quarter pulsation system with 4 pulsation channels instead of 2. Hyperkeratosis scores were converted to numerical values as follows: n = 1; S = 2; R = 3; VR = 4. The MIXED Procedure of SAS® (Cary, NC) was used to evaluate fixed effects of age, breed, parity, and teat position and their interactions with variables repeated by scoring with cow within breed as subject. The effects of position and scoring × breed were significant ($P < 0.01$ and $P = 0.02$, respectively). Hyperkeratosis scores improved for Holsteins from PRE1 to POST3 (1.75 ± 0.09 and 1.41 ± 0.10, respectively, $P < 0.01$), PRE1 to POST2 (1.75 ± 0.09 and 1.54 ± 0.09, respectively, $P < 0.01$), PRE2 to POST3 (1.64 ± 0.09 and 1.41 ± 0.10, respectively, $P < 0.01$) and POST1 to POST3 (1.62 ± 0.10 and 1.41 ± 0.10, respectively, $P < 0.01$) whereas Jersey and crossbred scores did not change among scorings ($P > 0.05$). Right front HK scores varied significantly from right rear and left rear scores (1.58 ± 0.09, 1.37 ± 0.09, and 1.36 ± 0.09, respectively, $P < 0.01$) and left front teat end HK scores varied significantly from right rear and left rear scores (1.62 ± 0.09, 1.37 ± 0.09, and 1.36 ± 0.09, respectively, $P < 0.01$). Teat end HK scores improved for Holsteins after installation of the individual quarter pulsation milking system.

Key Words: hyperkeratosis, teat end, individual quarter pulsation

535 Reducing dietary protein decreased the ammonia-emitting potential of manure from commercial dairy farms. A. N. Hristov,* K. Heyler, E. Schurman, K. Griswold, P. Topper, M. Hile, V. Ishler, E. Wheeler, and S. Dinh, *The Pennsylvania State University, University Park.*

The objective of this project was to decrease manure NH_3 emissions through reducing dietary crude protein (CP) concentration on commercial dairy farms. Twelve Pennsylvania dairies (169 ± 50 cows) with scrape, gravity-flow, or flush manure management systems participated in the project. Background data on barn floor and laboratory manure emissions (i.e., emitting potential, EP) of NH_3, N_2O, CH_4, and CO_2 were collected during 4 sampling events (2 in the spring and 2 in the fall) in Yr 1 of the project. In Yr 2, dietary CP concentration was reduced ($P < 0.001$) from an average across all farms of 16.5 (in Yr 1; HighCP period) to 15.4% (LowCP period) and data collection was repeated. Diets were sampled throughout the project to verify CP levels. Milk yield and milk composition data were also collected throughout the project. Data were analyzed with farm as random effect using the MIXED procedure of SAS. Barn floor NH_3 emissions were drastically lower during the LowCP compared with the HighCP periods (186 vs. 445 mg/m^2/h; $P < 0.001$). These results, however, were confounded by lower ambient temperature during the LowCP period (6.3 vs. 13.6°C, respectively). The NH_3 EP, which was based on evaluation of reconstituted (urine and feces) manure at the same temperature, was on average 23% lower ($P < 0.001$) for LowCP vs. HighCP manure (292 vs. 378 mg/m^2/h). Emissions of CH_4, and CO_2 were not affected by dietary CP and emissions of N_2O were negligible. Barn floor NH_3 emissions were lower ($P = 0.02$) for flush vs. scrape and gravity-flow manure management systems. The greatest ($P < 0.001$) CH_4 emissions were observed for the gravity-flow manure system (1,215 vs. 486 and 37 mg/m^2/h, gravity-flow, scrape, and flush, respectively). Milk yield (32.2 vs. 32.5 kg/d; $P = 0.81$) and milk composition were not different between the HighCP and LowCP periods. MUN tended to be lower during the LowCP period (13.2 vs. 14.5 mg/dL; $P = 0.06$). This on-farm project demonstrated that manure NH_3 emissions can be significantly reduced by moderately decreasing dietary CP content without affecting milk yield and composition in dairy cows.

Key Words: dairy farm, ammonia emission, dietary protein

536 Dose effects of monensin on methane emissions from lactating Holstein dairy cattle. S. E. Place*[1], Y. Pan[1], Y. Zhao[1], C. E. Moore[2], J. K. Wittman[2], and F. M. Mitloehner[1], [1]*Department of Animal Science, University of California-Davis, Davis,* [2]*Elanco Animal Health, Greenfield, IN.*

Monensin is a feed additive used in dairy cattle diets that may reduce methane emissions; however, past results have been variable, which could be due to the dose of monensin fed to cattle. To test the dose effects of monensin, 20 lactating Holstein cows were stratified by days in milk and randomly assigned to one of 4 treatments provided in a pelleted top dress (CON, LOW, MED, HIGH containing 0, 175, 368, and 518 mg cow^{-1} d^{-1} of monensin, respectively). All cows were fed the same basal TMR throughout the trial and CON top dress for 19 d (PRE period), then their respective treatment top dress for 21 d (MON period), then returned to the CON top dress for 21 d (POST period). Milk production and feed intake (DMI) were monitored daily, milk composition once during each period, and gas emissions were collected on the last day of each period for each cow. Gas emissions were sampled with a ventilated hood system. All statistical analysis was conducted using Proc Mixed procedures in SAS version 9.3 (SAS Institute Inc., Cary, NC). Methane emissions, milk production, DMI, and milk composition were similar across treatments in the MON period. There were no carryover effects of monensin in the POST period. The change in methane emissions from the PRE to MON period across treatments varied (6.4, 6.1, 1.6 and 3.9 g cow^{-1} h^{-1} for the CON, LOW, MED, and HIGH treatments, respectively), with MED having a lower ($P < 0.05$) change in methane emissions per cow, per kg of DMI, and per kg of milk compared with CON. Changes from the PRE to MON period in milk yield (3.5, 2.8, 1.3, and 2.4 kg cow^{-1} d^{-1} for CON, LOW, MED, and HIGH, respectively) and DMI (1.6, 0.63, 0.15, and 0.92 kg cow^{-1} d^{-1}, for CON, LOW, MED, and HIGH, respectively) were lower for the MED treatment cows compared with those in CON ($P < 0.05$). All treatments had similar emissions and animal performance measures within the MON period, but the MED treatment did have lower changes over time in methane emissions, DMI, and milk yield from the PRE to MON periods. Over time, monensin had dose effects on methane emissions, DMI, and milk yield, but the effects do not seem to be linear in nature.

Key Words: monensin, methane, dairy cows

537 Characterization of Shanghai dairy cattle lactation performance in 2008. C. G. Zhang[1], G. L. Liu*[1,2], L. M. Huang[1], Z. G. Wang[1], and G. Yang[1], [1]*State Key Laboratory of Dairy Biotechnology, Shanghai Bright Holstan Co. Ltd., Shanghai, China,* [2]*Shanghai Dairy Breeding Center Co., Ltd., Shanghai, China.*

Accurate knowledge of a lactation performance has an important relevance to management and research of dairy cattle production systems. The purpose of the study presented was to determine the characterization of Shanghai dairy cattle lactation performance in 2008. Milk production data for 157 dairy farms (31,800 cows and 357,600 data points) were obtained from Dairy Herd Improvement (DHI) project of Shanghai Dairy Breeding Center, the data of 305-d milk yield was collected and calculated by each farm′s records. Daily and 305-d milk yields were summarized and evaluated by parity using ANOVA procedure of SAS. We also compared 2008 milk yield with previous milk data from 2003 and 1998. The results indicated that average daily milk yield for parity 1, parity 2 and parity 3 or greater was 17.2 ± 2.9 kg, 23.5 ± 3.3 kg and 22.2 ± 3.9 kg, average peak milk yield was 29.5 ± 4.6 kg, 34.5 ± 6.2 kg and 33.4 ± 5.7 kg, and average days to peak milk were 65 ± 9 d, 47 ± 8 d and 54 ± 9 d, respectively. Parity 2 cows had greater ($P = 0.04$) average 305-d milk yield (8,300 ± 973 kg) than parity 1 (7,789 ± 845 kg) cows and tended ($P = 0.11$) to have greater yield than parity 3 or greater cows (7,956 ± 899 kg). In contrast, the highest average 305-d milk yield was found for parity 4 cows (7,569 ± 813 kg) in 1998 and parity 3 cows (8,361 ± 937 kg) in 2003. These results are valid to suggest that a better understanding of lactation curves would allow producers to evaluate their production compared with averages in Shanghai region.

Key Words: lactation curve, dairy cattle, Shanghai (China)

Ruminant Nutrition: Beef Production III

538 Effect of the forage-to-concentrate ratio on DMI and ruminal fermentation based on timing of feeding relative to feed restriction. R. I. Albornoz*[1], J. R. Aschenbach[2], D. R. Barreda[3], and G. B. Penner[1], *[1]University of Saskatchewan, Saskatoon, SK, Canada, [2]Free University of Berlin, Berlin, Germany, [3]University of Alberta, Edmonton, AB, Canada.*

The objective of this study was to evaluate the interaction between the forage-to-concentrate ratio (F:C) of diets fed before (baseline) and during short-term feed restriction (FR; collectively denoted as PRE) and those fed post-feed restriction (POST) on DMI and rumen fermentation. Twenty ruminally cannulated heifers (477 ± 38 kg BW) were exposed to 14 d for adaptation followed by 5 experimental periods; 5-d baseline, 5-d FR, and 3 wk of recovery (R1, R2, and R3). Heifers were fed, ad libitum, a high forage diet (HF; F:C = 92:8) or a moderate forage diet (MF; F:C = 60:40) during baseline, and FR was imposed at 25% of ad libitum DMI. During recovery, one half of the HF and MF heifers remained on the same diet, and the other half were exposed to an abrupt switch (e.g., HF/HF, HF/MF, MF/HF, and MF/MF). PRE × period ($P = 0.02$) and POST × period ($P = 0.04$) interactions were detected for DMI. Although DMI, within periods, was not different for HF and MF, heifers fed HF PRE increased DMI from R1 to R3. Heifers fed HF POST had higher intake during R1 than heifers fed MF with no differences observed between diets within other periods. A PRE × POST × period interaction was detected for butyrate concentration ($P = 0.01$). Butyrate was higher for cows fed MF PRE than HF PRE. Butyrate concentration decreased from baseline to FR and returned to baseline values by R3; although the extent of the increase was greater for heifers fed HF PRE than MF PRE. PRE × period ($P = 0.02$) and POST × period ($P < 0.01$) interactions were detected for mean pH. For the PRE × period interaction, heifers fed HF had higher pH than those fed MF during baseline, but pH did not differ between diets during FR. Despite this, pH was higher during FR than baseline and decreased for all heifers during R1 with mean pH returning to baseline values by R2 for HF heifers. For the POST × period interaction, mean pH during R1 was lower for MF than HF, but no other differences were detected among treatments. This study indicates that feeding MF before, and HF after FR reduces risk for ruminal acidosis following FR.

Key Words: beef cattle, feed restriction, rumen fermentation

539 Rumen and cecum methane emissions between steers that are either negative or positive for residual gain. H. Freetly*, K. Hales, and J. Wells, *USDA, ARS, U.S. Meat Animal Research Center, Clay Center, NE.*

Cattle produce CH_4 in the rumen and the cecum, and it represents a loss of feed energy. A possible cause of variation in feed efficiency may be differences in capacity to produce CH_4. We hypothesized that cattle with a higher residual gain (RG) would have a decreased capacity to produce CH_4. Individual DMI and BW gain were determined on crossbred steers (n = 132, initial age = 348 ± 1 d and BW 444 ± 4 kg) for 56 d. Steers were offered feed ad libitum and intake was measured using an Insentec RIC Feeding System (Insentec B.V., Marknesse, The Netherlands). The diet consisted of 82.75% rolled corn, 12.75% corn silage, and 4.5% Biegerts supplement (Bradshaw, NE; contains 0.066% monensin, 51% CP). On d 0, 1, 21, 42, 56, 62, and 63 BW was measured, and BW gain was calculated using the regression coefficient. Residual gain was calculated from the regression of BW on DMI; $f(x) = (0.1262 \pm 0.0128)x + (25.7 \pm 9.9)$, $R^2 = 0.43$. The 7 animals with the most extreme positive and negative RG that were within 32% of the STD of the mean DMI (772 ± 90 kg) were sampled. Steers received the diet until they were slaughtered. One positive and negative RG steer were slaughtered at 12, 13, 14, 15, 19, 20, and 21 d after the end of the feeding period. At slaughter, rumen fluid was filtered and placed in a flask in a 39°C waterbath and allowed to settle. Samples were taken from the center layer. Cecum contents were placed directly into an incubation flask. For each sample site, 10 g of sample was anaerobically transferred to incubation bottles (110 mL) that contained 70 mL of buffer (4 replicates/steer). Bottles received 40 mL of hydrogen gas and were incubated in a 39°C shaking waterbath. Gas volume and CH_4 concentrations were determined at 2, 4, 6, and 8 h. Rate of CH_4 production was the average of replicate bottles within steer. Data were analyzed as a 2 × 2 factorial with sample site and RG as fixed effects. Methane production per unit DM ($\text{mmol}\cdot\text{g}^{-1}\cdot\text{min}^{-1}$) was greater in rumen 0.000510 ± 0.000051 than cecum 0.000036 ± 0.000051 samples ($P < 0.001$). Methane production did not differ between high and low RG ($P = 0.98$). Partially funded by NIFA Grant 2011-68004-30214 National Program for Genetic Improvement of Feed Efficiency in Beef Cattle. USDA is an equal opportunity provider and employer.

Key Words: cattle, methane

540 Evaluation of a complete-feed (RAMP) receiving diet. C. J. Schneider*[1], B. L. Nuttelman[1], W. A. Griffin[1], D. B. Burken[1], R. A. Stock[2], T. J. Klopfenstein[1], and G. E. Erickson[1], *[1]University of Nebraska-Lincoln, Lincoln, [2]Cargill Inc., Blair, NE.*

Two receiving trials were conducted in 2010 and 2011 to evaluate effects of feeding RAMP on cattle performance during the receiving period. Crossbred steers (yr 1: n = 642; BW = 264 ± 12.3 kg, yr 2: n = 758; BW = 257 ± 15.3 kg) were received over 2 consecutive d in 2010 and 2 d, one wk apart in 2011. Steers were blocked by arrival date and location within the feedlot yielding 2 blocks in yr 1 and 3 blocks in yr 2. Cattle were randomly allocated based on processing order to 34 pens in yr 1 and 44 pens in yr 2, within block, resulting in 15 to 20 cattle per pen. Treatments included a control receiving diet (CON;35% alfalfa hay, 30% sweet bran, 30% dry rolled corn, and 5% supplement, DM basis; 16.7% CP, 36.7% NDF) and RAMP (21.9% CP, 41.9% NDF), a complete feed (formulated and provided by Cargill Inc., Blair, NE) that contained a high level of sweet bran with a minimal amount of forage. All diets contained 27.6 mg/kg monensin and 26.5 mg/kg thiamine. Cattle were offered ad libitum access to treatment diets for 30 or 31 d in yr 1 and 21, 24, or 28 d in yr 2. Following the feeding period, cattle were limit-fed a common diet (47.5% sweet bran, 23.75% grass hay, 23.75 alfalfa hay, and 5% supplement, DM basis) for 5 d before to collecting final BW to minimize variation in gut fill. Final BW were averages of 2-d weights. There was a year × treatment interaction for ADG ($P = 0.05$) and DMI ($P < 0.01$). RAMP increased ADG ($P < 0.01$) compared with CON in yr 1 (1.63 and 1.47 kg, respectively), but in yr 2 ADG was not different ($P = 0.93$) at 1.59 kg for CON and 1.60 kg for RAMP. In yr 1 DMI were not different ($P = 0.11$) with 7.11 and 7.34 kg/d for CON and RAMP, respectively. However, in yr 2, DMI was different ($P < 0.01$) with 6.37 and 5.82 kg/d for CON and RAMP, respectively. Across both yr, RAMP increased ($P < 0.01$) G:F compared with CON (0.250 and 0.230, respectively). Incidence of BRD was not different ($P = 0.27$) for CON and RAMP across both years. Feeding RAMP improved G:F compared with feeding a traditional receiving diet.

Key Words: beef cattle, feedlot, receiving

541 Effects of RAMP on feed intake and ruminal pH during adaptation to finishing diets. C. J. Schneider*[1], A. L. Shreck[1], R. A. Stock[2], T. J. Klopfenstein[1], and Galen Erickson[1], *[1]University of Nebraska-Lincoln, Lincoln, [2]Cargill Inc., Blair, NE.*

A metabolism trial was conducted using 6 ruminally fistulated steer calves (BW = 255 ± 30 kg) to evaluate using RAMP, a complete feed provided by Cargill containing Sweet Bran and minimal forage, to adapt cattle to finishing diets. Steers were gradually adapted to finishing diets using 4 adaption diets followed by 7 d feeding a common finishing diet for a total of 5 periods consisting of 7 d each. Treatments were imposed during grain adaption using 2 programs. One treatment used RAMP by decreasing RAMP (100 to 0%) while increasing inclusion of the finishing diet (0 to 100%). For this treatment RAMP was mixed with the finishing ration and fed as a single diet. The control adaptation treatment (CON) contained (DM basis) 25% sweet bran, 5% supplement, with alfalfa hay inclusion decreasing from 45 to 7.5% while increasing a 60:40 blend of high-moisture corn and dry-rolled corn from 25 to 62.5%. All diets contained 27.6 mg/kg monensin and 26.5 mg/kg thiamine. Steers were offered ad libitum access to feed and water and fed once daily at 0800 h. Ruminal pH was recorded every min continuously for all 5 periods using wireless pH probes. Adapting cattle with RAMP increased DMI ($P < 0.01$) by 45% relative to CON in period 1 and by 25% in period 3 ($P = 0.04$). Intakes were not different during periods 2 and 4 ($P = 0.14$ and $P = 0.12$, respectively). RAMP adaptation tended to increase DMI ($P = 0.09$) compared with CON when cattle were fed the common finishing diet (6.05 and 7.35 kg for CON and RAMP, respectively). Maximum pH tended ($P = 0.07$) to be higher for CON compared with RAMP in period 2, but maximum pH was not different ($P > 0.28$) between treatments for other periods. Average ruminal pH, minimum pH, time below pH 5.6 and area below 5.6 were not affected ($P > 0.23$) by adaption method in any period. Adapting cattle with RAMP had no effect ($P > 0.11$) on magnitude of pH change or ruminal pH variance in any period. Adapting cattle to high-grain finishing diets using RAMP increased DMI but did not affect ruminal pH.

Key Words: beef cattle, grain adaptation, metabolism

542 Effect of maturity on the yield and in situ digestibility of whole-crop cereals. C. L. Rosser*[1], A. Beattie[1], H. C. Block[2], J. J. McKinnon[1], H. A. Lardner[1,3], and G. B. Penner[1], *[1]University of Saskatchewan, Saskatoon, SK, Canada, [2]Agriculture and Agri-Food Canada, Brandon, MB, Canada, [3]Western Beef Development Centre, Humbolt, SK, Canada.*

The objective of this study was to determine the optimal maturity at harvest for common whole-crop cereals used in swathgrazing systems in western Canada. Four replicate plots of barley (*Hordeum vulgare* L. 'CDC Cowboy'), millet (*Panicum milliaceum* 'Red Proso'), oat (*Avena* spp. 'CDC Weaver'), and wheat (*Triticum aestivum* L. '07FOR21') were grown. Subsections in each replicate were randomly assigned to 1 of 4 harvest maturities (cut at a 5-cm stubble height); head elongation, late milk to early dough, hard dough, and fully mature. At each stage of maturity, the wet and DM yields and chemical composition (DM, OM, NDF, crude fat, and NFC) were determined. Whole-crop samples were ground to pass through a 2-mm screen, weighed into nylon bags, and exposed to rumen incubation for 0, 2, 4, 8, 16, 24, 48 and 72 h. Rates of degradation were determined using a first-order kinetic model. Data were analyzed with stage of maturity as a fixed effect and plot as a random effect. For all crops evaluated, DM yield increased ($P < 0.001$) with advancing maturity. The concentration of CP, and NDF decreased ($P \leq 0.012$) while the concentrations of OM and NFC increased ($P < 0.001$) with advancing maturity for all crops investigated. Despite the large increase for DM yield, the yield of CP was not affected by advancing maturity for all crops except that it increased for wheat ($P < 0.001$), whereas, the yields of OM, NDF, NFC, and crude fat increased ($P < 0.023$) for all crop types. The DM degradation rate (%/h) was not affected by maturity, but the rate for NDF degradation decreased for millet and oat as plants matured ($P \leq 0.031$). However, the stage of maturity did not affect NDF degradation rate for barley or wheat. The yield of effectively degradable DM for barley ($P = 0.196$) was not affected by maturity, but increased for millet ($P = 0.016$), oat ($P = 0.004$), and wheat ($P < 0.001$) with advancing maturity. These findings suggest that harvesting whole-crop annual cereals at a mature stage may maximize the yield of effectively degradable DM.

Key Words: harvest maturity, in situ, swathgrazing

543 Rumen bacterial population responses to inclusion of wet distillers grains plus solubles in finishing diets of feedlot cattle. G. M. Shipp*[1], W. E. Pinchak[2], D. W. Pitta[3], B. Milligan[4], S. L. Ivey[4], and J. C. MacDonald[1], *[1]Texas AgriLife Research, Amarillo, [2]Texas AgriLife Research, Vernon, [3]Department of Clinical Studies, School of Veterinary Medicine, University of Pennsylvania, Kennett Square, [4]New Mexico State University, Las Cruces.*

A 6 × 6 Latin square with repeated measures design with dry rolled (DRC), steam flaked corn (SFC), and SFC with levels of wet distillers' grains plus solubles (WDGS) at 15%, 30%, 45% and 60%. Rumen samples collected at 0 and 4 h post feeding on d 21 of each period were strained into fluid and solid fractions (FRAC) and archived. Genomic DNA was extracted for amplification of V4 region of 16S rDNA gene and sequenced utilizing a Roche 454 FLX platform. Phylogenetic distribution of taxa, multivariate non-metric multidimensional scaling (NMDS) to compare community populations and Proc MIXED models were used to determine the influence of diet, time, FRAC and their interactions on rumen bacterial communities. Total sequences (1,747,630) were assigned to taxa. Different rumen bacterial communities developed in response to diet ($P < 0.05$) and FRAC within diet ($P < 0.01$) but not time ($P > 0.05$) and were readily differentiated utilizing NMDS at respective taxa level. The phyla *Firmicutes* dominated solid FRAC (up to 85%) while *Firmicutes* and *Proteobacteria* co-dominated (up to 95%) fluid FRAC. In contrast, *Bacteriodetes* constituted < 5% of all communities. Quantitative differences ($P < 0.05$) in *Firmicutes*, *Proteobacteria*, *Cyanobacteria*, and *Tenericutes* existed among diets. The family *Lachnospiracea* dominated the solid FRAC and decreased with WDGS inclusion. In contrast, *Rumincocacceae*, increased with all levels of WDGS. *Veillonellaceae*, exhibited a quadratic ($P < 0.05$) response by decreasing above 30% WSDGS. Genera *Eubacterium*, *Schwartzia*, and *Acidaminococcus* were dominant at ≥30% WDGS compared with DRC, SFC and 15% WDGS diets. *Paralactobacillus*, *Slackia*, and *Desulfovermiculus* were unique to WDGS diets and associate to specific functions. In summary, decreased animal performance observed with increasing WDGS inclusion in SFC diets supports our tenant that the rumen microbiome plays a key role in production efficiency of feedlot cattle.

Key Words: cattle, microbial ecology, rumen microbiology

544 Effect of sugarcane fiber digestibility and mode of conservation on intake and rumen pH of growing Nellore steers. D. O. Souza, B. S. Mesquita, J. Diniz-Magalhães, F. D. Rodriguez, B. S. Marques, and L. F. P. Silva,* *Universidade de São Paulo, Pirassununga, SP, Brazil.*

Sugarcane attains maturity and is available for daily harvest during the dry season; however, ensiling is an effective option for reducing labor costs. The objective of this study was to evaluate the effects of sugarcane stalk fiber digestibility (NDFD), and of mode of conservation on intake and rumen pH. Eight ruminally cannulated Nellore steers (275 ± 20 kg BW) were used in a replicated 4 × 4 Latin square design. Two sugarcane genotypes with differing NDFD were used: IAC2480 with higher NDFD (15% 30-h NDF digestibility), and IAC2094 with lower NDFD (6.5% 30h-NDF digestibility). Treatment diets contained 40% sugarcane, of total DM, as sole roughage source given as freshly chopped, or as silage, to evaluate the possible interaction between NDFD and mode of conservation on DM intake. Diets were formulated to provide daily gain of 1.2 kg/d. Animals were housed individually in a tie-stall with free access to water and fed ad libitum with 10% orts. Periods lasted for 14d, being 10d for adaptation, and 4d for sample collection. DM intake was determined on d 10, 11 and 12, and rumen pH on d 14 at 6 time points: 0, 1, 3, 6, 9 and 12h after the morning feeding. Main effects of sugarcane genotypes (CANE), of mode of conservation (CONS), and their interaction were tested by ANOVA. Feeding sugarcane with higher NDFD increased DM intake (5.7 vs. 5.1 ± 0.5 kg/d, $P < 0.01$), however the interaction CANE x CONS was significant ($P = 0.04$). The effect of greater NDFD on DM intake was only significant when feeding sugarcane as silage ($P < 0.01$), having no effect on DM intake when sugarcane was offered and freshly cut ($P = 0.53$). The mode of conservation did not affect DM intake ($P > 0.05$). Regarding rumen pH, there was no effect of CANE, nor there was a CANE × CONS interaction ($P > 0.30$). Feeding sugarcane as silage, as opposed to freshly cut, increased mean rumen pH (6.69 vs. 6.37 ± 0.08, $P < 0.01$). There was a clear reduction of pH during the day ($P < 0.01$), but there was no effect of TIME x CONS on rumen pH ($P = 0.23$). We conclude that sugarcane silage with higher NDFD increased DM intake, and feeding silage as opposed to freshly cut increased rumen pH.

Key Words: cattle, NDF digestibility, sugarcane silage

545 Impact of diet on the abundance and diversity of fecal *Escherichia coli* shed from cattle in overwintering environments.

K. Christiuk,* D. O. Krause, K. Ominski, T. De Kievit, and E. Khafipour, *University of Manitoba, Winnipeg, Manitoba, Canada.*

The objective of this study was to determine the effect of diet and overwintering strategy on *E. coli* populations in beef cattle during 2, 21-d periods. Sixty beef cows were assigned to 3, replicated feeding strategies, each with 10 cows. Four groups of cows were fed using a bale-grazing strategy while the other 4 groups of cows were fed in dry lot pens. During period 1, 2 pens in the bale graze system received grass hay supplemented with DDGS (dried distiller's grains with solubles; 2.5 kg/cow every third day) while the remaining 4 pens received grass hay only. During period 2, the DDGS supplemented cows remained on the same diet while the other 4 pens received 1 kg/cow/day of barley. Three cows in each pen were randomly selected and individual fecal samples were collected and cultured on selective media (Eosin Methylene Blue Agar). Colonies of *E. coli* were counted and 3 isolates were selected for DNA extraction. Isolates were subjected to PCR in search of 18 selected genes encoding for a range of virulence factors, including adhesins, aggregation factors, toxins, pathogenicity islands, autotransporters, and capsule synthesis. There were no significant differences in *E. coli* numbers between the treatments ($\alpha = 0.05$;P-value = 0.06) but the highest number of *E. coli* were isolated from bale grazed cows receiving barley (6.71 log cfu/g) and the lowest number were from bale grazed DDGS cows (5.78 log cfu/g). Comparison of the virulence genes present in the *E. coli* isolates resulted in a significant difference in *cnf* (cytotoxic necrotizing factor; induces prominent stress fiber formation and increase adherence to epithelia) between treatments ($\alpha = 0.05$;P-value < 0.001). Contrast analysis of the virulence data by diet resulted in significant differences in the presence of *aidA* (adhesion involved in diffuse adherence), *fliC* (flagellan structural gene), and *cnf*. The data suggests that diet may affect the abundance of *E. coli* shed in the feces and increase the presence of *E. coli* harbouring particular virulence genes that mediates adhesion of the bacterium to the epithelial surfaces.

Key Words: *Escherichia coli*, dried distillers grains with solubles, virulence genes

546 Comparison of different supplemental cobalt forms on fiber digestion and cobalamin levels.

W. L. Kelly*[1], C. K. Larson[2], M. K. Petersen[1], and R. C. Waterman[1], [1]*USDA-ARS, Fort Keogh Livestock and Range Research Laboratory, Miles City, MT,* [2]*Zinpro Corporation, Eden Prairie, MN.*

Cobalt (Co) is essential for rumen microbial metabolism to synthesize methane, acetate and methionine. It also serves as a structural component of vitamin B_{12}, which functions as a coenzyme in energy metabolism. A study was conducted to determine if Co form (cobalt carbonate vs. cobalt glucoheptonate) supplemented above NRC requirements would improve fermentability of a low quality forage diet and change serum cobalamin concentrations. Twenty ruminally-cannulated cows (577 ± 13 kg) were individually fed in a completely randomized experimental design. Cows were fed a grass hay diet (7.9% CP, 56% TDN, 63% NDF, 87% DM) at 2.25% of BW for a 62 d study, which consisted of 3 periods: acclimation (AC), treatment (TR), and residual (RE). Cows were stratified by age (5 ± 0.37 yr) and lactational history, and assigned to receive 12.5 mg supplemental Co in 1 of 2 forms: (1) 27.2 mg of cobalt carbonate (CC, n =11 cows) or (2) 50 mg of cobalt glucoheptonate (CGH, n = 9 cows). Supplementation was administered daily via a gelatin capsule placed directly into the rumen 2 h after daily feeding. During the last 96 h of each period, forage fermentability was measured using an in situ nylon bag technique. Serum samples were collected 4 and 6 h following feeding, 24 h before the end of each period. Measurements taken in the AC period were used as covariates for analysis in the TR and RE periods. A treatment × period interaction ($P = 0.03$) was exhibited for in situ OM fermentability at 96 h; (TR period, 68.44 and 70.83 ± 0.81%, and RE period, 67.61 and 66.82 ± 0.75%, for CC and CGH; respectively). Once inclusion of Co in the CGH group was removed, fermentability was reduced by 4.01% compared with 0.82% in the CC cows. The NDF disappearance (OM basis) was lower for the TR period compared to the RE period at 48 h ($P < 0.001$; 62.95 and 65.18 ± 0.39%; respectively). However, by 96 h the NDF disappearance was higher for TR period than the RE period ($P = 0.02$; 70.44 and 68.89 ± 0.44%; respectively). No differences were detected for cobalamin serum levels or rate of fiber fermentation. The outcomes of this research signify that while there are no residual effects of Co supplementation on fermentation, there is an indication that Co glucoheptonate supplementation does enhance the overall extent of fermentation. The extent of fiber disappearance is also improved with Co supplementation regardless of form.

Key Words: beef cattle, cobalt, vitamin B12

547 Comparison of animal and dietary effects on ruminal methanogens and their association with protozoa in beef cattle.

M. Zhou*[1], M. Hünerberg[1], K. A. Beauchemin[2], T. A. McAllister[2], E. K. Okine[1], and L. L. Guan[1], [1]*Department of Agricultural, Food and Nutritional Science, University of Alberta, Edmonton, Alberta, Canada,* [2]*Agriculture and Agri-Food Canada Lethbridge Research Centre, Lethbridge, Alberta, Canada.*

This study investigated the effects of animal (host) and diet on the variation in ruminal methanogenic communities of 4 beef heifers sequentially adapted to corn- (CDDGS), wheat-based (WDDGS) dried distillers grain with solubles (DDGS), and WDDGS plus pure corn oil. The methanogenic diversity was examined using PCR-denaturing gradient gel electrophoresis (PCR-DGGE) and methanogen abundance was measured quantitative real-time PCR (qRT-PCR). The methanogen DGGE profiles were analyzed using BioNumerics software and Global R statistics. Methanogen abundance was compared host-wise and diet-wise using Analysis of Variation (ANOVA) and the correlation between methanogens and protozoa was analyzed using PROC CORR within SAS. Observed DGGE patterns of methanogens were similar among the 4 diets but distinctive within each individual animal (Global R = 0.87, $P < 0.01$). Methanogenic phylotypes displayed unique responses to the different sources of DDGS, and the ecological shifts were host-specific. Populations of methanogens and protozoa varied among animals and diets, while densities of *Methanobrevibacter* sp. AbM4 and *Methanosphaera stadtmanae* only differed among animals. The diversity and abundance of methanogenic community adapted to different diets uniquely within individuals. In addition, *Mbb.* sp. AbM4 and total number of protozoa ($P < 0.01$) were positively correlated within animal. In conclusion, the response of ruminal methanogenic community to different diets was host dependent, suggesting that the host biology should not be ignored if dietary strategies are used to manipulate ruminal methanogens.

Key Words: diet effect, host effect, methanogenic ecology

549 Assessing how RFI classification in the growing phase predicts RFI classification in the finishing phase. D. Johns,* G. Vander Voort, C. Campbell, M. Quinton, and I. Mandell, *Department of Animal and Poultry Science, University of Guelph, Guelph, ON, Canada.*

Residual feed intake (RFI) is being used to replace feed efficiency due to its accuracy in determining production efficiency. The objective of this study was to examine whether assessment of production efficiency via RFI in the growing phase (GP) accurately predicts production efficiency in the finishing phase (FP). RFI was calculated at the end of an 84 d GP for 204 crossbred steers. Steers were then allocated to one of 5 finishing management regimens (based on an 87% concentrate diet) designed to produce a wide range in growth performance (average daily gain (ADG), feed:gain (F:G), RFI) and carcass traits. Management regimens included a nonimplanted control (CON), Synovex implant (SYN), Revalor implant (REV), REV plus the β agonist (βA), Optaflexx (OPT), and REV plus the βA, Zilmax (ZIL). The allocation evenly distributed Low (RFI^-) and High (RFI^+) cattle from the GP across all finishing management regimens. Post-slaughter, RFI was calculated for the FP and the overall trial to examine how GP RFI classification predicted performance in the FP. FP ADG ranged from 1.60 (CON) to 2.23 (REV/ZIL) kg/d; F:G ranged from 7.17 (CON) to 5.61 (REV/ZIL). Over the entire trial ADG ranged from 1.72 (CON) to 1.94 (REV/ZIL) kg/d; F:G ranged from 6.37 (CON) to 5.68 (REV/ZIL). RFI ranged from −0.61 to 1.60 in the GP, −2.20 to 2.49 in the FP and −3.15 to 3.61 for the trial overall. The lowest overall and FP RFI was found in ZIL (−0.14 and −0.25 respectively), indicating the most efficient conversion of feed to gain. Overall RFI was improved in all management regimens using REV, with increased efficiency vs. GP RFI. There was limited improvement in efficiency for CON and SYN cattle between GP and FP RFI. For 14.4% of steers, RFI ranking changed from RFI^+ rank in the GP to RFI^- in the FP, becoming more efficient; 19.4% of steers became less efficient while 66.3% kept the same RFI ranking. RFI classification in the GP did not accurately predict RFI classification in the FP for all cattle. More work is needed to examine when RFI should be determined for predicting finishing performance.

Key Words: beef cattle, RFI, growth performance

Ruminant Nutrition: Dairy: Feed Additives

550 Effects of trace mineral source on oxidative metabolism, subclinical endometritis, and performance of transition dairy cows. T. Yasui*[1], C. M. Ryan[1], R. O. Gilbert[1], K. Perryman[2], and T. R. Overton[1], [1]*Cornell University, Ithaca, NY,* [2]*Micronutrients Inc., Indianapolis, IN.*

Multiparous Holstein cows (n = 60) were used to determine effects of trace mineral source on oxidative metabolism, subclinical endometritis, and performance of transition cows. After a 1-wk preliminary period, cows were assigned randomly to one of 3 topdress treatments from 21 d before expected calving through 84 d post calving: 1) Inorganic sources based upon sulfates of Zn, Cu, and Mn (ITM); 2) a blend (75:25) of sulfates and chelated sources of Zn, Cu, and Mn (ITM/OTM); and 3) Hydroxy Trace Minerals (HTM) of Zn, Cu, and Mn (IntelliBond; Micronutrients, Inc., Indianapolis, IN). Final concentrations of Zn, Cu, and Mn were similar among treatments and averaged 40, 10, and 27 ppm before calving and 59, 15, and 40 ppm after calving. An interaction of treatment and week existed ($P = 0.02$) for milk yield such that cows fed HTM increased milk yield faster than cows fed the other 2 treatments; a similar interaction was also present for yields of fat-corrected milk ($P = 0.03$) and lactose ($P = 0.05$). Cows fed HTM during the prepartum period tended ($P = 0.08$) to have higher body weight and had higher body weight during the postpartum period ($P = 0.04$) than those fed the other 2 treatments. Plasma antioxidant capacity was lower in cows fed HTM than ITM during both prepartum (1.84 vs. 2.09 mM; $P = 0.03$) and postpartum (1.95 vs. 2.16 mM; $P = 0.04$) periods; cows fed ITM/OTM had intermediate values. Cows fed HTM tended to have lower concentrations of plasma thiobarbituric acid reactive substances than those fed ITM during whole study period (1.95 vs. 2.11 µM; $P = 0.07$). Endometrial cytology as characterized by low volume uterine lavage at 7 d postcalving and on one day between 40 and 60 d post calving was not affected by treatment. In conclusion, supplementation with HTM sources of Zn, Cu, and Mn resulted in evidence of improved productive performance during early lactation along with modulation of plasma variables related to oxidative metabolism.

Key Words: trace minerals, oxidative status, subclinical endometritis

551 Effects of essential oils on methane production, fermentation, abundance and diversity of rumen microbial populations. A. Patra[1,2] and Z. Yu*[1], [1]*The Ohio State University, Columbus,* [2]*West Bengal University of Animal and Fishery Sciences, Kolkata, India.*

Five essential oils (EO), namely, clove oil (CLO), eucalyptus oil (EUO), garlic oil (GAO), origanum oil (ORO) and peppermint oil (PEO) were tested in vitro using 3 replicates at 3 different doses (0.25, 0.50 and 1.0 g/L) for their effect on methane production, fermentation, and select groups of ruminal microbes, including total bacteria, cellulolytic bacteria, archaea and protozoa. All the data were analyzed using the mixed model procedure of SAS. All the EO significantly ($P < 0.01$) reduced methane production with increasing doses, with a reduction by 34.4%, 17.6%, 42.3%, 87% and 25.7% for CLO, EUO, GAO, ORO and PEO, respectively, at 1.0 g/L compared with the control. However, apparent degradability of dry matter (DM) and neutral detergent fiber (NDF) also decreased linearly ($P < 0.01$) with increasing doses by all EO except GAO. The concentration of total volatile fatty acids (VFA) was not affected ($P > 0.05$) by GAO, EUO or PEO, but altered linearly and quadratically ($P < 0.01$) by CLO and ORO. All the EO also differed in altering the molar proportion of acetate, propionate, and butyrate. As determined by qPCR, all the EO decreased the abundance of archaea, protozoa, *Fibrobacter succinogenes*), *Ruminococcus flavefaciens* and *Ruminococcus albus*) linearly ($P < 0.01$) with increasing EO doses. Based on DGGE analysis, different EO changed the composition of both archaeal and bacterial communities to different extents. The Shannon-Wiener diversity index (*H'*) was decreased for archaea by all EO in a dose-dependent manner, but increased for bacteria at low and medium doses (0.25 and 0.50 g/L) for all EO except ORO. Due to the adverse effects on feed digestion and fermentation, a single EO may not effectively mitigate methane emission from ruminants unless used in combinations.

Key Words: essential oils, methane, microbes

552 Effect of dietary fat and Rumensin on ruminal bacteriome revisited using metagenomic analysis. M. Kim[1], M. Morrison[2,1], M. Eastridge[1], and Z. Yu*[1], [1]*The Ohio State University, Columbus,* [2]*CSIRO Livestock Industries, St Lucia, QLD, Australia.*

Monensin and dietary fats have been used to improve feed efficiency and to reduce methane production. However, the effect of these dietary manipulations on ruminal bacterial community (bacteriome) has not been examined in detail. The objective of this study was to examine and compare the effects of dietary addition of monensin alone (as Rumensin, 12 g/ton TMR) or monensin plus fat (4% supplemental) on ruminal bacteriome in lactating dairy cattle. Ruminal bacteriomes in the liquid and adherent fractions were analyzed using 454 pyrosequencing analysis. In total, 56,160 non-chimeric 16S rRNA gene (rrs) sequences were obtained. Most of the sequences were assigned to phyla *Firmicutes* and *Bacteroidetes*, irrespective of fractions. *Firmicutes* was more abundant in the adherent fraction than in the liquid fraction, while *Bacteroidetes* was less abundant in the adherent fraction than in the liquid fraction. Gram-positive *Firmicutes* was not affected by monensin. Two minor phyla, TM7 and SR1, were highly sensitive to monensin. In total, 13,041 species-level OTUs were identified from the 56,160 sequences across all the fractions. However, only 65 of them were represented by more than 30 sequences. Only 5 *Firmicutes* OTUs among the predominant OTUs were sensitive to monensin. On the other hand, 12 *Firmicutes* OTUs, most assigned to the family *Ruminococcaceae*, were stimulated by the combination of monensin and fat. These OTUs may be involved in lipolysis or biohydrogenation. These results suggest that some gram-positive rumen bacteria are not inhibited by monensin and that the interaction between monensin and fat can have an effect on rumen bacteriome.

Key Words: fat, monensin, rumen bacteriome

553 Effect of dietary potassium on water intake and rumen dynamics. S. E. Fraley*[1], M. B. Hall[2], and T. D. Nennich[1], [1]*Purdue University, West Lafayette, IN,* [2]*USDA-ARS, Madison, WI.*

Water is a critical nutrient for dairy cows, though little work has looked at the effects of water intake on rumen parameters. The objective of this study was to evaluate the effect of water intake on rumen parameters and determine effects of increased dietary K on water intake in dairy cows. Potassium carbonate was added to the diets of 9 ruminally cannulated, late lactation Holstein cows (207 ± 12 DIM) that were randomly assigned to 1 of 3 treatments in a replicated 3 × 3 Latin square design with 18-d periods. Dietary treatments (on a DM basis) were baseline dietary K levels of 0.94% dietary K (Control), 0.75% added dietary K (LowK), and 1.5% added dietary K (HighK). Cows were fed treatment diets for a 14-d adaption period followed by a 4-d collection period. Total rumen evacuations were conducted on d 4 of the collection period. Weights of rumen contents were recorded and subsamples were dried. Rumen fluid samples were collected to determine volatile fatty acids (VFA) and NH_3 concentrations. Milk samples were collected twice daily during the collection period. Data were analyzed using PROC MIXED of SAS with linear and quadratic contrasts. Milk, milk fat and protein yields showed quadratic responses ($P = 0.001$, 0.01 and 0.001, respectively) with greatest yields for LowK. Dry matter intake had a quadratic response ($P < 0.001$) with 21.8 kg/d for LowK and 20.4 and 20.5 kg/d for Control and HighK, respectively. Water intake showed a linear relationship with HighK being the greatest (102.4, 118.4 and 129.3 L/d, $P = 0.001$). Total and wet weight of rumen contents declined linearly ($P = 0.01$ and 0.01, respectively) and dry weight tended ($P = 0.09$) to decline linearly for LowK and HighK. There was a negative linear relationship for rumen NH_3 concentrations for LowK and HighK ($P = 0.004$). Concentrations of acetate as a percentage of total VFA linearly increased for LowK and HighK ($P = 0.002$), while concentrations of propionate declined ($P = 0.003$) as percentage of total VFA. Increasing dietary K in the diets of lactating dairy cows increased water consumption and rumen ammonia concentrations, while decreasing total water weight in the rumen.

Key Words: dairy cow, potassium, water intake

554 Effects of rumensin in lactating dairy cow diets with differing starch levels.

M. S. Akins*[1], K. L. Perfield[2], H. B. Green[2], and R. D. Shaver[1], [1]*Department of Dairy Science, University of Wisconsin-Madison, Madison,* [2]*Elanco Animal Health, Greenfield, IN.*

The objective of this study was to determine the effects of Rumensin on lactation performance in either reduced (RS) or normal (NS) starch diets. One hundred and 28 Holstein and Holstein × Jersey cows (90 ± 33 DIM) were stratified by breed and parity and randomized to 1 of 16 pens, each with 8 cows. Pens were then randomly assigned to 1 of 4 treatments in a 2 × 2 factorial arrangement of treatments. The RS and NS diets contained 20.4 and 26.9% starch (DM basis), respectively. A 4 wk covariate adjustment period preceded the treatment period with all pens receiving the NS diet with 18 g/ton Rumensin (NSR). Following the 4 wk covariate adjustment period, study animals were fed their assigned treatment diets of either NSR, NS with 0 g/ton Rumensin (NSC), RS with 18 g/ton Rumensin (RSR), or RS with 0 g/ton Rumensin (RSC) for 12 wk. Mean DMI (27.0 kg/d) was not affected by Rumensin, starch or their interaction. Inclusion of Rumensin, as well as feeding the NS diet, increased ($P = 0.01$) milk yield by 1.3 and 1.5 kg/d per cow, respectively. Feeding the NS diet compared with the RS diet increased ($P < 0.02$) milk protein percent and yield and lactose and SNF yields while decreasing ($P < 0.01$) MUN. Rumensin increased ($P < 0.05$) all measures of milk production efficiency (MPE; milk yield/DMI) as well as lactose yield and tended ($P = 0.06$) to increase SNF yield and MUN. Rumensin decreased ($P = 0.02$) milk protein percent, but did not affect protein yield, milk fat percent or yield, and lactose or SNF percentages. There was a tendency ($P = 0.08$) for a starch by Rumensin interaction for MPE such that Rumensin inclusion tended to increase MPE more for NS versus RS diets. Feeding RS diets reduced milk and protein yields, but had similar component-corrected milk yields and efficiencies when compared with NS diets. Rumensin improved MPE and lactation performance when added to both RS and NS diets.

Key Words: lactating cow, rumensin, starch

555 Feeding blood meal or two rumen-protected lysine sources in early lactation dairy cows and the effect of withdrawal on production parameters.

J. E. Nocek*[1] and I. Shinzato[2], [1]*Spruce Haven Farm and Research Center, Auburn, NY,* [2]*Ajinomoto Heartland Inc., Chicago, IL.*

Seventy-two multiparous cows were used to examine the effects of feeding rumen-protected lysine (RPL) sources or blood meal from wk 4 through 7 postpartum and then withdrawing them. All cows entered the individual tie stalls on d 14 ± 3 postpartum and received the Control diet through d 21 ± 3. Cows were balanced across treatments based on wk 3 postpartum milk production. In addition the information obtained during wk 3 was used as a covariate in the statistical analysis. Cows were assigned to one of 4 subsequent treatments: C: Control, BM: C with blood meal, AP: C with AjiPro-L (Ajinomoto Co., Inc.), and AS: C with AminoShure-L (Balchem Corporation). Manufacturer suggested bioavailabilities were used for RPL sources. Metabolizable Lys supply calculated by CPM Dairy was 153.1, 166.1, 166.8, and 166.8 g/d, for C, BM, AP, and AS, respectively. Cows remained on their treatment for 4 weeks (4–7 wk postpartum, phase 1). From wk 8 through 11 postpartum (Withdrawal, phase 2) all cows again received the Control ration. Individual dry matter intake (DMI) and milk yield was measured daily, and milk components were measured weekly. Body weights and BCS were recorded on d 21, 49 and 77 postpartum. During phase 1, AP showed higher ($P < 0.01$) milk yield compared with C, BM and AS. FCM was increased ($P < 0.01$) in AP compared with C and AS. Milk/DMI efficiency was higher for AP than AS. Milk fat yield was higher ($P < 0.01$) for AP than AS or C, whereas protein yield was highest ($P < 0.01$) for AP compared with other treatments. Milk fat percentage was highest ($P < 0.01$) for BM compared with C, with AP and AS being intermediate. Milk protein percentage was not affected by lysine supplementation. During phase 2, ECM yield was higher ($P < 0.01$) for AP compared with C, BM and AS. However, cows in AP treatment demonstrated the most dramatic drop in milk post withdrawal (1 kg from wk 5–6 on trial) compared with BM or AS. There was no effect of treatment on body weights or BCS. These results demonstrate that not all RPL sources perform in a similar fashion in early lactation cows.

Key Words: rumen-protected lysine, milk production, early lactation

556 Evaluation of dietary betaine (BET) in heat-stressed Holstein cows in lactation.

L. W. Hall*[1], F. R. Dunshea[2], J. D. Allen[1], A. Wood[1], S. D. Anderson[1], S. Rungruang[1], J. L. Collier[1], N. M. Long[1], and R.J. Collier[1], [1]*The University of Arizona, Tucson,* [2]*The University of Melbourne, Parkville, Vic, Australia.*

Betaine, a natural, organic osmolyte may reduce cellular work and improve efficiency and act as a chaperone, refolding denatured proteins. To test if dietary BET reduced the effect of heat stress, multiparous, lactating Holstein cows (n = 23) were blocked (n = 101.4 ± 8.6 DIM) and randomly assigned to one of 3 diets of BET; control (CON) group no BET, mid dose (MID) cows (57 mg of BET / kg BW), and high dose (HIGH) was (114 mg of BET / kg BW). Cows were fed twice daily and treatments were top-dressed at each feeding. Cows were milked 2 times/ d and milk samples and were taken daily for analysis. Milk components, yield, feed intake, and water intake records were taken daily. Temperature and respiration rates were taken 3 times/ d at 0600, 1400, and 1800. Cows were housed in environmentally controlled rooms and following acclimation for 7 d the cows were subjected to cyclic thermal neutral (TN mean THI of 56.6) for 7 d and heat stress, represented by the Thermal Humidity Index (THI) (HS mean THI of 71.5) for 10 d. Temperature data loggers were inserted vaginally to read the last day of TN and the first 2 d of HS to follow body temperature changes. Dietary BET increased milk yield and protein % during the TN period ($P < 0.01$). There were no differences between treatments in total milk production or % protein during HS. Feed and water intake decreased during HS with betaine treated (CON vs. MID, and CON vs. HIGH) cows ($P < 0.01$) with no difference in TN. The Con diets had higher pm HS respiration rates than both MID and HIGH treatments ($P = 0.04$, $P = 0.001$), but lower HS body temperature compared with BET treatments ($P < 0.05$). Vaginal temperatures were higher in BET treated cows and were highest in MID. We conclude that BET increased milk and protein production in TN conditions and was associated with reduced feed and water intake and slightly increased body temperatures during HS at the doses tested.

Key Words: betaine, dairy cow lactation, heat stress

557 Effect of dietary phytate on phosphorus digestibility in dairy cows.

P. P. Ray* and K. F. Knowlton, *Virginia Polytechnic Institute and State University, Blacksburg.*

The objective was to evaluate the effect of dietary phytate P (Pp) supply on ruminal and post-ruminal Pp digestion and net disappearance of P from lower digestive tract of lactating cows. Six ruminally and ileally cannulated crossbred lactating cows were used in 2 incomplete Latin squares with 4 21-d periods (17 d of diet adaptation, 4 d of total collection). Dietary treatments were low Pp, medium Pp, and high Pp, and a high inorganic P (Pi) diet with the same total P content as the highest phytate diet but with P mostly from inorganic sources. The diets contained 0.10, 0.18, 0.29 and 0.11% Pp and 0.43, 0.48, 0.54 and 0.52% total P on dry matter (DM) basis, with cottonseed meal used to increase Pp content. Ytterbium-labeled corn silage and Co-EDTA were used as particulate and liquid phase markers to measure omasal and ileal digesta flow. Omasal and ileal digesta were collected every 6 h on d 20 and 21 and rumen contents were collected on d 21. Samples were analyzed for total P (molybdovanadate yellow method), Pi (blue method), and Pp (high performance ion chromatography). Data were analyzed using PROC GLIMMIX in SAS. Polynomial contrasts were used to test the effect of increasing dietary Pp on intake, small and large intestinal disappearance, and fecal excretion, and to compare these measures in the high Pp and high Pi diets. Phytate P intake increased ($P < 0.05$) with increasing dietary Pp but dietary Pp did not influence ruminal Pp digestibility. Small intestinal total P disappearance decreased ($P < 0.05$) with increasing dietary Pp, but large intestinal disappearance of total P, Pi, and Pp were not affected by dietary Pp. Fecal DM increased linearly ($P = 0.002$) with increasing dietary Pp, as did fecal P excretion ($P < 0.05$). Dry matter digestibility was higher for high Pi than for high Pp ($P < 0.05$; 68.9 vs. 64.5%) but fecal DM was not affected by form of P. Fecal P excretion decreased ($P < 0.05$) when a portion of Pp was replaced with Pi (high Pi vs. high Pp) despite equal total P intake. In lactating cows phytate digestibility was not affected by phytate content but fecal P increased when P was from phytate rather than from inorganic sources.

Key Words: phytate, digestibility, dairy cow

558 Application of rumen-protected lysine to lower crude protein diets for lactating dairy cows.

J. P. Pretz*[1], M. J. de Veth[2], R. S. Ordway[2], and M. J. Brouk[1], [1]*Kansas State University, Manhattan,* [2]*Balchem Corp., New Hampton, NY.*

The study objective was to evaluate the application of supplemental rumen-protected Lys (RP-Lys) to maintain milk production when reducing crude protein levels in diets of lactating dairy cows. Twelve lactating multiparous Holstein cows, averaging 129 DIM, 50.2 kg milk yield, 3.6% fat and 2.9% true protein were randomly assigned to one of 4 3x3 Latin squares. Each 14-d period had 11-d for adaptation followed by 3-d of data collection. Cows were offered one of 3 experimental treatment rations formulated with CPM Dairy (v3.0); Positive control (PC) — formulated to meet all nutrient requirements; Test diet (Test) — negative control diet formulated to meet nutrient requirements, except deficient in MP (approximately 200 g/d) and first limiting in Lys (approximately 10 g/d); and Test+RPL — same basal diet as negative control + RP-Lys to provide 14.5 g/d of MP-Lys. For Test+RPL, 45g of RP-Lys (AminoShure-L; containing 23.4g Lys) was top-dressed on the TMR once daily. The PC diet resulted in lower intake ($P = 0.03$) as compared with either the Test or Test+RPL diet. PC, Test, and Test+RPL cows averaged 42.6, 42.9, 43.6 kg/d of milk and 27.3, 28.4, 28.8 kg/d of DMI, respectively. Crude protein intake for the PC, Test, and Test+RPL diets were 4.83, 4.67, and 4.74 kg/d respectively. MUN decreased ($P < 0.01$) for cows on Test and Test+RPL diets as compared with PC diet (12.5, 12.5 and 14.9 mg/dL, respectively). Milk yield, milk components, milk component yields, FCM, ECM, SCM and production efficiencies (milk, ECM, SCM and FCM) did not differ ($P > 0.05$) among treatments. A post-study CPM evaluation using final chemical composition analyses of the feedstuffs and average production data from the animals predicted that diets supported more than 47 kg of milk and Lys was not limiting. Cows on the study produced slightly less milk; however, DMI was 5–8% more than predicted by initial formulations. Formulation accuracy of the MP and Lys deficient diet may have been improved if data had been available from an initial adjustment period measuring DMI, body weight, milk yield and milk composition.

Key Words: amino acids, dairy cattle, rumen-protected lysine

559 A meta-analysis of the effects of feeding yeast culture produced by anaerobic fermentation of *Saccharomyces cerevisiae*, on milk production of lactating dairy cows.

G. D. Poppy*[1,2], A. R. Rabiee[3], I. J. Lean[3], W. K. Sanchez[2], K. L. Dorton[2], and P. S. Morley[1], [1]*Colorado State University, Fort Collins,* [2]*Diamond V, Cedar Rapids, IA,* [3]*SBScibus, Camden, NSW, Australia.*

The purpose of this study was to estimate the average impact of a commercially available yeast culture product on milk production and other production measures in lactating dairy cows through the use of a meta-analysis of random controlled trials. A total of 61 research publications (published journal articles, published abstracts, and technical reports) were identified through a review of literature provided by the manufacturer and search of published literature using 6 computer search engines. Thirty-six separate studies with a total of 67 comparisons met the criteria for inclusion in the meta-analysis. The fixed effect meta-analysis showed substantial heterogeneity for milk yield, ECM, 3.5% FCM, butterfat yield, protein yield and DMI. Sub-group analysis of the data set showed much less heterogeneity in peer reviewed studies versus, non-peer-reviewed abstracts and technical reports, and tended to show higher treatment effects. A random-effects meta-analysis showed an estimated weighted mean difference between treated and untreated cattle reported in peer-reviewed publications to be 1.18 kg/d (95% CI, 0.55 to 1.81), 1.61 kg/d (95% CI, 0.92 to 2.29), and 1.65 kg/d (95% CI, 0.97 to 2.34) for milk yield, 3.5% FCM and ECM respectively. Butterfat yield and protein yield for peer-reviewed studies increased 0.06 kg/d (95% CI, 0.01 to 0.10) and 0.03 kg/d (95% CI, 0.00 to 0.05). Dry matter intake was analyzed by the sub-groups early lactation (<70 DIM) and not-early lactation. The studies reported in peer-reviewed journals showed an increase in DMI between the treated and untreated cattle of 0.62 kg/d (95% CI, 0.21 to 1.02) for early lactation and a decrease DMI of 0.78 kg/d (95% CI, −1.36 to −0.21) for later lactation studies. These findings provide strong evidence that this commercially available yeast culture product provides significant improvement in several important milk production parameters as evaluated in production settings typical for commercial dairies in North America.

Key Words: yeast culture, meta-analysis, lactating

560 Impact of feeding yeast culture under normal and SARA conditions in lactating dairy cows. S. Li*[1], E. Tesfaye[1], H. Khazanehei[1], M. Scott[2], I. Yoon[2], E. Khafipour[1], and J. C. Plaizier[1], *[1]University of Manitoba, Winnipeg, MB, Canada, [2]Diamond V, Cedar Rapids, IA.*

Eight rumen- and cecum-fistulated cows (42–90 DIM, 605 ± 60 kg BW) were used in a crossover design to examine the effects of a *Saccharomyces cerevisiae* fermentation product (SCFP) on production performance and rumen and hindgut fermentation during normal and sub-acute ruminal acidosis (SARA) conditions in lactating dairy cows. Each experimental period consisted of 4 wk of normal feeding followed by 1 wk of SARA challenge. During normal feeding, cows received a diet containing 42% concentrate, 28% corn silage and 30% alfalfa baleage (DM basis). A grain-based SARA challenge was conducted by replacing 22% corn silage in the diet with the same amount of pellets that contained 50% ground wheat and 50% ground barley. Treatment cows were supplemented with 14 g/d of SCFP (Original XPC, Diamond V) mixed with 140 g/d ground corn, and control cows received ground corn only. During wk 4 and 5 of each period, DMI and milk production were determined daily and milk samples were collected from 4 subsequent milkings; rumen pH was monitored continuously by indwelling rumen pH data loggers; rumen fluid, cecal digesta, feces, urine and blood samples were collected on Tuesdays and Thursdays. SARA challenge increased ($P < 0.01$) time that rumen pH stayed below 5.6 (11.1 vs. 311.1 min/d), decreased ($P < 0.01$) average rumen pH (6.33 vs. 5.94), DMI (21.9 vs. 20.1 kg/d) and 4% FCM (29.6 vs. 26.2 kg/d). SCFP did not affect measures of ruminal pH, DMI or FCM. An interaction between SCFP and SARA challenge was observed ($P < 0.09$) for milk fat concentration; 3.25, 2.71, 3.24, and 2.92% for Normal-Control, SARA-Control, Normal-SCFP and SARA-SCFP, respectively. The SARA challenge increased ($P < 0.05$) free LPS in rumen fluid (18,858 vs. 101,158 EU/mL), in feces (15,367 vs. 29,978 EU/mL), and tended to increase ($P = 0.08$) LPS in the cecum (18,235 vs. 30,549 EU/mL). SCFP tended to decrease ($P = 0.13$) ruminal LPS (54,438 vs. 35,043 EU/mL). The LPS-binding protein concentration in blood plasma was increased, (9.9 vs. 38.0 μg/mL, $P < 0.01$) by the SARA challenge, but was not affected by the SCFP. Results indicate that SCFP can alleviate milk fat depression and may reduce the production of ruminal LPS during grain-induced SARA.

Key Words: cow, SARA, yeast culture

561 Effects of chromium propionate supplementation during the periparturient period and early lactation on metabolism, performance, and subclinical endometritis in dairy cows. T. Yasui*[1], J. A. A. McArt[1], C. M. Ryan[1], R. O. Gilbert[1], D. V. Nydam[1], F. Valdez[2], and T. R. Overton[1], *[1]Cornell University, Ithaca, NY, [2]Kemin Industries, Des Moines, IA.*

Multiparous Holstein cows (n = 61) were used to determine effects of chromium propionate supplementation during the periparturient period and early lactation on metabolism, performance, and subclinical endometritis. After a 1-wk preliminary period, cows were assigned randomly to one of 2 treatments from 21 d before expected calving through 63 d post calving: 1) control (n = 31) and 2) chromium propionate (n = 30; Cr-Pro, KemTRACE Chromium Propionate, Kemin Industries, Des Moines, IA) administered by daily topdress at a rate of 8 mg/d of chromium. Evaluation of endometrial cytology by low volume lavage was determined on all cows at 7 d postcalving (1st lavage) and on one day between 40 and 60 d (2nd lavage) post calving. There was a tendency for increased DMI during the prepartum period in cows fed Cr-Pro (16.5 vs. 15.8 kg/d; $P = 0.07$). Cows fed Cr-Pro tended to have lower plasma NEFA during the prepartum period (184 vs. 211 μEq/l; $P = 0.08$). Effects of Cr-Pro supplementation on postpartum DMI and milk yield were not significant; however, cows fed Cr-Pro had higher somatic cell counts (275 vs. 160 × 1000/ml; $P = 0.04$) and tended to have higher urea nitrogen concentrations in milk (11.2 vs. 10.6 mg/d; $P = 0.08$) than controls. An interaction ($P = 0.05$) of treatment and day existed during the postpartum period such that cows fed Cr-Pro had lower plasma glucose concentrations immediately postpartum than controls. Cows fed Cr-Pro had lower incidence of subclinical endometritis for between 40 and 60 d using a cut-point of 10% neutrophils (30% vs. 57% of cows; $P = 0.04$). In conclusion, supplementation with chromium propionate resulted in trends for increased DMI and lower NEFA prepartum. Postpartum milk yield and DMI were not affected by treatment; however, Cr-Pro supplementation decreased the incidence of subclinical endometritis between d 40 and 60 postcalving, suggesting the potential for effects on subsequent reproductive performance.

Key Words: chromium, subclinical endometritis, transition cow

Ruminant Nutrition II

562 Study of effects of conjugated linoleic acid (CLA) on milk production and composition, and milk fatty acid profile of Holstein dairy cows. A. Mahdavi,* K. Rezayazdi, A. Z. Shahneh, and M. Dehghan-Banadaky, *Department of Animal Science, College of Agriculture and Natural Resources, University of Tehran, Karaj, Tehran, Iran.*

The aim of this experiment was to determine the effects of conjugated linoleic acid (CLA) on milk production and composition, and milk fatty acid profile of dairy Holstein cows. Three lactating Holstein cows (203 ± 9 DIM; mean ± SD) fitted with rumen fistula were used in a 3 × 3 Latin square experiment with 21-d periods, including a 14-d adaptation period followed by a 7-d sampling period. Treatments were: 1) control (115 g/d calcium salts of palm fatty acids), 2) rumen protected CLA (120 g/d of lipid-encapsulated CLA), and 3) unprotected CLA (40 g/d unprotected CLA that replacing and balancing by Ca salts of palm fatty acids). Each dose provided 96 g/d fatty acids. Both of CLA supplements provided 12 g/d of trans-10, cis-12 CLA. Supplements were administered intraruminally once per day immediately before morning feeding. Individual milk yield and dry matter intake were recorded daily and milk composition was determined every day. Data were analyzed by MIXED procedure of SAS. Dry matter intake and milk yield were not affected by CLA supplements. The CLA supplements reduced milk fat content compared with control ($P < 0.01$), which were 2.58, 3.51, and 3.77 for rumen protected CLA, rumen unprotected CLA and control, respectively. In contrast, there were no significant differences in content of Milk protein and lactose between treatments. The milk fatty acid profile was significantly affected by rumen protected CLA. The proportion of short- and medium-chain fatty acids decreased in rumen protected CLA compared with control whereas the proportion of long-chain fatty acids increased in rumen protected CLA. The milk fat content of trans-10, cis-12 CLA was increased by CLA supplements compared with control ($P < 0.01$) especially by rumen protected CLA. The Δ^9-desaturase index was not affected by CLA supplements. The results of this experiment indicated that rumen protected CLA could decrease milk fat content and yield, and alter milk fatty acid profile, but has no effect on dry matter intake and milk yield during late lactation in Holstein dairy cows.

Key Words: conjugated linoleic acid, Holstein cow, milk fat

563 Measurement and regression models of methane emissions from sheep. Y.-G. Zhao, C.-G. Jiang, J. Liu, Y. Tu, K.-D. Deng, X.-H. Gao, and Q.-Y. Diao,* *Feed Research Institute of Chinese Academy of Agricultural Sciences, Beijing, China.*

This trial was designed to study the effects of dietary composition, nutrients intake, digestible nutrients, ruminal fermentable nutrients and volatile fatty acid (VFA) on rumen methane(CH_4) emissions from sheep and develop regression models. Eight rumen-fistulated adult crossbreed rams [Dorper (male) × Small Tail Han sheep (female)] with the body weight of (50.37 ± 1.13) kg, were used in an 8 × 4 incomplete Latin square with 8 different diets and 4 21-d periods. Eight total mixed rations (TMR) with different neutral detergent fiber (NDF) content of 51.83, 50.47, 44.58, 42.34, 38.20, 35.43, 30.10, and 27.03%, were offered to 8 sheep correspondingly and exchanged sequentially in 4 periods. The experimental duration consisted of a preliminary 8-d adaptation period followed by an 8-d period to conduct digestive trials in metabolism cages by total feces collection method and CH_4 was measured using open-circuit respiration calorimetry system with 3 sheep every 2 d, simultaneously. Nylon bags technique was used for the evaluation of ruminal fermentable nutrients with 6 different incubation times (0, 6, 12, 24, 48 and 72 h, respectively) from d 17 to d 19. Ruminal contents were taken through rumen cannulas of each sheep at 08.00 h, 14.00 h and 20.00 h on d 20 and at 02.00 h, 05.00 h, 11.00 h, 17.00 h and 23.00 h on d 21. The concentrations of VFA were measured after the liquor was strained through 4 layers of gauze. Prediction equations for CH_4 emissions were developed as linear or multiple regression models using the PROC REG of SAS software. Correlations were declared significant at $P < 0.05$. CH_4 per kg fermentable organic matter (L/kg FOM) of 8 diets was 81.64, 87.22, 77.42, 61.87, 52.19, 54.90, 57.07 and 58.72, respectively. In linear relationships, CH_4 (L/kg FOM) was negatively related to organic matter intake (OMI), gross energy intake (GEI), crude protein intake (CPI), digestible organic matter (DOM), digestible energy (DE), digestible crude protein (DCP), digestible ether extract (DEE), FOM, Butyrate/total VFA (TVFA) and Valerate/TVFA ($P < 0.05$) and positively related to NDF intake (NDFI), ADF intake (ADFI), digestible NDF (DNDF), digestible ADF (DADF), fermentable ADF (FADF), fermentable NDF (FNDF)/FOM, FADF/FOM, and Acetate/TVFA ($P < 0.05$). The relationship between methane energy (CH_4-E)/DE and DADF/DOM was CH_4-E/DE(%) = 0.17984 (±0.02178)DADF/DOM(%)+5.25136 (±0.43411) which obtained the highest R^2 (0.9191) and lowest P (0.0002) in all linear models. The multiple relationship between CH_4 and nutrients intake was CH_4 (L/kg FOM) = 0.18188 (±0.07433)OMI -0.54702(±0.09244)CPI-1.17661(±0.12692)NDFI+1.57775(±0.14902)ADFI-3.39557(±0.38786)EEI+154.94964(±40.25930) (all nutrients in kg) which increased R^2 to 0.9992 with a low P (0.0021). Multiple analysis of CH_4 and VFA resulted in CH_4 (L/kg FOM) = 0.82530(±0.10455)Acetate+4.57099(±0.30178) Propionate-7.15948(±0.30917)Butyrate-20.30966 (±1.04868)Valerate+10.49258 (±0.98749) Isovalerate+9.02963 (±5.09327) (all VFA in mmol/L) with a high R^2 (0.9989) and low P (0.0028). The results indicated that CH_4 (L/kg FOM), CH_4-E/GE and CH_4-E/DE were affected by the ratio of forage to concentrate (F:C) or dietary roughage content. In the linear regression models, NDF and ADF were more reliable than other nutrients to estimate methane emissions with higher precision. Compared with the linear regression models, the multiple regression models clearly provided a higher accuracy. Therefore, they may be useful to improve the prediction of methane emissions from sheep.

Key Words: methane, regression models, sheep

564 Response of postpartum dairy cows to contrasting feeding strategies: Grazing plus supplements versus confinement on milk and solids production. M. Sprunck[1,2], D. A. Mattiauda[1], G. Motta[1], M. Fajardo[1], and P. Chilibroste*[1], [1]*Facultad de Agronomía, Paysandú, Paysandú, Uruguay,* [2]*Agencia Nacional de Investigación e Innovación, Montevideo, Montevideo, Uruguay.*

The effect of feeding strategies involving grazing plus supplements (GS) versus confinement (TMR) on performance of early lactation Holstein dairy cows was under research. The experiment was carried out in autumn 2010 in Uruguay (30° S). Dairy cows (n=48, LW= 593 ± 94 kg and BCS = 3 ± 0.6) were randomly assigned to one of the following treatments: TMR (ad libitum; CP = 171 ± 10 g/kg of DM, NDF = 400 ± 20 g/kg of DM) and G+S with a herbage allowance of approximately 10 kg of DM/d per 100 kg of BW. Herbage chemical composition was: CP = 173 ± 31 g/kg of DM, NDF = 465 ± 65 g/kg of DM. Grazing took place on a 2nd year mix pasture (30% legumes and

70% grasses) between am and pm milking. After pm milking G+S cows were supplemented with 8.5 kg DM of TMR. The differential treatment duration was 8 weeks (2-10 postpartum) and residual measurement was until the end of lactation (week 11-30 postpartum). Cows in TMR had higher daily production of fat and protein during the first 8 weeks than cows on G+S treatments: +209 g/d and +266 g/d, respectively. G+S cows had a higher percentage of fat and a tendency to lower percentage of protein in milk. TMR cows had higher LW during the experimental period. Cows in TMR treatment results in greater solids production (kg of solids/d of fat and protein) and LW during treatment application, but differences disappear during the post-experimental period.

Table 1. Experimental period (E) and residual effects (R)

Treatment	G+S (E)	TMR (E)	P-value	G+S (R)	TMR (R)	*P*-value
L/cow per day	26.2	34.36	< 0.001	25.7	27.02	0.144
% fat	3.71	3.49	0.034	3.64	3.49	0.519
% protein	3.11	3.25	0.093	3.20	3.25	0.424
Fat (kg/d)	0.960	1.169	< 0.001	0.960	0.98	0.565
Protein (kg/d)	0.819	1.2	< 0.001	0.85	0.87	0.579
LW (kg)	558	606	0.004	572	587	0.219

Key Words: confining cows, early lactation, grazing cows

565 Effects of rumen-protected γ-aminobutyric acid on feed intake, performance and antioxidant status in transition cows. D. M. Wang*[1], C. Wang[1,2], H. Y. Liu[1], and J. X. Liu[1], [1]*Institute of Dairy Science, MoE Key laboratory of Molecular Animal Nutrition, College of Animal Sciences, Zhejiang University, Hangzhou, China,* [2]*College of Forestry and Biotechnology, Zhejiang A & F University, Lin'an, Hangzhou, China.*

The objective of this study was to investigate the effects of unprotected and rumen-protected γ-aminobutyric acid (GABA) addition on dry matter intake, energy balance, milk performance, and serum metabolites in transition cows. Forty cows were blocked based on previous milk production, parity, estimated calving date and body weight, and randomly assigned to one of 4 treatments: added with unprotected GABA (0 or 0.6 g/d) or rumen-protected GABA (1.2 or 2.4 g/d), respectively. The rumen-protected product was 50% GABA. The experiment lasted from 2nd week before calving to 4th week after calving. Milk yield and milk composition were recorded weekly. Serum concentrations of GABA, neuropeptide Y, cholecystokinin, leptin and biochemical and antioxidant metabolites were analyzed weekly. All the data were analyzed using the PROC MIXED of SAS with cow as the repeated subject using the covariance type AR (1). The model included week, treatment, and interaction of treatment × week. In 3rd and 4th weeks after calving, dry matter intake was higher ($P < 0.05$) in the cows fed 2.4 rumen-protected GABA, compared with that of the control. In 4th week after calving, milk protein yield was higher ($P < 0.05$) in the cows fed 2.4 g/d rumen-protected GABA than that of the control. No significances were observed in the serum concentrations of GABA, neuropeptide Y and leptin among all the treatments, while cholecystokinin concentrations decreased ($P < 0.05$) in cows fed 2.4 g/d rumen-protected GABA in 3rd and 4th weeks after calving. Serum concentrations of total antioxidant capacity, glutathione peroxidase and superoxide dismutase were not different among cows fed rumen-protected GABA. In conclusion, addition of rumen-protected GABA at 2.4 g/d could increase feed intake, improve milk protein yield, and be beneficial to postpartum dairy cows′ health.

Key Words: γ-aminobutyric acid, dry matter intake, transition cows

566 Productive performance by lactating cows fed with different levels of Palm kernel cake. R. L. Oliveira*[1], R. L. N. Vaz Silva[2], A. C. Ferreira[1], A. G. Leão[1], M. C. A. Santana[1], A. A. Pinheiro[1], O. L. Ribeiro[1], and L. F. B. Pinto[1], [1]*Universidade Federal da Bahia, Salvador, BA, Brazil,* [2]*Instituto Federal Baiano, Catu, BA, Brazil.*

With the objective of verifying the most appropriate level of inclusion of palm kernel cake in a dietary supplement for lactating cows on pasture, 16 multiparous dairy cows of the Holstein x Gir crossbreed, with an average weight of 436.6 kg (±59.7), were used. The experiment was conducted at the Experimental Farm of the Federal University of Bahia, Brazil, during August to October 2009. A Latin square design was utilizes, with the cows distributed in 4 Latin squares, 4 × 4 simultaneous (4 treatments × 4 periods × 4 animals in each treatment), data were analyzed using the GLM (General Linear Models) and REG (Regression). The growth performance was evaluated for the cows at pasture that were provided with a dietary supplement that contained levels of 0%, 25%, 50% and 75% of palm kernel cake. The available forage was *Panicum maximum* ‘Massai’. A decrease in the intake of the supplement was observed (R2 = 0.84, $P < 0.05$), however, the milk production and the body condition of the cows were not influenced by the levels of palm kernel cake within the supplement. The milk production and the milk production corrected for 3.5% fat (9.96 and 9.56 kg/day, respectively) can be considered normal for crossbred dairy herds in north-eastern Brazil, these values are associated with a lower degree of specialization of the experimental herd due to their low genetic potential. The body condition of the cows was not altered with the inclusion of palm kernel cake at increasing levels, as the intake of dry matter and total digestible nutrients was not suppressed and the observed body condition score mean (2.88) was close to that which would be expected (3.0 to 3.5), because the dairy farming techniques are demanding on the animals. This indicates that the nutritional requirements were met and that there was a significant mobilization of body energy reserves to produce milk. The low cost of the ingredient and the absence of the restrictive effects on the milk production and the body condition of the cows suggest that palm kernel cake is a suitable co-product for supplements designed for lactating cows at pasture, especially in scenarios of low income per kilogram of milk produced.

Key Words: co-product, milk, pasture

567 Effect of ruminal adaptation on short-chain fatty acid absorption and risk for ruminal acidosis. T. Schwaiger*[1,2], K. A. Beauchemin[2], and G. B. Penner[1], [1]*University of Saskatchewan, Saskatoon, SK, Canada,* [2]*Lethbridge Research Center, Lethbridge, AB, Canada.*

This study was conducted to determine if the duration of time that cattle are fed a high-grain diet affects short-chain fatty acid (SCFA) absorption and susceptibility to ruminal acidosis. Sixteen Angus heifers (BW ± SEM, 261 ± 6.1 kg) were assigned to 4 blocks, and fed a backgrounding diet consisting of 60% barley silage, 30% barley grain and 10% supplement (DM basis). Cattle were then adapted, over 20 d, to a high-grain diet containing 9% barley silage, 81% barley grain and 10% supplement (DM basis). Within block, cattle were randomly assigned to 1 of 2 treatments differing in the number of days they were fed the high-grain diet before an acidosis challenge: 34 d for long adapted (LA) and 8 d for short adapted (SA). Ruminal acidosis was induced by withholding feed to 50% of DMI for 24 h followed by an intraruminal infusion of ground barley at 0.33% BW on a DM basis. Cows were then given their regular diet allocation 1 h after the intraruminal infusion. Data were collected during the baseline period, following the acidosis challenge and after 1 wk of recovery. Absorption of SCFA was measured using the isolated washed reticulo-rumen technique. LA animals had greater fractional absorption rates of propionate (41.6 vs. 33.8%/h; $P = 0.032$) and butyrate (44.9 vs. 35.2%/h; $P = 0.012$) compared with SA animals. In addition, LA animals also had greater absolute butyrate absorption (94.9 vs. 76.9 m*M*/h; $P = 0.048$). Absolute and fractional absorption of all individual SCFA increased during the recovery period ($P \leq 0.050$) relative to the challenge, except for fractional acetate absorption, which only tended to increase ($P = 0.089$). Mean and minimum pH both increased during the recovery period ($P < 0.001$) while daily duration and area that pH <5.5 both decreased during the same time period ($P < 0.001$). There were no treatment differences for pH, DMI, or ruminal fluid SCFA concentrations. This study suggests that increasing the duration that cattle are fed a high-grain diet increases SCFA absorption, without affecting susceptibility to ruminal acidosis.

Key Words: diet adaptation, ruminal acidosis, short-chain fatty acid

568 Effect of simultaneous reduction of ruminally degradable protein and ruminally undegradable protein in dairy cattle. M. Aguilar* and M. D. Hanigan, *Virginia Polytechnic Institute and State University, Blacksburg.*

Previous studies have shown that RDP and RUP (Cyriac et al., 2008; Rius et al., 2010) can be reduced independently below NRC requirements, with no effect on milk production or animal health, suggesting requirements may exceed true needs. However, because some RDP requirement is met by urea recycling which is dependent on overall protein supply, reducing both RDP and RUP simultaneously could induce an RDP deficiency. We hypothesized that dairy cattle may be able to maintain performance when fed a combination of sub-NRC requirement levels of RUP and RDP. Thirty-six mid-lactation dairy cows (24 Holstein and 12 Jersey × Holstein cross-breds) were fed diets containing sufficient or deficient amounts of RDP and RUP in a 2 × 2 factorial arrangement within a 4 × 4 Latin Square design with 3-wk periods. Diets were formulated to contain 16.5, 15.75, or 15.0% CP (DM basis) with RUP and RDP balances of +57 and +58 g/d (High-RUP/High-RDP, 16.5% CP); +42 and −209 g/d (High-RUP/Low-RDP, 15.75% CP); −133 and +61 g/d (Low-RUP/High-RDP, 15.75% CP); or −182 and −186 g/d (Low-RUP/Low-RDP, 15.0% CP), respectively. All diets contained 46.8% forage and 53.2% concentrate on a DM basis. Milk yield and composition were measured and urinary purine output was calculated from urinary concentrations of allantoin and uric acid. Treatment had no effect on DMI, milk production, milk protein, lactose, or fat yield. Diets containing low levels of RUP had significantly reduced MUN and urinary urea N levels as compared with diets with higher RUP levels. Urinary N excretion was significantly reduced in the Low-RUP/Low-RDP diet. Microbial N flow, calculated from urinary purine derivatives, was not significantly affected by treatment. Reduced levels of dietary RUP and RDP reduced N excretion and improved N efficiency without altering microbial outflow.

Key Words: ruminally degradable protein, ruminally undegradable protein, nitrogen requirement

569 Effects of dietary forage-to-concentrate ratio and sulfur concentration on ruminal fermentation and sulfur metabolism in feedlot heifers. S. Amat,* J. J. McKinnon, G. B. Penner, E. Simko, and S. Hendrick, *University of Saskatchewan, Saskatoon, SK, Canada.*

This study was conducted to evaluate the effects of the dietary forage-to-concentrate ratio (F:C) and S concentration on ruminal fermentation, S metabolism, short chain fatty acid (SCFA) absorption, and histopathological changes suggestive of polioencephalomalacia (PEM) in the brain. Sixteen ruminally cannulated heifers (initial BW 628 ± 48 kg) were used in a randomized complete block with a 2 × 2 factorial treatment arrangement. Main factors included the F:C ratio (4% forage vs. 51% forage, DM basis), and the S concentration which was modified using differing sources of wheat dried distillers grains with solubles (DDGS) to achieve low and high S diets (LS = 0.30 vs. HS = 0.67% S DM basis, respectively). Elemental S was also added to increase the S content for the HS diets. Blood, rumen gas cap and urine samples were collected for serum sulfate, H_2S, and urinary sulfate analysis, respectively. Continuous rumen pH and SCFA (acetate, butyrate and propionate) absorption were measured. At the end of the study, heifers were euthanized and brain tissue was subjected to histopathological analysis. There were no interactions between the F:C and S concentration. The F:C did not ($P = 0.871$) affect DMI or ($P > 0.05$) S metabolism but ruminal pH was reduced ($P < 0.01$) and SCFA was greater ($P < 0.01$) for low-forage diets. Cows fed HS diets had reduced DMI ($P < 0.01$), greater rumen pH ($P < 0.01$) and greater concentrations of ruminal H_2S ($P < 0.01$), serum sulfate ($P < 0.01$), and urinary sulfate ($P < 0.01$) relative to low S diets. Ruminal H_2S was positively correlated with serum sulfate (r = 0.89; $P < 0.01$). Feeding HS diets reduced SCFA absorption ($P \leq 0.05$). No macroscopic or microscopic changes were detected in the brains of the heifers. In summary, S metabolism in feedlot heifers was not influenced by different F:C, but HS reduced DMI and inhibited SCFA absorption.

Key Words: DDGS, short chain fatty acids, sulfur metabolism

570 Intake, digestibility and microbial protein synthesis in heifers fed pasture, total mixed ration or both. A. Santana*[1], A. Perez-Ruchel[2], C. Cajarville[2], and J. L. Repetto[1], [1]*Facultad de Veterinaria, UdelaR, Depto. Bovinos, Montevideo, Uruguay,* [2]*Facultad de Veterinaria, UdelaR, Depto. Nutrición, Montevideo, Uruguay.*

We evaluated the intake and digestibility of dry matter (DM), organic matter (OM) and nitrogen (N), microbial protein synthesis (MPS), efficiency of microbial protein synthesis (EMPS) and nitrogen efficiency for MPS (NEMPS), in heifers. Nine individually housed cross-breed heifers (214 ± 18kg BW) were ad libitum fed total mixed ration based on sorghum plant silage, soybean meal, corn high moisture silage and dry corn, (TMR), fresh forage, cut daily from a temperate pasture (*Trifolium repens* and *Lolium multiflorum*) (PA) or TMR for 18h plus 6h pasture (TMR-PA) in a latin square design of 3 × 3 triplicate. Each experimental period consisted in 10d of adaptation and 8d for sampling. Intake was individually determined during 8d as the difference between offered and rejected food. Total feces and urine excretion were measured during 5d. The results are shown in the Table below. The TMR- PA presented similar intake, MPS, EMPS and NEMPS than TMR, being the intake of DM and OM and MPS of PA the lowest. There were no differences in DM and OM digestibility between treatments. Pasture addition for 6h allowed to maintain nutrient ingestion and did not affect microbial protein synthesis regarding to TMR.

Table 1.

	TMR	TMR-PA	PA	SEM	*P*-value
Intake, kg/d					
DM	5.99^{ab}	7.36^{a}	5.49^{b}	0.56	0.042
OM	5.84^{ab}	7.02^{a}	5.13^{b}	0.55	0.040
N	0.58	0.77	0.73	0.06	0.144
Digestibility, %					
DM	66.5	71.1	73.2	2.35	0.166
OM	71.6	74.2	75.4	1.70	0.329
N	61.1^{b}	69.8^{ab}	77.3a	2.38	0.003
MPS and efficiency[1]					
MPS, gmN/d	100.6^{a}	105.6^{a}	64.9b	8.9	0.018
EMPS, gmN/kg DOMI	39.8^{a}	24.7^{ab}	20.9b	5.2	0.053
NEMPS, gmN/gN intake	0.24^{a}	0.16^{ab}	0.10b	0.03	0.052

[1] MPS = microbial protein synthesis; gmN = g of microbial N/d; DOMI = digestible OM intake; EMPS = efficiency of MPS; NEMPS = N efficiency for MPS.

Key Words: feeding systems, fresh forage, ruminant

571 A technology that enhances the utilization of low quality forages in ruminant animals.

H.-L. Mao[1], H.-L. Mao[1], J. K. Wang*[1], J. A. Ye[1], J. X. Liu[1], and I. Yoon[2], *[1]Institute of Dairy Science, Zhejiang University, Hangzhou, China, [2]Diamond V, Cedar Rapids, IA.*

Effects of various levels (0, 1, 2 and 3 g/L) of *Saccharomyces cerevisiae* fermentation product (YC; Diamond V XP) on ruminal fermentation of major forage sources of China (rice straw, corn stover, corn silage with grain and corn silage without grain) were examined in an in vitro study with a 4 × 4 factorial arrangement of treatments. Rumen fluid was collected from 3 rumen cannulated Hu sheep fed a diet consisting of lucerne hay and concentrate mixture (50:50) twice daily. Gas pressure measurements were recorded at 3, 6, 9, 12, 24 and 48 h of incubation and then converted to gas volume. Ammonia N, pH, volatile fatty acids (VFA), and microbial crude protein (MCP) were determined at 12, 24 and 48 h. Microbial population was examined at 24 h incubation. Data were analyzed using the GLM procedure of SAS. Terminal pH varied within normal range (6.53 to 6.96) regardless of treatment or substrate. The YC showed inconsistent effect on ammonia N (8.0 to 23.1 mg/dL) with different substrates. Gas production reached peak at 2 g/L YC for rice straw and corn silage without grain, while reached peak at 1 g/L YC for corn stover and corn silage with grain. Total VFA concentration (mmol/L) at 24 h tended to increase with 1 and 2 g/L YC for rice straw, while increased ($P < 0.05$) with 1 g/L YC for corn silage with grain, 1 and 2 g/L YC for corn silage without grain, and 3 g/L YC for corn stover. Acetate, propionate and butyrate concentrations followed similar trend as total VFA. The MCP (mg/mL) increased ($P < 0.05$) with increasing level of YC at 24 h for rice straw. For corn silage without grain, MCP increased ($P < 0.05$) with 1 and 2 g/L YC at 12 h, became insignificant at 24 h, then increased ($P < 0.05$) again with all additional levels at 48 h. For corn silage with grain, 2 g/L YC increased ($P < 0.05$) MCP at 12 h, while 1 g/L YC showed the highest ($P < 0.05$) response at 24 h. Fungi population was increased ($P < 0.05$) with 1 g/L YC for all forages but corn silage without grain. Addition of YC also increased ($P < 0.05$) the percentages of protozoa, *Fibrobacter succinogenes*, *Ruminococcus albus* and *R. flavefaciens*. Although the optimum level of YC for different parameters varies depends on forage substrate and incubation time, rumen fungi was enhanced and VFA and MCP were increased with a stable rumen pH when the YC was added at a level of 1 or 2 g/L. It is suggested that addition of YC can improve the ruminal microbial utilization of low quality forages.

Key Words: forage, rumen fermentation, yeast culture

572 In vitro manipulation of Jersey cow rumen ecology with microbes from the wildebeest, horse and zebra.

F. N. Fon* and I. V. Nsahlai, *University of KwaZulu-Natal, Pietermaritzburg, South Africa.*

Ruminal microbes have the ability to convert low quality feeds into high quality protein and to utilize feeds (roughage) from land not suitable to grow crops for human consumption. Only 10–35% of energy intake is captured as net energy while 20–70% of cellulose may not be digested by herbivores. There is need to increase the amount of energy harvested by ruminant systems without necessarily increasing intake. The objective of the study was to compare fiber breakdown by microbes from the cow (CW) system (A) to its composite systems with the horse (H), wildebeest (WB) and Zebra (ZB). Four in vitro composite enzyme systems B (CW and H), C (CW and WB), D (CW and ZB) and E (CW, H, WB and ZB) were created. Exocellulase, endocellulase, xylanase and cellobiase specific activities of these systems upon incubation with cellulose, carboxymethyl cellulose (CM), xylan and cellobiose, respectively were determined by measuring the amount of reducing sugars released. The catalytic efficiency (Kcat) of the enzymes was also determined. In vitro microbial fermentation and degradability of maize stover (MS) and NDF with inocula from the 4 systems over 72 h at 39°C were determined by measuring the amount of gas released and true degradability (TD). Systems E (Kcat = 17.1 ± 1.28) and B (Kcat = 8.5 ± 1.28) were the most active ($P < 0.05$) enzyme systems upon incubation with cellulose with specific activity 9.6 ± 0.05 and 4.5 ± 0.05 µg glucose/mg/min, respectively. Upon incubation with CM, system B (Kcat = 15.4 ± 0.40) was more active ($P < 0.05$) than E (Kcat = 9.5 ± 0.40). Xylan hydrolysis was highest ($P < 0.05$) in E and D while B and C were intermediate. Gas released during MS fermentation was highest ($P < 0.05$) in system C (141 ± 9.9 mL) and intermediate in systems B, D and E(135 ± 0.4, 133 ± 0.4 and 134 ± 0.4 mL, respectively). MS fermentation was higher in B(694 ± 38.4 kg) and E(695 ± 38.4 kg) with gas volumes of 128 ± 58.1 and 118.62 ± 58.1 mL, respectively. TD of NDF showed that system D(709 ± 32.1 kg) and E(700 ± 0.4032.1 kg) were the most active ($P < 0.05$). These results suggest that mixing microbes from horses, wildebeest and zebras can improve the fibrolytic potential and digestion of roughages in cattle.

Key Words: exocellulase, in vitro fermentation, roughage digestibility

573 Growth curve analysis of Sahiwal calves up to six-month age given milk or milk replacer up to weaning.

M. S. Khan[1], S. A. Bhatti*[2], and H. A. Ahmad[3], *[1]Department of Animal Breeding and Genetics, University of Agriculture, Faisalabad, Pakistan, [2]Institute of Animal Nutrition and Feed Technology, University of Agriculture, Faisalabad, Pakistan, [3]Dept. Biology, Jackson State University, Jackson, MS.*

Data of 2 feeding trials were used to understand the growth patterns of Sahiwal calves fed different dietary treatments up to weaning and then a single treatment during post-weaning period. The objective of this study was to predict body weight changes of Sahiwal calves up to 6-mo of age. The Sahiwal calves (n = 48; 24 of each sex 3 ± 2 d of age) were divided into 4 groups of 12 animals each (6 of each sex) and were given following dietary treatments up to weaning: A) whole cow milk + starter ration (SR; CP = 20%, TDN = 72%) + Berseem clover hay (H; *Trifolium alexandrinum*; CP = 21% TDN = 63%); B) whole cow' milk + H; C)

Milk replacer (MR) + SR + H and D) MR + H. Milk or MR was offered at 10% of the body weight until d 56 and then gradually withdrawn until calves were weaned completely by d 84. The SR and H continued until d 84. During post-weaning period the calves were fed ad libitum a single mixed ration containing 16% CP and 70% TDN, from wk 13 to 24. Body weights were recorded weekly. Gompertz, Exponential, 3-degree Polynomial, Logistic and Sinusoidal models, using CurveExpert software, were tested to predict body weight during the experimental period. All the models explained variation in growth of Sahiwal calves reasonably well; R^2 ranged from 91.9 to 97.9% for individual treatments and 89.4 to 89.5% on overall basis. Female calves, on average, had 3% better fit than male calves (92 vs 89%). Growth curves of milk-fed and MR-fed calves had R^2 93.1 and 89.4%, respectively. Any of the 5 tested models may be used to predict first 6-mo growth pattern in Sahiwal calves with almost equal efficiency.

Key Words: computational models, growth curve, Sahiwal calves

Small Ruminant Symposium: Novel Uses of Natural Bioactive Compounds in Small Ruminant Production and Future Directions

574 Bioactive compounds and their mode of action in forage-fed ruminants. T. N. Barry,* *Massey University, Palmerston North, New Zealand.*

Bioactive compounds are generally secondary compounds and include lignin (all forages), condensed tannins (lotus, sulla and sainfoin), sesquiterpene lactones (chicory), endophyte alkaloids (perennial ryegrass and fescue), S-methyl cysteine sulphoxide (SMCO) and glucosinolates (brassica plants). They have all evolved as part of the plant's defense mechanism, to protect against microbial attack and being eaten by insects and herbivores. Hence high concentrations of all these compounds are associated with reduced voluntary feed intake (VFI) by ruminants and with animal health effects for SMCO (anemia) and endophyte alkaloids (staggers). Condensed tannins (CT) react reversibly with forage proteins, reducing protein degradation in the rumen and for some forages increasing the absorption of essential amino acids (EAA) from the small intestine, depending on the concentration and structure of the CT. For CT such as *Lotus corniculatus* beneficial effects are seen at 20–40 g/kg DM with no depression in VFI. For CT in this range that increase EAA absorption beneficial effects are reduced bloat in cattle, increased wool growth, ovulation rate, lactation performance, reduced parasite problems in sheep and reduced methane production. Methodology has just been published to induce CT production in legumes containing only traces of CT (white clover). Chicory is a herb that disintegrates rapidly in the rumen, has rapid rumen clearance, high VFI and promotes good growth in grazing ruminants. Young sheep and deer grazing chicory have reduced need for oral anthelmintics and part of this anthelmintic effect is due to its content of sesquiterpene lactones and to low levels of CT. Forages containing bioactive compounds can be used in sustainable grazing systems.

Key Words: bioactive plant secondary compounds, chicory, condensed tannins

575 Consequences of plant secondary compounds on ruminant nutrition. B. R. Min* and S. Solaiman, *Department of Agricultural and Environmental Sciences, Tuskegee University, Tuskegee, AL.*

Plant secondary compounds are varied in nature but are characterized by hydroxylated aromatic rings (e.g., flavan-3-ols). They are considered as secondary metabolites, and their nutritional aspects in ruminants are often poorly understood. This paper mainly considers 2 classes of plant secondary compounds in this context, i.e., proanthocyanidins (condensed tannins; CT) and hydrolysable tannins (HT) and their effect on rumen environment and animal nutrition. The CT are prevalent in browse materials and are expressed in the foliage of some legumes, but rarely in grasses. The HT are present in oak (*Quercus* spp.), Acacia, Eucalyptus and a range of browse and tree leaves. Nutritionists and researchers continue to define dietary CT and HT in terms of concentration, as well as either beneficial or detrimental effects on ruminant animals. Beneficial effects are dependent on the chemical and physical structure, and concentration of the CT and HT in the diet. The HT may be toxic because products of their metabolism can cause liver damage and other metabolic disorders. However, the CT, when present in diet at a proper level (2 to 4% DM) can exert beneficial effects on protein, and minerals metabolism; blood parameters; rumen fermentation (VFA and ammonia production); rumen and fecal microbial populations; feed efficiency; and overall animal performance. Dietary CT may also contribute to animal health by preventing the risk of frothy bloat in cattle. In contrast, high dietary CT concentrations (>5% DM) depress feed intake, digestive efficiency, and animal productivity. From the biochemical standpoint, CT have a wide range of biological activities and enormous potential for uses in livestock industry which requires in-depth investigation and evaluation in the perspective ruminant production systems. Future research should identify optimum level and chemical structures for expression in the high-quality diets to be offered as extract or mixed with grasses or with legumes. Animal feeding systems will be empowered by the choice of variety and concentration of CT in the diet. The potential of novel secondary compound plant sources for use in animal production warrants further investigation.

Key Words: plant secondary compounds, ruminants, tannins

576 Bioactive compounds for control of internal parasites. T. H. Terrill,* *Fort Valley State University, Fort Valley, GA.*

Livestock producers have used nutraceutical plants to improve health and productivity of their animals for several millennia. A large number of bioactive secondary plant metabolites with activity against gastrointestinal nematodes (GIN) of livestock have been identified, including alkaloids, terpenes, and various phenolics, although relatively few plants have been validated scientifically as anti-parasitic. A class of phenolic bioactive compounds for which there is a growing body of evidence for anti-parasitic properties in the diet of ruminants is condensed tannins (CT). Recent work with tropical and temperate CT-containing forages and CT extracts in a series of in vitro and in vivo studies have greatly expanded the scientific knowledge base on use of these compounds to control GIN of livestock. Evidence for these effects has been both direct and indirect. Direct effects of CT on all phases of the GIN life cycle (eggs, larvae, adults) have been reported, although for the most part, determining the exact mechanism of action has remained an elusive target. There have also been reports of indirect effects of certain types and concentrations of CT in the diet improving host resilience and resistance to GIN infection by improving the animal′s nutritional status and immune function. The anti-parasitic efficacy of CT-containing forage/browse in animal diets is likely due to a combination of direct and indirect effects and can vary greatly, depending upon the form of feed (fresh versus dried), CT astringency and concentration in extractable and bound forms, previous exposure to CT-containing plants, seasonal effects, animal age, and the parasite and host species involved. Nevertheless, there appears to be great potential for increased use of bioactive compounds as anti-parasitic agents in livestock production systems in the future.

Key Words: bioactive compounds, condensed tannins, gastrointestinal nematodes

577 Emerging opportunities and challenges on exploitation of bioactive plant secondary compounds to mitigate environmental impacts by ruminants. J.-S. Eun*[1] and B. R. Min[2], [1]*Utah State University, Logan,* [2]*Tuskegee University, Tuskegee, AL.*

Greenhouse gas (GHG) emissions from livestock and their impacts on climate changes are a major concern worldwide. It has been reported that enteric methane is the most important GHG emitted (50 to 60%), at the farm scale, in ruminant production systems. Methane represents also a significant energy loss to the animal ranging from 2 to 12% of gross energy intake. Therefore, mitigating the production of enteric methane from ruminants without altering animal production is desirable both as a strategy to reduce global GHG emissions and as a means of improving feed efficiency. Some of plant secondary compounds (PSC) such as tannins and polyphenols play key roles in animal health, quality of animal products, mitigation of GHG emissions, and efficiency of N use by ruminants. However, the beneficial effects on methane production and N utilization efficiency have not been consistently observed. The discrepancies among different studies in response to feeding PSC-containing forages or supplementing PSC extracts are attributed to the different chemical structures and concentrations of PSC and type of diets. For example, reliable and distinguishable effects of tannins on methane reduction can be expected only from levels >20 g/kg DM, a threshold often not exceeded in current commercial feed supplementation with tannins. Hence, the challenge is to identify PSC sources that can be feasibly added to the diet in a cost effective manner that also result in a net reduction in GHG emissions. Measurements with in vitro culture systems could provide an inexpensive starting point for screening of potential PSC, whereas individual promising PSC need to be investigated in detail in vivo. Different PSC exert their characteristic effects on ruminal fermentation in association with the inhibition of methanogenesis; however, their ultimate impacts on environmental performance by ruminants should be assessed on the amount of emissions/kg of livestock product.

Key Words: greenhouse gas emissions, methane, bioactive plant secondary compounds

578 Bioactive plant compounds and food safety. R. C. Anderson,* *Southern Plains Agricultural Research Center, United States Department of Agriculture/Agricultural Research Service, College Station, TX.*

The gut of food-producing animals is a reservoir for human pathogens such as *Salmonella*, *Campylobacter*, *Clostridium*, *Listeria*, enterohemorrhagic *Escherichia coli* as well as other commensal and pathogenic bacteria expressing important antimicrobial resistance traits. Food producers recognize a need to continuously develop new technologies that effectively minimize contamination of foods and may be used as alternatives to antibiotics at risk from regulatory restrictions. In the search for new interventions, the use of functionally bioactive plant compounds may be viewed favorably as many of these are generally recognized as safe (GRAS). Essential oils extracted from several different plant species have been shown to exhibit broad spectrum bactericidal activity against gram-negative and gram-positive foodborne pathogens, purportedly by disrupting bacterial cell wall integrity. The antimicrobial activity of tannin-derived compounds against a variety of bacteria has also been demonstrated. In the case of hydrolysable tannins such as tannic acid, bacterial growth is inhibited by chelation of iron thus reducing its availability. The mechanisms by which condensed tannins inhibit bacterial growth are less clear and have been proposed to be due to cell wall disruption or binding of proteins, enzymes or amino acids. The antimicrobial activity of hop extracts rich in lupulones has also been demonstrated against certain amino acid-fermenting bacteria such as *Campylobacter*, presumably by exhibiting an ionophore-like effect. While most commonly associated with yeast cell wall products, oligosaccharides produced in certain forestry products are now being explored for their ability to prevent gut colonization mediated by mannose-specific binding by *Salmonella* and *E. coli*. Whereas results from in vitro studies have shown good efficacy, often yielding several log-fold reductions in bacterial numbers, results from animal studies have been less conclusive, possibly because of their absorption or degradation in the stomach or proximal small intestine. Clearly, more research is needed to better understand how to fully harness the biological activity of these compounds.

Key Words: antimicrobial resistance, bioactive plant compounds, foodborne pathogens

Swine Species

579 Industry productivity analysis: Grow-finish traits. C. E. Hostetler*[1] and M. T. Knauer[2], *[1]National Pork Board, Des Moines, IA, [2]North Carolina State University, Raleigh*

The objective of this study was to quantify US swine production benchmarks and trends for nursery and finishing traits from a representative database. Data were provided by a data management company representing approximately 1.8 million sows in North America. Production records were available from 2005 to 2010. Nursery and finishing traits included entry age, entry weight, exit age, exit weight, ADG, G:F, caloric efficiency (kcal:kg) and mortality. Nursery and finishing kcal:kg were standardized from 5.4 to 22.7 kg and 22.7 to 118 kg, respectively. Data were analyzed in SAS using PROC MIXED. Models included year and month as fixed effects. Standard errors for nursery entry age, entry weight, exit age, exit weight, ADG, G:F, kcal:kg and mortality were 0.11, 0.026, 0.22, 0.09, 0.0041, 0.0031, 38.6 and 0.19, respectively. Standard errors for finishing exit age, exit weight, ADG, G:F, kcal:kg and mortality were 0.5, 0.41, 0.007, 0.0015, 79.4, 0.34, respectively. Nursery entry age and weight increased ($P < 0.05$) from 2005 to 2010 (19.2 to 20.5 d and 5.53 to 5.85 kg, respectively). Nursery exit age decreased ($P < 0.05$) from 68.3 to 67.1 d and exit weight increased ($P < 0.05$) from 22.7 to 23.4 kg. Finishing exit age decreased ($P < 0.05$) from 191 to 190 d and exit weight increased ($P < 0.05$) from 117.7 to 119.9 kg. Means for ADG, G:F, kcal:kg and mortality are shown by year in Table 1. Finishing ADG increased ($P < 0.05$) and mortality decreased ($P < 0.05$) indicating more weight sold in a fixed amount of time. However, finishing kcal:kg did not differ ($P > 0.05$) between 2005 and 2010. Both producers and scientists can use these grow-finish benchmarks to better understand swine industry trends.

Table 1. Grow-finish means for ADG, G:F, kcal:kg, and mortality

580 Periweaning failure to thrive syndrome in nursery pigs is associated with gastrointestinal lesions, but not enteric pathogens. C. K. Jones,* D. M. Madson, R. G. Main, N. K. Gabler, and J. F. Patience, *Iowa State University, Ames.*

Periweaning failure to thrive syndrome (PFTS) has challenged both the profitability and welfare of the US pork industry in recent years. However, it is unknown if PFTS is associated with increased disease incidence. Our objective was to determine if light birth weight (BRW) pigs or those from the bottom 10th percentile of transition ADG (tADG) have a higher incidence of gastrointestinal lesions and enteric pathogen presence compared with their heavier or faster-growing contemporaries. A total of 1,500 pigs were weighed at birth and divided into 5 BRW categories: <1 kg, 1–1.25 kg, 1.25–1.5 kg, 1.5–1.75 kg, >1.75 kg. At weaning, 1,054 randomly selected pigs were moved to a commercial wean-to-finish barn. Pigs were weighed individually at 0, 3, 6, and 22-weeks post-weaning. Gain from 0 to 3 weeks post-weaning was calculated and termed tADG. Pigs from 3 tADG percentiles were of interest: 10th, 30th, and 70th. Forty pigs from each of the 3 tADG percentiles were matched for sex, litter size, and sow parity, but not BRW to create 20 matched sets of 60 total pigs. This allowed for the main effects of BRW and tADG to be studied as a 5 × 3 factorial design. At 3-weeks post-weaning, pigs were necropsied and lesions on the gastrointestinal tract and other organ systems were characterized. Lung, lymph node, and fecal samples were analyzed for presence of various pathogens by PCR. Colon samples were cultured for *E. coli* and *Salmonella* spp. Data were analyzed using PROC GLIMMIX, where pig served as the experimental unit. The fixed effects were BRW and tADG; and the random effect was matched set. There were no BRW × tADG interactions ($P > 0.16$). Presence of lesions decreased linearly with increasing tADG in the large intestine ($P = 0.03$; 62, 55, 26% for 10th, 30th, and 70th percentiles, respectively) and total gastrointestinal tract ($P = 0.05$). However, tADG was not associated with increased incidence of pathogens ($P > 0.44$). Increasing birth weight was associated with a linear decrease in stomach lesion presence ($P = 0.05$; 29, 10, 15, 0, 0% for <1 kg, 1–1.25 kg, 1.25–1.5 kg, 1.5–1.75 kg, >1.75 kg, respectively), and was quadratically associated with the presence of *Salmonella* spp. ($P = 0.02$; 43, 10, 15, 40, 63% for <1 kg, 1–1.25 kg, 1.25–1.5 kg, 1.5–1.75 kg, >1.75 kg, respectively). In summary, PFTS appears to be associated with increased gastrointestinal lesions, but not with the presence of enteric pathogens.

Key Words: enteric disease, pig, periweaning failure to thrive

581 Umbilical vein blood-oxygen relationship with pre-weaning growth in piglets. E. A. Hale*[1], T. J. Safranski[1], M. C. Lucy[1], J. N. Rhoades[1], J. W. Ross[2], N. K. Gabler[2], R. P. Rhoads[3], and L. H. Baumgard[2], *[1]University of Missouri, Columbia, [2]Iowa State University, Ames, [3]Virginia Tech, Blacksburg.*

Management techniques to improve piglets′ chances of surviving are common, but North American farms still lose nearly 20% of piglets as stillborns plus pre-weaning mortalities. This project was to characterize the range in blood-oxygen levels in neonatal piglets and its effects on viability and growth. A group of 23 parity-one Large White × Landrace sows were monitored for 24h daily over one week beginning at the time the first sow was due and ending when the last sow farrowed. Each piglet was caught at birth and dried. A 3mL blood sample was taken from the umbilical vein and the sample ran through an IRMA blood analyzer. At birth piglet weight and rectal, rump, and back temperatures were recorded. After approximately 5 min under a heat lamp the piglets were placed at the udder to nurse. Piglets were weighed again at 2 h and 24h post birth and at weaning around 21d. All piglet processing was one day after farrowing. Of the total 264 piglets born alive, blood samples were obtained from 137 piglets (52%). Of the 264 piglets, 12 pre-wean mortalities were recorded, only 3 of which were successfully blood sampled. Birth order of all piglets in their respective litter was recorded. For analyses piglets with a 2 h weight change exceeding 400 g were excluded as were arterial samples resulting in 126 records. Weight changes at 2 h and 24 h as well as pre-weaning ADG were fitted to a least squares regression model including rectal temperature and weight at birth and birth order with dam fitted as a random effect. Two-hour weight change was affected by birth order; piglets born later in the litter gained less weight. No model effects affected 24hr weight change. Pre-weaning average daily gain was increased in piglets having higher blood oxygen or rectal temperatures at birth and unaffected by birth order. The low pre-weaning mortality precludes meaningful analyses of the effect of blood gas on this variable. While surprising that neonatal growth was affected by birth order and not blood oxygen at birth, the effect of the latter on subsequent growth is intriguing and implies a long-term impact on the physiology of the pig. Supported by USDA NIFA #2011–67003–30007

Key Words: neonatal growth, blood oxygen, piglet viability

582 Breed difference of porcine sirtuin 1 and its regulation by insulin. Y. Ren,* T. Z. Shan, L. N. Zhu, J. Huang, and Y. Z. Wang, *Institute of Animal Science, Zhejiang University, Key Laboratory of Molecular Animal Nutrition, Ministry of Education, Key Laboratory of Feed and Animal Nutrition of Zhejiang Province, Hangzhou, Zhejiang Province, China.*

Sirtuin 1 (*Sirt1*) plays an important role in insulin signaling pathway especially insulin sensitive organs. However, there were few data about the differences of *Sirt1* expression between fatty breed and lean breed of pigs. Furthermore, whether insulin could feedback or regulate the expression of *Sirt1* is unclear. Therefore, in the current study, the breed difference and the expression pattern of *Sirt1*, as well as key lipid metabolism enzyme adipose triglyceride lipase (*ATGL*) and hormone sensitive lipase (*HSL*), in adipose tissue, liver and pancreas between Jinhua pigs (a local fatty breed of China) and Landrace (a leaner breed) were investigated. In addition, the effect of insulin on gene expression of *Sirt1*, *ATGL* and *HSL* in fat metabolism was also studied in vitro. Results showed that at the age of 180 d, the body fat content of Jinhua pigs were significantly higher ($P < 0.01$). Serum triglyceride (TG), total cholesterol (TCHO) ($P < 0.01$) and glycerol ($P < 0.01$) of Jinhua pigs were lower comparatively. Higher serum insulin and leptin concentrations were consistent with higher fat percentage in Jinhua pigs. When compared with Landrace, *Sirt1* protein abundance and mRNA levels of Jinhua pigs were lower ($P < 0.01$) in adipose tissue. Likewise, in liver and pancreas, protein abundance and mRNA level of *Sirt1* were also lower ($P < 0.01$) in Jinhua pigs. Consistent with *Sirt1* gene, the mRNA expression of *ATGL* and *HSL* in Jinhua pigs were lower ($P < 0.01$) than Landrace in the 3 tissues. In vitro treatment with different doses of insulin (10, 50 and 100 nM) significantly decreased ($P < 0.01$) glycerol release and *Sirt1*, *ATGL* and *HSL* mRNA levels in porcine adipocytes. These results indicated that porcine *Sirt1* and key fat metabolic enzymes (*ATGL* and *HSL*) expressions are different between fatty breed and lean breed and insulin can decrease gene expression of *Sirt1*, *ATGL* and *HSL* in adipocytes. This will provide some information for further study of porcine *Sirt1* gene function and regulating fat metabolism in pigs and for dietary manipulation of expression of these genes.

Key Words: sirtuin 1, insulin, pig

583 Growth response and blood profile of weaner pigs fed additive-enhanced agro-industrial by-product based diet. A. O. K. Adesehinwa*[1], O. O. Mgbere[2], O. O. Obi[1], B. A. Makanjuola[1], and I. A. Okere[1], [1]*Institute of Agricultural Research & Training, Obafemi Awolowo University, Ibadan, Oyo State, Nigeria,* [2]*Hatfield International Biometrical Service Centre, Houston, TX.*

Ninety (90) weaner pigs (average initial weight 9.78 ± 0.36kg) were randomly assigned to 3 dietary treatment groups in a completely randomized design to evaluate the growth response and blood profile of weaner pigs fed additive-enhanced [directly-fed microbial (DFM) or Hemicell] agro-industrial by-product based diets. The 19.85% crude protein basal diet was formulated to contain 35, 20, 20, 12, 3 and 5% of yellow maize, brewers dried grain, palm kernel cake, groundnut cake, 72% fish meal and micro-nutrients respectively. The additive-enhanced diets contained either 1.5 L of direct-fed microbial, a source of live (viable), naturally occurring microorganism, also known as Rumen Enhancer 3 (RE-3)/tonne of basal diet, or 200 g Hemicell (a mannanase)/tonne of the basal diet. There were 6 pen replicates per treatment, with each pen containing 5 pigs. The pigs were allowed ad libitum access to the diets and water throughout the 35-d study period. Weekly weight and feed intake were recorded and used to determine the weight gain, average daily gain (ADG), average daily feed intake (ADFI) and gain:feed ratio (G:F). At the end of the study, blood samples were collected from 2 pigs/replicate to evaluate the hematological and biochemical profile. Data were analyzed as a completely randomized design using ANOVA procedures as described by Steel and Torrie (1997). The addition of DFM resulted in a higher ($P < 0.05$) ADFI compared with the results obtained with the basal-control and Hemicell-enhanced diets. However, pigs fed the DFM-enhanced diet consequently had a superior ADG (0.40kg) compared with the basal-control (0.35kg) but not the Hemicell-enhanced diet, as the gains were comparable ($P > 0.05$). The efficiency of feed conversion (G:F), hematological and biochemical indices were not significantly ($P > 0.05$) influenced by either of the additives but for a higher serum glucose obtained with Hemicell-enhanced diet. Arising from the comparable results obtained with direct-fed microbial and Hemicell-enhanced diets, it could be inferred that both diets could be used as animal feed additives to enhance the utilization of agro-industrial by-products in diets of this class of pigs.

Key Words: weaner pigs, feed additives, agro-industrial by-product

584 An evaluation of the effects of a blend of essential oil compounds (Crina Piglets AF), a feed-grade antibiotic program, and their combination in nursery diets on the growth and economic performance of pigs in a commercial research facility. J. Bergstrom*[1], D. Campbell[1], C. Paulus[2], and M. DeBeer[1], [1]*DSM Nutritional Products, Parsippany, NJ,* [2]*DSM Nutritional Products, Kaiseraugst, Switzerland.*

A total of 880 pigs (initially 6.8 kg) were used in a 42-d experiment to evaluate the effects of dietary supplementation with a blend of essential oil compounds (Crina Piglets AF, EO), a feed-grade antibiotic program (AB), and their combination on the performance of pigs in a commercial research facility. After weaning (d 0), pigs were randomly placed into 44 pens of 20 pigs each and allotted to one of 4 dietary treatments to provide 11 replicate pens per treatment. Treatments were arranged in a 2 × 2 factorial to evaluate possible EO and AB interactions. Dietary treatments consisted of 1) a control diet without EO and AB, 2) EO added, 3) AB added, and 4) both EO and AB added. Supplementation occurred at the expense of corn in the control diets and all pigs were fed the same 4-phase program of commercial starter diets. Diet phases were d 0 to 7, 7 to 14, 14 to 28, and 28 to 42. Pigs fed EO were supplemented with 100 mg/kg throughout the study. Pigs fed AB were supplemented with 39 mg/kg Denagard + 441 mg/kg Aureomycin from d 0 to 14 and 55 mg/kg Mecadox from d 14 to 42. Economic performance was also determined using costs of \$0.94, \$0.46, \$0.29, and \$0.28/kg for the phase 1 thru 4 control diets, respectively. Added costs for treated diets were \$0.029/kg for Denagard + Aureomycin, \$0.026/kg for Mecadox, and \$0.004/kg for EO. Value of BW gain was determined using \$1.33/kg. Growth performance, diet costs, and value of gain were used to determine feed cost per kg of gain (fd$/kg) and income-over-feed-cost (IOFC). Overall (d 0 to 42), there were EO × AB interactions for ADG ($P \leq 0.07$) and final BW ($P \leq 0.03$). No interactions occurred for other response criteria. Although EO and AB each improved ($P \leq 0.01$) ADG (490, 499, 513, and 562 g/d; treatment 1 thru 4, respectively) and final BW (27.6, 27.8, 28.4, and 30.8 kg), these improvements were considerably greater when EO and AB were used in combination. Pigs fed AB had greater ($P \leq 0.01$) ADFI (726, 708, 758, and 798 g/d) and pigs fed EO had improved ($P \leq 0.01$) G:F (0.67, 0.71, 0.67, and 0.70 g/g). Pigs fed AB had greater ($P \leq 0.01$) fd$/kg ($0.66, $0.64, $0.71, and $0.68), but fd$/kg was reduced ($P \leq 0.01$) for pigs fed EO; however, IOFC ($15.07, $15.89, $14.70, and $16.79) was only improved ($P \leq 0.01$) for pigs fed EO.

Key Words: essential oils, feed-grade antibiotics, pigs

585 Dietary antioxidant (Agrado Plus) sparing vitamin E in nursery pigs fed distillers dried grains with solubles (DDGS). J. Zhao*[1], T. Engle[2], T. Wineman[1], M. Vazquez-Anon[1], and R.J. Harrell[1], *[1]Novus International Inc., St. Charles, MO, [2]Colorado State University, Fort Collins.*

Synthetic dietary antioxidants have been shown to improve liver and plasma vitamin E levels in broilers regardless of dietary vitamin E levels. The objective of this trial was to test whether synthetic antioxidants spare vitamin E in nursery pigs fed distiller dried grains with soluble (DDGS). A total of 924 weanling pigs (PIC, 28 d of age, 7.0 ± 0.07 kg) were randomly assigned to 6 treatments blocked by sex and body weight, with 7 replicates per treatment and 22 pigs per pen. The trial was a 3 × 2 factorial arrangement with 3 levels of dietary vitamin E (0, 22, and 44 IU/kg) with or without synthetic antioxidant (Agrado Plus liquid, at 0.025%). Agrado Plus is a blend of synthetic antioxidants containing ethoxyquin and propyl gallate (Novus International Inc., St. Charles, MO). All pigs were fed a common nursery diet for 7 d post-weaning, and started the experimental diets on d 8. After 7 d, pigs were fed 2-phase commercial diets (d 0–14, d 14–35) with 20% and 30% DDGS, respectively. At the end of the study, one pig per pen was harvested for tissue vitamin E (liver and plasma) and oxidation status measurement. Growth performance (ADG, ADFI, G:F) was not affected by vitamin E, AOX, or their interaction ($P > 0.24$). Dietary AOX increased plasma (33%, $P < 0.01$) and liver vitamin E concentration (30%, $P = 0.04$) regardless of dietary vitamin E level (interaction, $P > 0.17$). Vitamin E concentration in the liver ($P < 0.01$) but not in plasma was linearly increased with dietary vitamin E supplementation. The non-responsive plasma vitamin E might due to transportation stress immediately before harvest. The result suggests that liver vitamin E is a better indicator of vitamin E status than blood vitamin E levels No statistical differences were observed on loin drip loss ($P > 0.26$), plasma free carbonyl ($P > 0.16$), plasma 4-hydroxynonenal (HNE, $P > 0.22$). In summary, AOX spared vitamin E in vivo based on liver and plasma vitamin E concentration, and can be used to spare dietary vitamin E in swine diets fed high DDGS diets.

Key Words: antioxidant, vitamin E, swine

Teaching/Undergraduate and Graduate Education: Graduate and Undergraduate Teaching

586 Gender has a substantial impact on student success in introductory animal science courses. C. G. Jackson*[1], B. J. Williams[2], and E. P. Berg[1], [1]*North Dakota State University, Fargo,* [2]*Hutchinson Community College, Hutchinson, KS.*

The demographic populations of animal science courses at land-grant institutions have changed in the last 20 years. More female and urban students are filling the chairs of agricultural classrooms. The objective of this study was to determine the effect of agricultural background and gender on determining student success in introductory animal science courses. Students enrolled in Introduction to Animal Science 114 (n = 150) and Livestock Production 220 (n = 69) from the spring and fall semesters of 2011 were included in the study. There were more females (n = 134) compared with males (n = 85) and as expected, freshman (n = 93) represented the majority followed by sophomores, juniors, and seniors (n = 56; n = 35; and n = 34; respectively). Each participant completed a survey consisting of 22 questions. Questions pertained to demographic information and their exposure to agriculture during their youth; whether it was participation in 4-H or FFA, showing livestock, or if they grew up on a farm/ranch. More than half of the students grew up on a farm/ranch (n = 127) and were involved in either 4-H or FFA (n = 113). Less than half of the students (n = 75) grew up showing livestock. Females finished the courses with greater semester percentage scores (final grade = 86%) compared with their male counterparts (80%). Female freshman received grades that were greater ($P \leq 0.02$) than both freshman and sophomore males. Additionally, females who participated in 4-H and FFA as well as those who did not performed better ($P \leq 0.05$) than males who were involved in both 4-H and FFA. Furthermore, females who did not show livestock had increased ($P \leq 0.04$) performance compared with males with showing and non-showing experience. Females not from a farm/ranch had greater ($P \leq 0.04$) success than males who grew up on a farm/ranch. Also, non-farm/ranch students had increased ($P \leq 0.03$) performance compared with those who grew up on a farm/ranch. Student gender was the largest factor influencing student success in introductory courses to animal science, for females performed greater than males regardless of agricultural background.

Key Words: animal science, gender, teaching

587 Meeting the changing needs of animal science majors. G. M. Hill* and J. E. Link, *Michigan State University, East Lansing.*

The composition of animal science classes has changed over time. Utilizing response clicker technology, we determined that our introductory animal science course has over 70% freshmen with 55 to 60% of students pursuing an emphasis in pre-veterinary medicine. However, the shift toward veterinary medicine is accompanied by fewer students being raised on farms. Our response technology found that 40% of today's students are from a small town, 20 to 25% are from a large city, and only 15 to 20% are from a farm of over 20 ha. Over 50% of the students reported that the animals they have the greatest contact with are dogs and cats. Hence, large agricultural enterprises are no longer the source of our animal science students. Additionally, we observed that the favorite lab for the past 5 yr was our sheep lab in which students had hands-on experience with the animals. This lab dropped out as the favorite when it was modified to an observation only lab in the spring semester of 2011. To meet the educational needs of this current population, we renovated the course curriculum in the fall semester of 2011 to increase access to livestock and begin early development of basic livestock skills. All labs now involve visits to the university farms and handling either animals or their products (eggs, carcasses, reproductive tracts). Students worked directly with livestock in 71% of the laboratories compared with 7% the previous spring semester. Numerous photos were taken of students' activities to share with family and friends and to serve as study material. Data from one semester of the new curriculum indicated that laboratories with hands-on livestock experience were consistently rated higher than laboratories that were facility tours with limited hand-on experience. Students rated the following lab sessions good or very good for tour vs. hands-on with animals, respectively: dairy: 89 vs. 93, poultry: 66 vs. 86, beef: 81 vs. 94, sheep: 83 vs. 90, swine: 77 vs. 84%. While this type of course takes accessible farms and dedicated managers, it appears that the needs of today's students are being met.

Key Words: undergraduate, livestock, teaching

588 Addressing agricultural and societal issues using a variety of teaching methods. E. L. Walker,* *Missouri State University, Springfield.*

To address societal issues related to agriculture a AGR 399 Animal Welfare Course was designed as a traditional 16 wk lecture type 3 credit hour course at Missouri State University (MSU). However, due to increased demand by place-bound students for quality courses, alternative teaching methods have been implemented. In the fall, 2011, AGR 399 was taught as a combined on-line and traditional 2 1/2 h live lecture course that was broadcast to an additional 5 locations via interactive television. Time was allocated during the lecture portion for invited speakers and discussions directed by student interest. Other than outside speakers, only short, non-formal discussions were planned by the instructor with most discussions being initiated by the students and moderated by the instructor allowing for student directed learning. As part of the online component, 9 PowerPoint lectures along with l notes were posted online using Blackboard 9.1. *Compassion by the Pound* by F. B. Norwood and J. L. Lusk (2011) was used as the text for the course. In addition, students were required to read and discuss assigned articles in 16 graded on-line discussions. One anonymous discussion was initiated so students could voice opinions they felt might not be popular. In total, there were over 1,100 posts from 25 students in a 16 wk period. The 2 reading assignments that generated the most discussion (over 80 each) covered ethics and morality. One was by S. L. Davis (Poult. Sci. 2008) *What Would the World Be Like Without Animals for Food, Fiber and Labor? Are We Morally Obligated To Do Without Them* and the other by J. Hodges (J. Anim. Sci. 2003) titled *Livestock, Ethics, and Quality of Life*. By using a variety of delivery methods, on campus as well as place-bound students have access to the class. In addition, the on-line portion of the class allows for all lectures, quizzes, exams, and homework to be done outside of a regular class period, thus allowing time for invited speakers, discussions over the readings, perusal over current event news headlines, and any topic that the students were deemed important that was related to animal welfare.

Key Words: teaching, distance education, animal welfare

589 Assessing the land-grant mission through undergraduate demographic data: A quantitative approach.

S. Archibeque-Engle* and K. Pond, *Colorado State University, Fort Collins.*

Part of the mission for land grant universities is to serve and represent the state of its location. This analysis was conducted to assess the representation of the state of Colorado by its land grant university and to identify potential talent pools for educated agriculturalists within Colorado. Colorado State University's (CSU) 2010 (n = 696) and 2011 (n = 696) annual fall census data for the Department of Animal Sciences are used and presented here as a model to examine the current situation of the intersection higher education and animal sciences. First, demographics of the undergraduate populations within CSU's Department of Animal Sciences are investigated to determine the current sex and ethnic representation. Second, the current demographics of the department are compared statistically and visually with those of the state of Colorado as a measure of meeting the land grant mission to represent the state. To explore differences statistically, expected frequencies were calculated and a Chi Square Goodness of Fit test was employed to compare the ethnic percentages observed in both 2010 and 2011 for the Department of Animal Sciences undergraduate students to what is expected if the Department of Animal Sciences is representative of the state of Colorado's ethnic demographics. For both 2010 and 2011 the Department of Animal Sciences Latina/o undergraduate representation is significantly lower than expected, $X^2 = 76.6$, $\Phi = 0.33$ and $X^2 = 69.8$, $\Phi = 0.33$; the African American undergraduate representation is significantly lower than expected, $X^2 = 17.1$, $\Phi = 0.16$ and $X^2 = 9.0$, $\Phi = 0.12$; no statistical difference for the Asian/Pacific Islander group was found; for 2010 no statistical difference for the Native American group was found and in 2011, the Native American undergraduate representation is significantly higher than expected, $X^2 = 17.1$, $\Phi = 0.16$. The effect sizes found in this comparison are small to very small and are due to the small numbers of ethnic minority students in CSU's Department of Animal Sciences. In summary, CSU's Department of Animal Sciences is not representative of the ethnic demographics of the state of Colorado.

Key Words: undergraduate education, demographics, land grant

590 Student perceptions of ethics and animal intelligence influenced by introductory animal science course.

A. L. Adams,* G. A. Holub, W. S. Ramsey, and T. H. Friend, *Texas A&M University, College Station.*

Instructors of introductory animal science classes are faced with a wide range of student experiences and perceptions of livestock production practices. This study examined whether these perceptions change as students acquire more knowledge and experience with different species. Students in an introductory animal science course participated in a 26-question pre-course (Pre, n = 310) and post-course (Post, n = 282) survey. Pearson correlation coefficients were used to determine if any associations occurred between responses. Pre and Post responses were analyzed using either the pooled or Satterthwaite *t*-test. Fifty-four percent of participants were first-year undergraduates, 70% were female, and 60% had not been involved in 4-H or FFA. Majority of participants were enrolled in the College of Veterinary Medicine and Biomedical Science (56%) and the College of Agriculture and Life Sciences (30%). Sixty-five percent of participants were interested in pursuing a career in veterinary medicine. Participants had the most experience handling horses (33%), but 30% of the participants had no experience handling livestock. All students considered horses (Pre = 64%, Post = 51%) and swine (Pre = 24%, Post = 44%) to be the most intelligent livestock species ($P = 0.001$). Pre and Post, participants agreed that animals have feelings (94%, $P = 0.76$) and deserve respect from humans (99%, $P = 0.49$). Pre, only 33% of the participants stated that the news media negatively portrays agriculture, whereas, 77% of the participants shared this view Post ($P < 0.0001$). Pre, only 51% of the participants agreed that it is ethical to clone animals, but 77% of the participants agreed with this statement Post ($P < 0.0001$). These results suggest that exposure to livestock production issues and multiple livestock species may influence student perceptions of different livestock species, along with the societal and ethical issues of livestock production.

Key Words: livestock, perceptions, teaching

591 Background experience affects student perceptions of the livestock industry.

A. L. Adams,* G. A. Holub, W. S. Ramsey, and T. H. Friend, *Texas A&M University, College Station.*

Demographic information of students in introductory animal science courses allows instructors to tailor content to student needs and interests. This study compared student demographics with student perceptions of livestock production practices. Students in 2 introductory animal science sections (A: n = 310, B: n = 328) participated in a 26-question pre-course and post-course survey. Pearson correlation coefficients were used to determine if any associations occurred between student responses. Pre-course and post-course survey responses were analyzed using either the pooled or Satterthwaite *t*-test. Both sections were comprised primarily of first-year undergraduate students; a majority was female with either horse experience or no livestock experience. Thirty percent of section A and 58% of section B was enrolled in the College of Agriculture. Sixty percent of section A and 40% of section B had no involvement in 4-H or FFA. Sixty-four percent of all participants were interested in pursuing a career in veterinary medicine. Pre-course, 61% of section A considered horses to be pets, 63% of section B considered horses to be livestock ($P < 0.0001$), 55% of section A stated media portrays agriculture without bias, and 56% of section B stated media negatively portrays agriculture ($P = 0.0004$). Both sections agreed that weather has the greatest influence on producer success ($P = 0.0003$) and genetically-modified foods are safe for consumption ($P = 0.003$), with more variation occurring in section B. Fifty-three percent of section A and 44% of section B believed slaughterhouse practices are inhumane ($P = 0.02$). Post-course, more of section A than section B considered horses as livestock ($P = 0.005$), and both sections agreed that media negatively portrays agriculture, weather has the greatest influence on producer success, genetically-modified foods are safe for consumption, and slaughterhouse practices are humane (all $P > 0.05$). These results suggest that students with no livestock experience may view agriculture differently than students with experience, but more exposure to livestock production issues may challenge students to evaluate their views of agriculture.

Key Words: experience, livestock, student

592 Beef production student instructional video project.

C. L. Pickworth*[1,3] and S. Boyles[2], [1]*The Ohio State University, Wooster,* [2]*The Ohio State University, Columbus,* [3]*North Carolina State University, Raleigh.*

Changes in information technology directly affects today′s beef producers. Developing means to provide fast, accurate information to these producers is a challenge that many extension educators face. To help address this need, students enrolled in the Beef Production II class at The Ohio State University Agricultural Technical Institute were challenged to develop and produce educational videos about basic beef management techniques. Students were randomly assigned to 6 groups and each group selected a topic from a list provided by the Ohio Beef Team extension educators. Students then were responsible for developing a script, filming and editing, the cattle management video. Extension educators worked with students to ensure accuracy of information and the educational value of materials. Student-developed videos were filmed using Flip Cam video cameras and edited with the associated software. Videos were evaluated for value of content, accuracy of information, and quality of visual attributes by the course instructor, extension educators, and peers within the course. Upon completion of the assignment, students were asked to evaluate the effectiveness of the video project. On a scale of 1 to 6 (1 = improved understanding or agree, 6 = detrimental to understanding or disagree), students favorably evaluated the educational value of this team video project. This project helped enhance teamwork (1.54 ± 0.78), knowledge of beef industry (1.62 ± 0.87), understand the difficulty of communicating beef management tasks (1.38 ± 0.51), and was valuable to the course (1.38 ± 0.65). Greatest limitations of the project included access to video cameras, inability to merge separate video and audio files, and having ample time for extension educators to review video clips before final video was developed. Copyright of the videos were provided to The Ohio State University by the students to allow extension educators the ability to use the movies they created in part or whole for extension education. Engaging students in video production on beef cattle management techniques can connect students with extension educators and enhance extension education resources.

Key Words: beef production, extension education, video

593 Integrated program for reducing bovine respiratory disease complex (BRDC) in beef and dairy cattle, coordinated agricultural project (CAP): overview of the teaching program. M. G. Thomas*[1], G. R. Hagevoort[2], T. T. Ross[2], R. M. Enns[1], H. Van Campen[1], A. L. Van Eenennaam[3], H. L. Neibergs[4], C. Chase[5], S. V. Dindot[6], N. D. Cohen[6], and J. E. Womack[6], *[1]Colorado State University, Fort Collins, [2]New Mexico State University, Las Cruces, [3]University of California, Davis, [4]Washington State University, Pullman, [5]South Dakota State University, Brookings, [6]Texas A&M University, College Station.*

Bovine respiratory disease complex is a common cause of morbidity and mortality in cattle, especially young animals exposed to stress. This disease is considered a complex because of numerous involved pathogens. The research objective of this CAP is to use genomic approaches to identify host chromosome regions associated with susceptibility to BRDC and then translate results to beef and dairy industries via selective breeding tools and increased awareness of the need for disease prevention and management (http://www.brdcomplex.org/). The translational effort is supported by teaching and extension efforts. Objectives of the teaching effort include: 1) develop 2 nationally accessible distance-learning courses on the integration of animal health management with genomic and animal breeding approaches (i.e., Improvement of BRDC Resistance and Animal Health and Genetic Approaches to Disease), 2) develop an undergraduate summer research internship program, 3) develop a veterinary feedlot and dairy internship program, 4), sponsor graduate and undergraduate students to attend the Southern Great Plains Dairy Consortium-Teaching (SGPDC-T), where research components of the project are ongoing, and 5) develop 4-H curriculum to expose and train youth on animal disease using BRD as an example application. The educational component of this CAP is greatly assisted because its activities are organized with infrastructure of established and collaborating programs, SGPDC-T; (http://sgpdct.tamu.edu/) and Breeding and Genetics Graduate Education Online (http://bggeo.iddl.vt.edu/). The internship programs are integrated with the research program as students are involved in animal and tissue sampling and data collection. This CAP is in the second year of a 5-year effort and welcomes additional student participation, especially students from under-represented minorities. In summary, the education component of the BRDC-CAP (USDA-AFRI 2011–68004–30367) is developing and offering distance and experimental multi-disciplinary learning approaches for undergraduate, graduate, and veterinary students studying BRDC.

Key Words: cattle, disease, genomics

594 Why your school should host a Block and Bridle National Convention. M. W. Orth,* *Michigan State University, East Lansing.*

Good communication, leadership, and problem solving skills are qualities we desire to see mature in our students. In the classroom, mastering disciplinary content is the primary objective. However, extracurricular activities such as clubs can facilitate the development of soft skills. In animal science departments, Block and Bridle (at some schools Saddle and Sirloin) is the club that includes students with interests in several livestock species. Besides participating in many local activities, each year a school or group of schools will host a National Convention that is open to all clubs across the country. Getting schools to commit to the undertaking has been difficult in the past few years. Michigan State University hosted the National Convention in the fall of 2010 for the first time in its history. Hosting a convention requires a tremendous amount of energy over several months. They are expensive to fund and require a lot of coordination with a very diverse group of people. However, the benefits for the students are well worth the effort. Organizing a convention requires a wide range of activities to make it successful. Students at Michigan State had to develop written materials, such as a sponsorship brochure and convention program, organize bus tours all around the state, stock buses with food and drinks before 6 a.m., and resolve conflicts quickly to name a few. Two unexpected benefits were the greater involvement of members in the club throughout the entire year and the initiation of the Sparty Farm Fresh Tour, a one-day bus tour designed to expose new students to animal agriculture in Michigan. With employers putting a greater emphasis on soft skills in hiring decisions, animal science departments must encourage activities to develop those skills. Hosting a Block and Bridle National Convention is one extremely effective activity that will help prepare a large number of students for their future professions. Additionally, it will showcase agriculture in your state and provide a lot of lasting memories.

Key Words: soft skills, block and bridle, student development

595 Enhancing the student learning experience through an undergraduate research program. E. L. Karcher* and N. L. Trottier, *Department of Animal Science, Michigan State University, East Lansing.*

Between fall 2009 and 2011, enrollment in the Department of Animal Science at Michigan State University (MSU) increased by 11.6%. This increase was accompanied by curricular change including a requirement for undergraduate students in Animal Science to participate in an experiential learning activity. Based on a perceived growing interest in undergraduate research, the Animal Science Undergraduate Research Student Association (ASURSA) was established in fall 2009. Three main learning outcomes were identified: 1) to engage students in annual group undergraduate research projects, 2) to increase general understanding and proficiency of the scientific method, and 3) to provide a forum for professional and social interaction. In spring and fall 2011, club members were identified to work with advisors to formulate a proposal and serve as project managers. Students submitted multiple grant applications and were successfully awarded $10,950 in funding.

During this process, bi-weekly club meetings were used as a forum to discuss the rationale for the project, steps of the scientific method, and discussions on the importance of animal care and use forms. In spring 2011, 18 ASURSA members conducted the first research project at the MSU Poultry Teaching and Research Center. In January 2012 a second study involving 29 members was initiated at the MSU Dairy Teaching and Research Center. Project managers were responsible for leading discussions at club meetings. Discussion topics included nutrition and diet formulation, rationale behind key laboratory techniques, and project updates. Communication of results included presentations by students at MSU and scientific meetings and submission of an article to *Poultry Science*. In addition to research, members host the MSU Animal Science Undergraduate Research Forum. This forum, initiated in 2009 by club members, offers students conducting research in animal science an opportunity to present their work to both students and faculty. In conclusion, the development of an undergraduate animal science club focused on research has offered a unique opportunity to engage a large number of students in research. This coincides with a time of increased student enrollment and increased desire by students to participate in undergraduate research.

Key Words: education, undergraduate research, experiential learning

596 Implementation of a capstone experience requirement in animal and poultry sciences. C. M. Wood,* D. M. Denbow, E. A. Dunnington, and R. K. Splan, *Virginia Tech, Blacksburg.*

Beginning with the graduating class of 2011, undergraduates in the Department of Animal and Poultry Sciences at Virginia Tech must complete a 2-credit capstone experience within 45 credits (3 semesters) of graduation. Each capstone experience is unique to the student who designs it in consultation with faculty. Specific learning objectives include: 1) using critical thinking skills to acquire, analyze, interpret, and integrate information from a variety of sources; 2) solving problems in authentic or realistic situations; 3) planning and completing a project pertaining to each student's discipline and field; 4) demonstrating verbal, visual, and written communication skills; 5) contributing to a team effort; 6) assessing and describing potential contributions to society; and 7) effectively competing for career and/or post-baccalaureate opportunities. An outline of the approval process was presented by Wood et al. (2008). The first proposals were approved in fall 2009. To date, 211 proposals have been approved; 55 of those are in progress and scheduled to be completed by May 2012. Internships (35% of the total) are more popular in the summer whereas formal courses (27%) are chosen most often in the spring semester. Independent studies (13%), undergraduate research (14%), and study abroad (7%) make up most of the rest. Some students (n = 7) fulfill the requirement through a semester spent in the equine program at the Middleburg Agricultural and Research Center in northern Virginia. Almost half the students participate in a poster symposium, held on campus fall and spring semesters, that highlights their accomplishments. Grades assigned by on-site supervisors are mostly A's but a few have assigned C's and D's. Analysis of student perceptions (n = 66 students) indicated that 97% of those completing an internship achieved at least 5 of the 7 learning objectives; 49% achieved all but one and 30% achieved all 7. With more than 450 APSC majors, the challenges presented by this new requirement are many but are outweighed by the tremendous opportunities for student growth.

Key Words: undergraduate education, experiential learning, capstone experience

597 The Graduate Experience Program: An opportunity for undergraduates to explore graduate study. E. L. Berg*[1], A. M. Meyer[2], and L. A. Lekatz[1], *[1]North Dakota State University, Fargo, [2]University of Wyoming, Laramie.*

The objective of the Graduate Experience Program (GEP) at North Dakota State University (NDSU) is to give undergraduate students the opportunity to explore graduate study in the animal sciences and provide mentorship opportunities for graduate students. This class is modeled after a course developed at the University of Missouri in 2006. Admittance into the class is dependent on an application and recommended GPA $\geq$3.0 and junior standing. Class discussion topics include research areas in animal sciences, the land-grant mission, searching for graduate programs, graduate program structure, professionalism, scientific reading and writing, and career options with an advanced degree. Undergraduates are paired with a graduate student mentor for one-on-one dialog and participation in their research. In addition, undergraduates are required to attend departmental seminars, complete a graduate school application, discuss a journal article, and present their future plans as a final project. Graduate student mentors are expected to explain research methods and lab techniques, keep mentees informed of research opportunities and be accessible to their mentees. Since inception of the course in 2009, 19 undergraduate and 13 graduate students have participated during 4 semesters. When asked to rate the overall quality of the course from very good (5) to very poor (1), the average response from undergraduates (n = 18) over 4 semesters was 4.1. When asked if they would recommend this course, the average response was 4.4 (strongly agree = 5; strongly disagree = 1). All students agreed that GEP was helpful in their decision to pursue or not pursue graduate study. Of the 19 undergraduates who participated, 37% (n = 7) are still completing their B.S., 26% (n = 5) are currently enrolled in animal science graduate programs, 26% (n = 5) are working in animal science-related industry jobs, 5% (n = 1) are working in non-animal science jobs and 5% (n = 1) are in veterinary school. In conclusion, the GEP helped NDSU students in the decision making process regarding pursuit of graduate school, as well as encouraged them to consider graduate study in the animal sciences.

Key Words: undergraduate, graduate

WSASAS Symposium: Growing Beef Cattle: The future of stocker/backgrounding systems in beef production

598 Improving the production, environmental, and economic efficiency of the stocker cattle industry in the Southeastern United States. P. Beck*[1], M. Anders[2], B. Watkins[2], S. Gunter[3], D. Hubbell[4], and S. Gadberry[5], *[1]University of Arkansas, Southwest Research & Extension Center, Hope, [2]University of Arkansas Rice Research & Extension Center, Stuttgart, [3]USDA-ARS Southern Plains Range Research Station, Woodward, OK, [4]University of Arkansas Livestock & Forestry Research Station, Batesville, [5]University of Arkansas Cooperative Extension Service, Little Rock.*

Grazing small-grain forage can be a profitable "2nd crop" for grain producers and an opportunity for retained ownership for cow-calf producers. The costs of conventional tillage and movement of soil nutrients into streams and water ways creates a need for sustainable production practices. Systems research at the Livestock and Forestry Research Station near Batesville, AR and the Southwest Research and Extension Center near Hope, AR has been conducted over a 9-yr span to characterize the effects of pasture systems on forage production, animal performance, soil quality, water runoff, and economics of stocker cattle enterprises. Compared with both bermudagrass or toxic endophyte-infected tall fescue, gains of growing cattle are increased by 80% with non-toxic endophyte-infected tall fescue and 150% with small-grain forages. Producers with spring-calving cowherds can utilize these improved forages to accelerate stocker programs with retained calves. Economic analysis indicates a 99% improvement in net returns for producers retaining ownership of calves with these production systems. Rainfall simulation indicates that runoff volume and nutrient load does not differ between conventionally tilled fields and no-till fields in the spring before tillage when surface cover is similar. In the fall following tillage operations conventionally tilled fields had 4-times greater runoff, 1.9-times greater N, and 3.2-times greater P leaving the field in runoff compared with no-till. Total natural rainfall runoff from conventionally tilled wheat fields were 2-times greater than that from no-till fields with 2.5 cm rainfall events yet were 4-times greater with 6.25 cm rainfall events. Soil analysis shows that soil aggregate content was greater in no-till compared with conventional till, indicating greater soil porosity, improved water infiltration rate, and reduced erositivity of soil. Carbon content of no-till soils was 50% greater than conventional tillage indicating increased C sequestration. Together these studies show that production systems can be designed that provide improved production economics, increase soil quality and C sequestration, and reduced nutrient loads of streams and water ways that also do not decrease productivity of pastures.

599 Growth, development, and the expression of genes in marketable tissues. P. A. Lancaster*[1], E. D. Sharman[1], M. A. Vaughn[2], C. R. Krehbiel[1], G. W. Horn[1], J. D. Starkey[2], and U. DeSilva[1], *[1]Oklahoma State University, Stillwater, [2]Texas Tech University, Lubbock.*

Increasing adipose tissue development during the stocker phase of production could increase value and efficiency of beef cattle production. Our objective was to evaluate rate of gain on growth and development of adipose tissue, and skeletal muscle characteristics in growing cattle. Two experiments were conducted where Angus cross-bred steers were grown on winter wheat pasture or dormant native range to achieve divergent rates of gain. A subset of steers was harvested at similar age (Exp. 1) or BW (Exp. 2) at the end of the stocker phase. During the stocker phase, ADG ranged from 0.19 to 1.37 kg/d in Exp. 1 and 0.49 to 1.41 kg/d in Exp. 2. At the end of the stocker phase, steers were fed a common finishing diet to a rib fat thickness of 1.27 cm. In Exp. 1, marbling score at intermediate harvest increased linearly with ADG, whereas rib fat thickness increased at an increasing rate. In Exp. 2, there was not a strong relationship between ADG and marbling score or rib fat thickness. In Exp. 1, there was no treatment × adipose tissue interaction for lipogenic gene expression indicating that each adipose tissue responded similarly to the treatments. Lipogenic gene expression increased with increasing ADG. There was a significant ($P < 0.05$) treatment × adipose tissue interaction for adipogenic gene expression, with no difference in subcutaneous adipose tissue (SC), but in intramuscular adipose tissue (IM) PPARγ mRNA expression increased and DLK1 mRNA expression decreased with increasing ADG. In contrast to Exp. 1, there was a treatment x adipose tissue interaction for both lipogenic and adipogenic gene expression in Exp. 2, where expression of FASN and PPARγ mRNA expression increased with increasing ADG in SC, but not IM. In Exp. 2, low rates of gain tended to increase satellite cell differentiation, Type 1 (oxidative) muscle fibers, and capillary density, as well as final marbling scores. These data indicate that rate of gain to similar BW affects metabolic pathways in SC and IM differently than rate of gain to similar age, and that low rates of gain result in skeletal muscle characteristics that are more favorable for marbling deposition.

Key Words: adipose tissue, growth rate, stocker cattle

600 Opportunities for grazing cattle systems. J. C. MacDonald*[1,2] and F. T. McCollum[3], *[1]Texas AgriLife Research, Amarillo, [2]West Texas A&M University, Canyon, [3]Texas AgriLife Extension, Amarillo.*

Yearling production systems serve several purposes in the beef cattle industry. Utilizing grazed forage resources to grow stocker cattle spreads the feeder calf supply across the calendar year from a national calf crop that is largely fall-weaned. Grazed forage resources have historically reduced the cost of gain over the lifetime of a feeder calf. Yearling production systems allow producers to fully utilize forage resources while providing flexibility to stock and manage grazed forages. Finally, yearling systems have increased beef supply by increasing carcass weights relative to feeder cattle entering the feedlot at lighter BW. Dynamics of agricultural enterprises have changed over the past decade and present new challenges and opportunities for yearling production systems. The size of the national cow herd has declined which increases competition for feeder calves. Volatility of commodity prices has increased which exposes producers to greater risk and often narrower margins. Increasing societal awareness of agricultural production practices will cause more scrutiny of the industry. However, the functional role of yearling operations in the US beef industry has not changed. The supply of byproduct and alternative feeds provides opportunities to increase production while cattle are grazing. The reduction in cow inventory may result in increased forage resources available for yearling systems, as well as the need for feeding entities to capture future supplies of feeder calves. Increased cooperation between the stocker and finishing segments may be the result. New information will be required to ensure the future success of these production systems. The upper BW limit of stocker cattle entering the feedlot has been discussed, but not clearly defined. Residual effects of stocker management on feedlot performance and beef quality will increase in importance. The age old issue of compensatory gain and body composition at feedlot entry will need to be clearly defined.

Despite reduced inventories relative to feeding capacity, higher feed commodity costs, relatively lower costs for grazing, and the continued need to spread the harvest of finished cattle across the year will ensure the role of stocker production in the future.

Key Words: grazing cattle, yearlings, beef production systems

601 Opportunities for drylot backgrounding systems in the beef industry. B. P. Holland,* *Department of Animal Science, South Dakota State University, Brookings.*

Traditional feedstuff prices, with roughages costing a premium to grains on an energy basis, resulted in the proliferation of cattle feeding and reduced the placement weight of cattle in feedlots. However, recent increases in the cost, and price volatility, of feedstuffs, inputs, and feeder cattle have put a strain on commercial feeders. Although roughage-based backgrounding and grazing programs often result in decreased G:F in subsequent finishing, increasing the weight of feeder cattle through backgrounding results in decreased days on feed and a potentially more economical system. In some scenarios, cattle can be grown on higher-roughage, lower-energy diets at a cost-competitive advantage to high-concentrate feeding. This is especially true in situations where a significant portion of feed is produced on-site and does not require outside purchase. Improvements in plant varieties allow the production of higher yield and quality forages for lower costs, and some available by-product feeds seem to have positive associative effects with roughages. These factors, combined with cattle that have superior growth potential, allow for high rates of gain on relatively low quality feeds. Traditional wisdom may have suggested purchasing feeder cattle with less condition, hoping to achieve compensatory growth in the feedlot. Because of this, there is a perceived upper gain limit for backgrounding cattle. However, in recent studies, fatter steers entering feedlots have been more efficient during finishing. This may be be indicative of backgrounding diet and intake having more impact on feedlot performance than empty body fat. As a result, the acceptable ADG range for backgrounding programs is increased. Viability of feedlots will depend on a steady supply of feeder cattle, and a greater flexibility by backgrounders to produce feeder cattle will reduce inefficiencies and risk associated with keeping lots full. This paper will highlight potential scenarios in which drylot-based backgrounding programs can fit into the beef industry.

POSTER PRESENTATIONS
Animal Behavior and Well-Being: Behavior Emphasis

W1 Ruminal fermentation and behavior in Simmental heifers fed TMR with non-forage fiber sources in feedlots. S. P. Iraira,* J. L. Ruíz de la Torre, M. Rodríguez-Prado, X. Manteca, S. Calsamiglia, and A. Ferret, *Universitat Autònoma Barcelona, Bellaterra, Spain.*

The objective of this experiment was to determine the effects of non forage fiber sources on rumen fermentation and behavior of heifers fed TMR. Eight rumen cannulated Simmental heifers (initial BW 313 ± 13.2 kg) were randomly assigned to 1 of 4 treatments in a 4 × 4 double Latin Square design. The experiment was performed in 4 28-d periods. Treatments were barley straw (BS), soybean hulls (SH), beet pulp in pellets (BP) and whole cottonseed (WCS). Fiber ingredients were incorporated at 10, 16, 17 and 17% (DM basis) in BS, WCS, SH and BP, respectively. Diets were isoenergetic and isonitrogenous and were offered ad-libitum as TMR. Each heifer was individually housed in a roofed pen. Feed offered and refusal samples of each heifer were collected over 7 d in the last week of each experimental period to determine DM intake, chemical composition and particle size. Particle size separation was performed using the Penn State Particle Separator. On d 28 of each period, rumen samples were taken immediately before feeding and at 4, 8, 12, 16, and 24 h after feeding. Behavior was video-recorded for 24-h on d 2 and d 6 of each experimental period. NDF intake and ruminal pH were statistically analyzed using the MIXED procedure and behavior activity using the GLIMMIX procedure, both in SAS. NDF intake was higher in WCS than in BS (1.4 vs 1.3 kg/d; $P = 0.001$). Proportions of offered particles that were greater than 8 mm were 15.3, 6.1, 23.0 and 36.9% for BS, SH, WCS and BP, respectively. Average rumen pH was 5.87 in SH and 6.32, on average, in BS and BP ($P = 0.006$), but there were no differences between SH and WCS (6.20, on average).Time spent chewing was higher ($P = 0.001$) in BS and WCS (355 min/d, on average) than in SH and BP (252 min/d, on average). Time spent doing tongue-rolling in BP (16.8 min/d) tended to be higher than in the other 3 treatments (3.4 min/d, on average; $P = 0.069$) and no differences were found for licking or biting the fixtures. In conclusion, SH affected ruminal fermentation and BP tended to increase stereotypies when used as fiber sources in feedlot diets.

Key Words: cattle behavior, non-forage fiber, ruminal pH

W2 Foraging behavior of beef cows grazing native grassland: Effect of herbage allowance on temporal and spatial grazing patterns. S. Scarlato*[1], M. Carriquiry[1], M. Do Carmo[1], A. Faber[1], C. Genro[3], E. Laca[2], and P. Soca[1], *[1]Unviersidad de la República, Paysandu Uruguay, [2]University of California, Davis, [3]Embrapa, Bage, Bage, RS, Brazil.*

A 2-year study was conducted on a native grassland located in South America, to quantify grazing and ruminating times and patterns of spatial use in beef cows grazing at 2 herbage allowances (HA; 4 and 2.5 kg DM kg-1 BW, for high and low, respectively) in a completely randomized block design (Block 1: Hereford and Angus purebred cows and Block 2: their F1 crossbred cows). Sixteen cows (n = 4 for HA and block) were assigned to 4 plots, remaining there in a continuous grazing system. The Put-and-take method was used monthly to adjust HA. Grazing and ruminating times were recorded over 24-h period using IGER recorders for 3 consecutive days. Location (bottom, toe slope and shoulder slope zones) of cows within the plot during grazing activity was recorded by direct observation during daylight hours, and a relative preference index (RPI) was used to quantify preference for each zone. Recording periods were: spring 2007, 2008, and 2009, autumn 2008, and winter 2008 and 2009. Mean daily grazing and ruminating times were 738 ± 27 and 453 ± 26 min, respectively. Grazing activity was largely diurnal with 2 main sessions, one in the morning and another in the afternoon. Daily grazing time was greater ($P \leq 0.047$) for low than high HA cows in spring and autumn, which could indicate a compensatory mechanism for reduced HA but also for the less forage mass and height. Daily ruminating time decreased ($P \leq 0.044$) for low than high HA cows in spring, autumn and winter, suggesting a reduced DM intake, and showing constraints to compensate for limitations imposed by pasture in low HA. In general, the RPI for plot zones were not affected by HA ($P > 0.05$) but were affected by session ($P \leq 0.005$). During the afternoon grazing session, cows grazed in the shoulder slope zone ($P \leq 0.002$), with greater forage mass availability, while during morning grazing session, the bottom zone, close to the water source, was preferred ($P \leq 0.005$). This spatio-temporal behavior pattern may indicate an attempt to maximize intake before dusk, through increasing intake rate, minimizing the risk of predation. Quantifying spatio-temporal behavior of grazing ruminants in heterogeneous environments may help to improve livestock systems by integrating behavioral principles and processes into management practices.

Key Words: beef cow, grazing behavior, native pasture

W3 Feeding behavior of grazing buffalo calves fed different types of supplement in tropical conditions. R. M. Patiño,* L. G. Altahona, and L. M. Botero, *University of Sucre, Sincelejo, Colombia.*

The objective of this study was to evaluate the effect of different types of supplementation on feeding behavior of buffalo calves grazing in tropical conditions. Thirty Murrah calves, with average initial BW of 65 ± 1.97 kg, were assigned to 3 treatments, in a completely randomized design. One group received mineral supplementation, another group mineral and concentrate (0.5% BW) supplementation, and the third group remained as control, without supplementation. The animals grazed a pasture of Canutillo grass (*Hymenachne amplexicaulis*). After the adaptation period, animals were individually identified and their feeding behavior (idling, ruminating and grazing) was observed using visual method from 0800 to 1700 h, every 5 min, during 12 d, in a period of 60 d. Watering, consuming supplement and suckling times were measured using stopwatch. The animals were weighted every 15 d. The daily time spent in each behavior was analyzed considering the effect of the type of supplement (Table 1). The animals supplemented with mineral mixture and concentrate had a greater ($P < 0.05$) average of daily gain (0.547 kg) compared with mineral mixture treatment (0.388 kg) and the control group (0.320 kg). Drinking water time was not affected ($P > 0.05$) by the type of supplementation. The other activities were affected ($P < 0.05$). The animals supplemented with mineral mixture and concentrate spent more time ($P < 0.005$) to feed intake (grazing, suckling and consuming mineral mixture), that explained the best weight gain.

Table 1. Means of behavior (min/d) of buffalo calves under grazing and supplementation

Behavior	Nonsupplement	Mineral mixture	Mineral mixture and concentrate	SEM	P-value
Grazing	299.3^a	336.3^b	356.0^b	5.656	<0.0001
Ruminating	312.8^a	261.8^a	253.8^b	8.286	0.005
Idling	640.3^{ab}	663.5^a	597.5^b	9.749	0.017
Suckling	7.0^a	3.5^a	15.3^b	1.345	0.001
Watering	6.3^a	3.5^a	7.3^a	0.784	0.129
Consuming mineral mixture		8.3	13.8	1.005	<0.0001

^{a,b}Means within a row followed by the same letter do not differ ($P > 0.05$) by Tukey test.

W4 Effects of housing systems on behavioral responses of newborn Holstein calves.

S. V. Matarazzo*[1], T. T. Fonseca[1], J. R. P. Arcaro[2], F. P. Campos[2], and S. A. de A. Fernandes[3], *[1]Universidade Estadual de Santa Cruz, UESC, Ilhéus, BA, Brazil, [2]Instituto de Zootecnia de Nova Odessa, Nova Odessa, SP, Brazil, [3]Universidade Estadual do Sudoeste da Bahia, Itapetinga, BA, Brazil.*

The objective of this research was to evaluate the effects of housing systems on behavioral responses of newborn Holstein calves. The experiment was carried out from October to December 2006. Twenty female Holstein calves, 1-mo old and 46.2 ± 7.0 kg of body weight were randomly assigned to the treatment groups. Treatments were: individual shelter with 0.9 m wide, 1.2 m tall and 1.1 m long covered with recycled tiles maintained in pasture or individual hutch with located at 0.5 m above the floor with 0.9 m wide, 0.9 m and 1.1 m long maintained inside the barn. Calves received 4 L of milk a day, divided into 2 meals (8am and 3pm). Shelters were provided with individual enclosures for provision of concentrated and hay, which were offered ad libitum. The behavioral patterns activities (standing or lying down, rumination, resting, drinking, eating) were evaluated once a week from 8:00am to 8:00pm. Time spent standing up was higher (41%) in calves of individual shelter in relation to individual hutch (22%). Due to space limitation, animals probably chose to spend more time laying down (78%) for overcoming the uncomfortable situation and even to avoid traumas and other physical damages. On the other hand, animals kept in pasture were tightened to a chain, which allowed them to move around, either searching for shadow, exploratory behavior or grazing. There was no difference among calves from the different treatments in terms of time spent in rumination (23%), eating (8%) or drinking (3%). Resting time of calves in individual cage was higher (51%) than those of individual shelter (43%). Probably, the reason this time lasted longer for animals inside barns was because space and environmental restriction. Once time consumed with other activities is concerned, this was more intense (24%) for animals in individual shelters in pasture than for animals in hutches (14%). These activities were related to elimination activities, exploratory behavior, such as grazing around the shelter, which could only be observed for the last group of animals, besides stereotypical behaviors, such as biting, grabbing, hit the head, typical of animals in hutches.

Key Words: newborn, welfare, housing systems

W5 A preliminary study on the behavior of rodeo animals just prior to bucking events.

E. A. Pajor*[1], T. Grandin[2], G. B. Bond[1], and C. Goldhawk[1], *[1]University of Calgary, Calgary, Alberta, Canada, [2]Colorado State University, Fort Collins.*

Animals are used in numerous types of competitions. Many animal owners describe their animals as enjoying and anticipating these competitions. Despite these assurances, many criticize such animal use and claim that animals experience fear and mistreatment. In fact, there is very little empirical evidence to support either claim. One of the most criticized competitive events is rodeo. The purpose of this preliminary study was to describe the behavior of animals before bucking events at a rodeo. Direct observations were carried out by 5 trained observers at a national rodeo between July 11 and July 17, 2011. Animals were observed over 3 bucking events, bareback (n = 48 horses), saddle bronc (n = 57 horses), and bull riding (n = 48 bulls). Behaviors quantified were those associated with frustration and arousal (eye white, tail swishing, defecation) and escape behaviors (kick, paw at ground, move back and forth in chute). The period immediately before performance was divided into 3 separate time periods, loading the chute, tacking up, and mounting the animal. Only descriptive results are presented. Bareback horses and saddle bronc horses responded in a similar fashion and are grouped as horses. Horses tended to kick more than bulls (45% compared with 15%), while bulls tended to show more eye white than horses (45% vs. 40%). Horses performed more behaviors associated with arousal and escape while being loaded in the chute and during tacking up than when being mounted, 45% vs. 20% of the animals. Bulls were more aroused when being mounted than when loading (40% vs. 15%). Mounting animals involves not just the cowboy but numerous individuals in close proximity to the bull. It is not clear if animals are responding to the upcoming performance or the presence of large groups of people to which they are unaccustomed. This preliminary study suggests that although some animals were aroused and demonstrated escape behaviors, the majority of animals were calm and showed little arousal before leaving the chutes. Additional results will be presented at the meeting. This study is one of the first to describe the behavior of rodeo animals before the event.

Key Words: behavior, welfare, rodeo

W6 Determining the effects of castration with or without analgesia on growth performance, hematology, and behavior in neonatal beef cattle.

A. C. Brown*[1], J. G. Powell[1], M. S. Gadberry[2], E. B. Kegley[1], J. T. Richeson[3], J. L. Reynolds[1], and Y. V. Thaxton[1], *[1]University of Arkansas Division of Agriculture, Fayetteville, [2]University of Arkansas Division of Agriculture, Little Rock, [3]West Texas A&M University, Canyon.*

Angus-cross bull calves (n = 61) were weighed within 72 h of birth and assigned randomly to 1 of 3 treatments. Treatments were surgical castration, oral administration of meloxicam (1 mg/kg of BW) followed by surgical castration, or bulls remained intact (control). Subsets of 7 calves/treatment for castrates and 15 calves that remained intact were selected randomly and calf standing and lying activity was monitored by recording x and y-axis positions of a datalogging accelerometer attached to a leg for 7 d, in addition blood was collected on d 0, 1, 3, and 7. Calves were weighed every 28 d through d 112. Body weight did not differ between treatments ($P \geq 0.74$). Castrated calves receiving meloxicam tended ($P = 0.06$) to have greater % neutrophils and lower % lymphocytes on d 7 compared with castrates that had not received meloxicam (treatment × day, $P < 0.02$). Hematocrit was greater ($P = 0.02$) in bulls on d 1 than in calves castrated without analgesic (treatment × day, $P = 0.03$). The XY plots from accelerometers revealed 3 distinct clusters of data and cluster analysis within calf was used to categorize observations into 3 clusters. Clusters (C) were determined to represent lying flat on side (C1), standing (C2) and lying (C3). Proportion of time expressed in C1, C2, and C3 was 0.36, 0.23, and 0.41, respectively. Proportion of daily activity expressed as C1 differed among treatments over time ($P = 0.05$); however, test of simple effects by day indicated no treatment differences on most days with the exception of d 5 where castration at birth with analgesia differed from castration without analgesia and non-castrated calves ($P < 0.01$). Proportion of time expressed as C3 was 0.38, 0.40, and 0.42 (SE 0.01) for castrated with analgesia, castrated without analgesia, and non-castrated, respectively; and differed for castrated compared with non-castrated ($P < 0.01$) and tended to differ for castrated calves given analgesia vs. those without analgesia ($P = 0.08$). Over the 7 d period following neonatal castration, use of pain control at the time of surgery had minimal effects on time spent standing and lying.

Key Words: castration, meloxicam, analgesia

W7 Pain and pessimism: Dairy calves show negative bias in judgment tasks following hot-iron disbudding. H. W. Neave,* M. A. G. von Keyserlingk, and D. M. Weary, *University of British Columbia, Vancouver, BC, Canada.*

Cognitive bias tasks involve interpretation of ambiguous stimuli. Depressed or anxious humans are known to judge ambiguous events negatively, and recent work on animals suggests that judgment bias can also provide a method of assessing emotions in non-human animals. No previous work has applied cognitive bias testing in cattle, and none has used judgment bias as a method of pain assessment. We assessed cognitive bias in dairy calves before and after hot-iron disbudding. Previous work has shown that calves experience pain for at least 24 h after this procedure. Holstein dairy calves (n = 8) were trained using a go/no-go task to expect positive (a milk reward) or negative (a time-out with no opportunity to access milk) outcomes following nose contact with a video screen that was either white or red; calves were alternatively assigned white or red as the positive training stimulus, and the opposite color as the negative training stimulus. Once calves had learned to discriminate between these 2 training stimuli (at least 90% correct over 3 consecutive training sessions), they were tested with unreinforced probes (screen colors at 25%, 50%, and 75% red) introduced randomly within training sessions. Probes were presented in sessions 1 d before and 1 d after disbudding. Calves approached the ambiguous probe screens less frequently after disbudding (78.1 ± 9.8, 31.3 ± 11.8, 2.5 ± 2.5% for the probe most similar to the positive screen, the mid-way probe, and the probe most similar to the negative screen, respectively) compared with before disbudding (84.6 ± 6.1, 48.7 ± 9.9, 18.5 ± 4.4%), a difference that was most pronounced for the probe closest to the negative screen. These results illustrate that calves experiencing pain during the hours after hot-iron disbudding interpret ambiguous stimuli negatively compared with before disbudding. This “pessimistic” bias supports the use of a cognitive bias task as a measure of emotional state, including pain, in dairy calves.

Key Words: animal welfare, cognitive bias, animal emotion

W8 The effect of previous experience on the adaptation to headlocks by Holstein dairy cows. P. D. Krawczel* and J. M. Hale, *Department of Animal Science, University of Tennessee, Knoxville.*

Moving dairy cows into new facilities requires an adaptation to novel environments. The objective of this study was to determine differences in behavior following the delivery of TMR between lactating cows with or without previous experience using headlocks. Forty-four Holstein dairy cows, from 3 different facilities, were assigned to 4 pens (n = 11 per pen) within a new facility using headlocks as the only feed barrier. Two pens comprised naïve cows (originating from facilities using only post-and-rail feed barriers; parity = 1.0 ± 0.0; body weight = 525.2 ± 13.5 kg; DIM = 234 ± 8; milk production = 25.8 ± 0.2 kg per d) and 2 pens comprised of experienced cows (originating from a facility with only headlock feed barriers; parity = 1.4 ± 0.1; body weight = 661.2 ± 22.1 kg; DIM = 328 ± 11; milk production = 18.6 ± 0.2 kg per d). Their response was assessed from the mean percentage feeding, lying, standing in the feed alley, or other using 10-min scan samples collected via direct observation. Data were collected during 2 h after the morning and afternoon delivery of feed for 7 d. Data were log-transformed (back transformed means reported) due to lack of normality and analyzed with the mixed procedure of SAS using repeated measures. More naïve cows engaged in feeding (47.3 ± 1.0%) than experienced cows (29.4 ± 1.0%; $P < 0.001$). However, a greater percentage of experienced cows engaged were lying (48.3 ± 1.0) and standing in the alley (15.4 ± 1.0%) relative to the naïve cows (lying = 20.9 ± 1.0% ($P < 0.001$) and standing = 13.7 ± 1.0% ($P = 0.02$)). Experience level had no effect on other behavior ($P = 0.71$). The initial hypothesis, previous experience would benefit cows (indicated by a greater percentage of cows feeding and a lower percentage standing in the feed alley following the delivery of TMR), was rejected. Experienced cows and naïve cows behaved differently following introduction to headlocks, but there was no indication of a benefit from previous experience. This suggests other factors may be more important during adaptation to novel environments.

Key Words: dairy cow, behavior, adaptation

W9 Lying behavior of lactating dairy cows is influenced by lameness especially around feeding time. C. Yunta*[1], I. Guasch[2], and A. Bach[1,3], *[1]Department of Ruminant Production, IRTA, Caldes de Montbui, Barcelona, Spain, [2]La Pirenaica, La Seu d’Urgell, Lleida, Spain, [3]ICREA, Barcelona, Spain.*

Lameness is considered one of the most common welfare and productive problem in dairy cattle. The objective of this study was to evaluate differences in lying behavior between lame and non-lame lactating cows under commercial conditions. Data were collected from 10 different free-stall commercial herds, which were feeding exactly the same ration once daily. All lactating cows were scored for lameness according to a 1–5 locomotion scoring system. Only cows with a lameness score between 1 and 4 were considered in the study. In each herd between 10 and 15 lame cows (scored as 3 or 4) were chosen for the study and for each lame cow, a non-lame cow (scored as 1) with same parity number and similar DIM was chosen within each herd. Pendant data loggers were then placed in the hind leg of each cow during 10 d to record lying behavior at 1-min intervals. In addition, the time of feed delivery was recorded in each herd on a daily basis. Total daily lying time, daily number of lying bouts, lying bout duration, laterality (side of recumbence), and lying behavior around feed delivery were evaluated using a mixed-effects model that accounted for the fixed effects of lameness score, DIM, parity, and the interaction between parity and lameness score, plus the random effects of herd and cow. Total daily lying time (721 ± 24.2 min/d) tended ($P = 0.07$) to increase with DIM, but it was not affected by lameness or parity. Likewise, no differences were found in the number of lying bouts (9.6 ± 0.49 d-1) or laterality (47 ± 2.6% of time lying on the right side). However, the mean bout duration was longer ($P < 0.05$) in lame compared with non-lame cows (89.3 ± 3.89 vs. 80.7 ± 3.90 min, respectively). Interestingly, lame cows stood up 13 min later ($P < 0.05$) than non-lame cows relative to the time when the ration was delivered. In addition, lame cows lied down 19 min earlier ($P < 0.05$) than non-lame ones after the feed was delivered, which implies that non-lame cows spent more time standing and probably eating than lame cows. It is concluded that lame cows have longer lying bouts than non-lame animals, and that lying behavior around feed delivery time may be an effective proxy to identify moderately lame cows.

Key Words: feeding time, lameness, lying behavior

W10 Effect of grouping calves post-weaning according to pre-grouping feed intake on eating behavior. C. M. Matuk*[1], M. Chahine[1], A. Bach[2,3], B. Ozer[1], M. E. de Haro Marti[4], J. B. Glaze Jr.[1], T. Fife[1], and M. Nelson[1], *[1]University of Idaho, Twin Falls, [2]IRTA, Caldes de Montbui, Spain, [3]ICREA, Barcelona, Spain, [4]University of Idaho, Gooding.*

The effect of grouping calves post-weaning according to pre-grouping feed intake on eating behavior was evaluated using 755 replacement Holstein calves raised on a large operation in southern Idaho. In 4 different periods, individual feed intake was recorded 4 times a week during the last 3 wk that calves were individually hutched (60 d of age). Calves were classified as high eaters (highest feeding level quartile) and low eaters (lowest feeding level quartile). When leaving the individual hutches in each period, calves were assigned to 6 treatments: 20 animals randomly chosen without considering their level of feed intake (CTRL), 20 calves within the highest quartile of feed intake during the 3 wk prior leaving the hutches (HH), 20 within the lowest quartile (LL), 10 from the highest and 10 from lowest feeding level (HL), 5 from the highest and 15 from lowest feeding level (HLL), and 15 from the highest and 5 from lowest feeding level (HHL). Thus, out of 755 tracked heifers, 480 were chosen to form the 20 groups (6 groups per period) that were studied. After grouping, calves received a TMR composed of 95% starter and 5% alfalfa. Pen eating behavior was video recorded twice a week after grouping for 4 wks. Heifers in the highest feeding quartile in the HL, HLL and HHL were differentiated from the lowest quartile in their groups with a red plastic collar and reflective tape. A total of 192 d of recordings were collected and analyzed. Heifers were recorded as eating after 5 s of eating at the feedbunk. Data were analyzed using a mixed-effects model accounting for the random effect of period and pen and the fixed effects of treatment and intake level class and their 2-way interaction. CTRL and HL Heifers spent more time ($P < 0.05$) eating than HHL and HLL heifers (6.9 ± 0.6 min/hr vs. 5.8 ± 0.6 min/hr respectively). There was no significant effect of intake level class in HHL, HL and HLL ($P > 0.05$) with high eaters spending 6.0 ± 0.4 min/hr eating and low eaters spending 6.3 ± 0.4 min/eating. In this study, grouping calves according to their individual feed intake had no effect on time spent eating post-grouping.

Key Words: calves, heifers, eating behavior

W11 Association between behavioral patterns and risk of elevated somatic cell count in lactating dairy cows. M. E. A. Watters[1], K. Meijer[1], H. W. Barkema[2], K. E. Leslie[3], M. A. G. von Keyserlingk[4], and T. J. DeVries*[1], *[1]Dept. of Animal and Poultry Science, University of Guelph, Kemptville Campus, Kemptville, ON, Canada, [2]Dept. of Production Animal Health, University of Calgary, Calgary, Alberta, Canada, [3]Dept. of Population Medicine, University of Guelph, Guelph, Ontario, Canada, [4]Animal Welfare Program, University of British Columbia, Vancouver, British Columbia, Canada.*

The objective of this study was to determine the association between dairy cow standing and lying behavior patterns and risk of experiencing a newly elevated somatic cell count (SCC). Five commercial free-stall dairy herds, milking 3x/d, were enrolled in a longitudinal study. Forty Holstein-Friesian cows/herd were selected as focal animals based on DIM (<200 d) and SCC (<100,000 cells/mL). The study consisted of four 5-wk periods. Cow-level composite SCC was recorded at the beginning of each period and the end of the final period. Elevated SCC (eSCC) was used as an indicator of subclinical mastitis. Incidence of a newly eSCC was defined as having a SCC > 200,000 cells/mL at the end of each period, when SCC was < 100,000 cells/ml at the beginning of the period. Standing and lying behavior of the cows, as well as the times of milking and fresh feed delivery, were collected for 5 d after each SCC sampling using data loggers. A multivariable logistic regression model was used to assess the relationship between post-milking standing time and occurrence of a newly eSCC. There was no effect of the time of feed delivery on post-milking standing time, which averaged 97.4 ± 15.5min. Over the study period 48 newly eSCC were detected, resulting in an incidence rate of 0.97 eSCC/cow-year at risk. A non-linear relationship between post-milking standing time and eSCC incidence was found ($P = 0.01$). Those cows that lie down >90 min after milking were found to have a lower risk (OR = 0.38, 95% CI = 0.18, 0.80) of an eSCC compared with cows that lie down for the first time < 90 min after milking. Further, the risk of experiencing an eSCC was increased ($P < 0.01$) in multiparous cows (OR = 3.72. 95% CI = 1.37, 10.14), and in cows with a higher SCC at the beginning of the study (OR = 1.92, 95% CI = 1.44, 2.55; for one standard deviation [23,071 cells/ml] increase in initial SCC). These results indicate that management practices that promote longer post-milking standing time may be recommended to reduce the risk of free-stall housed cows experiencing newly eSCC. This should, in the longer term, reduce the overall prevalence of eSCC.

Key Words: free-stall, somatic cell count, behavior

W12 Association of social rank during the prepartum period with health, reproduction, and milk production of dairy cows. K. M. Lobeck,* M. I. Endres, P. R. B. Silva, and R. Chebel, *University of Minnesota, St. Paul.*

The objective of this study was to examine social rank during the close up prepartum period and its association with health, reproduction, and milk production during early lactation. The study was conducted in a freestall sand-bedded dairy farm in south-central Minnesota from June to August 2011. One hundred and 90 Jersey cows were enrolled in the study 5 weeks before expected calving date. Cows were balanced for body condition score and those cows with locomotion score >2 were not included in the study. Displacements from the feed bunk were measured during 3 h on the day of move-in (d0) at 13:00 ± 1:00 and following fresh feed delivery (05:00 ± 1:00) on d 1, 2, 3 and 7 of each wk. A displacement index was calculated as the number of displacements initiated by a cow divided by the number of displacements initiated plus number of displacements received by a cow. Cows with a displacement index of <0.4 were categorized as low-ranking, 0.4 to 0.6 middle-ranking, and >0.6 were considered high-ranking. Health events for the first 100 DIM, milk production and composition for the first 3 DHIA tests, and first breeding pregnancy rate were recorded for each cow. The Logistic procedure was used to evaluate health and reproductive events. The Mixed procedure was used to analyze milk and milk composition. There was no association of social rank with retained placenta, metritis, death, displaced abomasum, and mastitis events. Displacement index was associated with first breeding pregnancy rate ($P < 0.01$). Middle rank cows were 3 times more likely to become pregnant after first AI than low ranking cows with no differences between low ranking and high ranking cows. There was no association between milk production and social rank. Percent milk fat from the second test was associated with social rank ($P = 0.04$). Milk fat percentage was greater in low ranking cows than high-ranking cows (4.1 ± 0.13 vs 3.7 ± 0.16%). Middle-ranking cows, however, had similar milk fat percentage to low and high-ranking cows. In summary, social rank in the prepartum period was associated with pregnancy status and 2nd test milk fat percentage in early lactation dairy cows. However, pregnancy status may be more complex than simply being associated with social rank.

Key Words: social rank, displacements, dry cow

W13 To move or not to move: When should dairy cows be moved to maternity pens? K. L. Proudfoot*[1], M. B. Jensen[2], and M. A. G. von Keyserlingk[1], *[1]University of British Columbia, Vancouver, British Columbia, Canada, [2]Aarhus University, Tjele, Denmark.*

Cows are often moved from a group to an individual maternity pen just before calving. However, moving cows too soon before calving may alter their behavior and delay labor. The aim of this study was assess if moving cows to a maternity pen at different time periods before calving would influence labor or cow behavior. Thirty-six multiparous Holstein dairy cows were moved from a group to 1 of 10 maternity pens adjacent to the group pen. Cows were moved either 3d before calving, or when signs of calving were present. The time of moving relative to calving was determined retrospectively and cows were assigned to 1 of 3 treatments: "very late" (2.5 ± 1.2 h (mean ± SD) range 1.5 to 5 h; n = 12), "late" (12.9 ± 4.0 h, range 8 to 20 h; n = 12) or "early" (83 ± 23 h, range 37 to 122 h; n = 12). Calves were weighed within 12 h of birth. Using video, behavioral data collected 4 h before calving was used to approximate the length of the second stage of labor (the time between first 'expulsive' contractions, recorded when the cow's abdomen engaged in rhythmic movements, to the delivery the calf). During the 1h before calving we recorded the total time of contractions, lying time and number of position changes made by the dam. The effect of treatment on these variables was tested with ANOVAs (Proc GLM in SAS); treatment was a fixed effect and calf BW and cow parity were covariates. There was an effect of treatment and calf BW on the length of the second stage of labor; cows with heavier calves ($P = 0.01$) and those moved very late took longer to expel the calf (very late = 76.6 ± 6.9, late = 56.9 ± 5.6, early = 58.3 ± 6.6 min; $P = 0.02$). Cows with heavier calves spent more time having contractions 1 h before calving ($P = 0.03$), but there was no effect of treatment ($P = 0.42$). Cows moved very late spent twice as much time standing 1h before calving (very late = 25.5 ± 4.5, late = 12.4 ± 3.6, early = 11.6 ± 4.3 min; $P = 0.01$), but there was no effect of treatment on the number of position changes ($P = 0.85$). Results suggest that moving cows within 5h of calving from a group to a maternity pen prolongs the second stage of labor, and this may partly be driven by a longer time spent standing during the final hour before calving.

Key Words: transition, labor, calving

W14 Web forums as a method for engagement on contentious issues in dairying: Should cows have access to pasture? M. A. G. von Keyserlingk,* C. A. Schuppli, and D. M. Weary, *University of British Columbia, Vancouver, BC, Canada.*

Animal welfare is emerging as one of the key social concerns regarding animal agriculture. Key welfare concerns include poor biological functioning (such as ill health), negative affective states (such as pain and distress), and inability to engage in important natural behaviors (such as the ability to walk and turn around in tethered cattle). Some concerns are shared broadly by the public and within the dairy industry. In other cases, practices within the dairy industry may fall out of step with public expectations in part because the industry lacks mechanisms to discuss these issues. For example, many producers no longer provide access to pasture for dairy cattle, but people outside the industry may view pasture and grazing behavior as important elements of cattle welfare. We used web-based virtual "town hall" meetings to provide opportunities for people to comment on the question "Should dairy cows be provided access to pasture"? A total of 178 people participated in 5 web forums. Across all groups the majority of participants (73%) chose "Yes," 24% chose "Neutral" and 3% chose "No." Responses varied with participant demographics, but the large majority of both producers (89%) and people not associated with the industry (91%) felt that cows should be provided access to pasture. Veterinarians, other dairy industry professionals and students, often chose "Neutral" (43%); the reasons participants used to explain their neutral votes included that they considered pasture access desirable but difficult to achieve on some farms because of a lack of available land, and concern about reduced milk production. That the majority of respondents indicated that cows should have pasture access suggests that common practice in the dairy industry (i.e., a high usage of zero grazing systems) does not correspond with widely held values of participants both within and outside of the dairy industry.

Key Words: animal welfare, attitudes, grazing

W15 Social learning of feeding behavior in weaned pigs: Effects of the familiarity with conspecific model on flavor preferences. J. Figueroa,* D. Solà-Oriol, J. F. Pérez, and X. Manteca, *Universitat Autònoma de Barcelona, Bellaterra, Barcelona, Spain.*

It has been observed in other species that feed cues can be transferred from one animal (demonstrator) to another (observer) due to a social learning process. The aim of this experiment was to evaluate if preferences for a flavor can be modified by previous interactions with conspecifics in pigs and if acquired preferences are affected by the familiarity of the demonstrator. A total of 256 piglets (49-d-old) were used. Animals were separated in 2 groups depending on the familiarity of the demonstrator/model. Sixteen pens (8 pigs/pen) were used for the familiar demonstrator condition (G1). Four animals per pen were randomly selected to act as observers and 4 as demonstrators. Demonstrator animals were temporary moved to an empty pen where a flavored feed (anis (A) or garlic (G); 0.075%) were offered for 30 min. After that, demonstrator piglets were mixed again with the observer animals for 30 min. In the unfamiliar demonstrator condition (G2), the same procedure was performed but unfamiliar next-door pen demonstrators were used. Flavors were counterbalanced across pens to act as the social or control flavor. After interaction time, a double choice test (DCHT) between A and G flavored feeds was performed in each observer group. Feed intake was measured after 30 min. Data was analyzed by using the GLM procedure of SAS. Intake was higher in observer pigs when the flavors had been previously eaten by familiar rather than by unfamiliar demonstrators (264g vs. 167g; $P < 0.01$). Animals that learned from a familiar conspecific showed higher intakes of the social learned flavored feed over the control flavored feed (264g vs. 154g $P < 0.005$). On the other hand, animals that interacted with unfamiliar conspecifics did not show different intakes during the DCHT between both feeds. It is concluded that piglets, like other mammals, are able to prefer flavors previously learned by social interactions, and that the familiarity of a conspecific demonstrators play a key role in learning probably due to less aggressive behaviors that allows them to get a close mouth to mouth contact.

Key Words: social, learning, pigs

W16 Effect of feeding DDGS diets on behaviors of gestating sows in different housing systems.

Y. Z. Li*[1], L. J. Johnston[1], S. K. Baidoo[2], C. E. Phillips[3], L. H. Wang[1], X. L. Xie[1], and G. C. Shurson[3], *[1]West Central Research and Outreach Center, University of Minnesota, Morris, [2]Southern Research and Outreach Center, University of Minnesota, Waseca, [3]Dept. Animal Science, University of Minnesota, St Paul.*

The high fiber content of DDGS (distillers dried grain with solubles) may affect behaviors and welfare of limited-fed gestating sows both in stalls and group-housed systems. A study was conducted to investigate the effect of feeding diets containing DDGS on stereotypic behaviors of gestating sows housed in individual stalls (n = 27, wt = 176.8 ± 16.5 kg) and aggression in group-housed system (n = 40, wt = 174.3 ± 14.1 kg). All focal sows (parity 1 and 2) were fed either control or treatment diets during their previous gestation and lactation. Control diets (CON) were corn-soybean meal based formulated according to NRC (1998) recommendations for gestating or lactating sows. Treatment diets (DDGS) were nutritionally identical to CON but included 40% DDGS during gestation and 20% during lactation. Behaviors of focal sows were video-recorded for 24 h during 4 to 8 d after breeding. For group-housed sows, video-recording was conducted immediately after mixing, and was analyzed by continuous observation of aggressive interactions involving focal sows during the entire 24 h. For stalled sows, video-recording occurred 10 d after sows were moved into stalls, and analyzed by instantaneous scan sampling of behaviors of interest (resting, eating, stereotypies, and others) at 5-min intervals for 24 h. Data were analyzed using Proc Glimmix of SAS. In the group-housed system, sows fed DDGS were more aggressive, fought for longer periods (16.49 vs. 3.98 s/sow/h; $P = 0.05$) and tended to fight more frequently (0.82 vs. 0.37 fights/sow/h; $P = 0.06$) compared with CON sows. In gestation stalls, sows fed DDGS spent more time resting (73.1% vs. 66.4%; $P = 0.02$) and less time performing stereotypic behaviors (23.3% vs. 28.5%; $P = 0.05$) compared with CON sows. Eating behavior was not affected (2.3% vs. 2.9% for treatment and CON, respectively) by dietary treatment. These results indicate that the effect of feeding DDGS diets on behavior and welfare of gestating sows depended on housing system. In the group-housed system, dietary DDGS increased aggression among sows at mixing, and consequently, may compromise welfare of sows. However, in gestation stalls, sows fed DDGS spent more time resting and less time performing stereotypic behaviors, indicating improved satiety and welfare of sows.

Key Words: behavior, DDGS, sow housing

W17 Piglet behavior as a measure of viability.

R. Muns, E. G. Manzanilla, X. Manteca, and J. Gasa,* *Servei de Nutrició i Benestar Animal, Departament de Ciència Animal i dels Aliments, Universitat Autònoma de Barcelona, Bellaterra, Barcelona, Spain.*

The aim of the study was to develop a vitality scoring method based on piglet behavior which may be related to piglet growth and mortality during lactation. Two hundred sixty-six piglets, from 21 multiparous sows, were used. Within 3 h after the end of the farrowing (d 0), piglets were weighed and individually tested for 2 parameters (Table 1) in a circular enclosure (55cm diameter) receiving a U and N score and a total UN score (sum of U and N: 0–3). All the sows that needed intervention during farrowing were excluded, and piglets were not removed from the dam. Piglets were weighed again on d 1 and d 20 (weaning). Piglet rectal temperature (RT) was recorded on d 0, 1, 2 and 3. Sow farrowing information was also recorded. Regression analyses were performed using GLIMMIX procedure of SAS for survival, and GLM procedure of SAS for body weight (BW) gain and RT. Piglet BW gain at weaning was influenced by BW at birth ($P < 0.001$), sow parity ($P < 0.05$), total number of piglets born per sow ($P < 0.001$) and UN score ($P < 0.05$). Piglet rectal temperature on d 3 was influenced by BW at birth ($P < 0.001$), litter weight ($P < 0.001$), and UN score ($P < 0.05$). Piglet survival during lactation was influenced by BW at birth ($P < 0.05$), N score ($P < 0.05$) and RT on d 3 ($P < 0.10$). Furthermore, N score is highly related with piglet survival and may be a good criterion to identify piglets with a low viability. UN score, in combination with BW at birth and information of the sow might be useful to predict piglet performance during lactation, thus becoming a useful tool to improve piglet management during the first days of lactation. In conclusion, UN score seems to be an easy way to assess piglet vitality for both scientific and commercial purposes.

Table 1. Description of the two different parameters evaluated to establish the vitality of the piglets

Udder searching (U)
- 0: No searching or udder stimulation behavior within 30s.
- 1: Searching or udder stimulation behavior within 30s.

Number of rounds (N)
- 0: Not able to turn 360° nor walk along the limits of the enclosure
- 1: Able to turn 360° or walk along the limits of the enclosure within 30s.
- 2: Able to turn 360° or walk along the limits of the enclosure at least twice within 30s.

Key Words: pig, viability, behavior

W18 Habitat selection and ranging patterns of the African elephant (*Loxodanta africana*) in the Pongola game reserve, South Africa.

E. Cuthbert,* F. M. van Beest, D. A. Christensen, and R. Brook, *University of Saskatchewan, Saskatoon, SK, Canada.*

African elephants (*Loxodanta africana*) were reintroduced to the Pongola Game Reserve (PGR), South Africa, in 1997 via translocation. Fourteen elephants established the original population in the 73.6 km^2 reserve and it has since grown to over 50 individuals. Elephant conservation and management has continued to increase in importance throughout the southern African countries, and along with efforts of Space for Elephants, the PGR currently monitors herd health and behavior, as well as habitat use of the elephants. The purpose of this research was to establish the unique dry season ranging patterns of the main herd of female elephants and bull elephants to help determine how they were utilizing the area within the reserve and what habitats they are selecting. Selection ratios were calculated using Jacob's Index to determine the degree of selection in each habitat. A total of 412 GPS location were collected between May and August, ranging patterns showed that the main herd has expanded to the western side of the reserve, increasing possible ranging area by 40 km^2. Selection ratios for both the main herd and bulls showed a positive selection of 0.59 and 0.54 respectively for Floodplain Grasslands (6.0% of total area of the reserve) and ratios of 0.48 and 0.40 for *Euclea* and *Acacia* thickets (4.2% total reserve area), areas that should have comparatively high moisture levels due to the presence of the Jozini Dam. Negative selection indices were calculated, −0.23 for the herd and −0.14 for bulls, for River line thickets (3.3% total reserve area), and −0.69 and −0.62 for *Acacia* and *Marula* Woodland (38.9% total reserve area). Results of this study indicate that the elephants are expanding their home ranges due to population increases and that dry season ranging patterns are mostly driven by the presence of water and vegetation quality. Further population control methods or herd size reduction may be required to sustain the population and avoid detrimental environmental damage.

Key Words: African elephant, ranging, selection conservation

Animal Health III

W19 Impaired vitamin E status in post-partum dairy cows as a complication of left displaced abomasum. G. Bobe,* K. Lytle, and M. Traber, *Oregon State University, Corvallis.*

Left displaced abomasum (LDA), a costly disease in early lactation dairy cows, is associated with hepatic lipidosis, inflammation, and increased hepatic lipid peroxidation. Alpha tocopherol (ATOC) is an antioxidant that can limit lipid peroxidation and potentially inflammation. The objective of this study was to evaluate the serum ATOC status in multiparous dairy cows with and without LDA. We hypothesized that the oxidative damage postulated to be associated with LDA depletes Vitamin E reserves and results in serum ATOC concentrations that are indicative of deficiency (<7.4 μM). Blood samples were taken at approximate prepartum d −28 (−34 to −27), −21 (−26 to −18), −14 (−17 to −11), −7 (−10 to −5), −3 (−4 or −3), −1 (−2 or −1); and d 0, 1, 3, 7, 14, 21, 28, 35, 42, and 49 postpartum. Serum concentrations of ATOC, cholesterol, haptoglobin, nonesterified fatty acids, and β hydroxybutyrate were determined in samples from cows that were visually healthy ($n = 9$) and those that developed LDA ($n = 7$). Serum ATOC concentrations decreased in healthy cows during the first wk postpartum to a nadir of 7.7 ± 0.9 μM and increased back to prepartal concentrations (~13 μM) by 28 d postpartum. By contrast, LDA cows′ serum ATOC concentrations between d 14 and 49 postpartum remained depressed compared with those in healthy cows (all $P < 0.01$). On average, LDA cows had serum ATOC concentrations <7.4 μM between d 3 and 21 postpartum. At d 14 postpartum, all LDA cows had ATOC concentrations <7.4 μM, which remained <10 μM until d 49 postpartum. Concentrations of ATOC concentrations were inversely associated with serum concentrations of haptoglobin ($r = -0.35$), nonesterified fatty acids ($r = -0.54$), and β hydroxybutyrate ($r = -0.50$) and positively associated with cholesterol concentrations ($r = 0.54$; all $P < 0.001$). These results demonstrate that LDA cows have an inadequate serum ATOC status, which may be caused by increased oxidative stress, or a result of liver damage and impaired lipoprotein secretion, a complication of hepatic lipidosis. Pre- or postoperative vitamin E alimentation may improve the recovery of cows with LDA.

Key Words: dairy cows, left displaced abomasum, serum alpha tocopherol

W20 Validation of three sampling strategies for estimating lameness prevalence in dairy herds. A. Hoffman[1], D. A. Moore*[1], J. R. Wenz[1], and J. Vanegas[2], [1]*Washington State University,* [2]*Oregon State University.*

Lameness is an important problem in dairy herds because it decreases production and reproductive performance, increases culling, and has a negative impact on animal welfare and longevity. Monitoring farm lameness prevalence has utility for dairy producers and veterinarians in their efforts to reduce lameness, animal welfare assessment programs, and researchers. Locomotion scoring is a method used to quantify lameness and calculate prevalence. Due to the time necessary to locomotion score each cow, a herd sampling strategy that allows one to score less cows would be useful. Such a sampling strategy must be validated for accuracy in comparison to true lameness prevalence. The purpose of this study was to assess the accuracy of 3 previously suggested methods of estimating lameness by strategic sampling of a dairy herd. Sampling strategies tested include: (1) sampling a calculated number of cows in the middle third of the milking parlor exit order, (2) sampling a calculated number of cows weighted across pens and distributed evenly within each pen, and (3) sampling all cows in a high production pen, a low production pen, and the hospital pen. All cows on 5 dairy farms in Washington and Oregon ($n = 4,550$) were locomotion scored to determine true herd level lameness prevalence. Additionally, milking order and order observed in pen was recorded for each cow. Individual cow data on days in milk and parity was collected from farm computer records. Information on pen grouping strategy was collected by interview with farm management. Sampling strategies were then tested using the locomotion score data set. Estimated prevalence using sampling strategy 1 and 2 were not statistically different than true herd level prevalence ($P < 0.05$), as true lameness prevalence fell within the 95% confidence interval of the sample proportions. Strategy 3 accurately estimated the lameness prevalence on one farm, but overestimated prevalence on 3 others. These data show that the sampling strategies using the middle of milking parlor exit order and a calculated sample distributed across the herd may be used to accurately estimate herd lameness prevalence.

Key Words: dairy, lameness, prevalence

W21 Effects of feeding endophyte-infected fescue seed to Holstein cows during the dry period on plasma nitric oxide (NO), xanthine oxidase (XO), and haptoglobin (Hp) status in newborn calves. S. Kahl*[1], T. H. Elsasser[1], R. L. Baldwin VI[1], A. V. Capuco[1], P. Grossi[2], and K. R. McLoad[3], [1]*USDA, Agricultural Research Service, Beltsville, MD,* [2]*Istituto di Zootecnica, Università Cattolica, Piacenza, Italy,* [3]*University of Kentucky, Lexington.*

Fescue toxicosis in cattle, caused by ingestion of endophyte-infected fescue (EIF), is associated with decreased feed intake, growth, milk production and reproductive efficiency as well as decreased resistance to heat, transportation and immune stress. Increased inflammatory response to immune challenge was also reported in steers grazing EIF. The purpose of this study was to evaluate whether in utero exposure to ergot alkaloids from EIF seed fed to cows during the dry period would affect the developmental pattern of plasma indicators of birth stress in newborn calves. Starting at 90-d prepartum, multiparous Holstein cows were fed endophyte-free fescue seed (CON; $n = 9$) or EIF seed as 10% of the as-fed diet (INF; $n = 8$). Newborn calves were separated from their dams after birth. Blood samples were collected from calves within 12 h of birth (d 0) and then at d 4, 7, 14, 21, 28, 35, and 42. No differences ($P > 0.05$) were found between CON and INF calves on d 0 in BW (41 ± 1 kg) and in plasma concentrations of urea nitrogen (PUN; 7.1 ± 0.4 mg/dL) and the acute phase protein, Hp (0.20 ± 0.04 mg/mL). However, on d 0, plasma concentrations of nitrate+nitrite (NO_x; an estimate of NO production and neonatal vascular adaptation) were lower (155 vs. 223 μmol/L; $P < 0.01$), whereas XO activities (generation of oxygen-derived free radicals) were greater (9.07 vs. 3.27 mU/mL; $P < 0.01$) in INF than in CON calves. Plasma Hp concentrations were greater ($P < 0.05$) at d 4 (0.44 vs. 0.29 mg/mL) and 7 (0.55 vs. 0.38 mg/mL) in INF than in CON calves although no differences were found thereafter. Between d 4 and 42, time related developmental changes in calf plasma PUN, NO_x and XO levels were observed ($P < 0.01$) but they were not affected by the dam's dietary treatment. These results indicate that feeding toxin-associated components of EIF seed to dairy cows altered selected plasma indicators of birth stress in newborn calves during the first week of life but had no long-term effect on the developmental pattern of these mediators.

Key Words: fescue, Holstein calves, neonatal stress

W22 Leukocyte profiles of cows with claw horn disorders. K. K. M. O'Driscoll* and B. Earley, *Teagasc, Animal & Grassland Research and Innovation Centre, Grange, Dunsany, Co. Meath, Ireland.*

Claw horn disruption (CHD) in dairy cows weakens the integrity of the hoof, results in lesions ranging in severity from mild hemorrhages to ulcers, and can cause lameness and pain. These 2 studies examined the hematology profiles of cows with sole ulcers (the most severe pathology associated with CHD), and of cows with moderate and severe hemorrhaging, with sound cows. Study 1: 12 cows clinically lame due to solar ulceration were identified using locomotion and hoof scoring. These were paired with cows (sound) of similar lactation number, DIM, BCS and liveweight, that had healthy feet. Study 2: Cows (n = 41) were locomotion and hoof scored at 111 ± 23 DIM, then assigned to 3 categories on the basis of hemorrhage score; 1 = no/minimal hemorrhage, 2 = moderate hemorrhage; 3 = severe hemorrhage. Blood samples for both studies were taken via jugular venipuncture on the morning of hoof scoring. Total leukocyte, neutrophil (N), lymphocyte (L), monocyte, eosinophil and basophil counts were determined within 3 h of blood collection from K3EDTA anti-coagulated blood (6 mL) using an automated hematology analyzer (ADVIA 2120, Bayer Healthcare, Siemens, UK). All data were analyzed using PROC MIXED in SAS v9.1. Study 1: Cows with ulcers had higher locomotion scores than sound cows (13.5 ± 0.54 vs. 6.7 ± 0.54; $P < 0.001$). There was no difference in total leukocyte counts, neutrophil, lymphocyte, or monocyte count, or of eosinophil or basophil count and percentage. However cows with ulcers had higher neutrophil % ($P < 0.05$) and tended to have a lower lymphocyte % ($P = 0.1$) than sound cows. Ulcer cows had a higher N:L ratio (1.04 ± 0.1) than sound cows (0.76 ± 0.1; $P = 0.05$). Study 2: There was no effect of hemorrhage category on locomotion score or on any hematology variable. Cows that were clinically lame with sole ulcers had a leukocyte profile indicative of systemic inflammation and stress. A similar pattern was not evident in study 2. It is possible that only CHD severe enough to cause clinical lameness, and thus a sickness response, affects leukocyte profiles.

Key Words: dairy cow, lameness, leukocyte

W23 Investigation on a bio-hygienizing additive for oral use in dairy cows: Effect on milk somatic cell count. P. Luparia*[1], M. Poggianella[1], and V. Bronzo[2], *[1]SOP srl, Busto Arsizio, VA, Italy, [2]Universita di Milano, Milan, Italy.*

The aim of the present study was to assess the efficacy of a technological feeding additive, put into the mixing wagon, on the somatic cell count in milk from a commercial farm situated in Northern Italy, housing 140 lactating cows on straw which were bedding packs renewed every 60–90 d. The commercial bio-hygienizing product (SOP GOLD COW), based on an inert material (verxite) treated with the frequential blend SQC 233, was monitored from April 2011 until September 2011, a period chosen for its critical somatic cell levels due to the seasonal increase in temperature. The most striking characteristic of this product is that it can be mixed directly with the feed in the mixer wagon, at a dosage of 2g /head (0.07 oz), once a day. The data gathered, resulted from official DHI controls (Dairy Herd Improvement test date) carried out, cow by cow, on a monthly basis and regarded the SCC level, fat %, protein % and average daily milk production. The data was elaborated using the statistical software SPSS 19.0 (IBM, SPSS, New York, U.S.A.) and compared the average SCC values with the linear score (LS) via analyses of the variance in the generalized linear model. The decrease in the SCC levels in the treated animals' milk was significant at 99% ($P < 0.01$). On monitoring the data regarding the qualitative component of the milk, the index used to evaluate the correct functioning of the rumen during this study did not show any statistically significant difference, as neither the data regarding milk production. Further investigations are planned to explore any beneficial influence of the product on the cellulosolytic ruminal bacteria populations.

Key Words: SCC, hygiene, cow

W24 Oral administration of lipopolysaccharide and lipoteichoic acid modulated innate and humoral immunity in periparturient dairy cows. S. Iqbal,* Q. Zebeli, D. A. Mansmann, S. M. Dunn, and B. N. Ametaj, *University of Alberta, Edmonton, Alberta, Canada.*

Various investigators have indicated that cell-mediated and humoral immune functions are suppressed in dairy cows around parturition. As a result, dairy cows are affected by different infectious diseases immediately after calving including infection of the mammary gland (mastitis), and uterus (metritis). The cause of infectious diseases are the presence of pathogenic gram-negative and gram-positive bacteria in the infected tissues. The objective of this study was to investigate immune responses of periparturient dairy cows repeatedly administered orally with lipopolysaccharide (LPS) and lipoteichoic acid (LTA). Thirty pregnant Holstein dairy cows were randomly assigned to one of the 2 treatment groups starting at 28 d before the expected day of parturition. Cows received orally either 2 mL of 0.85% saline solution (CTR), or 2 mL of saline solution containing 3 increasing doses of LPS from *Escherichia coli* 0111:B4 as follows: 1) 0.01 μg/kg BW on d -28 and -24, 2) 0.05 μg/kg BW on d -21 and -18, and 0.1 μg/kg BW on d -14 along with a flat dose of LTA from *Bacillus subtilis* (i.e., 120 μg/animal). Blood samples were collected on wk -4, -1, $+1$, and $+4$ around parturition and analyzed for plasma anti-LPS immunoglobulin-(Ig)A, IgG, and IgM, serum amyloid A (SAA), lipopolysaccharide binding protein (LBP), tumor necrosis factor-α (TNF-α), and Interleukin-1 (IL-1). Results indicated that cows treated with oral LPS-LTA had lower concentrations of plasma anti-LPS IgA, IgG, and IgM antibodies compared with the control group ($P < 0.01$). Furthermore, results showed a tendency for the concentration of plasma LBP to be lower in the treatment group ($P < 0.10$). Additionally, no differences were found in the concentration of plasma SAA between the control and the treated cows ($P > 0.05$). Also, cows treated with oral LPS and LTA had lower concentrations of TNF-α in the plasma ($P = 0.02$); whereas IL-1 was numerically lower, particularly during the week following parturition, although the value did not reach significance ($P = 0.60$). Altogether, results of this study indicated that repeated oral administration of LPS from *E. coli* 0111:B4 and LTA from *Bacillus subtilis* modulated systemic innate and humoral immune responses in periparturient dairy cows around parturition.

Key Words: lipopolysaccharide, lipoteichoic, innate and humoral immunity

W25 Repeated oronasal administration of lipopolysaccharide modulated selected markers of innate and humoral immune responses in periparturient dairy cows. S. Iqbal,* Q. Zebeli, D. A. Mansmann, S. M. Dunn, and B. N. Ametaj, *University of Alberta, Edmonton, Alberta, Canada.*

Dairy cows go through a decrease in their immune response around calving. This is associated with increased incidence of infectious diseases. There is a scarcity of research regarding strengthening of immune responses against common bacterial agents. In this study, we investigated the innate and humoral immune responses to repeated oronasal application of lipopolysaccharide (LPS) during the transition period in periparturient dairy cows. One hundred primiparous (P) and multiparous (M) Holstein dairy cows with average BW of 620 and 720 kg, respectively, were randomly assigned into control (CTR; $P = 18$; $M = 32$) and treatment (TRT; $P = 19$; $M = 31$) groups. Treatment cows were administered increasing doses (0.01, 0.05, and 0.1 μg/kg BW) of LPS from *Escherichia coli* 0111:B4 oronasally (1 mL nasally and 2 mL orally) or carrier alone (3 mL of 0.85% saline) twice a week on wk −4, −3, and −2 before the expected day of parturition. Blood samples were collected from the tail vein on wk −4, −1, +1, and +4 around parturition and analyzed for plasma anti-LPS immunoglobulin-(Ig)A, IgG, and IgM antibodies, serum amyloid A (SAA), lipopolysaccharide binding protein (LBP), tumor necrosis factor-alfa (TNF-α), and interleukin-1 (IL-1). Overall, results indicated that the treatment cows had numerically greater concentrations of plasma anti-LPS IgM ($P = 0.32$) and IgG antibodies, particularly during the wk following parturition with a sharp increase in the plasma anti-LPS IgG antibodies, although the value did not reach significance ($P = 0.40$). Additionally, plasma anti-LPS IgA antibodies were slightly lowered in the treated cows compared with the control group ($P = 0.32$), and this effect was more pronounced on wk 4 following parturition ($P < 0.01$). Moreover, there was a treatment by time interaction for plasma SAA, which was lower in the treated cows ($P < 0.01$) after parturition. There was no effect of oronasal LPS on plasma TNF-α and IL-1 ($P > 0.05$). In conclusion, oronasal treatment of prepartum dairy cows with LPS modulated selected plasma markers of the innate and humoral immune responses suggesting that oronasal treatment of periparturient dairy cows with bacterial LPS might modulate their immune status.

Key Words: lipopolysaccharide, Innate immunity, humoral response

W26 Effect of polyunsaturated fatty acids (PUFA) on the infection of bovine epithelial cells with *Chlamydia psittaci*.

A. Jaudszus[1], M. Grün[1], G. Jahreis[1], K. Sachse[2], and H. Sauerwein*[3], [1]*Institute of Nutrition, Department of Nutritional Physiology, Friedrich Schiller University Jena, Jena, Germany,* [2]*Institute of Molecular Pathogenesis, Friedrich-Loeffler-Institute (FLI), Federal Research Institute for Animal Health, Jena, Germany,* [3]*Institute of Animal Science, Physiology & Hygiene Unit, University of Bonn, Bonn, Germany.*

In cattle, several clinical syndromes but also subclinical infections compromising performance caused by *Chlamydia* (*C.*) infection are known around the world. The prevalence is high, the benefit of therapeutic antibiosis is limited, vaccines for cattle are not consistently available, and most efforts to control the infection thus focus on hygiene management. PUFA are known for their immune modulating effects; moreover, when considering the response of epithelial cells to infection with the obligate intracellular *C.* bacteria, PUFA are promising candidates to mitigate *C.* infection. We thus aimed to test various PUFA in a bovine epithelial cell line for their potential of reducing *C.* infection rates. Epithelial cells from embryonic bovine lung (EBL, DSMZ ACC192 provided by BgVV, Jena, Germany) were seeded at 1,5 x10^5 cells/mL and preincubated for 24 h in presence or absence of the individual PUFA (C18:3n-3, C18:3n-6, C18:2n-6, C18:1n-9, C20:4n-6, C20:5n-3, *cis*-9,*trans*-11-conjugated linoleic acid (*c*9,*t*11-CLA), and *t*10,*c*12-CLA) at 33 or 100 μM. Cells were then infected with *C. psittaci* DC15 at 4 cfu/cell in presence of PUFA. After 48 h incubation, cells immunofluorescence stained for *C.* were subjected to flow cytometric quantification (Grün et al. 2009. J Microbiol Methods 78:360–2). Prior to the experiments, culture and infection conditions were optimized; the uptake of PUFA into the cells as well as undisturbed viability of the cells in the presence of PUFA was confirmed. The portion of *C.* positive cells in the presence of PUFA was compared with the solvent (DMSO) control using 5 replicates per combination. From all PUFA tested, *c*9,*t*11-CLA and C20:4n-6 were able to reduce the infection rates. The effect of C20:4n-6 was dose-dependent and significant at 100 μM (by 42% reduced infection rate, $P < 0.01$, as determined by Student's *t*-test), whereas *c*9,*t*11-CLA caused a reduction by 29% already at 33 μM ($P < 0.05$,). At 100 μM, no further effect was observed for *c*9,*t*11-CLA. Based on our results, the spectrum of beneficial effects of C20:4n-6 and *c*9,*t*11-CLA might be extended to antichlamydial effects at least in vitro.

Key Words: chlamydia, polyunsaturated fatty acids, bovine cell line

W27 Immune status of dairy calves in the northern plains of Costa Rica: Year 1.

J. A. Elizondo-Salazar*[1], J. Sánchez-Salas[1], G. Arroyo-Quesada[2], E. González-Arias[2], and A. J. Heinrichs[3], [1]*Estación Experimental Alfredo Volio Mata. Facultad de Ciencias Agroalimentarias, Universidad de Costa Rica,* [2]*Programa de Transferencia Tecnológica, Cooperativa de Productores de Leche R. L. Dos Pinos,* [3]*The Pennsylvania State University, University Park.*

The objective of this study was to characterize the immune status of dairy calves in the Northern Plains of Costa Rica. The data correspond to total serum protein (TSP) measurements obtained during the period of August and November 2010 on 57 dairy farms. Of 506 animals sampled, 267 suckled colostrum from their dams and 239 received colostrum by bottle. Dam breeds were classified into Holstein, Jersey, Holstein × Jersey crosses, and other. For the purpose of this study, failure of passive immunity was considered when TSP concentration was <5.5 g/dL. Concentration of TSP ranged from 2.8 to 11.0 with an overall mean of 6.2 g/dL. Failure of passive transfer was observed in 31.8% of calves. A higher proportion of male than female calves failed to obtain adequate immunity (35.3 vs. 31.4%, respectively), and male calves had on average lower ($P < 0.05$) TSP than females (5.9 vs. 6.2 g/dL). Calves born to Holstein x Jersey crosses had higher ($P < 0.05$) TSP concentrations than calves born to Holstein dams. Offspring born to first-calf heifers had TSP concentrations of 6.3 g/dL and, compared with other parity groups, fewer of these calves had inadequate transfer of immunity. Method of colostrum feeding did not affect TSP; however, a higher proportion of calves that suckled colostrum showed inadequate passive transfer when compared with calves that received colostrum by bottle (34.1 vs. 29.3%). The findings of this study suggest that colostrum management practices should be improved to minimize the risk of failure of passive transfer in dairy herds in the Northern Plains of Costa Rica.

Key Words: passive immunity, immunoglobulin, total serum protein

W28 Effects of Calibrin-Z on weanling pigs fed diets with naturally occurring deoxynivalenol.

F. Chi[1], S. L. Johnston*[1], and D. C. Mahan[2], [1]*Amlan International Inc., Chicago, IL,* [2]*The Ohio State University, Columbus.*

One-hundred eighty weanling pigs were used to evaluate the effects of Calibrin-Z in diets containing naturally occurring deoxynivalenol (DON) and zearalenone in a 3 × 2 factorial arrangement of treatments (TRT). Pigs were fed a common diet from d 0 to 7. Treatment diets were fed from d 7 to 35 post-weaning (average wt d 7 = 6.76 kg). There were 6 TRT with 6 pens of 5 pigs each, pen was the experimental unit. Data was analyzed for main effects of anticipated mycotoxin effect (MXE) and Calibrin-Z concentration. Single degree of freedom contrasts were used to determine the effect of Calibrin-Z within each MXE. Defusion, (Akey, DEF) had previously been shown to decrease the effects of DON contaminated diets, so the 3 levels of MXE were: 1) low mycotoxins with DEF (LDEF); 2) high mycotoxins with DEF (HDEF); and 3) high mycotoxins without DEF (HIGH). These MXE levels were each fed with Calibrin-Z at 0 or 0.5%. Pigs were allowed to access feed and water ad libitum. The high DON TRT were manufactured with corn and DDGS with 3.3 and 13 ppm, of DON respectively. Zearalenone was found at <1 ppm in the low DON corn and >50 ppm in the high DON corn source. There was no effect of TRT for feed intake or for gain. From d 7 to 35 gain: feed (G:F) showed no difference ($P = 0.14$) between the LDEF, HDEF, and HIGH TRT, with values of 721, 692, and 696 g /kg, respectively. Analyzing the main effect of Calibrin-Z inclusion showed that G:F was not significantly improved ($P = 0.10$) when Calibrin-Z was added at 0.5%, with values of 692 vs. 714 g/kg, without and with Calibrin-Z. There was a MXE x Calibrin-Z interaction as G:F improved most when Calibrin-Z was added to the LDEF diet. When diets within MXE with and without Calibrin-Z were compared the LDEF diet had significantly improved ($P < 0.05$) G:F from d 7–35 with Calibrin-Z addition, with values of 693 g/kg and 749 g/kg for 0 or 5% Calibrin-Z, respectively. These results show that Calibrin-Z can improve feed efficiency in pigs, even under low mycotoxin challenge.

Key Words: mycotoxin, feed efficiency, pigs

W29 Reproductive toxicity of liquid dishwashing detergent on male Swiss albino mice. A. Ata, M. S. Gulay,* S. Gungor, O. Yildiz Gulay, and A. Demirtas, *Mehmet Akif Ersoy University, Faculty of Veterinary Medicine, Burdur, Turkiye.*

The aim of this study was to investigate the possible effects of liquid dishwashing detergent on some spermatologic parameters of male Swiss albino mice. Forty healthy male Swiss albino mice (60 d old) were randomly assigned to 5 groups of 8 animals each. Animals in TR1 served as control and received tap water while TR2, TR3, TR4 and TR5 received 0.1, 0.5, 1 and 5% v/v of the liquid detergent in tab water, respectively as the only source of water. The treatments lasted for 35 d (1 spermatogenesis duration). Mice were kept in plastic cages, under standard laboratory conditions. Food and water provided ad libitum. At the end of the experiment, mice were sacrificed under Sevorane anesthesia. For spermatological examinations, right cauda epididymis was excised and placed in a pre-warmed Petri dish containing Dulbecco Phosphate Buffered solution at 37°C for 30 min. Epididymal spermatozoa were used to evaluate spermatozoon concentration, progressive motility, viable spermatozoon rates, intact spermatozoon rates and hypo osmotic swelling positive (HOS+) test. Data were analyzed by one way ANOVA. At the end of the experimental period no differences due to detergent treatment were observed in spermatozoon concentration($P > 0.1$). However, significant differences were detected among the treatment groups for progressive motility (TR1 = 80.87 ± 2.01, TR2 = 75.37 ± 1.30, TR3 = 62.50 ± 3.60, TR4 = 52.12 ± 4.54 and TR5 = 56.00 ± 2.73%; $P < 0.01$), viable spermatozoon rates (TR1 = 84.25 ± 1.88, TR2 = 79.50 ± 1.75, TR3 = 70.50 ± 2.32, TR4 = 59.62 ± 1.77 and TR5 = 60.87 ± 1.48%; $P < 0.01$), and intact spermatozoon rates (TR = 86.12 ± 0.78, TR2 = 85.50 ± 1.16, TR3 = 83.37 ± 1.86, TR4 = 80.12 ± 1.60 and TR5 = 75.12 ± 1.05%;$P < 0.01$), and HOS+ (TR1 = 78.75 ± 1.03, TR2 = 75.37 ± 1.26, TR3 = 63.12 ± 3.99, TR4 = 44.00 ± 6.12 and TR5 = 43.62 ± 2.11%; $P < 0.01$). Therefore, the results of the current study suggested that daily oral consumption of liquid detergent exerted significant adverse effects on spermatologic parameters in swiss albino males.

Key Words: detergent, Swiss albino mouse, reproduction

W30 Valuation of antimicrobial activities of 29 kinds of Chinese herbs against *E. coli*. L. C. Xiao[1,2], X. F. Kong[1], M. Q. Huang[1,2], X. Q. Guo[2], and Y. L. Yin*[1], *[1]Research Center for Healthy Breeding of Livestock and Poultry and Key Laboratory for Agro-ecological Processes in Subtropical Region, Institute of Subtropical Agriculture, Chinese Academy of Sciences, Changsha, Hunan, China, [2]College of Animal Science and Technology, Jiangxi Agricultural University, Nanchang, Jiangxi, China.*

Chinese herbs, which contain many antimicrobial ingredients, are widely used to prevent and treat bacteriosis, especially infectious disease caused by antibiotic-resistant bacterium. To develop effective Chinese herbal extracts as feed additives with antimicrobial activity, the present study was conducted to determine the antimicrobial activity of Chinese herbs against E. Coli isolated from swine production. The aqueous and ethanol extracts (1 g/mL) of 29 kinds of Chinese herbs were prepared, respectively, and then their antimicrobial activities against 10 isolated strains of antibiotic-resistant E. Coli (including SEC023, SEC206, SEC298, SEC470, SEC616, SEC817, SEC911, SEC1284, C193 and C197) and 3 type strains of *E. coli* (including K88, K99 and K101) were evaluated by determining diameter of inhibition zone (IZD, mm). The data showed that the IZD of ethanol extracts from Chinese nut-gall were higher than 20 mm and of its aqueous extracts varied from 9.5 to 13.0 mm against all of the tested *E. coli* strains, as well as of extracts from Thea viridis and Thea nigra; the IZD of both ethanol and aqueous extracts from Weeping forsythia capsule varied from 10.0 to 14.0 mm, as well as from garden burnet root against SEC023, and from Cortex fraxini against SEC1284; the IZD of ethanol extracts from hawthorn fruit were higher than 10.0 mm against SEC470 (11.0), SEC817 (10.3), K101 (10.0) and SEC1284 (10.0), as well as from Granati cortex against SEC470 (13.3), SEC023 (10.3), SEC1284 (10.3), K99 (10.0) and C193 (10.0), and from Coptis root against SEC1284 (16.0), SEC470 (15.0) and SEC206 (10.0), and from Cortex fraxini against K101 (11.5), K88 (10.8), SEC206 (10.8), SEC616 (10.5), C197 (10.5) and SEC470 (10.0). These findings provided some theoretical basis for further study and application of Chinese herbal resources in animal feed.

Key Words: pigs, Chinese herbs, health

W31 Putrescine stimulates the mammalian target of rapamycin signaling pathway and protein synthesis in porcine trophectoderm cells. X. F. Kong[1,2], B. E. Tan[1,2], Y. L. Yin*[1], L. A. Jaeger[3], F. W. Bazer[2,3], and G. Y. Wu[1,2], *[1]Research Center for Healthy Breeding of Livestock and Poultry and Key Laboratory for Agro-ecological Processes in Subtropical Region, Institute of Subtropical Agriculture, Chinese Academy of Sciences, Changsha, Hunan, China, [2]Faculty of Nutrition and Department of Animal Science, Texas A&M University, College Station, [3]Department of Veterinary Integrative Biosciences, Texas A&M University, College Station.*

Impairment of placental growth is a major factor contributing to intrauterine growth retardation in domestic animal production. Growing evidence shows that the polyamines (including putrescine, spermine and spermidine) produced from arginine (Arg) or proline via catalysis of ornithine decarboxylase are key regulators of angiogenesis and embryogenesis as well as placental and fetal growth. However, the underlying mechanisms are largely unknown. The present study was conducted to test the hypothesis that putrescine (Put) stimulates the mammalian target of rapamycin (mTOR) signaling pathway and protein synthesis in porcine conceptus trophectoderm (pTr2) cells. The cells were cultured for 4 d in Arg-free DMEM containing 0, 10, 25, or 50 micromole Put and 100 micromole Arg. Cell count, protein synthesis and degradation, as well as the total and phosphorylated amounts of mTOR, ribosomal protein S6 kinase 1 (p70S6K), and eukaryotic initiation factor 4E-binding protein-1 (4EBP1) were determined. The pTr2 cells exhibited time (0 to 6 d)- and Put concentration (0 to 25 micromole)-dependent increases in the cell count. Addition of 25 micromole Put to culture medium increased the protein synthesis, amounts of total and phosphorylated mTOR and 4EBP1 proteins, as well as the phosphorylated p70S6K. The cell growth were only modestly affected when Put synthesis was inhibited by addition of 1 to 5 mM difluoromethylornithine. Collectively, these findings indicate a novel and important role for Put in promoting growth of porcine placental cells largely via an mTOR signaling pathway, which help to explain beneficial effects of Put supplementation on improving survival and growth of embryos/fetuses in mammals.

Key Words: pigs, growth, nutrition

W32 Dietary arginine supplementation confers immunostimulatory effects on inactivated *Pasteurella multocida* vaccines immunized mice. W. K. Ren[1], Y. L. Yin*[1], L. X. Zhou[2], Y. Wang[2], and Y. Peng[2], *[1]Institute of Subtropical Agriculture, the Chinese Academy of Sciences, Changsha, Hunan, China., [2]Chongqing Key Laboratory of Forage & Herbivorce, College of Animal Science and Technology, Southwest University, Chongqing, China.*

This study was conducted to test the adjuvant effect of arginine on inactivated vaccines immunized mice. Mice immunized with inactivated *Pasteurella multocida* (*P. multocida*) vaccines alone and with dietary 0.2% or 0.5% arginine supplementation showed 100% protection after challenge with *P. multocida* serotype A (CQ2) at dose of 4.4Ã—105 cfu (2LD50). However, the antibody titers in vaccine-0.2% arginine group were much higher than those in vaccine-oil adjuvant group before challenge, meanwhile immunization with inactivated vaccines and dietary 0.2% arginine supplementation significantly increased the antibody titers at 36 h post infection, compared with the mice immunized with inactivated vaccines alone or with oil adjuvant. Furthermore, immunization with inactivated vaccines and dietary 0.2% arginine supplementation significantly increased the serum Interleukin-1 β and glutathione peroxidase levels in comparison with the vaccine and vaccine-adjuvant groups of mice. Collectively, dietary arginine supplementation performs a significant immunostimulatory effects in inactivated *P. multocida* vaccines immunized mice, and dietary 0.2–0.5% arginine supplementation was the optimal supplementation dose in mouse model.

Key Words: amino acids, mice, nutrition

W33 Prevalence of clinical and subclinical ketosis at 8 and 30 days in milk and its relationships with parity, dry period length, peak milk yield and change in body condition score in a Jersey herd in the highlands of Costa Rica. J. M. l. Sánchez* and A. Saborío, *Centro de Investigaciones en Nutrición Animal. Universidad de Costa Rica, San José, Costa Rica.*

The prevalence and grade of ketosis at 8 and 30 d in milk (DIM), as well as its relationships with parity, dry period length, peak milk yield and change in body condition score (BCS) were measured in a 203 cows Jersey herd in Oreamuno, Cartago, Costa Rica (9° 55′ North Latitude, 83° 51′ West Longitude, 2350 m of altitude).The aim was to investigate management and feeding risk factors associated with this metabolic disease. Pre and post calving feeding practices were based on intensive grazing of 30 d regrowth kikuyu (*Kikuyuocloa clandestina*) and on average cows were supplemented with 4 kg of a concentrate mix (14% CP, 1.7 Mcal of NE_L/kg, 35% starch, 0.2% Ca) per day during the close up period, and 4 to 6 kg (20% CP, 1.9 Mcal NE_L/ kg, 48% starch, 1% Ca) in the fresh period. Average BCS at calving was 3.9 (1 to 5 scale). Prevalence of ketosis was determined by measuring blood concentration of β-hydroxybutyric acid (βHBA) at 8 ± 3 DIM in 117 animals and at 30 ± 3 DIM in 114 animals. No clinical ketosis was detected at 8 DIM, and 4.27% of the cows had subclinical ketosis (1.4 to 2.9 mmol/L) during this period. Percentages of cows with clinical (>2.9 mmol/L) and subclinical ketosis at 30 DIM were 3.51 and 9.65, respectively. Incidence of clinical and subclinical ketosis in this herd is under the average prevalence of 15% reported for confinement herds in literature. Cows developing ketosis at 30 DIM lost more body condition during the last week of gestation, than cows that did not develop this disease. During this week, body condition loss for healthy and ketotic cows was 0.09 and 0.31 points ($P < 0.05$), respectively. Cows with ketosis at 30 DIM were of greater ($P < 0.01$) parity, longer ($P < 0.05$) dry period length and greater ($P < 0.01$) peak milk yield. A logistic regression analysis showed that increments of one, 2 or 3 weeks over the 60 d dry period increases the risk of developing ketosis at 30 DIM 1.21, 1.47 and 1.79 times, respectively. Results suggest that scoring body condition during the last week of gestation could be useful to predict the risk of the animals developing ketosis at 30 DIM. Based on these results, management to avoid dry periods in excess of 60 d will help reduce the incidence of ketosis. Furthermore, feeding and management of older cows and higher producing cows to reduce the loss of body condition post calving could also reduce the incidence of ketosis.

Key Words: ketosis, β-hydroxybutyric acid, grazing cows

W34 Effects of soy isoflavones on the male reproductive regulation in Huanjiang male pigs. X. Yuan[1], L. Li[1], J. Fan[1,2], B. Zhang*[2], C. Xiao[3], and Y. Yin[1], *[1]Institute of Subtropical Agriculture, the Chinese Academy of Science, Changsha, Hunan, China, [2]College of Animal Sciences, Hunan Agricultural University, Changsha, Hunan, China, [3]Nutrition Research Division, Food Directorate, Health Products and Food Branch, Health Canada, Ottawa, Canada.*

To evaluate the effects of soy isoflavones on male reproductive regulation in Huanjiang male pigs. Fifty male black small-eared pigs were randomly divided into control group (fed a test diet), low, medium and high doses of soy isoflavones group and diethylstilbestrol group. Three different doses of soy isoflavones (125 mg/kg, 250 mg/kg, and 500 mg/kg) and 0.5 mg/kg diethylstilbestrol were evenly mixed in the feed and fed to pigs for 60 d (The purity of soy isoflavones is 80%). Analysis levels of GnRH, LH, FSH, Tes and E2 by radioimmunoassay; weigh testis and epididymis; the mRNA expression of P450scc, 3Î^2 -HSD and StAR in testicular tissue, which associated with testosterone synthesis, was measured by RT-PCR. In 250 mg/kg soy isoflavones group, testicular index increased by 44.76% than the control group, the difference was significant ($P < 0.05$); serum testosterone level increased by 51.49% than the control group, the difference was significant ($P < 0.05$); mRNA expression of StAR was up to 1.43%, a significant difference with control group ($P < 0.05$). In 500 mg/kg soy isoflavones group, testicular index decreased by 39.92% than the control group, the difference was significant ($P < 0.05$); serum testosterone level decreased by 53.69% than the control group, the difference was significant ($P < 0.05$); mRNA expression of StAR 0.49%, a significant difference with 250 mg/kg soy isoflavones group ($P < 0.05$). Soy isoflavones can affect the male reproductive hormone secretion, the growth and development of testis and epididymis, enzyme activity of testosterone synthesis, and expression of reproductive hormone genes in the brain, and in dosage-dependent ways.

Key Words: soy isoflavones, reproductive hormone, Huanjiang male pigs

W35 Estimate of serum IgG concentration using refractometry with or without caprylic acid fractionation. K. M. Morrill*[1], A. Lago[3], J. Polo[3], J. D. Quigley[3], and H. D. Tyler[2], *[1]Cornell Cooperative Extension, Westport, NY, [2]Iowa State University, Ames, [3]APC Inc., Ankeny, IA.*

The objective of this study was to develop a rapid, calf-side test to determine serum IgG concentration using a refractometer and caprylic acid (CA) fractionation. Serum samples (n = 200) were obtained from 1 d old calves on a single California dairy, frozen and shipped to Iowa State University. Samples were allowed to thaw at room temperature (1 h). Fractionation with CA was conducted by adding 1 mL of serum to a tube containing 45, 60 or 75 µL CA and 0.5, 1.0 or 1.5 mL 0.06 M acetic acid (AcO). The tube was shaken (10 s), allowed to react for 1 min and centrifuged (3,000 × *g*) for 0, 10 or 20 min. Refractive index (nD) of fractionated and whole serum was determined using a digital refractometer (SPER Scientific model 300034). Serum IgG concentration was determined by radial immunodiffusion (RID). The nD of whole and fractionated serum were compared with IgG concentration. Mean serum IgG concentration was 19.0 mg/ml (SD = 9.7) with a range of 3.5 to 47.0 mg/mL. Whole serum nD correlated with IgG concentration (r = 0.86, n = 185). Serum treated with 1 mL 0.6 M AcO and 60 µL CA and not centrifuged before analysis resulted in the strongest relationship between fractionated serum nD and IgG (r = 0.80, n = 45). Regression equations were used to determine cut-points that would be indicative of 10, 12 and 14 mg/mL to determine the sensitivity and specificity of refractometry to identify failure of passive transfer (FPT) calves. Fractionated samples were evaluated by cut-points 1.33895, 1.3392, and 1.3395 nD. The cut-point of 1.3395 resulted in the greatest specificity (100%) and positive predictive value (100%) for fractionated samples; however, 11.1% of samples with adequate IgG were incorrectly classified as inadequate. Whole samples were evaluated by nD cut-points 1.34414, 1.34448 and 1.3448. The cut-points of 1.34448 and 1.3448 resulted in identical specificities (86.67%), while the lower cut-point had a specificity of 60.0%. These results suggest that refractometry of whole or fractionated calf serum provides a strong estimate of IgG concentration and can be used to identify FPT calves before 24 h of age.

Key Words: passive transfer, IgG, refractometer

W36 Haptoglobin is a potential early indicator of postpartal diseases. D. Sabedra[1], E. Ramsing[1], C. Shriver-Munsch[1], J. Males[1], W. Sanchez[2], I. Yoon[2], and G. Bobe*[1], *[1]Oregon State University, Corvallis, [2]Diamond V, Cedar Rapids, IA.*

Haptoglobin is an acute phase protein that is elevated in response to tissue damage and infections in dairy cows. The objective of this study was to evaluate whether serum concentrations of haptoglobin are elevated before clinical signs of diseases can be observed. Blood samples were taken from 161 Holstein cows (2 to 7 parities) at d −28 (−34 to −27), −21 (−26 to −18), −14 (−17 to −11), −7 (−10 to −5), −3 (−4 or −3), −1 (−2 or −1), 0, 1, 3, 7, 14, 21, 28, 35, 42, and 49 postpartum during spring and summer 2010 and analyzed for serum haptoglobin concentrations. Between d −28 and 100 postpartum, cows were monitored daily for signs of diseases and treated according to standard treatment protocols. Based on the severity of the observed symptoms, cows were grouped into 4 health categories: visually healthy (n = 20), mild or subclinical disease (n = 41), severe disease requiring antibiotics, glucose precursors, or both (n = 70), and died or sold within the first 100 d postpartum (n = 30). In healthy cows, serum haptoglobin concentrations were increased in the first week after calving and peaked at d 1 postpartum. Compared with healthy cows, peak concentrations were greater and duration of elevated haptoglobin concentrations was longer in sick cows ($P < 0.001$). Cows that died or were sold had the highest peak concentrations and the longest duration of elevated haptoglobin concentrations ($P < 0.001$). The increase in haptoglobin concentrations in the first wk postpartum was observed in cows with various types of diseases (metritis, ketosis, laminitis, mastitis; all $P < 0.01$). These results suggest that prolonged elevated haptoglobin concentrations in the first week postpartum precede the clinical onset of various diseases and may assist in early detection and treatment of subclinically sick cows during the first phase of lactation.

Key Words: dairy cows, disease, haptoglobin

W37 Bovine hepatic retinol binding protein gene expression and its relationship with tumor necrosis factor-α. P. Rezamand[1], K. M. Hunt[1], J. S. Watts[1], J. D. Blickenstaff*[1], B. J. Bradford[2], and L. K. Mamedova[2], *[1]University of Idaho, Moscow, [2]Kansas State University, Manhattan.*

Circulating retinol binding protein (RBP) transports retinol from the liver to target tissues, has one binding site for retinol in the *all-trans* form, and is bound to transthyretin (TTR). The objectives were to determine the temporal pattern of bovine hepatic mRNA expression of RBP during the periparturient period and whether its expression is influenced by tumor necrosis factor (TNF)-α. In experiment I, hepatic mRNA expression of RBP during the periparturient period was assessed. Liver tissues were sampled from periparturient dairy cows (n = 9) at −21, −4, +1, +7 and +21 relative to parturition. Total RNA was extracted and cDNA was generated. Transcript abundance of RBP and β-actin, as a housekeeping gene, were measured in relative quantity using rt-PCR. Data were analyzed using delta Ct values and significance was determined at $P \leq 0.05$. Cows had variable hepatic RBP expression over the transition period ($P = 0.037$), with a decline around parturition and a rebound toward prepartum levels later in lactation, resembling abundance of plasma retinol. In experiment II, Holstein dairy cows were blocked by parity and feed intake, and randomly assigned to control, recombinant bovine (rb)TNF-challenge or pair-fed control (n = 5/treatment). Cows were either injected with rbTNF (SQ injection of 2 µg/kg BW in saline) or sterile saline (control and pair-fed control) once daily for 7 d. Liver biopsy was performed on d 7 and samples were processed for mRNA expression of RBP, TNF-α and GAPDH. Although TNF challenge caused an upregulation of hepatic TNF-α expression ($P < 0.01$), it did not cause an alteration in hepatic RBP expression ($P = 0.32$). Overall, temporal pattern of hepatic RBP gene expression during periparturient period followed that of plasma retinol. Although a strong positive correlation was previously detected between bovine hepatic RBP and TNF-α transcripts, rbTNF challenge did not cause an alteration in RBP expression. These observations collectively imply that regulation of RBP at the transcription level is influenced by physiological state but may be independent from that of TTR, which is altered by pro-inflammatory stimuli (e.g., TNF-α) via induction of transcription factor nuclear factor-interleukin 6.

Key Words: gene expression, retinol binding protein, TNF-α

W38 Dried citrus pulp modulates the physiological and acute phase responses of crossbred heifers to an endotoxin challenge. N. C. Burdick*[1], J. T. Cribbs[2], J. A. Carroll[1], T. R. Callaway[3], T. B. Schmidt[4], B. J. Johnson[2], and R. J. Rathmann[2], *[1]USDA-ARS, Livestock Issues Research Unit, Lubbock, TX, [2]Texas Tech University, Department of Animal and Food Sciences, Lubbock, [3]USDA-ARS, Food and Feed Safety Research Unit, College Station, TX, [4]Mississippi State University, Department of Animal and Dairy Science, Mississippi State.*

This study examined the effect of feeding dried citrus pulp (CP) pellets on the physiological and acute phase responses (APR) of newly received crossbred heifers to an endotoxin (lipopolysaccharide; LPS) challenge. Heifers (n = 24; 218.3 ± 2.4 kg) were obtained from commercial sale barns and transported to the Texas Tech Univ. Beef Center. Heifers were separated into treatment groups receiving a Control Diet (C; n = 8), CP10 (10% CP DM basis; n = 8) or CP20 (20% CP DM basis; n

= 8) and were fed for 65 d while being systematically stepped up to a finishing ration. On d 63, heifers were fitted with indwelling vaginal temperature (VT) recording devices and jugular catheters and moved into a barn with individual stalls. On d 64, heifers were challenged i.v. with LPS (0.5 µg/kg BW) and blood samples were collected every 0.5 h from −2 to 8 and again at 24 h relative to LPS challenge (0 h). Sickness behavior scores (SBS) were also assigned following collection of each blood sample. Serum was isolated and stored at −80°C until analyzed for cortisol, interleukin-6 (IL6), interferon-γ (IFNγ), and tumor necrosis factor-α (TNFα) concentrations. Pre-LPS VT were lower in CP10 (38.44 ± 0.02°C) than C (38.74 ± 0.02°C) and CP20 treatments (38.68 ± 0.02°C; $P < 0.01$). There was an increase in VT in all treatments post-LPS ($P < 0.001$), with CP10 (38.69 ± 0.02°C) maintaining lower VT post-LPS than C (38.98 ± 0.02°C) and CP20 treatments (38.97 ± 0.02°C; $P < 0.01$). Post-LPS SBS increased ($P < 0.01$) and were greater in CP10 (1.14 ± 0.02) than CP20 (1.09 ± 0.02) and C (1.03 ± 0.02; $P < 0.01$). Post-LPS cortisol concentrations were greatest in CP10 (68.1 ± 2.1 ng/mL) heifers than C (60.9 ± 2.0 ng/mL) or CP20 treatments (59.5 ± 1.9 ng/mL; $P < 0.01$). Concentrations of IFNγ, TNFα, and IL6 increased post-LPS ($P < 0.01$) and were greater in CP20 (24.6 ± 1.1, 123.03 ± 11.1, and 2370 ± 123 pg/mL, respectively) than CP10 (16.9 ± 1.0, 91.3 ± 11.1, and 1981 ± 124 pg/mL, respectively) and C treatments (12.2 ± 0.9, 19.1 ± 10.2, and 1175 ± 104 pg/mL, respectively; $P < 0.01$). These data indicate that CP inclusion in the diet can modulate both the physiological and APR of newly received heifers to an endotoxin challenge.

Key Words: acute phase response, cattle, citrus pulp

Beef Species

W39 Survey of beef quality assurance on California dairies. S. Aly[1], H. Rossow[1], G. Acetoze*[2], T. Lehenbauer[1], M. Payne[3], D. Meyer[2], J. Maas[4], and B. Hoar[3], *[1]Veterinary Medicine Teaching and Research Center, School of Veterinary Medicine, University of California-Davis, Tulare, [2]Department of Animal Science, University of California-Davis, Davis, [3]Western Institute of Food Safety and Security, University of California-Davis, Davis, [4]Veterinary Medicine Extension, School of Veterinary Medicine, University of California-Davis, Davis.*

In October 2010 a mail and internet survey of California's dairy industry was implemented to assess the Dairy Animal Care and Quality Assurance (DACQA) program. The DACQA program, which involves cattle of all ages, benchmarks practices on the dairy that affect the use of dairy cattle for beef. The survey was mailed to a random sample of 1071 California dairies (65%) stratified by county with allocation proportional to density of dairies in each of the state's 32 counties with dairies. Data from the 173 (16%) responses from 19 counties received which represented 10% of the state's milking herd, showed that 90% of culled cows on California dairies were sold for beef. Survey results also showed that personnel from 45% of California's dairies preferred injecting drugs subcutaneously if possible, 97% kept track of withdrawal periods and 49% maintained a form of drug inventory. Personnel who maintained a drug inventory were 3 times more likely to test for drug residues compared with those who didn't (P value 0.02). Furthermore, 44% of personnel of California's dairies reported knowledge of their culled cows' hot carcass weight or USDA carcass grade. In addition to the estimated 34% of California dairies that supported a beef quality assurance certification program, approximately 45% would specifically request more information on such a program. Although few dairies were familiar with the DACQA website, approximately half requested more information on the program. The likelihood that the DACQA certification program would be applied on California dairies is favorable given the interest support for it.

Key Words: beef quality, DACQA, survey

W40 Effects of stabilizing oxidative balance through dietary means on growth performance, antioxidant metabolites and fertility factors in bulls. T. J. Wistuba,* M. Becker, S. Court, and G. I. Zanton, *Novus International Inc., St. Charles, MO.*

One of the most important factors of farm profitability in Australian beef herds is fertility. Numerous factors can influence oxidative balance in livestock (environmental, dietary, health, etc.) and thus fertility, especially in young bulls. Nutritionally Cu, Mn and Zn have been shown to affect superoxide dismutase activity (SOD), Se has an important role in glutathione peroxidase activity (GPX), and dietary antioxidants have been shown to improve overall immune status. The objective of this study was to improve oxidative balance in young bulls through nutrition and measure the response in antioxidant metabolites, semen quality and morphology and animal performance. Two hundred-one Droughtmaster bulls (614.6 ± 35.61 kg) were tested for semen morphology 19 d pre-treatment. Animals were then blocked into pen groups by age, average sperm morphology and BW for apparent maturity and physiological status. The control ration was balanced to meet or exceed NRC (1996) requirements, the treatment diet was the control ration plus 2-hydroxyl-4-methyl-thio butanoic acid (MHA), Agrado Plus dietary antioxidant, Mintrex-Cu, -Mn and -Zn as well as Zorien SeY (Novus International) and was fed for 59 d. The ANOVA was generated utilizing the GLM procedure of STATA version 11 (College Station, TX); model included treatment, date and the interaction between treatment and date. Results indicated no benefit to sperm morphology or performance when compared with control. However, SOD/g Hemoglobin was reduced in both treatment and control. Semen concentrations of GPX increased significantly for treatment when compared with the control ($P = 0.025$). Rectal temperature increased to a greater degree ($P = 0.001$) for control compared with treatment ($P = 0.014$). Additionally, radiant temperature at the testicular surface increased significantly in control during the trial ($P = 0.008$). This study indicates feeding dietary antioxidants, hydroxy methyl analog, chelated trace minerals, and organic selenium can encourage maintenance of antioxidant metabolites.

Key Words: bull development, oxidative balance, semen quality

W41 Phenotypic correlations of the residual intake and gain with ultrasound carcass traits and other feed efficiency measures in Nellore cattle. R. C. Gomes*[1], S. L. Silva[2], M. H. A. Santana[2], J. B. S. Ferraz[2], P. Rossi Jr.[3], and P. R. Leme[2], *[1]Department of Animal Science, State University of Londrina, Londrina, Parana, Brazil, [2]College of Animal Science and Food Engineering, University of Sao Paulo, Pirassununga, Sao Paulo, Brazil, [3]Federal University of Parana, Curitiba, Parana, Brazil.*

The residual feed and gain (RI&G) was recently reported as an alternative feed efficiency trait in beef cattle; however, associations of RI&G with carcass traits have not been described. The aim was to evaluate the phenotypic correlations of RI&G with ultrasound carcass traits in Nellore bulls and steers. Individual dry matter intake (DMI) and average daily gain (ADG) were computed in Nellore steers (n = 267, 20-mo old; 346 ± 30 kg initial BW) and bulls (n = 277, 22-mo old; 391 ± 40 kg initial BW) in performance tests that were carried out from 2005 to 2011. Ultrasound backfat thickness (UBFT), rump fat thickness (URFT) and rib eye area (UREA) were measured at the beginning and at the end of each test and the daily gain of each trait was calculated. Residual feed intake (RFI), residual gain (RG) and RI&G were computed using test as a contemporary group effect in the model. Pearson correlation analyses were carried out separately for steers or bulls. Coefficients of correlation of RI&G with feed conversion ratio (FCR), RFI and RG were respectively −0.79; −0.86 and 0.86 for steers and −0.70; −0.87 and 0.87 for bulls ($P < 0.0001$). RI&G, RFI and RG were not correlated with mid-test body weight ($P > 0.05$). For steers, RI&G was not correlated with final UBFT (0.00, $P > 0.05$), final URFT (−0.03, $P > 0.05$) and with the daily gain of both traits (−0.03 and 0.01, respectively, $P > 0.05$). Positive low correlations were observed between RI&G and final UREA (0.13, $P < 0.05$) and with UREA gain (0.14, $P < 0.05$). In bulls, RI&G was not correlated with UREA gain (0.00, $P > 0.05$), final UBFT (−0.06, $P > 0.05$), final URFT (−0.04, $P > 0.05$) and with the gain of both traits (0.08 and 0.02, respectively, $P > 0.05$). A low positive correlation was observed between RI&G and final UREA (0.17, $P < 0.05$). In the same data set, RFI and RG were correlated with UBFT and URFT gains in steers, whereas RG was also correlated with final UREA in both genders. Residual intake and gain is highly correlated with other feed efficiency traits and seems independent of subcutaneous fat deposition, but not rib eye area.

Key Words: beef, *Bos indicus*, gain to feed

W42 Estimation of genetic parameters for carcass and image analysis traits of Japanese Black (Wagyu) in Australia.

S. Maeda*[1], J. Grose[2], and K. Kuchida[1], [1]*Obihiro University of A&VM, Obihiro, Hokkaido, Japan,* [2]*Wagyu Genetics Pty Ltd., Brisbane, QLD, Australia.*

Japanese Black (JB) is the major breed of beef cattle in Japan and is known for high marbling (intramuscular fat). JB were introduced into Australia in the 1990′s with importation of embryos and live JB from USA. Similar to Japan, improvement in marbling is rewarded in some domestic and export beef markets in Australia. The AUS-MEAT marbling score (MS) grading system was designed for rating relatively lean meat. The AUS-MEAT MS system has problems in adequately describing the relatively higher marbling that occurs in JB. The objectives of this study were to estimate genetic parameters for carcass and image analysis traits and to investigate an effective indicator of improving marbling of JB in Australia. Australian bred and raised JB (n = 414) were used for this study. All animals were fed in Australian feedlots and shipped to an Australian abattoir and processed from August 2010 to July 2011. Image analysis traits were collected with a Mirror Type camera taking digital images at the 5th-6th rib cross section. The mathematical model for genetic analysis included sex and month of kill data as fixed effects and slaughter age as covariate. Heritabilities and genetic correlations were estimated by the AIREMLF90 program. The peak of frequency distribution of AUS-MEAT Marbling Score with the range from 1 to 9 was 9. Estimated heritabilities for grading and image analysis traits were 0.23 for MS, 0.59 for HCW, 0.44 for rib eye area, 0.54 for marbling percent (intramuscular fat) (MP), 0.37 for coarseness index of marbling (CIM), 0.55 for fineness index of marbling, 0.32 for minor-major axes ratio of rib eye, 0.08 for complexity of rib eye shape, 0.57 for average luminance of lean, respectively ($P < 0.05$). Heritability of MS was less than MP. These results show that MS is an unsuitable evaluation value for JB, when compared with Image analysis traits for the effective genetic improvement of marbling in Australian JB. However, genetic correlation between MP and CIM was positive (0.33). Thus, marbling improvement using selection for MP may also increase the negative attribute of CIM.

Key Words: Australian Japanese Black (Wagyu), heritability, image analysis

W43 Effect of different feeding system on the fatty acid and lipid oxidation of raw and cooked meat of Sarda-Bruna young bulls.

S. P. G. Rassu, R. Boe, R. Rubattu, A. Mazza, G. Pulina, and A. Nudda,* *Dipartimento di Agraria, Sezione di Scienze Zootecniche, Università di Sassari, Sassari, Italy.*

Fatty acid composition, nutritional quality and oxidative stability was determined in raw (RW) and cooked (CK) samples of Longissimus dorsi (LD) of 10 Sardo-Bruna young bulls from 2 different feeding systems. After weaning (mean = 8.5 mo of age) bulls were divided into 2 groups: 5 animal reared on pasture during the daylight (5 - 6 h/d) and supplemented with a mixture of concentrate and of meadow hay (P), and 5 confined in stable (NP). Young bulls were slaughtered at about 500–550 kg live weight. Five days after slaughtering, the LD, between 5th and 7th rib, were remove and split into 2 pieces: 50 g of each sample was RW and 50 g was CK in a microwave at 650 W for 45 s to a final internal temperature of 75°C. Lipid oxidation was measured as mg of malondialdehyde (MDA) per kg of meat. Data were analyzed using a model including feeding systyem, cooking and their interaction. Fat content did not differ between P (1.42%) and NP (1.50%) groups in RW samples ($P = 0.68$), whereas it tended to be greater in CK samples ($P = 0.07$) of both groups (2.86% and 2.06 in P and NP, respectively). The RW samples of P group showed a lower content of PUFA n6 (12.7 vs 15.1; $P = 0.07$), and a greater proportion of PUFA n3 (1.7 vs 1.1; $P = 0.08$), with a more favorable n6/n3 ratio (7.6 vs. 14.5; $P < 0.01$) compared with NP group. In particular, the RW samples of P group had higher content of C18:3n3, C18:1t11, CLA c9t11 isomer and odd-branched fatty acids and a lower content of C20:2n6, C20:4n6 and C22:4n6 fatty acids than NP group ($P < 0.05$). The microwave cooking did not change the relative proportion of fatty acid in both feeding system treatment ($P = 0.23$). Lipid oxidation was not influenced by feeding, but was markedly increased by cooking ($P < 0.01$) in P (from 0.07 to 0.52) and NP (from 0.23 to 0.56). The results showed that grazing for few hours per day influenced positively the fatty acid profile of meat from young bulls. Research funded by Associazione Melina, Sardinia, Italy.

Key Words: beef meat, feeding system, fatty acid

W44 Analysis of twin births, calf stillbirth, abortion and calf death before 28 days of age in Irish Charolais and Limousin populations.

A. M. Doyle*[1], R. D. Evans[2], and A. G. Fahey[1], [1]*School of Agriculture and Food Science, University College Dublin, Ireland,* [2]*Irish Cattle Breeding Federation, Bandon, Co. Cork, Ireland.*

Twinning in beef cattle provides an opportunity for improvements in production efficiency. However, twinning may also have adverse effects on animal welfare and management. A greater understanding of factors associated with twinning will help us to formulate management strategies that will increase twinning while minimizing adverse affects. The objective of this study was to analyze the incidence of twin births in Irish Charolais (CH) and Limousin (LM) herds and potentially associated factors of calf stillbirth, abortion, and calf death before 28 d. Incidence of stillbirth, abortion and calf death before 28 d was analyzed through a comparison between single and twin births. Calving records of CH (n = 110,401) and LM (n = 138,416) herds from 2004 to 2009 were used for the analysis. The mean twinning, calf stillbirth, abortion, and calf death before 28 d was 4.5%,1.84%,0.32%, and 1.73% for CH and 1.5%, 1.35%,0.25%, and 1.45% for LM respectively. Twinning increased as the parity increased (Odds Ratio (OR) = 1.77 for CH parity 5 vs. parity 1; OR = 1.80 for LM parity 5 vs. parity 1). The greatest odds of twinning occurred for calves born in summer for each of the breeds. Calf stillbirth was higher for twin births than for single births in CH (OR = 3.78 twin vs. single birth) and LM (OR = 2.38 twin vs. single birth). Calving difficulty greatly influenced the odds of stillbirth occurring, particularly in twin births, where CH (OR = 16.30 calving score 4 vs. calving score 1) and LM (OR = 33.74 calving score 4 vs. calving score 1). Abortion is also more likely for twin pregnancies than single pregnancies in LM animals (OR = 4.14 twin vs. single birth). Season of birth, year or birth and dam parity also effected the odds of abortion occurring. The odds of calf death before 28 d was increased for twin births when compared with singles and were also affected by parity, season, sex of calf and year of calving. This research shows that twinning rate may be affected by breed and age of the dam, and can affect calving difficulty and mortality. Twinning rates are affected by breed and age of the cow and management strategies are therefore required to reduce calving difficulty and mortality where cows are pregnant with twins.

Key Words: twinning, abortion, stillbirth

W45 The effect of limiting feed intake on visceral organ mass and performance in the pregnant beef cow.

K. M. Wood*[1], C. J. Fitzsimmons[2,3], S. P. Miller[1], I. B. Mandell[1], B. W. McBride[1], and K. C. Swanson[4], [1]*Dept. of Animal and Poultry Science, University of Guelph, Guelph, ON, Canada,* [2]*Agriculture and Agri-Food Canada, Edmonton, AB, Canada,* [3]*Dept. of Agriculture, Food and Nutritional*

Science, University of Alberta, Edmonton, AB, Canada, [4]Dept. of Animal Sciences, North Dakota State University, Fargo.

Twenty-two multiparous pregnant beef cows were used to investigate the effect of dietary restriction on the visceral organ mass and cow performance. Cows were fed a haylage-based total mixed ration containing 20% wheat straw at either 85% ($n = 35$; LOW) or 140% ($n = 34$; HIGH) of NEm. Cows were blocked by date of parturition and were slaughtered at approximately 250 d of gestation, after 83 d on dietary treatment and every wk thereafter for 6 wks. Visceral organs were removed of digesta, trimmed of fat and weighed. Statistical analysis was conducted using Proc Mixed in SAS and included the fixed effect of dietary treatment, cow age, block and the random effect of pen. Cows fed HIGH consumed 10.9 kg DM per d and LOW consumed 6.8 kg DM per d ($P < 0.001$). Cows fed HIGH had a greater ($P = 0.003$) ADG than LOW. Cows fed HIGH had a greater final BW than LOW ($P = 0.04$), even though initial BW did not differ ($P = 0.9$). There were no differences ($P \geq 0.32$) between treatments for grade fat, ribeye area or marbling score, while HCW tended to be greater ($P = 0.07$) in HIGH. Rumen weight was greater ($P = 0.02$) in HIGH and liver weight tended to be greater ($P = 0.07$) in HIGH, however these variables expressed relative to HCW were not ($P \geq 0.40$) different. Weights (actual or relative to HCW) of kidney, lungs, heart, pancreas, spleen and lower GI (large + small intestine + cecum) did not differ ($P \geq 0.14$) between treatments. Total visceral fat was numerically greater in HIGH ($P = 0.2$) however large variation was observed. This data indicates that restricted dietary intake impacted the performance of the cow during late gestation, but did not affect visceral organ mass. This data will further the understanding of feed efficiency and maintenance energy requirements in the pregnant beef cow.

Key Words: beef cows, visceral organ mass, feed intake

W46 Whole cottonseed can promote as much rumination activity as barley straw when incorporated in TMR fed beef heifers at finishing period. S. P. Iraira,* J. L. Ruíz de la Torre, M. Rodríguez-Prado, X. Manteca, S. Calsamiglia, and A. Ferret, *Universitat Autònoma Barcelona, Bellaterra, Spain.*

Eight Simmental heifers (initial BW 313 ± 13.2 kg) were randomly assigned to one of 4 experimental treatments in a 4 × 4 double Latin square design. The experiment was performed in 4 28-d periods. Treatments tested were a control diet in which barley straw was used as a fiber source (BS), and 3 diets where the main difference was the non-forage fiber source used: soybean hulls (SH), beet pulp in pellets (BP) and whole cottonseed (WCS). Fiber ingredients were incorporated at 10, 17, 17 and 16% (on DM basis) in BS, SH, BP and WCS, respectively. All diets were offered ad-libitum as TMR and designed according to NRC (1996) to be isoenergetic (2.95 Mcal/kg DM) and isonitrogenous (15% on DM). Animals were individually housed in roofed pens. Intake was recorded over 7 d in the last week of each experimental period. Behavior was recorded for 24-h on d 2 and d 6 of each experimental week using a digital video-recording device. A digital color camera was set up in front of each pen. Recorded activities were registered together with their beginning and ending times. Data for each activity is presented as the total time, expressed in minutes per day, in which the animal showed the specific activity. An observation was defined as eating when the animal had its muzzle in the feedbunk or was chewing or swallowing food with its head over it. Ruminating included regurgitation, mastication and swallowing of the bolus. Intake of DM was statistically analyzed using the MIXED procedure of SAS. To test treatment effect for each behavioral activity, analysis was performed by using the GLIMMIX procedure of SAS. DM intake was higher in WCS than in the remaining treatments (7.9 vs 7.3 kg/d; $P = 0.05$). Time spent eating tended ($P = 0.10$) to be higher in WCS and BP (93 min/d) than in BS and SH (76 min/d). Time spent ruminating was not different between BS and WCS (294 and 249 min/d) but was lower ($P = 0.001$) in SH and BP (168 and 166 min/d). In conclusion, WCS can promote ruminating behavior as much as BS.

Key Words: cattle behavior, concentrate diet, whole cottonseed

W47 Protein supplementation of low-quality forage: Effects of amount and frequency on cow performance and intake and nutrient digestibility by steers. D. W. Bohnert[1], R. F. Cooke[1], B. I. Cappellozza[1], D. L. McGuire*[1], and S. J. Falck[2], *[1]Eastern Oregon Agricultural Research Center, Oregon State University, Burns, [2]Eastern Oregon Agricultural Research Center, USDA-ARS, Burns.*

Two experiments were conducted to determine the effects of supplement amount and supplementation frequency (SF) on performance, DMI, and nutrient digestibility by cattle consuming low-quality forage. Treatments were arranged in a 2 × 3 factorial design (2 levels of CP and 3 SF; CON = unsupplemented; D = supplemented daily; 5D = supplemented once every 5 d; 10D = supplemented once every 10 d; 1/2 D = supplemented at 50% of D; 1/2 5D = supplemented at 50% of 5D; 1/2 10D = supplemented at 50% of 10D). In Experiment 1, 84 cows in the last third of gestation were used in a randomized complete block design to evaluate treatment effects on BW and BCS change while in Experiment 2, 7 steers were used in a 7 × 4 incomplete Latin square to evaluate nutrient intake and digestibility. Soybean meal (SBM) was used as the source of supplemental CP. Full CP refers to D, 5D, and 10D (each full CP treatment received the same amount of CP over a 10 d period) and half CP refers to 1/2 D, 1/2 5D, and 1/2 10D dietary treatments. In Exp. 1, precalving BCS change was more positive ($P = 0.03$) for supplemented treatments. We did note a linear effect of SF × amount of CP for precalving BCS ($P = 0.06$), with full CP treatments decreasing more as SF decreased from D to 10D compared with half CP (0.1 to −0.3 and −0.2 to −0.3, respectively). Straw and total DMI were increased with supplementation ($P < 0.03$) in Experiment 2; however, we observed a linear effect of SF × amount of CP for both variables ($P = 0.02$); DMI with full CP decreased a greater amount as SF decreased compared with minimal change for half CP. Apparent total tract DM, OM, and NDF digestibility was not affected by supplementation ($P > 0.10$), while DM and OM digestibility responded quadratically to SF with lower digestibility occurring on 5D treatments ($P < 0.05$). Plasma urea was greater with supplementation ($P < 0.001$) and for full compared with half CP ($P < 0.001$). Reducing the amount of supplemental CP provided to ruminants consuming low-quality forages, when supplementation intervals are greater than 5 or 6 d, can be a management tool to maintain acceptable levels of DMI, digestibility, and performance while reducing supplement cost.

Key Words: cattle, frequency, supplementation

W48 Using corn stover and DDGS to conserve stockpiled forages and improve reproductive performance and progeny growth in fall-calving beef cows. P. J. Gunn*[1], R. P. Lemenager[1], and G. A. Bridges[2], *[1]Department of Animal Sciences, Purdue University, West Lafayette, IN, [2]North Central Research and Outreach Center, University of Minnesota, Grand Rapids.*

Angus-cross, fall-calving beef cows ($n = 153$; $BCS = 5.4 \pm 0.5$) were used to determine if incorporating a period of corn stover and dried distillers grains with solubles (DDGS) feeding into a preexisting nutritional program that included grazing stockpiled fescue affects reproductive performance and progeny growth. Calving began on Julian d 243. On Julian d 267, cows were stratified and allotted by BW, BCS, and calving date (if calved) to receive 1 of 2 isocaloric dietary treatments through timed-AI (TAI): stockpiled fescue (CON) or corn stover and DDGS (DG; DDGS at 0.7% BW per d). Following TAI, CON cows were fed grass hay, and DG cows were placed on stockpiled fescue until grass was exhausted (Julian d 20) and then fed grass hay. Cow BW and BCS were assessed every 28 d during supplementation. Estrous cycling status was determined by evaluation of progesterone in 2 blood samples taken at and 10 d before estrous synchronization, and on Julian d 336, TAI was conducted. Pregnancy determination was done by transrectal ultrasonography 35 d after TAI and the end of the breeding season. Calf weights were recorded at 62 ± 16 and 146 ± 16 d of age and again at weaning (steers and heifers were weaned at 144 ± 16 and 208 ± 18 d of age, respectively). Categorical and continuous data were analyzed with the GLIMMIX and MIXED procedures of SAS, respectively. Cow BW and BCS did not differ during the supplementation period. The proportion of cows cycling at breeding season initiation tended ($P = 0.06$) to be greater in CON (92.2%) than DG (80.6%) treated cows. TAI pregnancy rates did not differ between the CON (42.4%) and DG (50.0%) treatment. However, breeding season pregnancy rates were greater ($P = 0.03$) in the DG (89.6%) than CON (74.2%) treatment. DG progeny were heavier at 62 d of age and at weaning and had a greater 205 d adjusted weaning wt ($P \leq 0.03$) than CON progeny. In summary, including a dietary period of corn stover and DDGS to a traditional management practice of grazing stockpiled fescue and feeding hay resulted in greater breeding season pregnancy rates and heavier progeny.

Key Words: beef cow, DDGS, fertility

W49 Meta-analysis on the effects of supplementing distiller′s grains to beef cows during early lactation on reproductive efficiency and pre-weaning progeny growth.

P. J. Gunn*[1], J. P. Schoonmaker[1], R. P. Lemenager[1], and G. A. Bridges[2], [1]*Department of Animal Sciences, Purdue University, West Lafayette, IN,* [2]*North Central Research and Outreach Center, University of Minnesota, Grand Rapids.*

Three independent studies using Angus-cross beef cows (n = 284) at Purdue University assessed the effects of feeding dried distiller′s grains with solubles (DDGS) as a primary dietary energy source during various phases of production on performance, reproduction, and progeny development. The purpose of this meta-analysis was to determine the effects of DDGS supplementation during early lactation on reproductive performance and progeny growth. In all studies, cows were stratified and allotted by BW and BCS to 1 of 2 isocaloric dietary treatments initiated either at 192 d of pregnancy or during calving. Diets were: 1) corn silage and haylage, or stockpiled forage (CON); or 2) low quality forage with DDGS (DG) supplementation. DG supplementation concluded at either timed-AI or at ultrasonography pregnancy diagnosis approximately 30 d after timed-AI. All cows were synchronized for estrus using the 5 d CO-Synch + CIDR protocol. BW and BCS were assessed throughout the supplementation periods. Categorical and continuous data were analyzed with the GLIMMIX and MIXED procedures of SAS, respectively. Meta-analysis demonstrated that days postpartum, BW, and BCS at estrous synchronization, as well as the proportion of male offspring born did not differ ($P \geq 0.53$) between treatments. However, the meta-analysis revealed that timed-AI pregnancy rates were greater (64.1 vs. 50.0%; $P = 0.02$), and overall breeding season pregnancy rates tended to be greater (91.5 vs. 84.9%; $P = 0.10$) in DG than CON treatments. Although DG progeny were heavier than CON at birth (36.2 ± 0.5 vs. 34.4 ± 0.5 kg; $P = 0.01$), DG progeny had greater pre-weaning ADG (0.99 ± 0.01 vs. 0.95 ± 0.01 kg; $P = 0.009$), weaning weights (236 ± 3.1 vs. 228 ± 3.0 kg; $P = 0.04$), and 205 d adjusted weaning weights (230 ± 2.5 vs. 222 ± 2.4 kg; $P = 0.009$) than CON progeny. In conclusion, using a meta-analysis to combine 3 independent studies demonstrated that utilization of DDGS as a primary dietary energy source during early lactation appears to result in improved fertility and accelerated progeny growth.

Key Words: DDGS, developmental programming, fertility

W50 Effects of water stress and plant population on corn plant yields and composition.

S. Soderlund, C. J. Fagan, A. T. Hassen, and F. N. Owens,* *Pioneer Hi-Bred International, a DuPont Business, LaSalle, CO.*

Higher plant densities and adequate irrigation typically increase corn silage yield, but their effect on quality remains uncertain. Four elite commercial Pioneer corn hybrids (109–116 d CRM) planted in 4 rows 76 cm apart and 4.6 m long were thinned to 59, 89, and 119 thousand plants per hectare in quadruplicate subplots. In addition to 17 cm rain, sub-subplots received 65 cm (full), 34 cm (moderate), or 18 cm (limited) of subsurface irrigation water by irrigating at each, alternate, or every third cycle during the growing season. Whole plants were chopper harvested when kernels were fully dented (one-third milk line); hybrids averaged 30.4 to 33% DM. Harvest weight was measured and chemical components were determined for the 144 sub-subplots. Main effects are described only when interactions were not significant ($P > 0.05$). Although DM yield and calculated milk per acre were least ($P < 0.05$) with the lowest plant population, milk per ton of DM (Milk 2006) was reduced ($P < 0.05$) at the highest plant population. Limiting the water supply linearly reduced ($P < 0.05$) plant height, DM yield, and milk per acre. However, NDF digestibility increased linearly ($P < 0.05$; from 50 to 55%) as water supply was restricted; severe water restriction reduced milk per ton. NDF digestibility was greater ($P < 0.05$) for Pioneer BMR hybrid P1376XR than for the other 3 hybrids (55 vs. 50 to 52%). Averaged across hybrids, limiting the water supply decreased yield and concentration of starch but increased plant protein, sugar, and NDF; in vitro DM digestion and milk per ton was greatest when water supply was moderate. As plant population increased, DM yield increased but starch content and NDF digestibility decreased; in vitro DM digestion and milk per ton was greatest with the lowest plant population. Although hybrid rankings generally remain similar, local and yearly differences in both yield and quality of corn silage can be ascribed partially to differences in water availability and plant population.

Key Words: corn silage, irrigation, plant population

W51 Prediction of preweaning ADG in beef calves from milk fatty acid methyl esters.

Z. Deng*[1], M. A. Brown[2], Y. Peng[3], S. Coleman[2], and R. G. Mateescu[1], [1]*Oklahoma State University, Stillwater,* [2]*USDA-ARS, Grazinglands Research Laboratory, El Reno, OK,* [3]*Xi'an Vertexe Electronics Technology Co. Ltd., Xi'an, Shaanxi, China.*

Research has shown milk yield (MWT) has an important influence on calf preweaning ADG (PRWADG), but MWT accounts for only a moderate amount of variation in PRWADG. The objective of this study was to determine if milk fatty acid methyl esters (FAME), alone and in combination with MWT, could improve accuracy of prediction of PRWADG. Forty-five beef cows sired by Bonsmara, Brangus, Charolais, Gelbvieh, Hereford and Romosinuano bulls were used in a 2 yr study. Spring-calving cows were milked 6 times per year every 28 d beginning late May, and milk samples were analyzed for milk fat and protein. Milk samples collected in May, July and September each year were analyzed for FAME. Percentages of 42 FAME in each milk sample were acquired using a gas chromatograph flame ion detector. Milk weights, quality data, and FAME were averaged over collection dates before analyses. Stepwise regression was used to identify linear models to predict PRWADG using MWT, age of dam (AOD), and percent FAME. The R^2 and associated condition index (CI, an indicator of collinearity) were used in model evaluation. Condition indexes less than or close to 30 were considered to have low collinearity. Regression of PRWADG on MWT resulted in an R^2 of 0.35 with a CI of 9.4 while inclusion of AOD gave an R^2 of 0.4 and a CI of 21.6. A regression equation using 8 FAME accounted 54% of the variation in calf ADG with a CI of 33. When MWT and AOD were included with FAME as predictors, a prediction equation with 8 FAME, MWT, and AOD accounted for 69% of the variation in PRWADG with a CI of 29. Partial least squares regression (PLS) was also used to predict PRWADG from FAME, MWT, and AOD. Results from PLS analyses yielded a dependent variable R^2 of 0.61 using all 42 FAME with 7 extracted factors and a dependent variable R^2 of 0.78 when MWT and AOD were included with the 42 FAME with 7 extracted factors. Results from these preliminary analyses suggest that FAME composition of milk influences calf ADG and that data on percent FAME in combination with MWT and AOD can improve the accuracy of prediction of calf PRWADG compared with MWT and AOD alone.

Key Words: beef cattle, milk fatty acids, preweaning ADG

W52 Correlation of IGF-1, growth hormone, and leptin to breeding beef heifer productivity.

C. J. Mueller*[1], D. Keisler[2], H. DelCurto[1], and T. DelCurto[1], [1]*Eastern Oregon Agricultural Research Center, Oregon State University, Union,* [2]*University of Missouri, Columbia.*

The use of metabolic parameters associated with growth and tissue development may aid in predicting productivity of beef heifers, thus reducing potential production inefficiencies. Dam and offspring production variables were collected on 84 Angus-based crossbred heifers retained from the 2006 (n = 40 heifers; 3.42 parities/heifer) and 2007 (n = 44 heifers; 2.64 parities/heifer) calf crops. Blood samples were obtained at approximately 1 yr of age and analyzed for IGF-1, GH, and Leptin concentrations. Data within each hormone category were grouped (GROUP) into upper 25% (HIGH), middle 50% (MID), and lower 25% (LOW) of hormone concentrations using univariate analysis. Production variables within hormone category were analyzed as a one-way ANOVA with GROUP as the main effects and heifer birth year as a covariate. Experimental unit was heifer and the error term was residual error. Pearson correlation coefficients were determined between production variables and hormone concentrations. Pregnancy interval was correlated ($r = -0.273$; $P = 0.020$) with IGF-1, with higher concentrations associated with shorter intervals (−5 d/yr). Pregnancy interval was 5.9 d less ($P = 0.045$) for HIGH vs. MID IGF-1, 9.9 d less ($P = 0.013$) for HIGH vs. LOW GH, and tended ($P = 0.082$) to be 4.2 d greater for MID vs. LOW leptin. Number of parity was not associated ($P > 0.10$) with hormone concentrations or GROUP within hormone categories. Percentage of calves weaned/born tended ($P = 0.086$) to be less for HIGH (94.7%) vs. MID leptin (99.4%). No correlations ($P > 0.10$) between hormone concentrations and percent calves weaned/born were observed. Offspring carcass weights (HCW), ratio of ribeye area-to-HCW, and marbling scores were not affected ($P > 0.10$) by heifer hormone concentrations within any hormone category. Yield grade (YG) of offspring was correlated ($r = 0.256$, $P = 0.057$) with heifer IGF-1 concentrations; with MID (2.74) tending ($P = 0.073$) to have lower YG vs. HIGH (3.01). These data indicate that concentrations of IGF-1, GH, and Leptin at time of replacement heifer selection have limited value as prediction tools of female productivity.

Key Words: hormones, beef heifers, productivity

W53 Exposure of prepubertal beef bulls to cycling females does not enhance sexual development.

N. Miller* and K. Fike, *Kansas State University, Manhattan.*

The objectives of the study were to determine if continuous, long-term, fenceline exposure of prepubertal beef bulls to cycling beef females affects bull age at puberty and ability to pass their first breeding soundness examination (BSE). Angus, Simmental, and Hereford bulls (n = 77) within breed were stratified by age and assigned to treatment (average age of 196 ± 22 d). Exposed bulls (EXP) had continuous fenceline contact with cycling females for the duration of the study while control (CON) bulls were penned a minimum of 42 m from cycling females without visual or physical contact. Estrous cycles were synchronized, such that 2 to 5 females were in estrus each week. Body weights (BW) and scrotal circumference (SC) were measured every 28 d. When bulls achieved a ≥ 26 cm SC, semen samples were obtained monthly via electroejaculation until puberty was reached. Bulls were considered pubertal when sperm concentration was $\geq 50 \times 10^6$/mL and motility was ≥ 10 percent. Homosexual mounting behavior (MB) of bulls was assessed twice/mo during diestrus (D) and estrus (E) stages of females. BSEs were conducted when bulls averaged 364 ± 22 d of age. Normal sperm morphology of $\geq 70\%$ and sperm motility of $\geq 30\%$ were considered passing. Age and SC at puberty and MB were analyzed using PROC MIXED in SAS, with fixed effect of treatment and random effect of pen; mo and stage of estrous were included as fixed effects for MB. BSE data were analyzed using PROC GLIMMIX in SAS with fixed effect of treatment. Age and SC at puberty were similar for EXP and CON ($P > 0.10$; 323 d and 311 d, respectively; 34.6 cm and 34.9 cm, respectively). Treatment and female estrous stage interacted to affect bull MB ($P < 0.01$). EXP bulls had more MB when females were in E as compared with D ($P < 0.01$). Similar MB were observed for EXP bulls when females were in E compared with CON bulls during both E and D ($P > 0.10$). A similar percentage of bulls passed their first BSE ($P > 0.10$; EXP = 87.8% and CON = 74.4%). In conclusion, continuous, fenceline exposure of developing bulls to cycling beef females does not reduce age at puberty nor influence ability to pass first BSE.

Key Words: bulls, puberty, breeding soundness examinations

Breeding and Genetics: Molecular Biology and Genomics

W54 Protection and stabilization of whole blood at room temperature does not influence DNA yield, purity, and integrity. R. Flores*[1], M. Udtha[1], J. E. Sanner[1], E. A. Backes[2], L. S. Wilbers[2], and J. D. Caldwell[2], *[1]The University of Texas Health Science Center at Houston, Houston, [2]Lincoln University, Jefferson City, MO.*

Preservation of bio-specimens for molecular biological applications traditionally involves freezing which increases laboratory and research project costs. Protection and stabilization of DNA at room temperature (RT) may eliminate the costs associated with freezer storage. However, there is a paucity of information describing the yield, purity, and integrity of DNA stored at RT. Objectives were to evaluate the yield, purity, and integrity of DNA extracted from whole blood samples stored at RT, low (−20°C), and ultra-low (−80°C) temperatures. Sheep (n = 4 [7 mL]) and human (n = 6 [4 mL]) whole blood samples were collected and aliquots stored at RT, −20°C, and −80°C. Blood samples at RT were stored utilizing bio-stabilization technology (DNAstable Blood and DNAgard Blood; Biomatrica, San Diego, CA) designed to protect genomic DNA in whole blood from degradation resulting from unprotected RT storage. Negative control samples were stored unprotected at RT. Genomic DNA was extracted by using the QIAamp DNA Blood Mini Kit (Qiagen, Valencia, CA). Quantification and purity of the extracted DNA was determined by spectrophotometry and the integrity was assessed following electrophoresis. The DNA yield was not influenced by a species × storage temperature interaction ($P = 0.84$). Similarly, storage temperature did not influence DNA yield ($P = 0.52$) and averaged 13.6 ± 1.2 ng/μL across all storage temperatures. Among samples stored protected at RT, species, type of technology utilized, and the interaction did not ($P > 0.13$) influence DNA yield with yield averaging 12.5 ± 1.2 and 12.7 ± 1.2 ng/μL for DNAgard and DNAstable, respectively. The 260/280 ratio was influenced by a species × storage temperature interaction ($P = 0.01$). In general, the 260/280 ratios were higher ($P < 0.05$) for human samples stored at low and ultra-low temperatures compared with sheep samples stored at similar low temperatures. In conclusion, ambient temperature-based bio-stabilization technologies may offer an alternative to traditional low temperature-based bio-specimen preservation and storage.

Key Words: blood, DNA, temperature

W55 Maximum differences analysis: An empirical method for genome-wide association studies. M. Cellesi, N. P. P. Macciotta,* G. Pulina, G. Gaspa, and C. Dimauro, *Dipartimento di Agraria, Universitá di Sassari, Italy.*

Genome-wide association studies have rapidly become the most popular method to discover associations between SNPs and quantitative traits. Marker significance is traditionally assessed by using the Bayesian or the frequentist approach. Both methods have positive and negative aspects. In the present study we suggest an empirical method which combines the simplicity of the frequentist approach with the reliability of Bayesian inference. We called this method maximum difference analysis (MDA). A total of 2,093 Italian Holstein bulls were genotyped with the Illumina BovineSNP50 BeadChip. Polygenic EBV for milk yield, fat and protein content were available. MDA starts by randomly choosing 1,500 animals and retaining the best 100 (B) and the worst 100 (W) animals for a particular trait. Relative genotypes frequencies for each marker were calculated for B and W group, respectively. Then the difference between genotype having the highest frequency in B and the corresponding frequency in W were calculated. In every single chromosome, the above mentioned differences were considered as a random variable and, after standardization, SNPs with difference higher than 1.96 standard deviations were retained as possible candidate for association. This procedure was repeated 5,000 times and the frequency (fi) of the previous detected association for each SNP annotated. A marker was considered significantly associated with the specific trait if $pi = fi/5000 > 0.99$. For milk yield, fat and protein, 93, 40 and 92 markers were selected, respectively. Several SNP were found to be significantly associated to more traits: 19 for milk and protein, 19 for milk and fat, 12 for fat and protein and 10 among all traits. Moreover, 19, 7 and 17 SNPs, for milk, fat and protein, respectively, were selected with $pi = 1$. The reliability of results obtained by MDA was confirmed by the detection of several SNPs located near genes known to affect the specific trait, as the DGAT1 and the casein cluster.

Key Words: gene association

W56 Adjustment of selection index coefficients and polygenic variance to improve regressions and reliability of genomic evaluations. P. M. VanRaden, J. R. Wright,* and T. A. Cooper, *Animal Improvement Programs Laboratory, USDA-ARS, Beltsville, MD.*

In multi-step genomic evaluations, direct genomic values (DGV) are computed using either marker effects or genomic relationships among the genotyped animals, and information from non-genotyped ancestors is included later by selection index. The DGV, the traditional evaluation (EBV), and a subset breeding value (SBV) estimated using pedigree relationships among the genotyped animals are combined according to theoretical weights based on reliabilities of the 3 terms. In official yield trait evaluations of young Holstein bulls, the weights average 0.99 for DGV, 0.12 for EBV, and −0.11 for SBV. Alternative weights have been proposed by other countries to increase reliabilities and regressions of predicting future data from past. Most US regressions were close to expected values and increased when some weight was removed from the DGV and added to either the EBV or SBV or both. Reliabilities decreased slightly for Holsteins with weight added to either EBV or SBV, but reliability increased for some traits of Jerseys if weight was added to SBV. Maximum weights on DGV of 1.0, 0.9, and 0.8 were compared. For each 0.1 decrease, regressions increased by about 0.02. Regressions for a few traits were lower than expected, and limiting the DGV weight to 0.9 or 0.8 instead of the theoretical value of 1.0 helped bring the regressions into compliance with validation tests. Adjustments to polygenic variance also increased the regressions by about 0.02 for each 0.1 increase, but reliabilities were slightly reduced when compared with adjusting the selection index weights. Finding optimum percentages of polygenic variance required more computation and was less flexible than finding optimum weights, because recombining 3 terms in a final step is easier than re-estimating all marker effects. Conclusions are that index adjustments can help to pass genomic validation tests for some traits by removing small biases in regressions, but that the theoretical selection index weights currently in use are close to ideal.

Key Words: multi-step evaluation, direct genomic value, validation

W57 Use of canonical discriminant analysis to distinguish among three bovine breeds by using a low number of selected SNP markers. C. Dimauro,* M. Cellesi, R. Steri, S. Sorbolini, and NPP Macciotta, *Dipartimento di Agraria, Universitá di Sassari, Sassari, Italy.*

Multivariate statistical techniques are commonly used to synthesize genomic information in animal breeding studies. In the present work, the multivariate canonical discriminant analysis (CDA) was used to discriminate between 3 bovine breeds. Data consisted of 2,090 Holstein, 750 Brown, and 480 Simmental bulls genotyped by using the Illumina BovineSNP50 BeadChip. After data editing, SNP in common to the 3 breeds were 30,055. A sample of 30 randomly selected bulls (10 for each breed) were used as new observations in the cross-validation data set. When 3 groups are involved, CDA derives 2 canonical functions (CAN1 and CAN2) which are linear combination of the original variables (SNP genotypes coded as 0,1 and 2). Coefficients of the linear combination are the canonical coefficients (CC) and represent the correlation among SNP and canonical functions. CDA was first applied separately on the 29 bovine autosomes. For each chromosome, SNP with CC >0.90 in CAN1 and CC > 0.50 in CAN2 were selected. Results indicated that CDA was able to efficiently separate the 3 breeds also at chromosome level. At the end of the procedure, 295 SNP out of 30,055 were retained. These markers were then used to develop a CDA on the entire genome. The Mahalanobis distance test was highly significant ($P < 0.001$) for all comparisons (distances: Holstein vs. Brown 2,941, Holstein vs. Simmental 3,127, Simmental vs. Brown 410). In particular, CAN1, which accounted for 95% of the total variability, separated Holstein from Brown and Simmental bulls. This result could be due to the high selection pressure exerted on Holstein population and the 129 SNP with CC > 0.90 could be the related signatures. CAN2 was able to significantly separate Brown and Simmental groups. In this case 7 SNP with CC > 0.60 were found. Finally, individuals in the cross-validation data set were 100% correctly classified. The above described procedure could be therefore tested for developing a test for the traceability of breed products. Low-density SNP panels (295 markers in this work), with moderate price, could be specifically developed for routine analysis.

Key Words: genomic association

W58 Reliability of genomic breeding values at different reference population's designs when some or all animals are genotyped. M. Pszczola[1,3], T. Strabel*[3], J. A. M. van Arendonk[2], and M. P. L. Calus[1], [1]*Animal Breeding and Genomics Centre, Wageningen UR Livestock Research, Lelystad, the Netherlands,* [2]*Animal Breeding and Genomics Centre, Wageningen University, Wageningen, the Netherlands,* [3]*Department of Genetics and Animal Breeding, Poznan University of Life Sciences, Poznan, Poland.*

Reliability of genomic breeding values with different structure of a small reference population including ungenotyped animals was investigated. Data reflecting a dairy cattle population structure was simulated for a trait with heritability of 0.3. Reference populations were small and consisted of cows only. Reference populations consisted of highly, moderately, lowly, and randomly related animals by choosing appropriate family structure. Evaluated animals were one generation younger than the reference populations. Four scenarios in which reference population and evaluated animals were not genotyped (AA), reference population was genotyped and the evaluated animals were not genotyped (GA), reference population was not genotyped and the evaluated animals were genotyped (AG) and both groups were genotyped (GG). Reliabilities of direct genomic values were predicted deterministically using selection index theory. For GG, reliabilities were considerably higher than in the other cases. In AG, reliabilities were somewhat higher, than in GA. AG achieved substantially higher reliabilities than AA. Reliabilities increased with decreasing average relationship within the reference population. The main source of the gain in reliability is genotyping the evaluated animals, however, the benefit from genomic selection is substantially higher when all animals are genotyped.

Key Words: genomic selection, reliability, dairy cattle

W59 Dealing with uncertainty of dependent variables in genome wide association studies. S. Smith,* E. H. Hay, and R. Rekaya, *University of Georgia, Athens.*

In genome-wide association studies (GWAS) using multiple-step procedures, the dependent variable (DV) is often a pseudo-observation such as estimated breeding values (EBVs) or de-regressed proofs. Thus, these "estimated" DVs include a certain level of uncertainty. If the sampling errors (SE) attached to these variables are constant across all records, regression analyses will accommodate this situation without major difficulty. However, when SE are heterogeneous across observations, the case with pseudo-records used in GWAS in livestock applications, the situation is more complex. The residual terms of the regression models include 2 components, the SE due to estimation of the DV, i.e., EBVs, and white noise that will exist if it was possible to observe (measure) the DV. Unfortunately, this type of data are often analyzed using an ordinary least square (OLS) assuming homogeneous residuals or weighted least square (WLS) where both components of the residual are assumed to be heterogeneous when only the first component is. In this study we present a method for analyzing uncertain DVs when only one component (SE) of the residual term is heterogeneous with applications in GWAS. Further, we assumed SE to be either completely known or only known up to a proportionality constant to mimic scenarios of using EBVs as DVs. A real data set consisting of 1989 animals genotyped for around 56k SNPs was used. EBVs for growth and associated prediction error variance (PEV) and reliability were computed using phenotypic and pedigree information. After SNP selection using single marker analyses and stepwise regression, 209 SNPs were retained for association with growth EBVs. Four analyses were conducted: 1) OLS (M1); 2) WLS (M2); 3) WLS assuming only heterogeneous SE using the estimated PEV (M3) and 4) WLS assuming only heterogeneous SE using a transformation of the estimated reliabilities (M4). Using a 5-fold cross validation, the results (correlation between EBVs and the prediction) showed a superiority of M3. This superiority ranged from 3% between M3 and M4 to 8% between M3 and M1.

Key Words: uncertainty, genome-wide association, prediction error variance

W60 Increased use of young bulls in dairy cattle breeding programs. H. D. Norman, J. L. Hutchison,* and J. B. Cole, *Animal Improvement Programs Laboratory, ARS, USDA, Beltsville, MD.*

Availability of genomic evaluations since 2008 has resulted in many changes in breeding programs. The contribution of young bulls (0.8 to 3.9 yr old) to those programs was investigated. The number of Holstein sires of young bulls doubled from 2008 (126 sires) to 2011 (276 sires); 14% of sons were sired by a young bull in 2008 compared with 40% in 2011. Corresponding values for Jerseys were 34 and 54 sires of young bulls in 2008 and 2011, respectively, with 19 and 40% sired by young bulls. From US breeding records from 2007 through 2011, 19,359,730 Holstein and 1,133,090 Jersey breedings were examined. Young bulls were used for 28% of Holstein breedings in 2007, 29% in 2008, 39%

in 2009, 43% in 2010, and 48% in 2011; annual percentages for young genotyped Holstein bulls were 0, 8, 36, 42, and 48%. Genotyped bulls accounted for 0, 26, 92, 98, and 99% of breedings to young Holstein bulls annually from 2007 through 2011. Young bulls were used for 25, 27, 31, 33, and 40% of Jersey breedings annually, with 0, 0, 22, 32, and 39% of breedings to young genotyped bulls; genotyped bulls accounted for 0, <1, 72, 98, and 98% of breedings to young Jersey bulls. Percentage of female progeny sired by young bulls was calculated by progeny birth year for 5,035,103 Holstein and 496,062 Jersey heifers. Young bulls annually sired 24, 23, 23, 33, and 40% of Holstein heifers born from 2007 through 2011 and 29, 27, 30, 33, and 35% of Jersey heifers. Mean sire age for Holstein progeny born in 2011 was 23 mo younger than in 2006 for bulls and 12 mo younger for heifers; corresponding values for Jerseys were 15 and 4 mo. Mean net merit from December 2011 weighted by number of breedings was $290 for 2008 breedings, $339 for 2009 breedings, and $361 for 2010 breedings of active Holstein bulls and $230, $483, and $532 for genotyped Holstein bulls (a difference of $60, $144, and $171, respectively). Corresponding values for Jerseys were $270, $286, and $324 for active bulls and $396, $448, and $510 for genotyped bulls (differences of $126, $162, and $186). Use of young bulls has greatly reduced the generation interval and improved the rate of genetic gain since implementation of genomic evaluations.

Key Words: breeding, service sire, genomics

W61 Accuracy and bias for final score in US Holsteins from adding genomic information on bulls and cows.

S. Tsuruta*[1], I. Misztal[1], and T. J. Lawlor[2], [1]*University of Georgia, Athens,* [2]*Holstein Association USA Inc., Brattleboro, VT.*

Obtaining genomic information on animals should lead to a greater opportunity for earlier and more accurate selection. Selective genotyping of validation bulls will lead to a regression coefficient (b) for later daughter deviations on early genomic parent averages to be less than 1.0. A recent study by Olson, et al. (2011) indicates that the current expected b-value for US final score for bulls is 0.781. The objective of this study was to compare the change in accuracy and potential bias from adding genomic information on bulls and cows for final score of US Holsteins. A total of 39,741 animals (5,235 cows and 34,506 bulls) had either a final score themself or progeny with a final score. A SNP chip containing 42,503 usable markers was available for all genotyped animals. The full data set included 10,944,571 records in 2011. The reduced data contained 9,602,030 records in 2007. Validation animals were 760 young bulls born after 2004 and with at least 50 daughters in 2011 and 2,098 young cows born after 2006. Genomic breeding values were calculated with a single-step procedure. Including genotypes on bulls only, raised the R2 from 23.4 to 33.3 along with a slight increase in the b-value. Including genotypes on both bulls and cows improved the R2 to 34.2 and slightly lowered the b-value for the bulls. Including genotypes on bulls and cows improved the cow's accuracy (R^2) from 16.1 to 24.2 with a b-value that went from slightly overestimating the genomic breeding values to slightly underestimating it, i.e., 0.978 and 1.042, respectively. Inclusion of bull and cow genotypes in the single-step procedure improves the accuracy of selection with a small change in the indication of bias from the parent averages.

Key Words: genomic evaluation, final score, US Holstein

W62 SNPs that affect microRNA binding sites in the bovine ACACA gene are associated with polyunsaturated fatty acid (PUFA) content of Canadian Holstein cows.

E. M. Ibeagha-Awemu*[1], K. A. Akwanji[2], Z. Wang[3], and X. Zhao[2], [1]*Dairy and Swine Research and Development Centre, Agriculture and Agri-Food Canada, Sherbrooke, QC, Canada,* [2]*Department of Animal Science, McGill University, Ste-Anne-De-Bellevue, QC, Canada,* [3]*Department of Agricultural, Food and Nutritional Science, University of Alberta, Edmonton, AB, Canada.*

Bovine milk has beneficial lipids that contribute positively to human health. These lipids include some isomers of CLA, oleic and α-linolenic acids and represent a very small portion of the total fatty acids (FAs) in milk. FAs in milk arise from dietary sources or are synthesized de novo in the mammary epithelial cells through the action of enzymes including acetyl-CoA carboxylase-α (ACACA). Fat synthesis is a complex trait that is regulated by genetic, environmental and epigenetic (e.g., microRNA) factors. microRNAs are functional non-coding small RNA molecules that have emerged as important regulators of gene expression. microRNA dis-regulation has been shown to be associated with disease conditions in humans and production traits in farm animals. In this study, we identified 6 SNPs in the 3′UTR of the ACACA gene by sequencing 50 samples and genotyping of 150 samples from Canadian Holstein cows by Sequenom iPLEX Gold technology. The FA profiles of milk from the same cows were analyzed by GC and HPLC. In silico analysis showed that SNPs ACACA-80 A > G affected a binding site for bta-miR-126 while ACACA-83 C > T and ACACA-84 G > A disrupted the binding site for bta-mir-3432. Relationship between FAs and SNPs were analyzed using PROC MIXED of SAS (version 9.3) with genotype as fixed factor. Multiple comparisons of means was done with Turkey adjustment. Significant associations were found between SNPs, total PUFA and other FA isomers in the milks of Canadian Holstein cows. Cows ACACA-80 AA had higher concentrations ($P < 0.05$) of PUFA (2.902 ± 0.122) as compared with cows GG (2.333 ± 0.159) but similar to cows AG (2.576 ± 0.090). ACACA-80 AA also had significantly higher concentrations of C16:1T, C18:1n9c and lower content of total saturated FAs as compared with cows AG and GG. Similarly, cows ACACA-83 CT (3.126 ± 0.185) had significantly higher PUFA content as compared with ACACA-83 CC (2.608 ± 0.067) and ACACA-83 TT (2.256 ± 0.586). PUFA of cows ACACA-84 GG (2.839 ± 0.107) was also higher ($P < 0.05$) as compared with ACACA-84 AA (2.334 ± 0.158) and ACACA-84 AG (2.488 ± 0.129). SNPs ACACA-83 and 84 also affected the content of C16:1, C16:1T, C18:2n6cc, C20:3n6, C6:0, C8:0, C10:0 and C12:0. These results demonstrate that SNPs in the 3′UTR of the ACACA gene may be involved in the regulation of PUFA synthesis and as such may act as potential candidate genes for breeding for improved PUFA content of bovine milk. Our results further suggest that microRNA may be involved in the regulation of mammary milk FA synthesis. We are in the processing of validating our results with a larger data set.

Key Words: ACACA gene, Canadian Holsteins, SNP

W63 Genomic-polygenic evaluation of postweaning weight and ultrasound carcass traits in an Angus-Brahman multibreed population.

M. A. Elzo*[1], C. A. Martinez[1], G. C. Lamb[1], D. D. Johnson[1], M. G. Thomas[2], I. Misztal[3], D. O. Rae[1], J. G. Wasdin[1], and J. D. Driver[1], [1]*University of Florida, Gainesville,* [2]*Colorado State University, Fort Collins,* [3]*University of Georgia, Athens.*

The objectives of this study were to estimate the fractions of additive genetic variances for postweaning weight (PW) and 3 ultrasound traits explained by SNP included in the Illumina3k chip, to compare EBV rankings predicted using genomic-polygenic, genomic, and polygenic models, and to assess EBV trends as Brahman fraction of calves increased from 0 to 1 in an Angus-Brahman multibreed population. Ultrasound traits were ribeye area (UREA), percent of intramuscular fat (UPIMF), and backfat thickness (UBF). Trait measurements on 623 calves born between 2006 and 2010 were collected at the Feed Efficiency Facility of the University of Florida. Single-trait genomic-polygenic (GP) models were used to estimate variance components using Markov Chain Monte Carlo procedures (option VCE from program GS3). Fixed effects were contemporary group (year-pen), age of dam, sex of calf, age of calf, Brahman fraction of calf, and heterozygosity of calf. Random effects were additive SNP, additive polygenic, and residual. Subsequently, EBV were computed with option BLUP of program GS3 using GP models and models that included only genomic (G) or polygenic (P) effects. The fractions of the additive genetic variance explained by SNP in the Illumina3k chip were 0.09 for UREA, 0.38 for UBF, 0.06 for UPIMF, and 0.08 for UW. Rank correlations between EBV from GP and P models were high (0.89 to 0.99), and moderate (0.51 to 0.65) between EBV from G and P models. Regression coefficients for all models and traits showed that calf EBV tended to decrease as Brahman fraction of calves increased suggesting that calves with higher Brahman fraction were leaner, had smaller ribeye areas, and grew more slowly than calves with higher Angus fractions. The low fraction of additive genetic variances accounted for by the markers in the Illumina3k chip indicated that higher density chips would be needed to more completely account for additive genetic variation in multibreed populations.

Key Words: cattle, genomic, multibreed

W64 Genomic-polygenic evaluation of Angus-Brahman cattle for carcass traits with the Illumina 3K chip. M. A. Elzo*[1], G. Hu[1], C. A. Martinez[1], G. C. Lamb[1], D. D. Johnson[1], M. G. Thomas[2], I. Misztal[3], D. O. Rae[1], J. G. Wasdin[1], and J. D. Driver[1], *[1]University of Florida, Gainesville, [2]Colorado State University, Fort Collins, [3]University of Georgia, Athens.*

The objective of this research was to assess the effect of including genotypic information from the Illumina 3k chip on the genetic evaluation of animals for 5 carcass traits in an Angus-Brahman multibreed population using genomic-polygenic (GP), genomic (G), and polygenic (P) models. Fractions of additive genetic variances associated with markers in the Illumina3k chip were computed, and animal EBV rankings and EBV trends as calf Brahman percent increased from 0 to 100% were compared across models. Traits were hot carcass weight (HCW), dressing percent (DP), ribeye area (REA), fat over the ribeye (FOE), and marbling (MAB). Phenotypic and genotypic data were from 202 steers born from 2006 to 2010. Data were analyzed with single-trait models. All models had contemporary group (year-pen), Brahman fraction of calf, heterozygosity of calf, and slaughter age as fixed effects. Random effects were additive SNP (GP and G models), additive polygenic (GP and P models), and residual. Program GS3 was used to compute variance components and heritabilities with option VCE (Markov Chain Monte Carlo), and EBV using option BLUP. Heritabilities were 0.72 for HCW, 0.25 for DP, 0.53 for REA, 0.44 for FOE, and 0.23 for MAB. Fractions of additive genetic variance explained by Illumina 3k SNP were 0.08 for HCW, 0.47 for DP, 0.19 for REA, 0.27 for FOE, and 0.23 for MAB. Higher rank correlations existed between EBV from GP and P models (0.94 to 0.99; $P < 0.0001$) than between EBV from G and P models (0.78 to 0.84; $P < 0.0001$). Regressions of calf EBV on Brahman fractions were non-significant for all traits indicating that calves of comparable EBV for carcass traits existed across all breed compositions. The low fractions of additive genetic variances accounted for by the Illumina3k chip indicated that GP models would need to be used to compute EBV if this chip were used to help predict animal EBV, and that higher density chips would be needed to better account for additive genetic variation in multibreed populations.

Key Words: carcass, cattle, genomic

W65 Using low-density commercial DNA-marker panels on prediction accuracy for expected progeny differences of selection criteria: An application in a marker-assisted breeding program for Nellore cattle in Brazil. J. B. S. Ferraz*[1], F. M. Rezende[1], R. C. G. Silva[1,2], X. Wu[3], S. Bauck[2], J. P. Eler[1], and E. C. Mattos[1], *[1]University of Sao Paulo/FZEA/ZAB/GMAB, Pirassununga, SP, Brazil, [2]Igenity Livestock Production Business Unit, Merial Ltd., Duluth, GA, [3]Department of Animal Science, Univ. of Wisconsin, Madison.*

The objective of this study was to evaluate the effect of inclusion of molecular information on estimated accuracy for expected progeny differences of the following selection criteria of a breeding Nellore project in Brazil: weaning weight (WW), post weaning gain up to 18 mo (PWGAIN), scrotum circumference (SC) and muscle score (MUSCLE), when predicted molecular breeding values (MBV) of these traits, based on low-density SNP panels developed by Igenity in Brazil (released in June 2011), were included in the analysis. Low-density SNP panels were selected using the parallel Bayes CpiC package, in which a BayesC π model was used for feature selection and a BayesC model was used for post-selection statistical inference and cross-validation. (Co)variance components and genetic parameters were estimated using a large data set with 97,580 animals included in the A^{-1} matrix. Heritability were estimated to 0.19 for WW, 0.82 for MBV of WW, and genetic correlation between them was estimated to be $r_g = 0.36$. Heritability and genetic correlation for other characters were: 0.21 (PWGAIN), 0.86 (MBV of PWGAIN), with $r_g = 0.50$; 0.52 (SC), 0.67 for (MBV of SC), with $r_g = 0.33$; 0.20 for (MUSCLE), 0.70 (MBV of MUSCLE) with rg = 0.32. Further, those genetic parameters were applied to genetic evaluation analyses with single traits (considering phenotypes only in appropriate models) and 2 traits (phenotypes as trait 1 and MBV for the same trait as trait 2), using REML approach, in a large data set ($A^{-1} = 520{,}169$) and from that analysis new predictions of EPD were obtained. From the large data set, close to 3,500 animals were genotyped. BIF accuracies were calculated for all animals in single-trait analysis. The effect of including MBV on accuracy of prediction of marker-EPD varied with subgroups of animals as well as different traits: prediction accuracy obtained for young replacement bulls with genotypes showed an increase of up to 22%; similar increment of predictive accuracy was observed for bulls 13 progenies or more. It is hence concluded that selected low-density SNP marker panels was useful in marker-assisted selection programs for Nellore population analyzed.

Key Words: MAS, beef breeding program, impact on accuracy

W66 SNP AY428575.1:g.346G>A of the bovine *TCAP* gene: Genotyping with PCR-RFLP and occurrence in Nelore animals (*Bos indicus*) and Angus (*B. taurus*) × Nelore. B. Borges*[1], R. Curi[2], A. Tamanaha[2], and L. A. Chardulo[3], *[1]College of Agrarian and Veterinary Sciences, UNESP, Jaboticabal, SP, Brazil, [2]College of Animal Production and Veterinary Medicine, Animal Breeding and Nutrition Department, UNESP, Botucatu, SP, Brazil, [3]Bioscience Institute, Chemistry and Biochemistry Department, UNESP, Botucatu, SP, Brazil.*

Genetic mapping studies and physiological analysis have resulted in identification of candidate genes related to meat quality on beef cattle, including the titin-cap gene (*TCAP*). It encodes teletonin, a protein found at skeletal and cardiac muscles linked to the Z1-Z2 domains of titin. This protein is degraded into the *post mortem* period and influences the reduction of tenderness between 24 and 72 h after slaughter. The major objective of this work was genotyping the SNP AY428575.1:g.346G>A of the bovine *TCAP* gene by PCR-RFLP technique, and report its use for the first time. Using the forward primer 5′ GGGAGTGAGCAGTCAT-CATGGC 3′ and reverse primer 5′ AGAGGCAGCACCCGCTGGT 3′, amplification products of 517 bp were acquired. They were submitted to digestion with *Bts*CI enzyme, which resulted in the genotypes AA (approx. 177, 154, 128, and 58 bp), AG (approx. 305, 177, 154, 128, and 58 bp) and GG (approx. 305, 154 and 58 bp). A total of 118 Nelore (*B. indicus*) and 8 Angus × Nelore (*B. taurus* x *B. indicus*) animals were genotyped. The use of the PCR-RFLP for the genotyping of SNP of the bovine *TCAP* gene was inexpensive and robust, which will greatly facilitate analysis of this polymorphism by basic laboratory equipment and reagents when compared with the single-base extension method. There were slight variation among Nelore animals with just 1 genotype AG and 117 genotypes GG. In the same way, there were found 6 Angus × Nelore with genotype AG and 2 GG. These preliminary results suggest the worthlessness of SNP AY428575.1:g.346G > A of the bovine *TCAP* gene to association studies with traits of interest to Nelore breed and, probably, to the subspecie *B. indicus*. On the other hand, they show the viability of these studies with the crossbreed Angus × Nelore, with Angus and, possibly, to all subspecies *B. taurus*. Acknowledgments to FAPESP for financial support.

Key Words: beef cattle, candidate gene, meat quality

W67 Association study of heat shock protein 70 gene with serum biochemical indices in Sanhe cattle. Y. Wang*[1], L. Liu[1], Q. Xu[2], Q. Chu[3], Y. Yu[1], H. Wu[4], D. Wang[4], P. Yuan[4], and A. Liu[5], [1]*College of Animal Science and Technology, China Agricultural University, Beijing, China,* [2]*College of Biology, Beijing Jiaotong University, Beijing, China,* [3]*Institute of Animal Husbandry and Veterinary Medicine, Beijing Academy of Agriculture and Forestry Sciences, Beijing, China,* [4]*Xiertala Breeding Farm, Hailaer Farm Buro, Hailaer, Inner Mongolia, China,* [5]*Hailaer Farm Buro, Hailaer, Inner Mongolia, China.*

Resistance to extreme cold is one of the distinct characteristics of Sanhe cattle, a dual purpose breed developed in Northern China. To quantify the ability of cold resistance and explore the genetic mechanism of cold resistance, some physiological and biochemical indicators in the serum were chosen and polymorphism of Heat Shock Protein 70 gene (HSP70) were screened, and the association between those indicators and polymorphism of HSP70 was analyzed. Blood samples from 170 Sanhe cows were collected and 6 biochemical indicators-corticosteroid (CORT), adrenocorticotropic hormone (ACTH), thyroxin (T4), triiodothyronine (T3), Glutathione peroxidase (GSH-Px) and erythrocyte potassium in the serum were tested. Pooled DNA sequencing method (36 unrelated Sanhe cows) was used for identifying the polymorphisms of promoter and exon in HSP70. Individual genotypes were detected using the MALDI-TOF-MS technique. For the association study, a fixed effect model considering parity, sire and genotype of each single SNP was employed. Descriptive statistics of CORT, ACTH, T4, T3, GSH-Px and erythrocyte potassium in Sanhe cattle were 277.79 ± 30.47 ng/mL, 23.81 ± 9.29 pg/mL, 66.43 ± 13.91 ng/mL, 1.18 ± 0.36 ng/mL, 777.73 ± 126.40 U/mL and 22.74 ± 2.48 mmol/L, respectively. Research showed that serum biochemical indices changes when animal are exposed to hot or cold environment, and variations were found in Sanhe cattle, so serum biochemical indices can be used as auxiliary indicators for assessing the degree of cold stress. Totally 13 SNPs (6 SNPs in promoter region and 7 SNPs in exons) were detected using pooled DNA sequencing method, and all were found polymorphic in the sampled population. Minimum allele frequency of these SNPs was 0.027–0.423. The association study showed that parity significantly ($P < 0.05$) effected CORT level and sire significantly ($P < 0.05$) effected ACTH level in all situations. Three novel SNPs were found significantly ($P < 0.05$) associated with some biochemical indices, namely A1679G with ACTH level, C620G with GSH-Px activity and C1784T with erythrocyte potassium concentration. Current results provide evidence that HSP70 gene is an important gene associated with serum biochemical indices, therefore, assumed to have influence on cold resistance ability.

Key Words: HSP70 gene, Sanhe cattle, serum biochemical index

W68 Molecular characterization of constitutive androstane receptor (CAR) and its association with feed efficiency of Nellore (*Bos indicus*) cattle. P. Alexandre, M. H. A. Santana, R. C. Gomes, J. B. S. Ferraz,* and H. Fukumasu, *College of Animal Science and Food Engeneering - Animal Breeding and Biotechnology Group (USP/FZEA/ZAB/GMAB), Pirassununga, SP, Brazil.*

The constitutive androstane receptor (CAR) was initially characterized as a key regulator of xenobiotic metabolism. CAR has also been implicated in various physiological pathways such as energy metabolism and homeostasis of lipids, triglycerides, cholesterol and other endogenous hydrophobic molecules. Here, our focus was to detect genetic polymorphisms (SNP) of CAR of Nellore beef cattle, predict their functional role and associate them to residual feed intake (RFI) and residual body weight gain (RIG), a recently proposed measure of feed efficiency. Genomic DNA was extracted from blood of 50 Nellore bulls and the entire CAR gene was amplified and sequenced with 8 pairs of primers. Molecular characterization was performed for polymorphism identification, phylogenetic analysis and prediction of functional consequences of SNPs. Also, statistical association with RIG was performed with PROC MIXED (SAS). We found 24 SNPs in CAR gene, being one in the promoter region, 8 exonic, 13 intronic and 2 SNPs after the 3′ UTR. We did not find any SNPs in the DNA binding domain of the receptor (DBD); however, 2 SNPs were found between DBD and the ligand binding domain (LBD), both being synonymous: SNP10 (Leu→Leu) and SNP11 (Ser→Ser). The LBD was the most genetically variant region presenting 5 SNPs, being 4 synonymous: SNP14 (Asp→Asp), SNP17 (Ala→Ala), SNP18 (His→His) and SNP19 (Ala→Ala); and 1 non-synonymous: SNP13 (Ala→Treo). No SNPs were found in exons 8 and 9, which codes for 3′UTR. Phylogenetic analysis demonstrated that exons from CAR gene are highly conserved between *Bos indicus* and *Bos taurus* and are closer to primates than to dog or chicken. The single SNP found upstream of CAR gene (SNP01 c.-81–176G>A) changed the transcription factor binding sites due the variation of G to A. Interestingly, this SNP was the only one associated with RIG ($P = 0.0221$). These results lead us to consider that CAR expression might be associated with the complex physiology of feed efficiency in Nellore. Efforts to comprehend the role of CAR on molecular pathways related to feed efficiency and validate this marker for RIG in Nellore are under investigation by our group.

Key Words: Nellore, RFI, SNP

W69 Assessment of 16 candidate genes for growth and maternal ability traits in Mexican Charolais cattle. L. A. Meza-García, V. I. Pacheco-Contreras,* G. M. Parra-Bracamonte, and A. M. Sifuentes-Rincón, *Laboratorio de Biotecnología Animal, Centro de Biotecnología Genómica, Instituto Politécnico Nacional, Reynosa, Tamaulipas, México.*

Maternal ability, birth and weaning weights, are some of the most important traits considered as selection criterion in Mexican cattle. They are complex and quantitative traits, and have shown significant association with some gene polymorphisms in different cattle breeds. Here, we evaluate the gene-trait association of a selected panel polymorphisms located at 16 candidate genes in a Mexican Charolais cattle herd to estimated their utility in gene assisted selection. Based on literature reports, we selected 24 polymorphisms located at POU1F1, FGF2, PRL, STAT5A, LEP, ABCG2, CCR2, BLG, CYP11B1, GHRL, GHR, GHRH, Prop1, NPY, UCP3, UCP2 genes, 24 RFLP-based procedures were designed to genotype 57 samples of Charolais cows with records for total maternal (TM), yield milk (YM), birth weight (BW) and weaning (WW) weight. Polymorphism was confirmed for 22 SNPs in the analyzed population. The effect of genotypes on the maternal ability (MA) (measured as TM and YM) and weight traits were analyzed using the least square analysis of the GLM procedure including genotype as fixed effect. No marker showed association with BW and 3 markers (GHR555, UCP2–380 and LEP3100) were significantly ($P \leq 0.05$) associated with MA and WW traits and 5 markers shows trends for these traits. Regression analyses were achieved to determine the allele substitution effect of associated markers on each trait (Table 1). Before these makers can be used to assist the Charolais selection, more studies with larger data sets are necessary to confirm the found associations and observed trends.

Table 1. Estimated allele substitution effect ± SE of 3 SNP on weaning weight (kg) and maternal ability traits (EBV kg)

SNP ID	Allele substitution	WW	YM	MT
GHR555	G>A	12.16 ± 5.53		
LEP3100	T>C		0.25 ± 0.50	0.23 ± 0.22
UCP2-380	G>C		−0.90 ± 0.48	

Key Words: Charolais cattle, polymorphisms, maternal ability

W70 Distribution of molecular markers and determination of molecular breeding values associated with feed efficiency, beef tenderness, and marbling in Senepol cattle.

B. Velez,* B. Diaz, and M. Pagan, *University of Puerto Rico, Mayaguez, Puerto Rico.*

Molecular breeding values (MBV) for feed efficiency (FE; net feed intake), marbling (MAR), and tenderness (TEN) were obtained using a commercially available 56 genetic marker panel to compare the genetics of a group of Senepol bulls (n = 153) used as sires in Brazil, Colombia, Puerto Rico, St. Croix (US Virgin Islands) and in the continental US with the currently available MVP database for such economically relevant traits. In addition, the distribution of individual alleles associated with FE, TEN, and quality grade (QG) and its corresponding potential phenotypic differences (traditional GeneSTAR candidate gene panel; Pfizer Animal Genetics) were determined in another group of animals 75% to purebred Senepol (n = 47). The multinational sire sample (n = 153) showed MAR, FE, and TEN MBVs of −0.31, −0.45, and 0.44, respectively. The current Senepol breed reference MBV average for MAR, FE, and TEN are −0.02, −0.27, and −0.04, respectively, and the across breed average MBVs are 0.03 MAR, −0.15 FE, −0.02 TEN (for FE and TEN, lower MBVs are more desirable). For bulls (n = 47) genotyped for individual alleles, from 8 favorable alleles/stars (2 corresponding to thyroglobulin 5, TG5) for QG, 5 alleles were present and arranged in 10 different combinations corresponding to a 4.75% probability of their carcasses been classified as USDA Choice or better. For FE (8 favorable alleles/stars), 13 different allele combinations were present, which indicated a predisposition within these animals to consumed 1.62 Kg (out a maximum of 1.8 Kg for animals with all desirable alleles) less dry matter per day and have a similar or better weight gain than an animal without any desirable allele. For TEN, in average, it would be expected to have 0.53 kg less of Warner Bratzler shear force from these animals as compared with animals without a tender allele (6 favorable alleles/stars; test candidate genes = calpain-316, calpain-4751, and calpastatin). These results suggest that the Senepol breed have a genetic predisposition to gain weight efficiently and produce lean beef.

Key Words: Senepol, molecular breeding value, feed efficiency

W71 Function analysis of liver X receptor α regulating fatty acid synthesis in mammary epithelial cells of dairy goats.

W. Wang, J. Luo,* Y. Zhong, X. Lin, and H. Shi, *Shaanxi Key Laboratory of Molecular Biology for Agriculture, College of Animal Science and Technology, Northwest A&F University, Yangling, Shaanxi, China.*

Liver X receptor α (LXRα) is a nuclear receptor of the transcription factor and known to play a crucial role in lipid metabolism such as bile acid and fatty acid synthesis in humans and rodents. However, very little information is available on the role of LXRα in the regulation of fatty acid synthesis in goat mammary glands. In this study, a novel cDNA was isolated from the mammary gland of a Xinong Saanen dairy goat and designated as goat LXRα. RT-PCR and RACE were used to obtain the full-length cDNA of LXRα, which is comprised 1654 bp with an ORF (open reading frame) of 1344 bp, the 5′-and 3′-UTR regions of 150 bp and 160 bp, respectively. The deduced amino acid sequence encodes 477 amino acids with a predicted MW of 50.4 kDa and a theoretical pI of 6.3. Additionally, homology search and sequence multi-alignment indicated that the putative goat LXRα amino acid sequence shares a high similarity with bovine, mouse, rat, pig and human counterparts. Bioinformatics predictions demonstrated that the LXRα protein, which is located in the nucleus containing characteristic signatures of nuclear receptor with DBD (DNA binding domain) and LBD (ligand-binding domain). Real-time quantitative PCR presented that LXRα was predominantly expressed in goat small intestine, liver, spleen and mammary gland. Treatment of goat mammary epithelial cells with different concentrations (0.01, 0.1, 1 μM) of T0901317, a synthetic agonist of LXRα, resulted in elevating SREBP1 (sterol regulatory binding protein 1) and FASN (fatty acid synthase) mRNA levels in response to the LXRα activation. The association between the different T0901317 concentrations and fatty acid compositions in goat mammary epithelial cells also was examined using gas chromatograph. The results showed that activation of LXRα significantly increased goat mammary epithelial cells C18:1 and C18:2 content, but did not affect SFA (saturated fatty acids). These discoveries are consistent with the notion that LXRα plays a key role in controlling lipogenesis and regulating UFA (unsaturated fatty acids) synthesis of goat mammary glands, which may prove useful in regulating milk fatty acid composition in lactating dairy goats.

Key Words: dairy goats, LXRα, fatty acid synthesis

W72 Structural and functional analysis of fatty acid synthase gene promoter of Xinong Saanen dairy goat.

J. Li, J. Luo,* and Y. Sun, *Shaanxi Key Laboratory of Molecular Biology for Agriculture, College of Animal Science and Technology, Northwest A&F University, Yangling, Shaanxi, China.*

The objective of the study was to analyze the structure and function of fatty acid synthase (FASN) gene promoter in the mammary gland epithelial cells of Xinong Saanen dairy goat, and further explore the transcriptional regulatory mechanism of FASN gene. The biopsy mammary gland tissue samples were collected from 3 does during lactation for epithelial cell culture; all measurements on epithelial cells were replicated 3 time for statistical analysis by SPSS. The 5′ flanking region of goat FASN gene cloned from genomic DNA included a 591 bp region upstream of the transcription initiation site (+1), exon1, intron1 and partial exon2. TATA box and CAAT box, which are typical eukaryotic promoter elements, were located at −41 and −74 respectively. G and C accounted for 76% of the whole upstream region sequence, and 4 GC boxes (GGGCGG and CCGCCC) were found upstream of the TATA box. Bioinformatic analysis showed that there were potential transcription factor binding sites of LXR(−400), ER(−390), SREBP-1c(−150), NF-Y(−90) and E-box(−65) in goat FASN gene promoter. To define the core region of the FASN promoter, chimeric constructs containing serial 5′ and 3′ deletion sequences and the luciferase reporter gene were transfected into goat mammary epithelial cells. The luciferase activity was determined using dual-luciferase reporter assay system. The results indicated that the core region of FASN gene promoter was from −293 to −14 conferring basal transcriptional activity. Moreover, transcription factor binding sites of LXR, ER, SREBP-1c, NF-Y and E-box were mutated using overlap extension PCR. Site-directed mutagenesis analysis showed that binding sites of SREBP-1c, NF-Y and E-box could significantly downregulate the FASN gene promoter activity in goat mammary epithelial cells ($P < 0.05$), while binding sites of LXR and ER had no effect on the gene promoter activity. It is concluded that transcription factors including SREBP-1c, NF-Y and E-box were involved in regulating FASN gene at the transcriptional level.

Key Words: dairy goat, FASN gene promoter, site-directed mutagenesis

W73 Use of different statistical approaches to study genetic variability of OAR6 in sheep breeds farmed in Italy.

R. Steri[1], A. Criscione[2], E. Ciani[3], B. Moioli[4], P. Crepaldi[5], L. Nicoloso[5], D. Marletta[2], E. L. Nicolazzi[6], A. Passero[3], G. Catillo[4], F. Pilla[7], and N. P. P. Macciotta*[1], *[1]Università di Sassari, Sassari, Italy, [2]Università di Catania, Catania, Italy, [3]Università di Bari, Bari, Italia, [4]CRA, Rome, Italy, [5]Università di Milano, Milan, Italy, [6]Università Cattolica, Piacenza, Italy, [7]Università del Molise, Campobasso, Italy.*

Dense marker maps allow for the investigation of genomic regions that differentiate between breeds. In this work, 496 sheep belonging to 20 Italian sheep breeds were genotyped with the Illumina OvineSNP50 BeadChip. After data editing, 2,180 SNP located on chromosome 6 were analyzed with 4 different approaches. I) Fst Outlier Detection (FOD), implemented in the LOSITAN software, based on the comparison between Fst calculated on actual data and expected heterozygosity (He) and Fst under an island model. II) Composite Log-likelihood (CLL), based on calculation of CLL of the observed allelic frequencies across overlapping windows of 9 markers. III) Correspondence analysis (CA). VI) Canonical Discriminant Analysis (CDA). The different approaches were able to identify regions at OAR6 that expressed variation between breeds. Highest values for all statistics were found for a region spanning between 35 and 41 Mb known to harbour BMPR1b and ABCG2 loci. SNPs with a relevant discriminating power between breeds were also found at 76, 96 and 107 Mb, near to KIT, IL8 and SCD5 genes respectively. FOD detected 227 not neutral markers (17 under positive and 210 under balanced selection) using a confidence interval of 0.95. A total of 62 windows out of 242 were significant for CLL ($P < 0.01$). Several 85 and 135 SNPs exceeded empirical threshold for CA and CDA, respectively. The discriminating power was high for all methods and in general, they revealed a geographical pattern of variation between breeds. Moreover, each method provided specific information. FOD supplied a relatively low number of markers in divergent selection but it was able to identify loci under balanced selection. CA and CDA allowed a decomposition of total variability in different and uncorrelated variables that could be useful for the identification of genes influencing complex traits. The use of different statistical methods to study genetic variability between ethnic groups could provide indications about the adaptation to local conditions as well as the effect of selection.

Key Words: sheep breeds, SNP, statistical approaches

W74 Genotyping of five Chinese local pig breeds focused on meat quality by using PCR-RFLP based on halothane and Mx1.

Z. M. Feng, G. G. Lian, X. F. Kong, X. Zhou, and Y. L. Yin,* *Institute of Subtropical Agriculture, Chinese Academy of Sciences, Changsha, Hunan, China.*

In recent years, due to the increasing demand for pork with high quality, a more convenient and fast way to test pigs is required for breeding, which enhances investigations on genetic variations associated with meat quality. So far, many genetic variations associated with meat quality have been investigated, such as myxovirus resistance protein 1 (Mx1), which was first found to be related to meat quality using samples from Chinese local pig breeds, and Halothane (Hal). Effects of Mx1 on meat quality of Chinese local pig breeds were demonstrated by Li in her Master's thesis in 2005 (Huazhong Agric. Univ. Wuhan, China), which was published in Chinese. The current study focuses on the use of RCR-RFLP of Hal and Mx1 for evaluating meat quality traits of several Chinese local pig breeds (Bama mini-pig, Huanjiang mini-pig, Lantang pig, Ningxiang pig and Xiangxi black pig including Daheping black pig, Pushi black pig and Taoyuan black pig) and Landrace pig (a foreign pig breed). The results indicated that the genotypes of Chinese local pig breeds were mainly shown as HalNN, while rarely in HalNn, rather than Halnn. The recessive allele (n) frequency in Chinese local pig breeds was significantly lower than that in Landrace pig. The recessive allele (B) frequency in the sixth intron of Mx1 in Chinese local pig breeds was generally higher than that in Landrace pig. The B frequency in the ninth intron of Mx1 was commonly higher in both Chinese local pig breeds and Landrace pig. In general, these findings have manifested that the Chinese local pig breeds, particularly Xiangxi black pig and Ningxiang pig, have a better meat quality.

Key Words: pig, nutrition, digestion

W75 Which housekeeping gene can be used in gene expression analysis in Chinese local pig breeds?

Z. M. Feng, J. P. Guo, X. F. Kong, and Y. L. Yin,* *Institute of Subtropical Agriculture, Chinese Academy of Sciences, Changsha, Hunan, China.*

Relative quantification real-time PCR (RT-PCR) is widely used for the quantification of mRNA expression level. The expression level should be normalized by using one or more reference genes. In this study, 3 frequently-used endogenous reference genes, including glyceraldehyde-3-phosphate dehydrogenase (GAPDH), β-actin (ACTNB), and 18S rRNA (18S), were evaluated by comparing their expression levels in 864 samples from 5 Chinese local pig breeds (Huangjiang mini-pig, Bama mini-pig, Taoyuan black pig, Lantang pig, and Ningxiang pig) and Landrace pigs (a foreign pig breed). The results, which were analyzed by Fisher's Least Significant Difference test after ANOVA using SPASS, showed that ACTNB and GAPDH had no significant different expression in overwhelming majority of the tissues investigated in the present study. We conclude that ACTNB and GAPDH had higher stable expression levels in various tissues, which indicated that both of them could be used as reference genes for the quantification of mRNA expression in some Chinese local pig breeds. For Chinese local pig breeds, ACTNB might be more suitable as a reference gene for target genes with high expression levels, while GAPDH might be better for target genes with low expression levels. Our findings also suggested that evaluation of reference genes is necessary for research among different local pig breeds. Otherwise, absolute quantification RT-PCR should be recommended.

Key Words: local pig breeds, mRNA expression, nutrition

W76 Genotype imputation accuracy in an F_2 pig cross using high-density and low-density SNP panels. J. L. Gualdrón Duarte*[1,3], R. O. Bates[1], C. W. Ernst[1], N. E. Raney[1], R. J. C. Cantet[3], and J. P. Steibel[1,2], [1]*Department of Animal Science, Michigan State University, East Lansing,* [2]*Department of Fisheries and Wildlife, Michigan State University, East Lansing,* [3]*Departamento de Producción Animal, Facultad de Agronomía, UBA - CONICET, Ciudad Autónoma de Buenos Aires, Buenos Aires, Argentina.*

High resolution SNP genotyping can be used for QTL mapping to facilitate meta-analysis across multiple populations. Typical swine F_2 populations have only a few founders (F_0), and a relatively small number of recombinations are expected in each generation. For that reason, genotyping the F_0 and F_1 generations with a high-density (HD) panel and typing the F_2 with a reduced number of tagSNP would enable high imputation accuracy of HD genotypes in the F_2 generation at a fraction of the cost. The goal of this study was to estimate imputation accuracy of F_2 genotypes when HD (44,752 SNP after data cleaning) genotypes are available for F_0 and F_1 generations. Starting with genotypes for F_0 and F_1 animals from the MSU Duroc × Pietrain resource population obtained using the Illumina Porcine SNP60 BeadChip, we simulated F_2 genotypes ($n = 932$) conditional on the real pedigree using a gene-dropping model. Subsequently, we applied 2 different methods to select tagSNP for F_2 animals: 1) statistical criteria based on pair-wise linkage disequilibrium on F_1 haplotypes, and 2) evenly-spaced markers. Imputation was performed assuming that F_0 and F_1 were typed at HD. Average imputation accuracy was calculated as the mean difference between observed and expected allelic dosage. We found that using panels of similar size, from evenly spaced selection or statistical selection resulted in similar imputation accuracy. When both F_0 and F_1 were typed at HD, imputation accuracy was approximately 0.97 if 2% of the HD markers, approximately evenly spaced every 2.1 Mb were used as tagSNP. Based on these results, we recommend using HD SNP genotyping in F_0 and F_1 and evenly spaced tagSNP panels consisting of at least 1200 tagSNP to obtain average inter marker distances of 2.1 Mb and to guarantee imputation accuracy above 0.97 in the F_2. Furthermore, forward imputation of HD-SNP in F_2 is appealing, since the resulting association tests could be combined across multiple populations using meta-analysis.

Key Words: imputation accuracy, F_2 cross, swine

W77 The proteome and mRNA expression of vimentin in the adipose tissue of broiler chickens. G. Kelley,* A. Stewart-Bohannon, F. Chen, X. Wang, and S. Nahashon, *Tennessee State University, Nashville.*

Increased fat deposition in broiler chickens is a major concern to poultry producers and consumers alike. Genomic approaches have been employed to discern the mechanisms of adiposity in food animals. These approaches have provided key transcriptional information depicting the possible role of gene sequences and their expression on fat deposition. However, they do not provide insight on the translational events that may contribute to adiposity although it is understood that proteins are the executants of most of most biological functions. We hypothesize that chicken adiposity is highly influenced by factors beyond the genome. Therefore, the aim of this study was to employ a proteomics approach to identify proteins that may be associated with fat accretion in broiler chickens and to evaluate the mRNA expression of genes that encode these proteins. One hundred twenty 1-d-old broiler chickens were randomly assigned to floor pens and fed standard broiler diet until 8 weeks of age (WOA). At 8 WOA, experimental birds were sacrificed and adipose tissue from the abdominal and visceral areas was collected, weighed and frozen in liquid nitrogen before storage at −80 oC until used. Adipose proteome from 16 birds with the highest and lowest abdominal fat percentage was assayed using 2-dimensional differential gel electrophoresis (2D-DIGE) followed by in-gel digestion and matrix-assisted laser desorption/ionization time-of-flight (MALDI-TOF) mass spectrometry. A total of 132 spots were found to be differentially expressed between the extreme fat and lean birds ($P < 0.05$). Among them was vimentin, which was highly expressed in obese birds and was confirmed by Western blot. The mRNA abundance of vimentin was assayed at 8 WOA using Real Time-Polymerase Chain Reaction. A student t-test revealed no significant differences ($P > 0.05$) in the threshold cycles (Ct values) of vimentin between the lean and obese birds. The Ct values were 14.67 and 14.34 for the lean and obese birds, respectively. These results indicate that there are factors beyond the genome that influence vimentin expression in broiler chickens.

Key Words: adipose tissue proteome, broiler chickens, vimentin

Dairy Foods: Microbiology and Dairy Chemistry

W78 Viability of free and encapsulated *Lactobacillus acidophilus* ATCC 4356 in yogurt and artificial human gastric digestion system. F. Ortakci*[1,2] and S. Sert[2], [1]*Western Dairy Center Nutrition Dietetics and Food Sciences Department, Logan, UT,* [2]*Ataturk University, Erzurum, Turkey.*

The objective of this study was to determine the effect of encapsulation on survival of probiotic *Lactobacillus acidophilus* ATCC 4356 (4356) in yogurt and during gastric digestion. 4356 was added to yogurt in calcium-alginate microencapsulated or free form at a level of 8.26 and 9.47 log cfu/g respectively, and the influences of alginate microcapsules (1.5 to 2.5 mm) on sensorial characteristics of yogurts were also investigated. Survival of 4356 in simulated gastric and bile juices included incubation in 0.08 N hydrochloric acid (pH 1.5) containing 0.2% NaCl and a simulated bile juice consisting of 1.2% bile salts in MRS broth. There were similar and statistically significant ($P < 0.01$) reductions (~1 log cfu/g) in both free and encapsulated 4356 during 4 wk refrigerated storage of yogurts. When incubated for 2h in gastric juice, the free 4356 did not survive (>7 log cfu/g reduction). There was, however, greater survival of encapsulated 4356 with only a 3 log cfu/g reduction occurred. Incubation in simulated bile juice (6h) did not significantly affect ($P > 0.05$) the viability of both free and encapsulated 4356 due to the natural bile resistance of the bacteria. The addition of probiotic cultures either in free or alginate encapsulated forms did not significantly ($P > 0.05$) affect appearance and color, flavor and odor of the yogurts. There were, however, significant deficiencies ($P < 0.05$) in body and texture (graininess) of encapsulated 4356 containing yogurts. It was concluded that incorporation of free and encapsulated probiotic bacteria do not substantially change the overall sensory properties of yogurts and alginate microencapsulation using extrusion method greatly enhanced the survival of probiotic bacteria against artificial human gastric digestive system.

Key Words: probiotic, microencapsulation, artificial gastric system

W79 Complete genome sequence of *Bifidobacterium animalis* subspecies *lactis* BF-6. A. Baker[1], A. Negrete-Raymond[2], K. Polzin[1], M. Souza[2], Y. Yu*[3], J. Loquasto[3], J. Amos[3], and R. Roberts[3], [1]*Cargill Texturizing Solutions, Waukesha, WI,* [2]*Cargill Biotechnology Development Center, Navarre, MN,* [3]*The Pennsylvania State University, Department of Food Science, University Park.*

The primary objective of the present work was to sequence and evaluate the complete genome of *Bifidobacterium animalis* ssp. *lactis* BF-6, a common commercial probiotic originally isolated from the feces of a healthy human, and use this information to assess relatedness to other completely sequenced strains of the same subspecies. Genomic DNA was harvested and subjected to sequencing. Shotgun sequencing using 454 GSFlx Titanium pyrosequencing resulted in 20× coverage of the genome, which was assembled using Newbler into 24 contigs. The contigs were ordered and oriented with SeqMan software using the genome of *B. animalis* ssp. *lactis* DSM 10140 as a scaffold. After ordering, primers were designed on the ends of each contig and the intervening sequence was amplified by PCR. Amplicons were Sanger sequenced to close the gaps. For repeated elements, such as rRNA operons and transposons, long-PCR was conducted and the resulting amplicons were used as templates for additional nested PCR and sequencing reactions. The final genome was 1,938,607 base pairs (bp) in length with GC content of 60.48%. Annotation of the genome using the RAST and Artemis genome browser revealed the complete genome contains 1604 genes with a coding percentage of 85.9%, 4 complete rRNA operons and 52 tRNAs. Genome wide SNP analysis revealed BF-6 was highly similar to, but distinguishable from, other fully sequenced *B. animalis* ssp. *lactis* strains. The complete genome of *B. animalis* ssp. *lactis* BF-6 reported in this study provides additional insight into the phylogenetic organization of the *B. animalis* ssp. *lactis* taxon as well as into the biological and probiotic characteristics of this microorganism.

Key Words: *Bifidobacterium animalis* ssp. *lactis*, genome, SNP

W80 Growth of yogurt culture bacteria in the presence of two antimicrobials. M. Vives[1,2] and K. Aryana*[2,1], [1]*Louisiana State University,* [2]*Louisiana State University Agricultural Center.*

Antimicrobials such as potassium sorbate are added in the manufacture of dairy products such as flavored yogurts and process cheeses. Potassium nitrite and potassium metabisulfite have been reported to have an antimicrobial effect on pathogenic microorganisms such as *Clostridium botulinum, Listeria monocytogenes, Staphylococcus aureus, Escherichia coli* and *Pseudomonas fluorescens*. Potassium nitrite is commonly used in cured meats, canned cured meats, vacuum-packaged and fermented meats, bacon, cheese and seafood, while potassium metabisulfite is used in beverages and fruits. Yogurt is known for its health benefits, mainly due to the presence of its cultured bacteria. potassium nitrite and potassium metabisulfite are not commonly used in the dairy industry. How well the yogurt bacteria grow in the presence of 2 antimicrobials (potassium metabisulfite and potassium nitrite) at different concentrations is not well known. The objective was to study the influence of potassium nitrite and potassium metabisulfite at various concentrations, on the growth of *Lactobacillus bulgaricus* and *Streptococcus thermophilus*. Different concentrations of potassium metabisulfite and potassium nitrite (100, 1000, 10,000, 100,000, and 1,000,000 ppm) were added to MRS broth previously inoculated with *Lactobacillus bulgaricus* and *Streptococcus thermophilus* separately. Peptone water 0.1% w/v was inoculated with 1% (v/v) of freshly thawed *Lactobacillus bulgaricus* and *Streptococcus thermophilus* previously exposed to the different antimicrobial concentrations. The control did not have any concentration of either antimicrobial. Growth was determined by plating the different treatments and the control at 0, 24, 48 and 72 h of incubation of both microorganisms. Data were analyzed using Proc Mixed model of Statistical Analysis System with a repeated measures design. Three replications were conducted. All concentrations for both antimicrobials where significant for the growth of *Lactobacillus bulgaricus* LB-12 and *Streptococcus thermophilus* ST- M5 at 0, 24, 48 and 72 h ($P < 0.0001$). The highest concentration of potassium metabisulfite and potassium nitrite (1,000,000ppm) was significantly different from the rest of the lower concentrations, having the highest counts of bacterial populations for *Streptococcus thermophilus*. The effect of the antimicrobial at the highest concentration did not inhibit the growth of *Streptococcus thermophilus* at 72 h, but showed an exponential growth at this time period. Potassium metabisulfite and potassium nitrite did not negatively affect the growth of yogurt bacteria.

Key Words: yogurt, culture, antimicrobial

W81 Acquired resistance of yogurt culture bacteria to two different antimicrobials.

M. Vives[1,2] and K. Aryana*[2,1], [1]*Louisiana State University,* [2]*Louisiana State University Agricultural Center.*

A bacterial strain can said to be resistant if it can survive and multiply itself in the presence of an antimicrobial agent that would normally inhibit or kill this particular kind of microorganism. Potassium nitrite and potassium metabisulfite have been reported to have an antimicrobial effect on pathogenic microorganisms such as *Clostridium botulinum, Listeria monocytogenes, Staphylococcus aureus, Escherichia coli* and *Pseudomonas fluorescens*. Potassium nitrite is commonly used in cured meats, canned cured meats, vacuum-packaged and fermented meats, bacon, cheese and seafood, while potassium metabisulfite is used in beverages and fruits. Antimicrobials such as potassium sorbate are added in the manufacturing of several products such as flavored yogurts and process cheeses. Antimicrobials such as potassium nitrite and potassium metabisulfite are not commonly used in the dairy industry. Yogurt is known for its health benefits, mainly due to the presence of its cultured bacteria. Whether yogurt bacteria can acquire resistance to 2 different antimicrobials (potassium metabisulfite and potassium nitrite) is not known. The objective was to study the possibility of an acquired resistance of these 2 bacterial strains to higher doses of the 2 antimicrobial compounds after prior exposure to lower doses of these antimicrobials. Treatments consisted of the transfer of previously grown cultures at the lower concentrations i.e., 100 and 1000 ppm of both antimicrobials, after 24, 48 and 72 h, into 2 higher concentrations 10,000 and 100,000 ppm, of both antimicrobials and growth was measured after 0, 24, 48 and 72 h of incubation. Data were analyzed using Proc Mixed model of Statistical Analysis System with a repeated measures design. Experiments were replicated 3 times. There was a significant interaction effect between the antimicrobial × microorganism × treatment × transfer hour × growth hour, on the growth of the bacterial strains ($P = 0.0015$). There were significantly higher counts ($P < 0.005$) of *Streptococcus thermophilus* compared with the control. For *Lactobacillus bulgaricus* the growth was similar to the control which suggests there are no significant differences between the growth at higher concentrations and the control. *Streptococcus thermophilus* exhibited resistance to the higher doses of antimicrobial compounds.

Key Words: resistance, yogurt culture, antimicrobial

W82 Isolation of an oligotrophic *Lactobacillus* species that may be associated with late gas production and splits in cheese.

C. J. Oberg*[1,2], M. Culumber[1], T. Oberg[2], J. R. Broadbent[2], and D. J. McMahon[2], [1]*Department of Microbiology, Weber State University, Ogden, UT,* [2]*Western Dairy Center, Utah State University, Logan.*

A wide variety of facultative and obligate heterofermentative bacteria, including several lactobacilli, have been associated with late gas production in aged cheese. Such cheese can suffer from splits and slit defects during cheese storage, especially when storage temperature is increased to accelerate flavor development. The objective of this study was to identify bacteria in aged Cheddar cheese that causes late gas production. We isolated a novel heterofermentative *Lactobacillus* species (WDC04) following incubation on MRS agar at 6°C for 35 d. BLAST analysis against the 16S rRNA gene database of GenBank revealed WDC04 had 97% sequence identity with *Lactobacillus suebicus* strain CECT5917 (AJ575744), *Lactobacillus vaccinostercus* (AB218793), and an uncultured compost bacterial sequence (FN667177). Cellular morphology and colony morphology were consistent with related species. API CH50 fermentation panels showed a preference for utilization of ribose and galactose over other carbohydrate sources, and WDC04 is difficult to grow expect on MRS broth supplemented with galactose and ribose. As a nonstarter lactic acid bacteria (NSLAB), WDC04 ecologically falls into the category of being an oligotroph that undergoes slow growth in conditions of low nutrient availability. In contrast, lactococcal starter bacteria have copiotroph attributes and exhibit high growth rates when resources are abundant such as occurs in milk. In the harsh environment of ripening cheese (no residual lactose, low pH, low temperature and high salt concentration), viability of starter bacteria usually declines. At the same time, oligotrophic NSLABs utilize amino acids and bacterial debris to supply their energy needs, and will slowly increase in numbers until they are the predominant organism(s) of aged cheese microflora. Gas production by WDC04 was observed at 5 d in MRS broth incubated at 25°C with significant gas production by 9 d. Gas production was also observed after incubation for 28 d in MRS at 8°C. It was concluded that WDC04 is a potential cause of gas production during storage of cheddar cheese.

Key Words: cheese, nonstarter, heterofermentative

W83 Influence of various health beneficial spices on the acid tolerance of *Streptococcus thermophilus* ST-M5.

M. Sanchez-Vega*[1,2] and K. Aryana[2,1], [1]*Louisiana State University,* [2]*Louisiana State University Agricultural Center.*

There is a great deal of public interest in the use of herbal remedies. Garlic is said to be antibacterial, antiviral, and antifungal and also prevent cardiovascular diseases and some types of cancer. Ginger is effective against nausea and cardiovascular diseases and is also an analgesic and has antibacterial properties. Onion is effective against the common cold and reduces the risk of developing diabetes; it also has antiinflammatory, anticholesterol, anticancer and antioxidant properties. Many studies have been conducted using spice extracts, but the effect of pure spice juice has not been studied. According to some studies, spices might have the capacity of enhancing the growth of certain probiotic strains while acting as a bactericide for harmful bacteria. The main objective of this study was to elucidate the influence of garlic, ginger, and onion on the acid tolerance of *Streptococcus thermophilus* ST-M5. Freshly thawed culture was inoculated in acidified MRS broth at pH 2 and 1% v/v of freshly extracted spice juice was added. Control was without spice juice. Growth was determined hourly during 2 h of incubation at 37°C. The data were analyzed using Proc Mixed model with a Tukey adjustment of Statistical Analysis System. Experiments were replicated 3 times. All 3 spices showed a significant ($P < 0.05$) increase in counts at 0 h of incubation when compared with control. After 1 h of incubation, all 3 spices had significantly ($P < 0.05$) higher counts than control. After 2 h of incubation, ginger showed no significant ($P > 0.05$) difference compared with control (5.5 log cfu/mL), while there were slight yet significantly lower counts for garlic (4.3 log cfu/mL) and onion (5.1 log cfu/mL). Among the spices, ginger had the best overall effect. These 3 spices can be used with *Streptococcus thermophilus* enabling health benefits from both sources.

Key Words: spice, culture, acid tolerance

W84 Bile tolerance of *Lactobacillus delbrueckii* ssp. *bulgaricus* LB-12 subjected to mild sonication intensities at different temperatures.

M. Moncada*[1,2] and K. Aryana[2,1], [1]*Louisiana State University,* [2]*Louisiana State University Agricultural Center.*

Low sonication intensity is a non-destructive technique that consists on the application of low energy, high frequency (1–10 MHz) and power intensities below 1 W/cm2. It has been reported that the survival of lactic acid bacteria is increased with the application of "mild" sonication condition. One of the requirements for a bacterium to be called probiotic is the ability to survive the gastrointestinal stress factors such as acid and bile conditions. *Lactobacillus bulgaricus* is widely used in the fermentation of dairy products. The objective of this study was to determine the effect of various mild sonication intensities at different temperatures on bile tolerance of *Lactobacillus bulgaricus* LB-12. Freshly thawed *Lactobacillus bulgaricus* LB-12 culture was suspended in 0.1% peptone water and sonicated using a 13 mm diameter probe set at a maximum acoustic power output of 750 W, frequency 24 kHz. Before sonication, the inoculated samples were set at 3 temperatures (4, 22, and 40°C). Four sonication treatments with intensities of 8.07, 14.68, 19.83 and 23.55 W/cm^2 were performed in a random manner at the 3 different temperatures mentioned above. Control samples did not receive any sonication treatment. Bile tolerance of samples was determined every 2 h for 12 h of incubation. Data were analyzed using ANOVA of Statistical Analysis System. Three replications were conducted. At 4°C, bile tolerance of cultures subjected to control and 14.68 W/cm^2 was significantly ($P < 0.05$) higher compared with the rest of mild sonicated intensities. Bile tolerance at 22°C was significantly ($P < 0.05$) higher than at 4 and 40°C during the 12 h of incubation. Log reduction at 22 and 40°C showed that samples treated with mild sonication intensities had higher bacterial growth than the control. It is concluded that certain mild sonication conditions improved bile tolerance of *Lactobacillus bulgaricus* LB-12.

Key Words: sonication, culture

W85 A new approach to make milk calibration standards for electronic somatic cell counters.

J. Podoll, D. M. Barbano,* and K. L. Wojciechowski, *Cornell University, Department of Food Science, Northeast Dairy Foods Research Center, Ithaca, NY.*

Our objective was to develop a procedure to make milk somatic cell count (SCC) reference materials for calibration of electronic somatic cell counters (ESCC). The key innovation was the use gravity separation to produce a naturally occurring high and low SCC milk. One batch of whole raw milk was separated into 2 portions. One portion was gravity separated at 4°C for 24 h and the second portion was centrifugally separated at 4°C to produce raw skim milk that was also gravity separated. The somatic cells concentrated at the top of both gravity separation tanks. Milk was collected from the top and the bottom of the tanks to produce a high and low SCC milk from each tank. These 4 bronopol preserved milks were analyzed using direct microscopic somatic cell count by 2 laboratories. A set 12 milk dilutions of the high SCC whole and skim milks were made (mass/mass) combinations of the high and low SCC skim and whole milks, respectively. The experiment was replicated 3 times. The range of SCC within a set was from approximately 5,000 to 950,000 somatic cells per mL. Two laboratories analyzed 3 sets of these milks per week by ESCC over a period of about 21 d of 4oC storage. ANOVA was used to determine the effect of laboratory, set type (skim or whole milk), and sample age on the observed electronic milk SCC. No effect of laboratory or set type ($P > 0.05$) on observed milk ESCC was detected. There was a mean decrease ($P < 0.05$) in ESCC with time of storage (about 7,000 cells per mL at 350,000 cells per mL during 2 weeks of refrigerated storage). Gravity separation can be used to produce a set of milk SCC reference standards with a wide range somatic cell count with 12 incremental SCC distributed evenly from low to high across the range.

Key Words: somatic cells, gravity separation, reference standards

W86 Freezing and thawing milk calibration standards for electronic somatic cell counters.

L. V. Marzo[1] and D. M. Barbano*[2], [1]*University of Sao Paulo, Pirassununga, Brazil,* [2]*Cornell University, Department of Food Science, Northeast Dairy Foods Research Center, Ithaca, NY.*

Our objective was to determine the effect of freezing and thawing on electronic milk somatic cell count (ESCC) standards. Whole raw milk (350 kg) was pasteurized and split into 2 portions. One portion was gravity separated at 4°C for 22 h and the second portion was centrifugally separated at 4°C to produce skim milk that was also gravity separated. After 22 h the somatic cells were concentrated at the top of both gravity separation tanks. Stock solutions (3: high SCC skim and whole milk stock and a low SCC skim stock) were prepared and preserved (bronopol). Standards were formulated by diluting high SCC (whole or skim milk) stock with low SCC skim stock to make 1600 g of each of a series of 12 whole and 12 skim standards. The range of SCC was from approximately 2,000 to 1,150,000 SCC/mL and from 2,000 to 800,000 SCC/mL for the skim and whole milk sets, respectively. Half of the sets were kept refrigerated at a 4°C and the other half were frozen at −80°C for 24 h, and then moved to a −20°C freezer. On each day of analysis, 1 set of skim and 1 set whole refrigerated milks were tested and 1 set of skim and 1 set whole frozen milks were tested on 2 different cell counters in different labs. Refrigerated and frozen samples were put in the water bath at the same time and were analyzed when their temperature reached 40 to 42°C. Analysis was repeated 4 times during a 2 week storage and replicated 3 times. Effects of freezing, laboratory, set type (skim or whole milk), and sample age on the ESCC were determined. For the skim SCC standards there was no effect of freezing on mean ESCC during a 2 week period. For the whole milk SCC standards there was an effect of freezing with the frozen and thawed set having a mean SCC of about 6,000 SCC/mL lower than the unfrozen samples over a 2 weeks period. Skim milk SCC standards had a larger range of SCC than whole milk. Frozen and thawed skim standards may have better homogeneity with longer frozen storage time and avoid problems of oiling off during thawing and heating of milks.

Key Words: somatic cells, freezing, gravity separation

W87 Protease activity of *Streptococcus thermophilus* ST-M5 subjected to mild sonication intensities at different temperatures.

M. Moncada*[1,2] and K. Aryana[2,1], [1]*Louisiana State University,* [2]*Louisiana State University Agricultural Center.*

Streptococcus thermophilus is a bacterium used widely for the production of many fermented dairy products. Protease activity degrades the milk proteins to peptides and influence the quality characteristics namely texture and flavor of several aged dairy products. “Mild” sonication intensity is a technique that uses sound waves to cause cavitation in liquid solutions and may improve the permeability of the cell membrane. The objective of this study was to evaluate the influence of “mild” sonication intensities on protease activity of *Streptococcus thermophilus* at different temperatures. Freshly thawed *Streptococcus thermophilus* ST-M5 culture was suspended in 0.1% peptone water and sonicated using a 13 mm diameter probe set at a maximum acoustic power output of 750 W, frequency 24 kHz. Before sonication, the inoculated samples were set a 3 different temperatures (4, 22 and 40°C). Four sonication treatments with intensities of 8.07, 14.68, 19.83 and 23.55 W/cm^2 were performed in a random manner at the 3 different temperatures mentioned above. Control samples did not receive any sonication treatment. Protease activity was determined at 0, 12 and 24 h of incubation spectrophotometrically at 340 nm. The experimental design was completely randomized design. Data were analyzed using ANOVA of Statistical Analysis System.

Three replications were conducted. Differences of least squares means were used to determine significant differences at $P < 0.05$ for main effect (mild sonication intensity) and interaction effect (mild sonication intensity × time × temperature). Absorbance units increased over time from 0 to 24 h. At 4°C, protease activity of cultures subjected to 8.07 W/cm^2 was significantly ($P < 0.05$) higher than the control at 12 and 24 h. At 22°C the protease activity at all sonication intensities and all time points were lower than the control except for 19.83 W/cm^2 at 24 h. At 40°C, 23.55 W/cm^2 showed significant ($P < 0.05$) increase in protease activity compared with the control at 0, 12 and 24 h. The optical density (OD) values at 0, 12, and 24 h after using 23.55 W/cm^2 were 0.11, 0.16 and 0.17 absorbance units while OD values for control were 0.09, 0.12 and 0.15 absorbance units at 0, 12, and 24 h, respectively, at 40°C. *Streptococcus thermophilus* treated with some mild sonication intensities improved its protease activity.

Key Words: protease, culture, sonication

W88 Prediction of fatty acid chain length and unsaturation of milk fat by mid-infrared milk analysis.

K. L. Wojciechowski[1], D. M. Barbano*[1], and E. de Jong[2], [1]*Cornell University, Department of Food Science, Northeast Dairy Foods Research Center, Ithaca, NY,* [2]*Delta Instruments, Drachten, the Netherlands.*

Our objective was to predict mean fatty acid chain length (mCL, carbon number) and mean fatty acid unsaturation (mUnsat, double bonds per fatty acid) of milk fat from mid-FTIR spectra. Calibration models for both parameters were calculated, using partial least squares, based on spectra for 268 samples collected over a period of 1.5 year. Of which 219 samples (largely herd milks) were selected to cover a wide variation in regional and dietary dependent milk fat composition. The set was complemented with 49 modified milks spanning an orthogonal set in fat, protein and lactose. Milks were analyzed for fat by ether extraction and fatty acid composition by GLC. Standard errors for calibration, determined using full cross validation (SECV) on the calibration set were 0.11 carbons for mCL and 0.012 double bonds for mUnsat. Validation was on the basis of an independent set of 47 milks, for which mean and range in mCL were 14.47, 14.00 to 14.85 carbons and mean and range in mUnsat were 0.319, 0.236 to 0.394 double bonds, respectively. The mean difference, standard deviation of the differences, relative coefficient of variation for prediction of mCL compared with GLC reference values was 0.056 carbons, 0.063 carbons, and 0.4%, respectively, and 0.003 double bonds, 0.011 double bonds, and 3.3%, respectively. Future work will determine if estimates of fatty acid composition by mid-FTIR can be used in real time to improve the accuracy of prediction of total fat content of milk.

Key Words: mid-infrared, fatty acids, chain length

W89 A ruggedness study: Casein content of milk by Kjeldahl analysis for milk concentrates and non-bovine milks.

K. L. Wojciechowski and D. M. Barbano,* *Cornell University, Department of Food Science, Northeast Dairy Foods Research Center, Ithaca, NY.*

The objective of our work was to develop a modification of Association of Official Analytical Chemists International (AOACI) method 998.05 (optimized for a raw bovine milk matrix) so that it could be applied to milk concentrates and milks of other species (goat, sheep, and water buffalo). A ruggedness study was carried out that demonstrated that as concentration of protein in milk increased (either in bovine milk concentrates or in milks of other species), the amount of buffer needed in the noncasein nitrogen sample preparation method to achieve a filtrate pH of 4.6 increased. In the first part of the study using a series of bovine milk ultrafiltration concentrates, it was demonstrated that the method gave more consistent predictions of casein as a percentage of true protein when the NCN filtrate pH was between 4.5 and 4.6, regardless of total protein concentration. The study was designed with a series of UF retentates ranged from 3 to 9% protein but all contained the same casein as percentage of true protein, regardless of TP concentration. Thus, when the reagent concentration was correct the casein as a percent of true protein at all protein concentrations. When the amount of buffer added to the sample was not sufficient (i.e, the filtrate pH was too high), the filtrates were not clear. A polynomial equation was developed for prediction of the amount of acetic acid - sodium acetate buffer required to achieve pH for milk protein concentrations from 3 to 9% protein. The modified method was tested on goat, sheep, and water buffalo milks. The results of this study will be used as the basis for proposed changes in the official (AOAC and International Dairy Federation) methods for measurement of the casein content of milk to expand the scope of the method so it can be used to achieve accurate results for milk concentrates and milks of other species.

Key Words: casein, milk concentrates, sheep and goat

W90 A review of the pH influenced casein-whey protein interactions in heated milk.

H. Taterka,* B. Guamis, and M. Castillo, *Universitat Autònoma de Barcelona, Barcelona, Spain.*

During the heat treatment of milk, denatured whey proteins associate to the casein micelle, affecting the functional properties of milk in downstream applications such as milk and yogurt. Although the specific mechanism of attachment is not entirely understood, after partial denaturation, β-lactoglobulin (β-LG) attaches via available sulfide groups to κ-casein (κ-CN). Additionally, there is conflicting evidence, apart from the more commonly accepted mechanism in which the κ-CN/β-LG complex is formed on the surface of the micelle, that may indicate that β-LG does not attach to κ-CN on the surface of the casein micelle, but rather that κ-CN first interacts with β-LG preferentially in the serum matrix and later the κ-CN/ β-LG complex can re-associate with the casein micelle. Furthermore, it is believed that α-lactalbumin (α-LA) does not attach directly to the micelle, but instead forms an association with β-LG portion of the κ-CN/β-LGcomplex, and is therefore dependent on this association to attach to the casein micelle. After heat-treatment and attachment, the milk matrix contains 3 types of whey proteins: native whey proteins, protein aggregates, and those aggregates that have formed an association on the surface of the casein micelle. The percentages of these whey protein-types are highly dependent on the extent of heat treatment (temperature and time) as well as milk pH. Methods have been used to separate and quantify these types of whey proteins in heated milk including acid separation, rennet separation, and ultracentrifugation. To quantify the whey protein forms in milk, different analytical methods can be used such as HPLC, capillary electrophoresis and gel electrophoresis. This work reviews the mechanism of the attachment of partially denatured whey proteins to the surface of the casein micelle, the various types of whey proteins that can be found in the milk matrix after heat treatment, as well as the various methods of determination and quantification of whey proteins.

Key Words: whey protein, casein, denaturation

W91 Gel-based shotgun proteomics analysis of cow milk fat globules. T. J. Yuan, J. Q. Wang,* Y. X. Yang, D. P. Bu, J. H. Yang, P. Sun, and L. Y. Zhou, *State Key Laboratory of Animal Nutrition, Institute of Animal Science, Chinese Academy of Agricultural Sciences, Beijing, China.*

This study was designed to characterize protein expression profiling of cow milk fat globules (MFG). Four different lysis buffers were applied to improve protein extraction from the cow MFG, and extracts were subjected to SDS-PAGE separation followed by liquid chromatography-tandem mass spectrometry (LC-MS/MS) for identification and characterization. The result indicated different lysis buffers led to different quality of protein extraction and resolution. All 224 MFG proteins (MFGP) were identified by 2 or more unique peptide sequences. The identified MFGP ranges from 8 kDa to 546 kDa in molecular weight mass, and 4.61 to 11.36 in isoelectric point. The Gene Ontology (GO) classification for localization and function of these proteins was presented. Among all identifications, 69 were not reported before in bovine MFG or MFGM, and the majority of these proteins are involved in membrane and vesicular trafficking, cell signaling, immune function, protein synthesis, binding and folding, fat transport/metabolism, enzymatic activity or poorly defined functions. Our work presents a detailed picture of the cow MFG proteome at the physiological conditions based on gel LC-MS/MS analysis, providing a useful source for future studies on lactation biology and on physiopathological evaluation of the mammary gland on the basis of their proteomic assortment.

Key Words: milk fat globule, shotgun proteomics, Gene Ontology classification

Forages and Pastures III

W92 Chemical composition of oats straw treated with oxidizing and alkali-based agents. F. E. Miccoli[1,2], H. M. Arelovich*[2,3], R. D. Bravo[2,3], and M. F. Martínez[2,4], *[1]Facultad de Ciencias Agrarias, Universidad Nacional de Lomas de Zamora, Buenos Aires, Argentina, [2]Departamento de Agronomía, Universidad Nacional del Sur, Bahía Blanca, Argentina, [3]Comisión de Investigaciones Científicas (CIC), Buenos Aires, Argentina, [4]CERZOS-CONICET, Bahía Blanca, Argentina.*

Specific chemical treatments improve feeding value of straws by dissolving chemical bonds of cell wall components without affecting lignin content, which may be decreased by oxidizing agents. The objective was to evaluate the effect of oxidizing and alkali-based agents added in aqueous solution to improve feeding value of chopped oats straw (*Avena sativa*, OS). Treatments were CON (control); U = urea (4 g/100 g DM); SH = NaClO (1 g active Cl/100 g DM); SC = NaCl (4 g/100 g DM); and the combinations U-SH; U-SC; SH-SC and U-SH-SC. A volume of 30 mL of each solution was sprayed and homogenized with 100 g DM of OS, compacted and stored for 10, 20 or 30 d in 10 × 15 cm PVC cylinders. The storage temperature was 24.1 ± 1.8°C. After storage samples were dried (65°C), ground (2mm) and analyzed for IVDMD, CP, NDF, ADF and ADL. Data were analyzed as a factorial arrangement of treatments with 4 replicates and means were compared using Tukey's test. Interaction ($P < 0.01$) between chemical treatments and storage length was only found for CP and ADL. Thus IVDMD, NDF and ADF across storage lengths are reported on Table 1 since chemical treatment is the main factor. The CP concentration did not change within treatments without urea in any storage length, averaging 2.36%. However, U, U-SH, U-SC and U-SH-SC averaged 10.30% CP being 4.4 times greater than treatments without urea. The combination of urea with oxidizing and alkali-based agents (U-SH, U-SC and U-SH-SC) promoted even larger N retention in OS than U alone ($P < 0.05$). The main reduction of ADL was noted at 30 d storage length ($P < 0.05$) with SH-SC (4.43%) vs. CON (6.28%). Combined oxidizing and alkali-based agents substantially improved feeding value of OS.

Table 1. Effect of oxidizing and alkali-based agents on oats straw quality

Treatment	IVDMD	NDF	ADF
CON	47.38^{a}	79.57^{e}	44.37^{c}
U	52.10^{bc}	76.72^{cd}	43.27^{bc}
SC	49.77^{ab}	78.85^{e}	43.72^{c}

W93 In vitro true organic matter digestibility, partitioning factor, and ruminal microbial protein synthesis of crown rust resistant and susceptible oat cultivars in Northern Mexico. H. Bernal Barragán*[1,4], M. A. Cerrillo Soto[2,4], A. S. Juárez Reyes[2,4], M. Guerrero Cervantes[2,4], N. C. Vásquez Aguilar[1], F. G. Ríos Rincón[3,4], E. Gutiérrez Ornelas[1,4], and J. E. Treviño Ramirez[1], *[1]Universidad Autónoma de Nuevo León, Fac. Agronomía, San Nicolás de los Garza, NL, México, [2]Universidad Juárez del Estado de Durango, Fac. Medicina Veterinaria y Zootecnia, Durango, México, [3]Universidad Autónoma de Sinaloa, Fac. Medicina Veterinaria y Zootecnia, Culiacán, Sin, México, [4]Red Internacional de Nutición y Alimentación en Rumiantes, México.*

This study was conducted to evaluate the nutritional value of 3 crown rust (*Puccinia coronata*) resistant oat cultivars (CRR = L112, L124 and L164), released from the Agronomy Dept. of the University of Nuevo Leon, Mexico, and of 2 commercial crown rust susceptible cultivars (CRS = Guelatao and Chihuahua) using in vitro procedures. Whole plant samples were harvested April 2008 at 3 growth days (d), and grouped in a 2 × 3 factorial arrangement of treatments, with 2 groups of cultivars (CRR and CRS), and 3 growth stages (101, 110, and 117 d), in a complete randomized design, without accounting for single varieties. No crown rust disease infested any of the experimental plots. Incubations of 500 mg samples were set in 40 mL of a 1:2 mixture of rumen fluid from 3 fistulated sheep fed 75% alfalfa hay and 25% concentrate, and buffer solution, in calibrated 100 mL glass syringes at 39°C, to determine mL gas production at 24h (GP_{24h}). True in vitro dry matter degradability (TIVDMDegr) was determined after refluxing the 24h-incubation residuals in NDF solution. Partitioning factor (PF) was calculated as mg true degraded DM/GP_{24h}. Microbial protein (MP) synthesis was estimated measuring UV-spectrophotometrically the purine content (µmol) of additional freeze-dried 24h-incubation residuals. True in vitro OM digestibility (TIVOMDig) was determined after incubating 250 mg samples in a Daisy (ANKOM) fiber digester. There was an interaction ($P < 0.01$) for GP_{24h}, since beginning with similar values at 101 d (avg. 86.5 ± 1.8), GP_{24h} for CRS increased until 117 d (89.9 ± 2.2 SE), whereas CRR decreased to 74.3 ± 1.8 mL. TIVDMDegr increased ($P < 0.05$) at 117 d (58.1 ± 0.9%) compared with 101 and 110 d (avg. 42.8 ± 0.9%). The PF of CRR at 117 d was higher than CRS (3.80 ± 0.08 *vs* 3.35 ± 0.10, $P < 0.05$), however (interaction $P < 0.05$) PF was similar earlier (avg. 2.50 ± 0.08). TIVOMDig at 101 d was higher than 117 d (72.1 ± 0.8 *vs* 66.8 ± 0.8%, $P < 0.01$); no difference was found between CRR and CRS. There was increased MP of CRS compared with CRR at 110 (9.0 ± 0.6 *vs* 7.5 ± 0.5) and 117 d (8.1 ± 0.6 *vs* 5.8 ± 0.5 µmol) but (Interaction $P < 0.05$) MP was similar (avg. 6.0 ± 0.6) at 101 d. In conclusion, TIVOMDig was higher at 101 d than later. GP_{24h} and MP of CRS at 110 and 117 d were higher than CRR.

Key Words: oat forage, crown rust, ruminal digestibility

W94 On farm corn silage evaluation method and its validation in a field study. B. Andrieu,* A. Perilhou, and J. Sindou, *Lallemand SAS, Blagnac, France.*

Many silages present some preservation issues, but measuring silo parameters on farm is not always an easy practice. Therefore, a toolbox and its accompanying software (Corn Silage Investigation (CSI) software) were developed to allow a diagnosis of corn silage quality on farm. To validate the concept a large-scale field study was performed. 51 farms located in several areas of France were diagnosed using the toolbox. Temperature, pH and density were recorded as described by the method and the corresponding values were entered in the CSI-software. In addition, parameters describing the farm (breeding performance, field management) and the harvest (type of harvester, speed, yield and application of silage inoculants) were noted. Samples at specific sampling points were taken for chemical analysis (VFA, ammonia, feeding value, monopropylene glycol). Data from the field survey were subjected to 1-way ANOVA. For each farm the CSI-sofware provided a report in which their values were graphically depicted versus benchmarks, which facilitates interpretation of the data. Results from the field survey showed that 30% of the silos had a density lower than the target value (240 kg DM/m3). The density was correlated with parameters at harvest (weight of the tractor, harvest speed), specifications of the corn (DM and chop length) and bunker specifications. It was also recorded that 36% of the investigated silage was heating up (>3°C above ambient temperature). Treating the silage with an inoculant showed to be beneficial. Not only was the percentage of silages that showed heating lower (60% for non treated (NTS) vs 16% for treated silage (TS)), the average increase of temperature was also significantly lower (+8°C for NTS versus +1°C for TS, $P \leq 0.05$) as well as the maximum temperature reached (51°C for NTS versus 28°C for silage treated with *L. buchneri* 40788 versus 47°C for silage treated with *L. buchneri* 202118, $P \leq 0.01$). The toolbox and the CSI-software have proven a practical tool to evaluate the quality of silage. The field study confirms that good management of several parameters (silo design, harvest parameters, etc.) are essential for good silage quality. The addition of a silage additive such as *Lactobacillus buchneri* can help optimizing these good management practices.

Key Words: corn silage quality, field survey, *L. buchneri*

W95 Transgenic corn hybrids reduce fungi in silage. G. B. Neto*[1], T. M. dos Santos Cividanes[1], R. B. F. Branco[1], A. L. Fachin[2], M. C. Beraldo[2], and T. A. Bitencourt[2], [1]*Agência Paulista de Tecnologia dos Agronegócios da Secretaria da Agricultura e Abastecimento do Estado de São Paulo, Ribeirão Preto, São Paulo, Brazil,* [2]*Universidade de Ribeirão Preto, Ribeirão Preto, São Paulo, Brazil.*

The presence of fungi was evaluated in 4 hybrid maize silages, DKB 390 and AG 8088, with (GMO) or without (near-isogenic non *Bt*) the *cry*1Ab *Bacillus thuringiensis* gene. The GMO was not treated with insecticide, and the conventional hybrids received one deltamethrin (2.8%) application 42 d after planting. The harvest was done 95 d after planting. The experimental design was the randomized block with 5 replications in a 2 × 2 factorial arrangement. The GMO had a reduce incidence of fungi in the silage ($P < 0.001$). The total-count averages in the GMO and conventional hybrid silages for filamentous fungi were of 12×10^3 and 3.4×10^5 cfu/g and 13×10^3 and 1.1×10^6 cfu/g for yeast, respectively. However, grain, leaf and stalk ionizant radiation samples were tested for their capacity to inhibit the formation of fungi, such as *Aspergillus flavus, Penicillium sp, Fusarium oxysporum, Fusarium verticilloides*, and no significant differences were found ($P > 0.05$). Thus, the smaller fungi population in the GMO silage was attributed to a higher defense capacity of the plant against the armyworm *Spodoptera frugiperda*. The average damage caused by the *S. frugiperda*, determined in 25 plants per treatment through a visual scale from 0 (no damage) to 5 (dead plants), was of 1.04, 1.60, 1.52, 1.52, 1.68 in GMO and 2.08, 2.28, 2.68, 2.84 and 2.80 in conventional hybrids 15, 22, 29, 36 and 46 d after planting, respectively. Although the GMO was highly effective against *S. frugiperda* ($P < 0.001$), it was not as effective against *Helicoverpa zea* 71 and 78 d after planting ($P > 0.05$). The average damage caused by *H. zea*, determined through a visual scale from 0 (no damage) to 4 (severe damage), was of 0.72 and 1.04 in GMO and 0.84 and 0.96 in conventional hybrids, respectively. Insect damage in plants plays an important role in mold infestation because these events cause the disruption of the protective cell wall. This creates entry points for infective molds. In addition, it causes release of nutrients from the plant endosperm that can be used by molds for growth. The results indicate that the GMO studied likely indirectly reduces fungi populations in silage through reduced impact of armyworm infestations.

Key Words: armyworm, mold

W96 Effects of DM concentrations and inoculants on Jiggs and Tifton 85 bermudagrass silage. J. M. B. Vendramini*[1], A. T. Adesogan[2], L. E. Sollenberger[3], A. D. Aguiar[1], A. Valente[1], and P. Salvo[1], [1]*UF/IFAS Range Cattle Research and Education Center, Ona, FL,* [2]*Department of Animal Sciences, Gainesville, FL,* [3]*Department of Agronomy, Gainesville, FL.*

Bermudagrass is the main warm-season grass species preserved as silage or haylage by dairy producers in Florida; however, the nutritive value and silage fermentation parameters are often less than desirable. The objective of this study was to investigate the effects of DM concentrations on nutritive value and fermentation parameters of Jiggs bermudagrass (*Cynodon dactylon* L.) and Tifton 85 bermudagrass (*Cynodon* sp.) silages treated with sugarcane (*Saccharum officinarum*) molasses [1 kg molasses (DM)/50 kg forage (As fed)], Ecosyl inoculant [EcoSyl, MTD/1; 100 mg/50 Mg forage (As fed)], B 500 inoculant [*Lactobacillus buchneri*, 8 mg/kg forage (As fed)], or control. The experiment was conducted in Ona, FL. Tifton 85 and Jiggs plots were distributed in a randomized complete block design with 3 replicates. The data were analyzed using PROC MIXED with bermudagrass cultivars (main plot), DM concentrations (sub-plot), and inoculants (sub-sub-plot) as fixed effects, and block and its interactions as random effects. Forage was harvested with 4 wk regrowth and readily ensiled (22% DM) or wilted on the field for 4 h (53% DM). Forage was packed into a mini-silo at a density of approximately 400 kg fresh forage/m^3 and ensiled for 90 d. There were no effects ($P < 0.05$) of species, DM concentrations, or inoculants on CP concentrations (12.2%). Forage with greater DM concentration had greater in vitro true digestibility (IVTD; $P < 0.01$, SE = 1, 56 vs. 53% for 53 and 22% DM, respectively) and the molasses treatment resulted in forage with greater IVTD than the other inoculant treatments ($P < 0.01$, SE = 1, 58 vs. 53%). However, silage with greater DM concentration had greater pH ($P = 0.02$, SE = 0.6, 4.5 vs. 4.8 for 22 and 53% DM, respectively) and decreased lactic acid concentrations ($P < 0.01$, SE = 0.1, 3.8 vs. 2.9% for 22 and 53% DM, respectively). Silage treated with molasses had decreased pH ($P < 0.01$, SE = 0.04, 4.3 vs. 4.8), increased acid lactic concentrations ($P < 0.01$, SE = 0.05, 5.4 vs. 2.4), and decreased aerobic stability when compared with forage treated with Ecosyl, B 500, and control ($P < 0.01$, SE = 11, 205 vs. 288 h). Using molasses as an additive may improve the nutritive value and fermentation characteristics of bermudagrass silage.

Key Words: bermudagrass, silage, inoculant

W97 Effects of *Lactobacillus* inoculants and forage dry matter on the fermentation and aerobic stability of ensiled mixed-crop tall fescue and meadow fescue. X. S. Guo[1], D. J. Undersander[2], and D. K. Combs*[2], [1]*State Key Laboratory of Pastoral Ecosystem, Lanzhou University, Lanzhou, China,* [2]*University of Wisconsin, Madison.*

This study evaluated the effects of *Lactobacillus plantarum* with or without *Lactobacillus buchneri* on the fermentation and aerobic stability of a mixture of tall fescue and meadow fescue ensiled at different dry matter. The first cut was harvested at boot stage and second-cut grasses were harvested when 30 to 35 cm tall. Four DM content treatments of the first-cut were 17.9%, 24.9%, 34.6%, and 48.7%; and of second-cut were 29.1%, 36.3%, 44.1%, and 49.2%. Chopped grasses at each DM content were treated with 1) deionized water (control); 2) *L. plantarum* MTD1

(LP); 3) a combination of *L. plantarum* MTD-1 with *L. buchneri* 40788 (LP+LB). The application rate of each inoculant to the fresh forage was 1×10^6 cfu/g. Grasses were ensiled in vacuum sealed polyethylene bags for 60 d with 4 replicates for each treatment, and each bag contained 150 g of DM. Aerobic stability was defined as the time after bag opening for the silage temperature to increase by 2°C above ambient temperature. Data were analyzed by using the GLM procedure of SAS according to a randomized complete block design. Silages inoculated with LP+LB or LP had greater pH compared with untreated silages (5.07, 5.04, 4.86, respectively, $P < 0.05$). Lactate was greater in LP silage (5.25% DM) than control (3.75%DM) or LP+LB (2.84%DM) silages ($P < 0.05$). As silage DM increased, lactate in untreated and LP treated silages decreased, but increased in LP+LB treated silage ($P < 0.001$). Acetate concentration decreased with increased DM in all silages. LP+LB treated silage had the longest and control silage the shortest aerobic stability for both harvests. The greatest values in aerobic stability were observed in silages with highest DM content ($P < 0.05$). In this study, aerobic stability of grass mixes ensiled between 18% and 44% DM increased as DM% increased. LP and LP+LB inoculants improved aerobic stability of silages harvested between 18% and 44% DM.

Key Words: fescue, silage, inoculant

W98 Effect of corn silage sample handling on nutritional parameters measured by wet chemistry.

L. C. Solórzano*[1], D. Sawyer[2], and A. A. Rodríguez[3], [1]*Chr. Hansen Inc., Milwaukee, WI,* [2]*Rock River Laboratory Inc., Watertown, WI,* [3]*University of Puerto Rico, Mayagüez, PR.*

Prior to ration balancing, nutritionists submit samples to a laboratory for analysis. Many times, samples must be shipped to the laboratory as services may not be readily available nearby. Shipping methods vary, thus the time that lapses between sample collection and sample analysis may range from a few hours to a few days. A study was undertaken to determine the effect of silage sample handling on nutritional parameters measured by wet chemistry at a commercial laboratory. Eleven silage storage bags were sampled with a silage probe. Each individual silage bag sample was thoroughly mixed and divided into 5 sub-samples that were treated as follows: 1.Silage sub-sample placed in air tight bag and iced immediately, taken to the laboratory within 3.5 h (ICE); 2. Silage sub-sample placed in airtight bag, taken to the laboratory within 3.5 h (NO-ICE); 3. Silage sub-sample placed in airtight bag, taken to post office for overnight delivery (24H); 4. Silage sub-sample placed in air tight bag, iced, taken to freezer overnight and taken to post office for overnight delivery (48HFZN); 5. Silage sub-sample placed in airtight bag, kept overnight at room temperature in garage and taken to post office for overnight delivery (48H). All 55 silage sub-samples were analyzed for pH, CP, ADF and heat damaged CP at a properly accredited commercial laboratory (Rock River Laboratory, Inc., Watertown, WI). Statistical analysis was performed using SAS with a model containing terms for silage bag number and treatment. Separation of treatment means was conducted using the Tukey-Kramer test. Silage pH did not differ among treatments and averaged 3.84. The CP content (%) for 48HFZN (7.39) was increased ($P < 0.03$) relative to ICE (6.97), NO-ICE (6.91), 24H (6.79) and 48H (7.1). The available CP (DM %) for 48HFZN (7.16) was increased ($P < 0.03$) relative to ICE (6.71), NO-ICE (6.69), 24H (6.57) and 48H (6.74). The ADF insoluble CP (% CP) was increased in 48H (5.09) relative to ICE (3.8), NO-ICE (3.11), 24H (3.32) and 48HFZN (3.12). There were no treatment effects ($P > 0.10$) for ADF or energy parameters. Samples arriving to the laboratory after 24 h post-sampling are subject to increases in CP content regardless of the handling method. Samples arriving to the laboratory after 24 h post sampling are subject to increases in heat-damaged protein when not kept cold or frozen. Data suggest that samples should arrive to the laboratory within 24 h post sampling in tightly sealed bags.

Key Words: corn silage, nutrients, sample handling

W99 The effect of ensiling duration on fatty acid profile and concentration of corn silage.

M. C. Der Bedrosian*[1], L. Kung Jr.[1], K. E. Nestor Jr.[2], C. L. Preseault[3], and A. L. Lock[3], [1]*University of Delaware, Newark,* [2]*Mycogen Seeds, Indianapolis, IN,* [3]*Michigan State University, East Lansing.*

The profile and concentration of fatty acids (FA) in feed has been shown to affect rumen function, and the yield of milk and milk components. The objective of this study was to evaluate the effect of ensiling duration on the profile and concentration of FA of corn silage. Treatments were a brown midrib (BMR) and a non-BMR silage hybrid (nBMR), both harvested at a normal DM (32%) and a high DM (41%). Forages were sampled, vacuumed and heat-sealed in storage bags (n = 5) and ensiled for 45, 90, 180, 270, or 360 d, before analyses. Fatty acids were analyzed by gas-liquid chromatography. Data were analyzed as a 5 × 2 × 2 factorial arrangement of treatments, with main effects of hybrid, DM at harvest, ensiling duration, and interactions of each. The total concentration of FA (DM basis) was 1.9%, 2.0%, 1.9%, and 2.20% after 0, 45, 90 and 180 d, respectively. After 270 d and 360 d, the concentration of FA was increased ($P < 0.01$) over d 0 and 90 d to 2.3%. Harvesting nBMR at a normal DM (1.3 ± 0.06%) resulted in lower ($P < 0.01$) FA concentration, than harvesting at a high DM (2.4 ± 0.06%). This difference was absent in BMR silages, averaging 2.5% and 2.3% for normal and high DM silages, respectively ($P > 0.05$). When the FA profile was examined, the concentration of total PUFA was lower in high DM BMR (50 g/100 g FA) than low DM BMR (53 g/100 g FA) and normal DM nBMR (53 g/100 g FA) ($P < 0.01$). Levels of total PUFA were highest in high DM nBMR (55 g/100 g FA). Total PUFA concentration was, on average, 52.7 g/100 g FA after 0 d, decreased ($P < 0.01$) to 49.9 g/100 g FA after 45d, then increased ($P < 0.01$) to 51.0 g/100 g FA, 54.8 g/100 g FA, 54.8 g/100 g FA and 55.3 g/100 g FA after 90, 180, 270 d, and 360 d, respectively. The mean concentration of linoleic acid and oleic acid was 48 and 25 g/100 g FA, respectively, averaged over all time points and silages, and remained steady over time. Linoleic acid was highest in high DM nBMR (51.2 g/100 g FA) and was lowest in normal DM nBMR (44 g/100 g FA, ($P < 0.01$). Linoleic acid concentration increased with time ($P < 0.01$) in all other silages, and this increase was most dramatic in normal DM nBMR. Total MUFA (g/100 g FA) were steady over time in nBMR silages, ranging from 24.4 g/100 g FA, before ensiling, to 23.2 g/100 g FA, after 360 d of storage. In BMR silages, total MUFA levels peaked after 45 d of ensiling at 29.0 g/100 g FA, then decreased steadily ($P < 0.01$) to 26.8 g/100 g FA. Levels of oleic acid remained steady over time in nBMR silages, but fluctuated over time ($P < 0.01$), peaking after 45 d of ensiling at 27.9 g/100 g FA, and decreasing to 26.1 g/100 g FA after 270 d. These results indicate that on a DM basis FA concentration in corn silage changes during ensiling. It remains to be determined, however whether such changes are an increase in actual FA yields or due to a reduction of non-FA material within the forage. Future work should examine whether these FA are present as free or esterified FA and if this changes during ensiling.

Key Words: corn silage, BMR, fatty acids

W100 Relationship between organoleptic characteristics, pH, and aerobic deterioration of alfalfa and orchard grass silages.

R. González-Ortiz[1], L. Miranda-Romero[1], J. Burgueño-Ferreira[2], and R. Améndola-Massiotti*[1], [1]*Posgrado en Producción Animal Universidad Autónoma Chapingo, Chapingo, Estado de México, México,* [2]*CIMMYT, Texcoco, Estado de México, México.*

The perception of organoleptic properties (OP; odor, color, structure and moisture) of silages by trained observers enables an easy subjective evaluation of quality. On the other hand, chemical properties (CP) as pH and aerobic deterioration (measured as CO_2 production $TPCO_2$, mmol CO_2 g^{-1} dry matter d^{-1}, measured during 5 d of exposure to air) are quantitative objective assessments of silage quality, but they are not easily available to small farmers. The aim was to estimate the relationship between OP and CP of 46 alfalfa (*Medicago sativa* L.) and orchard grass (*Dactylis glomerata* L.) silages. The experiment was carried out between June and August 2011, at Chapingo University, México. The silages resulted of the factorial combination of cutting at 2 different hours (8:00 and 14:00), 3 wilting times (0, 1 and 2 h) and 2 levels of bacterial inoculants (0 and 5g t^{-1}) with 4 replicates. Forage was ensiled in 200 L plastic containers, and opening of silos took place 60 d after ensiling. Perception of OP was carried out by 5 previously trained independent observers. The different OP were classified in 4 classes ranging between 1 (bad) and 4 (excellent). Silage samples were taken for measurement of pH and $TPCO_2$. Correlations analysis and principal components analysis were carried out. Correlation coefficients (r) among OP ranged between 0.57 and 0.87, while r between CP was 0.39; CP were negatively correlated with OP, r ranged between −0.34 (pH-odor) and −0.67 ($TPCO_2$ -moisture). Even though r were low, they were all significant ($P \leq 0.02$). Principal components analysis enabled the classification of silages according to their quality. The first 2 components explained 80% of the variation; the first component (70%) implied the negative relationship between CP and OP; according to the second component CP were positively related to odor and color and negatively related to moisture. Due to the close relationship between OP and CP it is concluded that small farmers might reliably use perception of OP for the evaluation of silage quality.

Key Words: *Medicago sativa*, *Dactylis glomerata*, principal components analysis

W101 Effect of rate of application of various commercial exogenous fibrolytic enzymes on preingestive fiber hydrolysis and release of sugars and phenolics from bermudagrass haylage.

J. J. Romero*[1], K. G. Arriola[1], M. A. Zarate[1], C. R. Staples[1], C. F. Gonzalez[2], W. Vermerris[3], and A. T. Adesogan[1], [1]*Department of Animal Sciences, IFAS, University of Florida, Gainesville,* [2]*Department of Microbiology and Cell Science, IFAS, University of Florida, Gainesville,* [3]*Department of Agronomy, IFAS, University of Florida, Gainesville.*

The objective was to examine effects of the dose rate of 5 commercial exogenous fibrolytic enzymes (EFE; E1, E2, E3, E4, and E5 containing 1506, 286, 3624, 1693 and 70 µmol/min/g endoglucanase activity, respectively) on fiber hydrolysis of a 4-wk regrowth of Tifton 85 bermudagrass haylage. Dose rates were 0x (Control), 0.5x, 1x, 2x and 3x; where 1x was the recommended rate of 10, 15, 2.25, 2.25, and 15 g/kg ground (1 mm) substrate, respectively. Enzymes were diluted in citrate-phosphate buffer (pH 6) containing sodium azide (0.02% w/v) and were applied in quadruplicate in 2 runs. Suspensions were incubated at 25°C for 24 h before addition of 15 mL of water followed by shaking for 1 h and filtration through a Whatman 451 paper. Data for each enzyme were analyzed separately as a completely randomized block design. The model included effects of dose, run, and the interaction. Linear (L), quadratic(Q) and cubic (C) polynomial contrasts and the PDIFF statement of SAS were used to evaluate means. Increasing the dose rate increased ($P < 0.05$) DM loss (%) of substrates treated with E3 and E4 (C), E1 (Q), and E2 and E5 (L); decreased ($P < 0.04$) the NDF (%) of all enzyme-treated substrates (C); decreased ($P < 0.01$) ADF (%) of E2, E3, E4 and E5 (C), and E1 (Q); decreased ($P < 0.02$) hemicellulose (%) of E2, E3 and E5 (C), and E1 and E4 (Q); decreased ($P < 0.03$) cellulose (%) of E2, E3, E4, and E5 (C), and E1 (Q); increased ($P < 0.01$) release of water soluble carbohydrates (WSC, %) from E2, E3, E4, and E5 (C), and E1 (Q) and increased ($P < 0.01$) release of ferulic acid (FER, µg/g) from E1, E2, E3 and E5(C), and E4 (L). Optimal doses for reducing the % NDF of E1, E2, E3, E4 and E5 were 2x (−6.7), 0.5x (−1.9), 3x (−8.3), 2x (−3.8) and 3x (−4.0), respectively. Optimal doses for increasing release (%) of WSC and (µg/g) FER were 3x (+5.9), 3x (+0.7), 3x (+5.1), 3x (+2.4) and 3x (+1.3) and 3x (+37), 0.5x (+6), 3x (+54), 2x (+11) and 2x (+30), respectively. Increasing dose rates beyond manufacturer recommendations increased fiber hydrolysis by enzymes to different extents.

Key Words: forage, enzyme, dose

W102 The effects of bacterial inoculants and enzymes on the fermentation, aerobic stability and in vitro organic matter digestibility characteristics of sunflower silages.

M. L. Ozduven*[1], F. Koc[1], and V. Akay[2], [1]*Namik Kemal University, Tekirdag, Turkey,* [2]*Global Nutritech Biotechnology LLC, Richmond, VA.*

This study was carried out to determine the effects of lactic acid bacteria, enzymes, and lactic acid bacteria+enzyme mixture on the fermentation, cell wall contents, aerobic stability and in vitro organic matter digestibility characteristics of sunflower silages. Sunflower was harvested at the milk stage of maturity. Treatments were: 1) control; 2) lactic acid bacteria (I; Global Nutritech Biotechnology LLC, Richmond, VA); 3) enzyme (E; Global Nutritech Biotechnology LLC, Richmond, VA); and 4) lactic acid bacteria+enzyme mixture inoculants (I+E; SILAID; Global Nutritech Biotechnology LLC, Richmond, VA). Inoculants were applied to silages at the rate of 6.00 log cfu/g. Treated chopped sunflower was ensiled in 1.0-l special anaerobic jars equipped with a lid enabling gas release only. The jars were stored at 25 ± 2°C under laboratory conditions. Three jars from each group were sampled for chemical and microbiological analysis at 2, 4, 8, 15 and 60 d after ensiling. At the end of the ensiling period, all silages were subjected to an aerobic stability test for 5 d by measuring pH, production of CO_2, and growth of yeast and mold. In addition, in vitro organic matter digestibilities of these silages were determined. Both treatments (I and I+E) increased characteristics of fermentation but impaired aerobic stability of sunflower silages compared with control ($P \leq 0.05$). Bacteria+enzyme treatment decreased both neutral detergent fiber and acid detergent fiber contents of silage compared with control ($P \leq 0.05$). In vitro organic matter digestibility was numerically increased for treated silages compared with control silages. In conclusion, I and I+E inoculants can be used for sunflower silages.

Key Words: sunflower, silage, inoculant

W103 The inoculation rate of a mixture of homo-fermentative and hetero-fermentative bacteria strains affects the aerobic stability of tropical corn (TC) silage.

A. A. Rodríguez*[1], L. C. Solórzano[2], and V. Rivera[1], [1]*University of Puerto Rico, Mayagüez, PR,* [2]*Chr. Hansen Inc., Milwaukee, WI.*

The objective was to evaluate the effects of inoculation rate of a microbial additive containing homo-fermentative and hetero-fermentative lactic acid-producing bacteria strains (LAPBI) on the ensiling characteristics and aerobic stability of TC fermented during 45 and 90 d (FD) at 27°C. Chopped TC (38.21% DM) was ensiled in 1.2 kg capacity micro-silos and assigned to 1 of 3 treatments (TRT); no additive, LAPBI applied at 10^5 or at 10^6cfu/g fresh forage. Three samples of fresh forage and silage from each TRT and FD were analyzed to determine pH and fermentation products. Statistical analysis was performed according to a Completely Randomized Design with a 3 TRT by 3 FD factorial arrangement. For aerobic stability, triplicate samples from each TRT and FD were placed in styrofoam containers lined with plastic. Temperature was measured at 6 h intervals from 0 to 108 h and at 124, 130, 134, 140, 148, 158, and 176 h. Data was analyzed using a split plot design with a 3 TRT by 2 FD by 26 h factorial arrangement using silo as the repetitive measurement. No significant ($P > 0.05$) responses on pH and fermentation characteristics were observed. After 45 d of ensiling and during the aerobic exposure (AE) period temperature was lower ($P < 0.05$) in TC treated with 10^6 cfu/g LAPBI than control or TC inoculated with LAPBI applied at 10^5cfu/g. After 90 d of ensiling temperature was lower ($P < 0.05$) in treated silages vs. control. The temperature of inoculated silages fermented during 45 and 90 d was lower ($P < 0.05$) vs. control from 54 to 84 h and from 90 to 108 h of AE, respectively. Compared with ambient temperature, after 45 d of ensiling temperature started to rise at 36 h of AE for control and silage treated with 10^5 cfu/g, whereas in silage treated with 10^6 cfu/g it occurred after 54 h. After 90 d of ensiling, inoculation with 10^6 or 10^5 cfu/g delayed the start of temperature rise for 78 or 72 h, whereas for untreated TC the delay was 66 h. In summary, inoculation of TC did not enhance the fermentation characteristics, but improved aerobic stability. A greater response in aerobic stability was observed with the higher inoculation rate.

Key Words: tropical corn silage, microbial inoculants, inoculation rate

W104 Infrared thermography to assess the relationship between corn silage quality and face temperature.

L. O. Abdelhadi*[1], P. A. Saravia[2], W. R. Barneix[2], C. A. Malaspina[2], C. de Elia[3], and J. M. Tricarico[4], [1]*Est. El Encuentro, Research and Extension in Ruminant Nutrition, Brandsen, Buenos Aires, Argentina,* [2]*Cámara Argentina de Contratistas Forrajeros (CACF), Argentina,* [3]*Alltech Biotechnology, Argentina,* [4]*Innovation Center for U.S. Dairy, Rosemont, IL.*

Feedout exposes silage to air consequently reducing silage quality and resulting in environmental implications. The aim of the study was to evaluate the utilization of infrared thermography (IRT) to relate face temperature with quality loses and ethanol emissions, and develop a tool that allows us to act rapidly to improve management and hence reducing the negative effects of air exposure. A randomized complete block design was used with bunker silos as blocks and face temperatures as treatments. Corn silage storage in bunker silos were sampled in 18 commercial well managed dairy and beef farms. A hand portable infrared camera (Ti45, Fluke thermal imagers) was used to measure IRT in each silo at a fixed distance of 4 m. From this measurement, the locations of maximum (Hot) and minimum (Cold) temperatures were established in exposed silo face. At each point samples were taken using a forage sampler (between 0 and 50 and 50–100cm depth), frozen and analyzed for DM, OM, CP, pH and in vitro DM digestibility (DMD) at 6, 12, 24 and 48h of incubation (DAISY). As expected, temperature from hot to cold locations differed by 13.9 ± 3.5°C ($P < 0.01$). Although no differences in quality parameters and pH were detected between 0 and 50 cm depth, a reduction in OM was detected from 50 to 100 cm in hot areas ($P < 0.09$). DMD at 48h was lower ($P < 0.01$) both between 0 and 50 and 50–100 cm depth in hot areas, when compared with cold ones. Besides at 6h, DMD was higher in cold areas. Although strong correlations were no detected for temperature and quality parameters in the type of silos involved in this trial, we conclude that hot areas in silo faces represents reductions in DMD which could be detected by IRT technology.

W105 Fermentative losses and yeasts population in sugarcane ensiled with different particle sizes.

A. F. Campos*[1], G. R. Siqueira[1,2], V. D. Monção[3], and R. A. Reis[1], [1]*São Paulo State University, Jaboticabal, São Paulo, Brazil,* [2]*Agência Paulista de Tecnologia dos Agronegócios, Colina, São Paulo, Brazil,* [3]*Centro Universitário de Barretos, Barretos, São Paulo, Brazil.*

The objective of this study was to evaluate the gas losses, effluent production, dry matter recovery, pH and the dynamics of yeasts population in silages of sugarcane with different particle size (0.5; 1.0; 1.5 and 2.0 cm). The silages were evaluated during the storage period of 0, 3, 7, 14, 28 and 56 d of fermentation. Results were analyzed in a completely randomized design, with 3 replications, with time repeated measures, using plastic bucket like experimental silos. Statistical analyzes were developed using MIXED procedure of SAS 9.0. It was observed significant differences ($P < 0.01$) in gas production. Silage with particle size of 1.0 cm showed greatest losses (85.4 × 66.4, 72.3 and 61.2 g/kg on the silages of 0.5; 1.5 and 2.0 cm, respectively).The gas losses increased until 28 d of fermentation. There were no significant differences ($P > 0.05$) in the dry matter recovery among the treatments, but there was a reduction ($P < 0.01$) along the days of fermentation. Yeast population was higher in the silages with 1.0 and 1.5 cm of particle size, compared with the treatments with 0.5 and 2.0 cm (5.94 and 5.91 × 5.47 and 5.34 log cfu/ g forage, respectively). There were no effluents losses in this trial, due to the high dry matter content of the ensiled forage (390 g/kg). The pH of the silages decreased ($P < 0.01$) along the fermentation period, with average values of 5.13 at the ensilage moment, and 3.63 after 56 d of fermentation. Among the treatments, the silage with particle size of 0.5 cm present lower value of this variable. Particle size of 0.5 cm can reduce fermentative losses of the sugarcane silage.

Key Words: dry matter recovery, gas losses, pH

W106 A preliminary evaluation of corn silage affected by Hurricane Irene in 2011.

J. M. Lim*[1], E. A. Cummings[2], H. M. Darby[2], and L. Kung Jr.[1], [1]*University of Delaware, Newark,* [2]*University of Vermont, Burlington.*

Hurricane Irene caused severe flooding and (or) lodging of crops in the Northeastern US. The objective of this study was to evaluate the chemical composition and fermentation of corn silage harvested from 5 farms affected in Vermont. All forages had large amounts of silt on the plants at harvest. Forage was harvested 42–43 d after the hurricane and was ensiled in vacuumed and heat-sealed bags in quadruplicate per farm and allowed to ferment for 60 d at 25°C. All analyses were by wet chemistry methods. Forages averaged 34.3% DM (28.6 to 40.3%) and 6.8% CP (4.8 to 8.4%, DM basis) at harvest. Concentrations of ADF and NDF (corrected for ash) were normal. Ash content was higher than normal (4.2%, NRC, 2001) ranging from 6.2 to 24.7% (ave. 10.6%). The concentrations of Ca, P, K, and Mg were within normal ranges. High concentrations of Fe (ave. 3409 ppm, range 1256 to 4397 ppm) and Al (ave. 2211, range 1256 to 4397 ppm) were detected. Forages also contained 37%, 767% and 314% more Cu, Zn and Mn than normal, respectively. The numbers of yeasts, molds, and enterobacteria averaged 4.6, 3.8, and 6.6 $\log_{10}$cfu/g of fresh forage, respectively. Numbers of yeasts (3.2 $\log_{10}$cfu/g) decreased by 1 $\log_{10}$ cfu/g of silage whereas molds and enterobacteria were not detectable after ensiling. The average pH of silages was 3.85 (3.71 to 4.19). All silages had more lactic than acetic acid with the exception of 1 farm where this was reversed. Overall, the concentrations of lactic acid, acetic acid, and ethanol were within normal ranges and averaged 3.34, 1.27, and 0.94% of DM, respectively. Butyric acid was detected in silage from only 2 farms (range 0.05 to 0.22% DM). The chemical composition and content of heavy metals in silages were similar to that of the fresh forage. Vomitoxin was detected (0.5 to 1.4 ppm) in all silage samples from 2 farms while 15-acetyl deoxynivalenol (0.9 ppm) and zearalenone (2.1 ppm) was detected in 1 out of 4 samples from 1 of these farms. Corn silage affected by Hurricane Irene generally ensiled well, but contained high levels of ash and certain minerals which when fed long-term may have negative effects on animal performance.

Key Words: corn silage, cow

W107 Feeding red clover cut at sundown and harvested as baleage did not improve milk yield in late-lactation dairy cows.

N. T. Antaya*[1], A. F. Brito[1], R. Berthiaume[2], G. F. Tremblay[3], N. L. Whitehouse[1], G. M. Soule[1], N. E. Guidon[1], and E. S. Fletcher[1], [1]*University of New Hampshire, Durham,* [2]*Dairy and Swine R&D Centre/Agriculture and Agri-Food Canada, Sherbrooke, QC, Canada,* [3]*Soils and Crops R&D Centre/Agriculture and Agri-Food Canada, Québec City, QC, Canada.*

Forages cut at sundown (PM) generally yield higher concentration of nonstructural carbohydrates (NSC) than those harvested at sunup (AM). In late-lactation Holstein cows fed only forage, we showed that PM-cut alfalfa baleage increased milk yield compared with cows fed the AM-cut counterpart. In the current study, 12 multiparous and 2 primiparous Holstein cows averaging 238 DIM received a TMR containing, on a DM basis, either 65% PM- or AM-cut red clover (RC) baleage plus 35% of a common concentrate in a crossover design with14 d for diet adaptation and 7 d for sample collection. A well established RC field was split in 2 with one half cut at sundown and the second half at sunup the next day. The PM- and AM-cut RC baleages contained (g/kg DM): 103 vs.75.6 total ethanol soluble carbohydrates, 8.83 vs. 7.91 starch, and 112 vs. 83.5 NSC (total ethanol soluble carbohydrates + starch); baleage DM averaged 442 g/kg of fresh matter. Feeding late-lactation cows PM- vs. AM-cut RC baleage did not improve ($P > 0.05$) animal performance (see table below). However, MUN was lower ($P < 0.001$) in cows fed the PM- vs. the AM-cut RC indicating enhanced N utilization. Although cows were in late lactation, milk yield was relatively high (mean = 28 kg/d). Hence, the difference in NSC between RC baleages (28.5 g/kg DM) may not have been large enough to elicit a positive response in animal performance. Alternatively, the amount of concentrate fed may have offset the potential positive effect of the PM-cut RC baleage on improving milk yield. Research is needed to examine the interaction between forage NSC and dietary levels of concentrate.

Table 1. Milk yield and composition in cows fed TMR containing PM- or AM-cut red clover (RC) baleage

	TMR			
Item	PM-cut RC	AM-cut RC	SED	*P* > *F*
Milk yield, kg/d	27.7	28.3	0.57	0.28

Key Words: dairy cows, red clover, nonstructural carbohydrates

W108 The effect of feeding normal corn silage, BMR corn silage or 50:50 mixture of the two on the production performance of lactating cows.

J. M. Lim*[1], M. C. Santos[1], M. C. der Bedrosian[1], K. E. Nestor Jr.[2], and L. Kung Jr.[1], [1]*University of Delaware, Newark,* [2]*Mycogen Seeds, Indianapolis, IN.*

This study evaluated the feeding value of corn silage from a normal (NML, Mycogen TMF2W726, Dow AgroSciences, Indianapolis, IN), brown midrib (BMR, Mycogen F2F700) and a 50:50 mixture (MIX) of these 2 hybrids for lactating dairy cows. The NML and BMR were planted separately whereas MIX was planted in alternating rows of each hybrid. Corn was harvested at approximately 36% DM, chopped (~19 mm length), processed, and ensiled in bag silos for 6 mo. Twenty-four Holstein cows in early lactation were fed a TMR containing silage from one of the 3 corn hybrids (52% of DM) with alfalfa silage (5%), alfalfa hay (3%), and concentrate (40%) in a simultaneously replicated 3 × 3 Latin square design of experiment with 28 d periods. The chemical compositions of the corn silage were similar among hybrids except for 30-h in vitro NDF digestibility, which was lower for NML (61.48%) by 6.59 and 3.24 percentage units than BMR (68.07%) and MIX (64.72%), respectively. Milk production, percentage and yield of milk fat and protein, 3.5% FCM and ECM were not affected by treatments. Lactose was highest ($P < 0.05$) in the milk of cows fed the BMR (4.82%) silage, intermediate for NML (4.78%), and lowest for MIX (4.73%). The milk urea nitrogen (MUN) of cows fed NML (11.25 mg/dL) was higher ($P < 0.05$) than those cows fed BMR (10.27) and MIX (10.43) suggesting that there is more efficient use of dietary N for productive purposes when cows are fed BMR and MIX corn silage. Intake of DM was lower ($P < 0.05$) for cows fed BMR (26.7 kg/d) and MIX (26.9 kg/d) than NML (28.2 kg/d) silage. Feed efficiency was higher ($P < 0.05$) for the cows fed BMR (1.90) and MIX (1.84) than NML (1.73) corn silage. Growing

BMR and normal corn together produced silage with a chemical composition almost comparable to pure BMR and when fed to cows this mixture resulted in greater feed efficiency and lower milk MUN than cows fed normal silage.

Key Words: corn silage, cow, brown midrib corn

W109 Effects of an esterase-producing inoculant and chop-length on fermentation and aerobic stability of barley silage.

W. Addah*[1,2], J. Baah[1], E. K. Okine[2], and T. A. McAllister[1], *[1]Lethbridge Research Centre, Agriculture and Agri-Food Canada, Lethbridge, Alberta, Canada, [2]Department of Agricultural, Food and Nutritional Science, University of Alberta, Edmonton, Alberta, Canada.*

Forage chop length affects packing density of silage and thus the penetration of air into the silo face. Inoculation of silage with *Lactobacillus buchneri* inoculants has been shown to improve the fermentation and aerobic stability of cereal silages. This study investigated the effects of forage chop length and an esterase-producing inoculant on fermentation characteristics, DM loss and aerobic stability of barley silage. Whole-crop barley (*Hordeum vulgare* L.; 31% DM) was chopped to theoretical lengths of 0.95 cm (SC) or 1.90 cm (LC) and ensiled with or without an inoculant containing esterase-producing *L. buchneri* LN4017, and *Lactobacillus plantarum* LP7109 and *Lactobacillus casei* (2.8×10^5 cfu/g forage) in mini silos. Silos were opened after 64 d of ensiling for determination of fermentation characteristics and assessment of aerobic stability over an 8-d period. Thermocouples were embedded in the d-64 silages to measure temperature over the period of assessment of aerobic stability. Data were analyzed by the mixed procedure of SAS in a 2 × 2 factorial design. Inoculation decreased ($P = 0.01$) pH in SC (pH = 3.87) but not LC (pH = 4.02) silage. Inoculated LC had higher ($P = 0.01$) acetic acid concentration (1.8% DM) compared with the inoculated SC (1.4% DM) silage. Lactic acid concentration was also higher ($P = 0.01$) in the LC (8.2% DM) than in SC (6.7% DM) silage regardless of inoculation. Lactic: acetic acid ratio was lower ($P = 0.01$) with inoculation of LC (4.6) compared with the ratio in the SC (4.5) silage. Regardless of chop length, inoculation increased ($P = 0.01$) lactic acid bacteria and decreased ($P = 0.03$) yeast populations. Neither chop length, inoculation nor their interaction affected silage DM losses. Short-chop silage remained stable during 8 d of aerobic exposure; however, the inoculated LC silage was stable for 7 d compared with only 4 d without inoculation. In both lengths of chop, the inoculant caused shifts in silage fermentation and lengthened the duration of aerobic stability in LC silage compared with the SC.

Key Words: aerobic stability, silage chop length, barley silage

W110 Effects of applying bacterial inoculant with different shooting height on fermentation quality of barley silage.

D. H. Kim*[1], H. J. Lee[1], S. M. Amanullah[2], S. C. Kim[2], Y. M. Song[3], H. Y. Kim[3], and S. B. Kim[4], *[1]Division of Applied Life Science (BK21), Gyeongsang National University, Jinju, Gyeongsangnamdo, South Korea, [2]Department of Animal Science (Inst. Agric. Life Sci.), Gyeongsang National University, Jinju, Gyeongsangnamdo, South Korea, [3]Department of Animal Resource Techology, GNUST, Jinju, Gyeongsangnamdo, South Korea, [4]Dairy Science Division, NIAS, Cheonan, Chungnam, South Korea.*

This study was conducted to evaluate the effect of bacterial inoculant with the different shooting height on fermentation quality of barley silage. Barley forage (Yuyeon hybrid) was grown at Animal Research Unit, Gyeongsang National University, Jinju, South Korea. Barley forage (500 kg) was harvested at 25% DM with 2 different shooting heights (5 cm and 15 cm), chopped 5 cm length and divided 2 piles. One half of barley forage at each shooting height was used for no inoculant treatment and the other for inoculant treatment. The inoculant was applied at 1.2×10^3 cfu/g of forage (*L. plantarum*). The experiment was conducted in a 2 × 2 factorial design with 5 replications. Barley forage was ensiled into 10 L bucket silo for 2, 5, 7, 28, 49 and 100-d durations. Dry matter, CP, and NDF concentrations of barley forages at 5 cm and 15 cm of shooting height were 26.1, 7.03 and 58.4% vs. 24.9, 8.92 and 60%, respectively. Inoculant increased ($P = 0.001$) DM (20.2 vs. 19.2%) of barley silage ensiled for 100-d, but decreased ($P < 0.005$) CP, crude ash, NDF and ADF concentrations (8.1 vs. 8.8%, 7.7 vs. 8.2%, 55.1 vs. 58.4% and 35.8 vs. 38.9%, respectively). Increased shooting height increased ($P < 0.001$) CP concentration (9.2 vs. 7.7%), whereas decreased ($P < 0.05$) DM, crude ash, NDF, ADF and hemicellulose concentrations (19.4 vs. 20.0%, 7.7 vs. 8.2%, 54.6 vs. 58.8%, 35.8 vs. 38.8% and 18.8 vs. 20.1%, respectively). Yeast was decreased (9.5 vs. 7.0 $\log_{10}$ cfu/g, $P < 0.001$) by increasing shooting height. Increased shoot height in absence of inoculants had the decrease effects ($P < 0.05$) on acetate concentration (6.0 vs. 3.7%) and mold (5.6 vs. 4.5 $\log_{10}$ cfu/g), but the increase effects of lactate concentration (2.8 vs. 5.9%) and lactate to acetate ratio (0.5 vs. 1.6). However these measurements were not affected by shooting height with inoculant. Gel electrophoresis analysis and band mass after PCR amplification of DNA indicated higher *L. plantarum* in barley silage with applied inoculant and increased shooting height. Therefore, applying bacterial inoculant and increased shooting height can improved the fermentation quality of barley silage.

Key Words: barley silage, inoculant, shooting height

W111 Effects of bacterial inoculant and shoot height on fermentation quality of barley silage.

H. J. Lee*[1], D. H. Kim[1], S. M. Amanullah[2], S. C. Kim[2], Y. M. Song[3], H. Y. Kim[3], and S. B. Kim[4], *[1]Division of Applied Life Science (BK21), Gyeongsang National University, Jinju, Gyeongsangnamdo, South Korea, [2]Department of Animal Science (Inst. Agric. Life Sci.), Gyeongsang National University, Jinju, Gyeongsangnamdo, South Korea, [3]Department of Animal Resource Techology, GNUST, Jinju, Gyeongsangnamdo, South Korea, [4]Dairy Science Division, NIAS, Cheonan, Chungnam, South Korea.*

This study was carried out to determine the effect of applying inoculant and shoot height on fermentation quality of barley silage. Youngyang hybrid barley forage was grown at Animal Research Unit, Gyeongsang National University, Jinju, South Korea, and harvest at 27% DM with 2 different shoot heights (5 cm and 15 cm). Approximate 500kg of barley forage with 5cm or 15cm shoot heights were chopped 5 cm length and divided 2 piles for with or without inoculant application at 1.2×10^3 cfu/g of forage (*L. plantarum*). A 2 (inoculant) × 2 (shoot height) factorial design with 4 replications was used in this study. Barley forage was ensiled into 10 L mini silo (3 kg) for 2, 7 and 100 d fermentations. Before ensiling, barley forages of 5 cm and 15 cm shoot heights had 25.7 vs. 28.6% of DM and 54.6 vs. 55.5% of NDF, respectively. After 100 d of fermentation, ash content decreased by applying inoculant (2.3 vs. 2.5%, $P = 0.021$) or increased shoot height (2.3 vs. 2.6%, $P = 0.008$), while ether extract (3.7 vs. 2.9%, $P = 0.069$) tended to increase with increased shoot height. By increase of shoot height, crude protein concentration decreased (8.8 vs. 8.2%, $P < 0.05$) in without inoculant, but increased (8.2 vs. 9.0%, $P < 0.05$) in with inoculant. The concentrations of ammonia N (0.32 vs. 0.23%, $P = 0.001$) and ammonia N of total N (23.4 vs. 16.9%, $P = 0.004$) were increased by applying inoculant, while propionate concentration (0.48 vs. 0.71%, $P = 0.004$) was decreased with increase of shoot height. Lactate concentration (2.9 vs. 4.9%) and lactate to acetate ratio (0.5 vs. 1.1) were increased ($P < 0.05$) by increased shoot height and applied inoculant, but no effects on them by increased shoot height and without inoculant. Gel electrophoresis and band mass after PCR amplification of DNA had shown higher *L. plantarum* in barley silage by inoculant application and increase of shoot height. These results indicate that Youngyang hybrid barley silage has better quality without *L. plantarum* irrespective of shoot height.

Key Words: barley forage, silage quality, fermentation indices

W112 Effects of inoculant blends on emissions of volatile organic compounds, oxides of nitrogen, carbon dioxide, ammonia, and dry matter losses in alfalfa silage.

R. B. Franco*[1], J. A. McGarvey[2], D. H. Putnam[3], P. G. Green[4], and F. M. Mitloehner[1], [1]*Department of Animal Science, University of California, Davis,* [2]*United States Department of Agriculture, Agricultural Research Service, Albany, CA,* [3]*Department of Plant Sciences, University of California, Davis,* [4]*Department of Civil and Environmental Engineering, University of California, Davis.*

The San Joaquin Valley (SJV) in Central California exhibits high ground-level ozone pollution that may affect human, animal, and plant health. Silage and other feedstuff were identified as a major source for volatile organic compounds (VOCs) and nitrogen oxides (NOx) which could be a contributor to ozone formation in this area. Gaseous losses from silages also affect feed quality and silage dry matter (DM) losses of 20–30% have been widely reported to occur in the SJV. These DM losses include gaseous losses of VOCs and NOx but also carbon dioxide (CO_2) and ammonia (NH_3). Microbial inoculants are utilized in silage to promote effective fermentation, and thus could affect the amount and species of gases emitted, dry matter losses from original material ensiled, and subsequently, animal performance. This study quantified the different VOCs, NOx, (CO_2), (NH_3) emitted from alfalfa silage (*Medicago sativa* L.) and DM losses after microbial inoculation for 60 d. Twenty-five mini-silos (22 L) were built and used in a repeated measures design over time. Five mini-silos were assigned to 5 treatments: (X) control, (A) heterofermentative, (B) homofermentative 1, (C) a mix of homofermentative and heterofermentative microbes, and (D) homofermentative 2. Emissions were measured using a photoacustic gas monitor and a NO/NO_2/NOx analyzer, using 5 L Teflon bags for gas collection. Concentrations of NOx, predominantly nitric oxide (7.35 ± 1.65 µg NOx-N g DM silage^{-1}) on treatment C were measured (p-value = 0.046). Ethanol and methanol were also detected but with no differences across treatments. No differences in DM losses were observed across treatments, however differences were observed over time (p-value = 0.03). Further studies in quantification and monitoring of these emissions are critical for assessment and therefore response to the specific needs of the air quality in the SJV.

Key Words: NOx, alfalfa silage, alcohols

W113 Screening of bacteriocinogenic lactic acid bacteria from tropical legume silage.

M. Silva, H. Mantovani, O. Pereira,* C. Moraes, A. Ribon, and W. Souza, *Universidade Federal de Viçosa, Viçosa, Minas Gerais, Brazil.*

Ensiling has been used worldwide to preserve the nutritional quality of field crops used as animal feeds. The objective of this work was to isolate and characterize bacteriocinogenic lactic acid bacteria (LAB) during the ensiling of Campo Grande *Sylosanthes* (a mixture of *Stylosanthes capitata* and *S. macrocephala*). Mini-silos made of plastic bags and containing 600 g of chopped forage added with increasing amounts of citrus pulp were used in this study. Samples (25 g) harvested at d 1, 7, 14, 28 and 56 of fermentation were serially diluted in Na-phosphate buffer and plated in selective MRS media containing purple bromocresol. Colonies of gram-positive bacteria that produced acid and were catalase negative were picked for further characterization. Antimicrobial activity was determined against *Listeria monocytogenes* ATCC 7644. The genetic diversity of selected isolates was determined by BOX-PCR fingerprinting and identification was achieved by phenotypic characterization and sequencing of the 16S rDNA. Two hundred and 50 6 cultures were isolated during the ensiling process and 83% (n = 214) of the isolates showed some antagonist activity against *L. monocytogenes*. From these, 22 isolates with simple growth requirements were grouped by BOX-PCR in 2 separate clades, which distinguished the isolates by the period of ensiling (first day and 14 d of fermentation). The fermentation pattern of 49 carbohydrates and the sequencing of the 16S rDNA indicated that the isolates with greater ability to compete during ensiling (n = 8) belonged to the species *Pediococcus pentosaceus*, *Pediococcus acidilactici* and *Lactobacillus plantarum*. The antimicrobial activity of acidic cell-free extracts obtained from *P. pentosaceus* MP6.16, *P. acidilactici* MP10.4 and *P. acidilactici* MP10.6 was sensitive to proteinases, indicating its proteinaceous nature. Based on the inhibitory activity against other gram-positive bacteria (e.g., *Staphylococcus*, *Micrococcus*, *Streptococcus*) and their simple growth requirements, the isolates obtained in this study could be tested as inoculants for legume silages. Financial support by CNPq and FAPEMIG.

Key Words: antimicrobial activity, *Listeria monocytogenes*, lactic acid bacteria

W114 Chemical composition and fermentation profile of *Brachiaria brizantha* and Campo Grande *Stylosanthes* mixed silages.

J. P. Rigueira, O. Pereira,* K. Ribeiro, A. Cezário, and W. Souza, *Federal University of Vicosa, Viçosa, Minas Gerais, Brazil.*

The aim of this study was to evaluate the chemical composition, fermentation profile and dry matter recovery in *Brachiaria* grass silage with increasing levels of Campo Grande *Stylosanthes* (0, 10, 20 and 30%), with and without bacterial inoculant. The *Brachiaria* was harvested at 70 d of regrowth and the *Stylosanthes* at the pre-flowering stage. The inoculant used was Sil All C4 (Alltech Brazil). The material was ensiled in laboratory silos of 20 kg capacity, equipped with Bunsen valves. A 4 × 2 factorial arrangement of treatments (4 levels of *Stylosanthes* × with and without inoculant) was used, in a completely randomized design, with 4 replications. There was interaction effect ($P < 0.05$) of *Stylosanthes* levels and inoculants on dry matter (DM) content, effluent losses, dry matter recovery and mold and yeast populations. The DM content of silage with and without inoculant increased linearly with increasing levels of *Stylosanthes* in the silages. The crude protein (CP) content increased linearly while the neutral detergent fiber (NDF) content decreased linearly with increasing levels of *Stylosanthes* in the silages. The pH and NH_3-N content were affected only by *Stylosanthes* levels. There were effects ($P < 0.05$) of inoculant and levels of *Stylosanthes* on LAB populations. The DM recovery increased linearly with increasing levels of *Stylosanthes* in the silage without inoculant. However, in inoculated silage the maximum recovery of DM was found in silages containing 17% of *Stylosanthes* . We concluded that the Campo Grande *Stylosanthes* improves the nutritive value and reduces the losses of DM in mixed silages of *Brachiaria* and *Stylosanthes* . Financial support by CNPq and Fapemig

Key Words: ADF, NDF, pH

W115 Feedtech CustomChop F-20 enhances the fermentation characteristics of elephant grass (*Pennisetum purpureum*) after 45 d of ensiling.

A. A. Rodríguez*[1], L. C. Solórzano[2], and T. Hemling[3], *[1]University of Puerto Rico, Mayagüez, PR, [2]Chr. Hansen, Milwaukee, WI, [3]DeLaval Manufacturing, Kansas City, MO.*

This study determined the ensiling characteristics and aerobic stability of *Pennisetum purpureum* (PP) fermented with or without a microbial additive containing the lactic acid-producing bacterial strains (LAPBI) *Lactobacillus plantarum* MiLAB 393; *Pediococcus acidilactici*, *Lactococcus lactic*, and *Enterococcus faecium*. Forage (23.43% DM) was chopped at 2.5 cm and assigned to 1 of the 2 treatments (TRT). Additive was added to weighed portions of PP and packed into PVC micro-silos (1.8 kg) to ferment for 45 d at 25 to 27°C. The LAPBI were applied to the forage at a rate of 2×10^5 cfu/g of fresh material. Five silos from each TRT were analyzed for pH, populations of lactic acid-producing bacteria (LAPB), fermentation products, and DM losses. Statistical analysis was a completely randomized design with a 2 additives by 2 d of ensiling (0 and 45) factorial arrangement of TRT. Tukey-test was used for mean separation. Temperature was monitored for aerobic stability determination at 29 6 h intervals (168 h total) in 5 samples from each TRT (1000 g). Statistics were performed as a split plot design with a 2 additives by 29 times as repeated measures factorial arrangement using silos replicates. Treated silage had lower ($P < 0.05$) pH and higher LAPB population than control (3.74 vs. 4.16 and 6.78 vs. 6.01 cfu/g, respectively). Lactic acid % and lactic acid:acetic acid ratio were higher ($P < 0.05$) in PP fermented with LAPBI than control (3.47 vs. 2.24 and 6.61 vs. 1.56, respectively). Acetic, butyric, and propionic acid % were lower ($P < 0.005$) in treated PP than control (0.71 vs. 1.47, 0.00 vs. 0.09, and 0.00 vs. 0.47, respectively). Forage treated with LAPBI also had a numerically lower NH_3-N/total-N ratio and DM losses associated with the fermentation process than untreated silage. In summary, addition of the LAPBI improved the fermentation characteristics of PP. Forage fermented with or without the microbial additive resulted in silage stable to aerobic conditions.

Key Words: *Pennisetum purpureum*, microbial inoculant, fermentation

W116 Intake and total apparent digestibility of nutrients of corn and *Stylosanthes* silages in diets for sheep.

L. Silva, O. Pereira,* K. Ribeiro, S. Valadares Filho, and T. Silva, *Federal University of Vicosa, Viçosa, Minas Gerais, Brazil.*

The Campo Grande *Stylosanthes*, native from Brazil, is one of the most important legumes of tropical and subtropical regions due to adaptation to low soil fertility. The objective of this study was to evaluate the nutrient intake and total apparent digestibility of corn and stylosanthes silages in diets for sheep. The experimental diets consisted of: 1- corn silage and concentrate (CS+C), 2- *Stylosanthes* silage and concentrate (StS+C) and 3- *Stylosanthes* silage exclusive (StS). The concentrate represented 50% of total DM of diets 1 and 2. Diets were formulated to be isonitrogenous, 12.0% CP on DM basis, similar to the content found in StS, 11.7% CP. The concentrate consisted of corn, soybean meal and a mixture of urea and ammonium sulfate 9:1 to adjust the CP content of diets due to differences in the CP content of silages. Twelve crossbred Santa Ines sheep, weighing on average 32.2 kg BW, were allotted in 4 3x3 Latin squares. The animals were kept in individual pens with protected feeders and wateriers. Each experimental period lasted 16 d, being 10 d for adaptation and 6 for collection of data and sample. It was performed 4 d of total collection of feces through tailored bags to the animals. The data were subjected to statistical analysis using the SAS. Intake of DM, CP and NDF was lower ($P < 0.05$) for animals fed StS compared with that observed for StS+C and CS+C which were similar (Table 1). Intake of EE was lower ($P < 0.05$) for animals fed CS+C compared with other treatments. Diets containing CS or StS, supplemented with concentrate can be considered nutritionally equivalent. Financial support by CNPq and Fapemig.

Table 1. Average daily intake and total apparent digestibility coefficients of dry matter (DM), crude protein (CP), neutral detergent fiber (NDF) and ether extract (EE) in the diets

	Intake (g/d)			Digestibility(%)		
Item	CS+C	StS+C	StS	CS+C	StS+C	StS
DM	1,047.3^{a}	958.9^{a}	557.9^{b}	74.1^{a}	64.3^{b}	40.1^{c}
CP	112.6^{a}	110.3^{a}	62.1^{b}	67.9^{a}	60,8^{b}	51.3^{c}
NDF	398.3^{a}	434.5^{a}	339.7^{b}	61.53^{a}	53.0^{b}	42.6^{c}
EE	11.9^{b}	13.5^{ab}	16.3^{a}	71.85^{a}	63.7^{b}	74.5^{a}

$^{a–c}$Means followed by the same letter in the row for intake and digestibility did not differ ($P > 0.05$) by Tukey's test.

W117 Condensed tannins concentrations of prairie legume forages at different phenological stages.

Y. Li[1,2], A. D. Iwaasa*[1], Y. Wang[3], L. Jin[3], and G. Han[2], *[1]Semiarid Prairie Agricultural Research Centre, Agriculture and Agri-Food Canada, Swift Current, Saskatchewan, Canada, [2]Colleges of Ecology and Environment Science, Inner Mongolia Agricultural University, Huhhot, China, [3]Lethbridge Research Center, Agriculture and Agri-Food Canada, Lethbridge, Alberta, Canada.*

Although studies have shown that condensed tannins (CT) at appropriate concentration improves protein utilization and prevents bloat in ruminant animals, information on CT content in different phenological stages and different portions of forages growing in North America prairie is still lacking. Objective of this study was to determine the CT concentration in legume forages at different phenological stages and plant portions. Whole plant samples of purple prairie clover (*Dalea purpurea* Vent., PPC), white prairie clover (*Dalea candida* Michx. ex Willd, WPC), sainfoin (*Onobrychis viciifoliav* Scop.) and Canadian milkvetch (*Astragalus Canadensis* L., CMV) were collected in 2011 from replicated small plots (n = 4) at different phenological stages: flowering and seed maturity stage. The samples were manually separated into leaf, stem and floral/seed pod plant portions depending on the phenological stage. Samples were freeze-dried, ground (1 mm) and analyzed CT by a modified Butanol-HCL procedure. Measurement of CT for every plant portion by phenological stage was done by legume forage and Proc Mixed proceduce of SAS was used to analyze data. Differences ($P < 0.05$) were observed between each plant portions for each phenological stage for PPC and WPC. Condense tannins were highest for floral/seed pod > leaf > stem. The highest average CT contents for PPC and WPC at flowering and floral/seed pod were 161.63 ± 5.58 g kg^{-1} DM and 149.53 ± 4.03 g kg^{-1} DM, respectively. For sainfoin the CT contents were different ($P < 0.05$) between plant portions and phenological stages with the leaf having the highest contents (78.41 ± 1.70 g kg^{-1} DM) and the stem having the lowest content (10.17 ± 0.48 g kg^{-1} DM). With the exception of the seed pod, no CT contents were detected for CMV in the leaf, stem or flower portions at any phenological stage. Results demonstrate that CT levels can be quite variable among legumes and were dependent upon phenological stage and plant portion. Time of grazing of these CT legumes is important to optimize ruminant performance and productivity.

Key Words: condensed tannins, legume forage, leaf, stem, floral/seed pod

W118 Mixing purple prairie clover with alfalfa reduced alfalfa N transforming to ammonia-N.

L. Jin[1,2], Z. Xu[1], A. D. Iwaasa[3], Y. G. Zhang[2], M. P. Schellenberg[3], T. A. McAllister[1], and Y. Wang*[1], [1]*AAFC, Lethbridge, AB, Canada,* [2]*Northeast Agricultural University, China,* [3]*SPARC-AAFC, Swift Current, SK, Canada.*

Although mixing condensed tannin (CT)-containing forage with alfalfa (Alf) reduces protein degradation it is not known if this is due to the binding of CT to Alf protein. The objective of this study was to assess the effects of purple prairie clover (PPC) CT on N transformation of Alf during ruminal fermentation. Alfalfa was grown in a greenhouse in a nutrient solution containing ^{15}N labeled ammonium sulfate and harvested at the vegetative growth stage. Native PPC was harvested at the full-flower and early seeding stage. Both forages were freeze-dried, ground (1 mm) and then mixed in ratios (DM basis) of 0:100, 25:75, 50:50, 75:25 and 100:0. The forage mixtures were incubated in mixed rumen batch cultures in serum vials supplemented with or without polyethylene glycol (PEG) for 6, 12, 24 and 48 h. Gas and methane production, VFA, NH_3-N and NH_3-^{15}N were determined. Effect of CT was assessed by comparing differences in fermentation parameters between incubations with and without PEG. Data were analyzed statistically by ANOVA as a 5 × 2 factorial design using the MIXED procedureof SAS. A forage × PEG interaction was observed ($P < 0.05$) for gas production (ml/g DM), NH_3-N (mg/g DM) and NH_3-^{15}N (µg/g Alf ^{15}N) accumulation. Inclusion of PEG did not affect CH_4 or VFA production in any of the forage mixtures. However, gas production and accumulation of NH_3-N and NH_3-^{15}N were linearly ($P < 0.05$) increased (6, 12, 24 and 48 h) by PEG as the proportion of PPC increased in the forage mixture. The proportion Alf ^{15}N transformed to NH_3-^{15}N was reduced ($P < 0.001$) by PPC CT for 50:50 and 25:75 Alf-PPC mixtures at 12, 24, 48 but not 6 h of incubation. This indicates that PPC CT reduced transformation of Alf N to NH_3-N and that mixing PPC with Alf has the potential to improve the utilization of Alf protein by ruminants.

Key Words: condensed tannins, alfalfa, N transformation

W119 Effect of sainfoin condensed tannins on the N transformation of alfalfa forage preserved as silage.

Y. Wang,* Z. Xu, S. Acharya, and T. A. McAllister, *AAFC, Lethbridge, AB, Canada.*

Our previous study demonstrated that ensiling fermentation was improved and protein degradation was reduced by mixing alfalfa and sainfoin during the ensiling process, presumably due to the presence of condensed tannins (CT) in sainfoin. The objective of this study was to assess the effects of sainfoin CT on the N transformation of alfalfa during ensiling. Freshly harvested vegetative alfalfa grown in greenhouse with nutrient solution containing ^{15}N labeled ammonium sulfate, and pre-buds-stage sainfoin from field plots were chopped and mixed manually to the ratio of (alfalfa:sainfoin; DM basis) 100:0, 75:25, 50:50 and 25:75. Each mixture was made in 6 portions and half of them were sprayed with polyethylene glycol (PEG) to deactivate CT. The PEG and non-PEG treated forages were then ensiled in laboratory silos. At d 7, 14 and 74 of the ensiling, triplicate silos were opened and the content was processed for laboratory evaluation. After 74-d ensiling, increasing proportion of sainfoin in the mixtures increased concentrations of lactic acid (L; $P < 0.001$) and total VFA (Q, $P < 0.001$), resulting in decreased silage pH (L; $P < 0.001$). Inclusion of PEG did not affect silage pH or concentration of VFA, but increased ($P < 0.01$) concentration of lactic acid. Interactive effects of forage × PEG were observed ($P < 0.05$) in concentrations of NPN (mg/g total N), ^{15}NPN (µg/g alfalfa N), NH_3-N (mg/g total N) and NH_3-^{15}N (µg/g alfalfa N). The concentrations of NPN and NH_3-N were linearly increased ($P < 0.05$) by PEG as the proportion of sainfoin increased. The inclusion of PEG also linearly increased ($P < 0.05$) concentrations of ^{15}NPN and NH_3-^{15}N as the proportion of sainfoin increased. The results demonstrated that co-ensiling sainfoin and alfalfa improved ensiling fermentation in laboratory silos and alfalfa protein degradation was decreased by sainfoin CT. Co-ensiling sainfoin and alfalfa has the potential to reduce alfalfa protein degradation and improve the silage quality.

Key Words: condensed tannins, alfalfa, silage

W120 Effect of application rate of a fibrolytic enzyme product on in vitro ruminal fermentation of three low-quality substrates.

A. Díaz[1], I. Mateos[1], C. Saro[1], E. N. Odongo[3], M. D. Carro[1,2], and M. J. Ranilla*[1,2], [1]*Dpto. Producción Animal, Universidad de León, Campus de Vegazana, León, Spain,* [2]*Instituto de Ganadería de Montaña (CSIC-ULE), Grulleros, León,Spain,* [3]*International Atomic Energy Agency, Vienna, Austria.*

The effects of a fibrolytic enzyme product (Dyadic Xylanase PLUS, Dyadic Inc. USA) on the in vitro ruminal fermentation of 3 low-quality forages (rice straw, corn stover and grass hay) were investigated using batch cultures of mixed ruminal microorganisms. Five different treatments were tested: 0X (control), 0.5X, 1X, 4X and 10X (where 1X was the manufacturer recommended dose, 20 mg/g DM). Enzymes were applied directly onto the forages 24 h before incubation with buffered ruminal fluid at 39°C for 9 h. Four incubation runs were performed on different days. Gas production was measured at 3, 6, 9 h, and the main fermentation parameters were determined at the end of the incubation. Five concentrations of enzyme, 3 substrates, and the interaction of enzyme x substrate were included in the model as fixed effects, whereas incubation day was considered as a random effect. There were enzyme x substrate interactions for all the parameters measured, indicating different effects on each feed. All doses of enzyme product increased ($P < 0.05$) gas production after 3, 6 and 9 h of incubation for corn stover and grass hay, whereas only 10X increased ($P < 0.05$) gas production at 3 and 6 h for rice straw, compared with the control. All doses stimulated ($P < 0.05$) gas production after 9 h of incubation for the 3 substrates. Dry matter disappearance increased ($P < 0.05$) with doses 4X and 10X for the 3 substrates. Doses 0.5X, 1X and 4X decreased ($P < 0.05$) NH3 concentrations for the 3 substrates, but 10X had no effect ($P > 0.05$). Enzyme treatment increased ($P < 0.05$) total VFA production to 116, 120, 131 and 177% of control values for 0.5X, 1X, 4X and 10X, respectively, for grass hay, to 147, 173, 190 and 268% of control values for corn stover, and 125, 149, 160 and 282% of control values for rice straw. Acetate:propionate ratio decreased ($P < 0.05$) in grass hay and maize stover treated with any dose of the enzyme product, but in the case of rice straw, 0.5X, 1X and 4X doses increased ($P < 0.05$) this ratio and 10X decreased ($P < 0.05$) it, compared with the control. The results indicate that the pre-treatment of these low-quality forages with a wide range of doses of the fibrolytic enzyme has a positive effect on ruminal fermentation and the enzyme product is a good candidate to improve their digestibility.

Key Words: xylanase, low-quality forages, In vitro ruminal fermentation

Growth and Development III

W121 Effect of hay or corn silage in pre-weaned calf diets on eating behavior and rumen development. F. X. Suarez-Mena* and A. J. Heinrichs, *The Pennsylvania State University, University Park.*

The objective of this experiment was to study effects of including corn silage or grass hay in pre-weaned calf diets on rumen development and eating behavior. Male Holstein calves (n = 15, 43.60 ± 3.91 kg BW at birth) were housed in individual pens on rubber mats with no bedding. Water and calf starter (56% whole corn grain, 40% pelleted supplement, and 4% molasses; as is) were offered free choice, and milk replacer was fed to 12% of birth BW. Calves were randomly assigned to treatments, either calf starter as the only solid feed (S), starter plus chopped hay (H), or starter plus corn silage (CS), H and CS were also offered free choice. Solid feed was offered from d 2 of age. At 35 ± 1 d of age calves were euthanized and organs where harvested, emptied, rinsed and weighed to determine treatment effects on rumen development. Total 35 d DMI (milk replacer + starter + forage; 34.23 S, 33.10 H, and 34.08 CS ± 2.62 kg) and total starter intake (33 d; 11.65 S, 9.58 H, and 10.46 CS ± 2.18 kg) were not different ($P > 0.05$). Calves on H and CS treatments preferred starter over forage as total forage intake (33 d) was lower (kg; 0.86 ± 1.03 H, and 0.19 ± 0.13 CS, mean ± SD). In the last week, starter intake (5.14 S, 5.08 H, and 5.27 CS ± 1.10 kg), and starter plus forage intake (5.14 S, 5.46 H, and 5.35 CS ± 1.17 kg) were not different. Mass of reticulorumen (1.22 ± 0.07), omasum (0.23 ± 0.02), abomasum (0.56 ± 0.02), and liver (2.31 ± 0.11) as a percentage of BW were not different ($P > 0.05$). Papillae length (1.22 S, 1.28 H, and 1.18 CS ± 0.10 mm) and width (0.69 S, 0.75 H, and 0.73 CS ± 0.04 mm), rumen wall thickness (0.89 S, 0.99 H, and 0.80 CS ± 0.06 mm) and rumen contents pH (4.97 S, 5.31 H, 5.15 CS ± 0.11) were also not different ($P > 0.05$). High standard errors may be in part due to poor calf health as many calves from all treatments were treated for diarrhea and/or pneumonia, which had a negative effect on intake. This study shows that when palatable calf starter is available free choice, forage intake is minimal. Forage was not a palatable feed source for calves in this study.

Key Words: calf, rumen development, forage intake

W122 Exogenous palimitic and palmitoleic acids respond differently in stearoyl-CoA desaturase (SCD1) inhibited bovine adipocytes. A. K. G. Kadegowda,* T. A. Burns, and S. K. Duckett, *Clemson University, Clemson, SC.*

Objectives were to determine the effect of exogenous palmitoleic acid (C16:1) or palmitic acid (C16:0) with or without SCD-1 inhibitors on adipogenesis in primary bovine adipocytes. Bovine primary preadipocyte cultures were isolated from intermuscular fat of Angus crossbred heifers (n = 2). Preadipocytes were differentiated (D0) in differentiation media [DMEM containing 10% fetal calf serum, 2.5 μg/mL insulin, 0.25 μ*M* DEX, 5 μ*M* troglitazone, 0.5 m*M* IBMX, and 10 m*M* acetate] for 2 d and from D2 to D12 without DEX and IBMX. From D0 to D6, cells were treated with SCD-1 inhibitors, sterculic acid (SA) or trans-10, cis-12 conjugated linoleic acid (CLA), at 0 or 50 μ*M* . In addition, from D2 to D6, cells were treated with (0 or 150 μ*M*) of C16:0 or C16:1 and harvested for fatty acid analysis by GLC and gene expression by RT-qPCR. The effect of the treatments on cell viability in differentiated cells was assayed using Cell Counting Kit-8. Glycerol-3-phosphate dehydrogenase (GPDH) activity was assayed to determine the effect on adipocyte differentiation. The treatment effects were analyzed by ANOVA using Proc Mixed of SAS 9.2. The C16:0 decreased ($P < 0.05$) total cellular fatty acid (FA) yield (minus supplemented FA) due to reduced cellular viability of differentiated adipocytes. In contrast, a similar decrease in total cellular FA content was seen in C16:1/CLA treatment without affecting cellular viability. Palmitic acid supplementation reduced ($P < 0.01$) GPDH activity compared with controls (3.09 ± 0.2 vs. 9.51 ± 0.2 nmol/mg protein.min), which was further exacerbated in SCD1 inhibited adipocytes (0.49 ± 0.2 and 0.9 ± 0.2 in SA and CLA treatments, respectively). In contrast, C16:1 increased GPDH activity (14.81 ± 0.2) which was reduced with CLA (4.17 ± 0.2). Compared with SA treated cells, C16:0 and C16:1 decreased the expression of fatty acid synthase, fatty acid elongase 6 and diacylglycerol acyltransferase. Furthermore, C16:0 increased *SCD1*; whereas C16:1 increased adipose triglyceride lipase. In summary, the results showed that the responses of lipogenic enzymes in bovine adipocytes differ when supplemented with C16:0 and C16:1, and with or without SCD1 inhibitors.

Key Words: adipocytes, gene expression, fatty acids

W123 Steroyl-CoA desaturase 1 (SCD1) inhibition decreases de novo fatty acid synthesis in primary bovine adipocytes. A. K. G. Kadegowda,* T. A. Burns, N. Tharayil, S. L. Pratt, and S. K. Duckett, *Clemson University, Clemson, SC.*

We have previously shown that sterculic acid [8-(2-octyl-1-cyclopropenyl) octanoic acid] (SA) and *trans*-10, *cis*-12 conjugated linoleic acid (CLA) inhibit SCD1 activity at 50 μ*M* concentration in primary bovine adipocytes. The objectives were to determine the effect of SCD1 inhibition on de novo fatty acid synthesis and expression of lipogenic and lipolytic genes. Bovine primary preadipocyte cultures were isolated from intermuscular fat of carcasses from 18-mo-old Angus crossbred heifers (n = 2). Preadipocytes were differentiated (D0) in differentiation media [DMEM containing 10% fetal calf serum, 2.5 μg/mL insulin, 0.25 μ*M* M dexamethasone (DEX), 5 μ*M* M troglitazone, 0.5 m*M* isobutylmethylxanthine (IBMX), and 10 *mM* acetate] for 2 d. Cells were further differentiated from D2 to D6 in media without DEX and IBMX. From D0 to D6, cells were treated with 0 or 50 μ*M* of SA or t10c12 CLA and harvested for gene expression by RT-qPCR. In addition, cells were incubated with acetate ($^{13}C_2$) from D4 to D6 to estimate lipogenesis using GLC-MS. The geometric mean of Eukaryotic translation initiation factor 3, subunit k (EIF3K) and glyceraldehyde-3-phosphate dehydrogenase (GAPDH) was used for normalization of gene expression data. In acetate ($^{13}C_2$) supplemented cells, the mass isotopomer distribution analysis showed that the fractional synthesis rate [molar percent excess (MPE)/h]) of ^{13}C-16:0 was reduced in SA (0.49 ± 0.07, −51.2%, $P < 0.01$) and CLA (0.43 ± 0.07, −43.68%, $P < 0.01$) treatments compared with control (0.89 ± 0.07 MPE /h). Of the lipogenic genes, CLA treatment decreased the expression of *SCD1* ($P < 0.01$), acetyl-CoA carboxylase (*ACC*; $P < 0.05$), fatty acid synthase (*FASN*), whereas SA supplementation decreased the expression of *ACC* ($P < 0.05$). Both SA and CLA increased the expression of hormone-sensitive lipase ($P < 0.05$) known to be involved in lipolysis. The results showed that SCD1 inhibition by SA and CLA in the bovine adipocytes decreases de novo fatty acid synthesis by downregulating genes involved in lipogenesis and upregulating gene involved in lipolysis.

Key Words: SCD1, adipocyte, GLC-MS

W124 Metabolic differences in hepatocytes from Iberian and Landrace pigs.

L. Gonzalez-Valero, J. M. Rodriguez-Lopez, M. Lachica, and I. Fernandez-Figares,* *CSIC (Spanish National Research Council), Granada, Spain.*

There are important differences when Iberian are compared with modern pigs in terms of metabolic activity, energy utilization and capacity of protein and fat deposition. In an attempt to partially explain differences we have used the primary culture of hepatocytes to evaluate the hepatic function and sensitivity to hormones without the interference of circulating blood factors. Hepatocytes were isolated from pure Iberian and Landrace pigs of similar body weight (n = 5; 25 kg BW), by collagenase perfusion and seeded into collagen-coated T-25 flasks. Monolayers were established in medium containing fetal bovine serum for 1 d and switched to a serum-free medium for the remainder of the culture period. Hepatocytes were maintained in William's E amended with β-mercaptoethanol (0.1 mM), glutamine (2 mM), antibiotics (gentamicin, penicillin, streptomycin and amphotericin B), DMSO (1ng/ml), dexamethasone (10–8 M), insulin (1 and 100 ng/ml) and glucagon (1 and 100 ng/ml) for 24–48h. IGF-1 synthesis, urea synthesis, gluconeogenesis, insulin and glucagon impact on glycogen content were determined. Gluconeogenesis was measured in glucose free Dulbecco's modified Eagle's medium with glucagon (100 ng/ml) and lactate (5 mM), pyruvate (5 mM) and alanine (5 mM). For urea synthesis, cells were cultured in basal medium amended with ammonium sulfate (2.5 and 5mM). All results were expressed relative to the protein content of the culture. As the metabolic activity may vary among pigs, data were analyzed using the PROC MIXED procedure of SAS. Although insulin and glucagon regulated glycogen content, the difference between breeds was not significant ($P > 0.10$). Nevertheless, gluconeogenesis, urea synthesis and IGF-1 synthesis were 69, 38 and 22% lower ($P < 0.05$), respectively, in hepatocytes from Iberian compared with Landrace. In conclusion, the genetic background should be considered when hepatocyte culture is used for metabolic studies.

Key Words: hepatocytes, metabolism, breed

W125 Effect of betaine and conjugated linoleic acid on porcine subcutaneous adipose tissue lipolysis.

M. L. Rojas-Cano[1], M. Martinez-Perez[2], M. Lachica[1], L. Lara[1], T. Ramsay[3], and I. Fernandez-Figares*[1], [1]*CSIC (Spanish National Research Council), Granada, Spain,* [2]*Instituto de Ciencia Animal, La Habana, Cuba,* [3]*BARC, ANRI. USDA, Beltsville, MD.*

Betaine (Bet) and CLA have the potential to alter body composition in swine by decreasing body fat.The aim of the present study was determine if Bet and CLA have an effect on lipolysis in the adipose tissue of Iberian pigs. Five Iberian pigs were used (38kg BW). Adipose tissue samples were acquired following slaughter by electrical stunning and exsanguination. The adipose tissue was diced into strips and placed in Hanks' buffer (37°C, pH 7.4). In the laboratory, the strips were dissected clean of any extraneous muscle tissue and further separated into 1-cm cubes in a laminar flow hood. Adipose tissue explants (approximately 100mg) were prepared by slicing tissue cubes with a microtome. Tissue slices were blotted free of excess liquid, weighed, transferred to 6-well tissue culture with 2 mL of basal medium per well (DMEM/F12 (50:50), 25% bovine serum albumin, 25 mM HEPES, gentamycin, amphotericin B and penicillin-streptomycin) and incubated (5% CO2, 37°C) for one hour to wash away endogenous glycerol and fatty acids. Triplicate tissue slices were then incubated in test medium (Basal medium amended with 10mM Linoleic acid (control), 10mM 10-t, 12-c CLA, 10mM Linoleic acid + 200mM Bet and 10mM 10-trans, 12-cis CLA + 200mM Bet). To estimate the direct effects of CLA and Bet on lipolysis, incubations were performed for 2 and 72 h. To examine the ability of Bet or CLA to inhibit insulin's suppression of isoproterenol-stimulated lipolysis after acute and chronic exposure, the test medium was amended with 1 µM isoproterenol ± 10 nM insulin. Media glycerol concentration was measured at the end of the incubations. Data were analyzed by multifactorial ANOVA and mean separated by Fisher's LSD test. No effect of Bet or CLA on acute lipolysis was observed ($P > 0.10$). Nevertheless, adipose tissue supplemented with 10-t, 12-c CLA decreased (22%; $P < 0.05$) chronic lipolysis challenges compared with control. As expected, chronic exposure of adipose tissue to isoproterenol increased lipolysis (83%; $P < 0.05$), and insulin inhibited isoproterenol stimulated lipolysis (50%; $P < 0.05$). In conclusion, CLA decreased lipolysis in adipose tissue isolated from Iberian pigs while Bet had no effect in acute or chronic lipolysis.

Key Words: lipolysis, conjugated linoleic acid, betaine

W126 *T-box (Tbx)-2* is required for proliferation of osteoblast cells.

N. Francis[1], S. M. Tornaquindici[1], S. Mohan[2], and K. E. Govoni*[1], [1]*Department of Animal Science, University of Connecticut, Storrs,* [2]*Musculoskeletal Disease Center, Jerry L. Pettis VA Medical Center, Loma Linda, CA.*

Bone related diseases and injuries affect many livestock species and have an enormous impact on efficiency of production and quality of life. Transcription factors are key regulators of osteoblast function; however our understanding of this complex process is limited. We recently demonstrated that *Tbx3*, a transcription factor implicated in ulnar mammary syndrome, is required for osteoblast proliferation. However, the mechanisms by which a closely related member, *Tbx2*, regulates skeletal development is unknown. We hypothesized that *Tbx2*, like *Tbx3*, is required for proliferation of osteoblasts. We used SaoS-2 cells, osteoblast-like human osteosarcoma cell line, and mouse preosteoblast cells (MC3T3-E1). To evaluate the role of *Tbx2*, we knocked down *Tbx2* expression by transfecting SaoS-2 and MC3T3-E1 cells with species-specific, *Tbx2*-specific small interfering (si) RNA (66 nM) and determined cell proliferation by alamarBlue assay and bromodeoxyuridine (BrdU) incorporation. Surprisingly, although we were able to detect a signficiant knockdown of mRNA expression of *Tbx2* in MC3T3-E1 cells, we were unable to detect *Tbx2* protein in MC3T3-E1. However, we were able to detect *Tbx2* protein in the SaoS-2 cells, therefore the SaoS-2 cell model was used for further experiments. In SaoS-2 cells, *Tbx2* siRNA reduced *Tbx2* mRNA expression 90 ± 4% ($P \leq 0.01$) and protein by 62 ± 4% ($P < 0.01$). Cell number was reduced 29 ± 2% and BrdU incorproration was reduced 40 ± 2% in *Tbx2* siRNA transfected cells compared with control cells ($P < 0.001$). To determine if *Tbx2* is required for differentiation, we cultured control and siRNA transfected cells in media containing β-glycerophosphate and ascorbic acid and determined alkaline phosphatase (ALP) activity, a known marker of osteoblast differentiation. Knockdown of *Tbx2* did not alter ALP activity ($P \geq 0.50$). In conclusion, 1) similar to *Tbx3*, *Tbx2* is required for optimal proliferation of osteoblast cells, 2) *Tbx2* may not be required for differentiation of osteoblasts, and 3) *Tbx2* and *Tbx3* may have both redundant and distinct functions in regulating bone development.

Key Words: bone, *T-box*, osteoblast

W127 Comparison of feed form (pelleted vs. textured) on growing performance and rumen papillae development of dairy steers.

J. A. Davidson*[1], T. E. Johnson[1], B. L. Miller[1], K. B. Cunningham[1], H. C. Puch[1], K. M. O'Diam[2], and K. M. Daniels[2], *[1]Land O' Lakes Research Farm, Land O' Lakes Purina Feed, Webster City, IA, [2]Ohio Agricultural Research and Development Center, The Ohio State University, Wooster.*

The objective was to determine if feed form affects the growth performance of dairy steers from 13 to 24 wk of age and alters rumen papillae surface area. At 13 wk of age, 32 Holstein steers were blocked by weight and assigned to groups of 4 per pen (4 replicates per treatment). Pens were assigned to one of 2 grain mixes: pelleted (PL) or textured (TT, coarse mix of pellets and grains). Steers were limit fed 4.55 kg/d of the grain mixes (20% crude protein and 3.0 Mcal/kg, dry basis) with mixed grass hay offered, ad libitum. Body weight (BW, kg), hip height (HH, cm), heart girth (HG, cm), body length (BL, cm) measurements, and calculated body volume (BV, cm^3) were completed every 2 wk. No differences were detected for any of the growth measurements or total dry matter intake. Initial measures were 101 kg BW; 95 cm HH; 104 cm HG; 100 cm BL; and 318 cm^3 BV. Final measures were 212 kg BW; 116 cm HH; 133 cm HG; 135 BL; and 665 cm^3 BV. Average daily gain and feed to gain ratio were not different (1.3 kg/d and 3.9, respectively). At 24 wk of age, 2 steers were randomly selected from each treatment and euthanized to evaluate rumen papillae surface area. Rumen papillae of PL and TT had similar surface area for portions of the rumen identified as cranial ventral (57 and 38 mm^2, SE 8.7); cranial dorsal (13 and 11 mm^2, SE 3.8); and caudal dorsal (32 and 19 mm^2, SE 6.4). The caudal ventral region tended to be greater for PL steers (29 mm^2) compared with 15 mm^2 for TT fed steers (SE 3.3, $P = 0.10$). Empty rumen weight and content DM were 5.4 and 3.4 kg for PL; 5.0 and 2.6 kg for TT, respectively. Ruminal pH tended to be different: 6.3 vs. 6.9 for PL and TT, ($P = 0.15$). Histological analysis did not indicate differences by form of feed for mucosal surface length, sub-mucosa thickness, and muscle thickness measurements of the rumen determined via a digital image analysis program (CellSens Imaging Software; Olympus Corp.). Feed delivery form (pellets or textured) did not differentially influence calf growth performance, nor were there negative effects on rumen size, ruminal papillae surface area, or histology.

Key Words: rumen, papillae, pellets

W128 Effect of parenteral administration of glutamine on autophagy of liver cell and immune responses in weaned calves.

Z. Hu,* Z. Cao, and S. Li, *State Key Laboratory of Animal Nutrition, College of Animal Science and Technology, China Agricultural University, Beijing, China.*

The objectives of this study were to determine the effects of an increased jugular supply of L-Gln on postweaning growth, immune responses and autophagy of weaned calves. At 35d of age, 24 Holstein calves (initially 50 ± 2.3kg; 35 ± 2 d of age) were randomly allocated to 4 treatments, and each treatment included 5 male and 1 female calves. Holstein calves were assigned to treatments of 1) no L-Gln and milk supplementation, but infusion of 2 L of 0.85% NaCl solution, Control group [C] 2) no milk supplementation, but infusion high dose L-Gln (0.64g/kg BW/day) mixed with 2 L of 0.85% NaCl solution [H], 3) no milk supplementation, but infusion moderate dose L-Gln (0.32g/kg BW/day) mixed with with 2 L of 0.85% NaCl solution [M], 4) no milk supplementation, but infusion low dose L-Gln (0.16g/kg BW/day) mixed with 2 L of 0.85% NaCl solution [L]; each treatment was delivered 2 h/d for each of 7 consecutive days starting on d1 after weaning. The dose of L-Gln for calves were calculated from published data on i.v. infusion rates for sheep (Hoskin et al., 2001) and adjusted on the basis of metabolic BW. Feed and water were freely available to all calves. All calves were euthanized at the end of infusion 7 d for measurements of autophagy of liver cell and intestinal morphology. The ADG and growth rate increased quadratically ($P < 0.05$) with increasing infusions of Gln. Infusion N increased linearly in response to the graded amount of Gln infused ($P < 0.05$). At the end of infusion 7 d, a blood sample was collected into a 10 mL EDTA vacuum tube to analyze immunological assays. Infusion Gln increased the abundance of CD4 and the ratio of CD4/CD8 linearly, but decreased CD8 linearly ($P < 0.05$). Characterization of blood lymphocyte populations was performed by flow cytometry analysis. The urea N, Gln in plasma increased linearly with increasing Gln loads ($P < 0.001$). After harvest, Villi and their crypts were identified and measured in duodenum, jejunum, and ileum of each calf using standard histomorphometric methods. Infusion Gln also increased villus height and crypt depth of intestine quadratically ($P < 0.05$). In summary, the Gln supplied by milk replacer may be inadequate to meet calf metabolic demands under weaning physiological conditions.

Key Words: calf, L-Gln, autophagy

W129 Influence of hay type on ruminal papillae surface area of growing dairy steers from 13 to 22 wk of age.

J. A. Davidson,* T. E. Johnson, H. C. Puch, and B. L. Miller, *LongView Animal Nutrition Center, Land O' Lakes Purina Feed, Gray Summit, MO.*

The objective was to determine if hay type affects ruminal papillae surface area and growth of dairy calves from 13 to 22 wk of age. At 13 wk of age, 72 Holstein steers were blocked by weight into groups of 6 per pen (6 replicates per treatment). Steers were fed 2 different hays ad libitum: grass (GR) or alfalfa (AF) along with a complete grower feed at 3.3 kg DM/d per head. GR was 9.9% CP, 35.0% ADF, and 57.1% NDF; and AF was 18.7% CP, 31.1% ADF, and 43.8% ADF, dry basis. Hay intakes of the pens were measured every 2 weeks. Measurements of full BW were completed every 2 wk, and hip heights (HH) were recorded at wk 13 and 22 of age. No significant differences were detected for any of the growth measurements. Initial BW and hip heights (HH) were 114 kg and 96 cm, and final weights were 195 kg with HH of 112 cm. The pooled feed:gain efficiency was 3.9 with an ADG of 1.2 kg BW/d. The total DMI (sum of forage and concentrate intake) was slightly greater for steers fed AF compared with GR during the final 2 weeks of the study (5.6 vs. 5.2 kg/d per head). The intake of hay was similar for each feeding rate of grower during wk 13 to 20, but 0.3 kg/d per head greater for AF during wk 20 to 22 of age. At 22 wk of age, 4 steers per treatment were euthanized to examine ruminal papillae surface area. The wet weight of the rumen contents was 26.7 vs. 19.7 kg for GR and AF, respectively ($P < 0.05$). Papillae surface area was measured at 4 regions: caudal dorsal, cranial dorsal, caudal ventral, and cranial ventral. Absorptive surface area was greater for steers fed AF compared with GR fed steers: caudal ventral (21.9 vs. 14.6 mm^2) and caudal dorsal (22.6 vs. 16.2 mm^2) regions ($P < 0.01$). No difference for the cranial dorsal region was detected, but a tendency for greater surface area of cranial ventral region ($P = 0.10$, 31.1 vs. 43.3, GR and AF, respectively). Overall, alfalfa hay resulted in greater papillae surface area of the rumen compared with grass hay.

Selection of the forage quality or type may have a significant impact on transitioning growing calves from all grain diets to higher forage diets.

Key Words: dairy calves, rumen papillae, growth

W130 Intake and performance of dairy heifers 12 to 24 wk of age following a full potential calf feeding program. J. A. Davidson,* D. C. Brown, and B. L. Miller, *LongView Animal Nutrition Center, Land O' Lakes Purina Feed, Gray Summit, MO.*

The objective was to determine optimal feeding recommendations for dairy heifers from 12 to 24 wk of age during transition from complete feeds to greater forage diets and maintain growth performance. At 12 wk of age, 46 heifers were blocked by birthdate into groups of 3 to 4 heifers per pen (6 replicates per treatment). Heifers were fed 2 different rates of complete grower feed (AMPLI-Calf Grower): 3.3 or 4.1 kg DM/d. Both groups received ad libitum chopped alfalfa hay (16% CP, 41% ADF, and 49% NDF, DM basis). Hay and grower feed intakes were measured daily. Measurements of full BW, hip heights (HH), heart girths (HG), and body lengths (BL) were completed every 2 wk, and BCS were recorded every 4 wk. No significant differences were detected for any of the growth measurements. Initial BW and HH were 104 kg and 98 cm. At 24 wk of age, heifers weighed 199 kg with HH of 113 cm, HG of 133 cm, and BL of 126 cm. Calculated body volume was 345 and 605 cm3 at 12 and 24 wk, respectively. The pooled feed:gain efficiency was 4.2 with an ADG of 1.1 kg BW/d. Final BCS was slightly greater for 4.1 kg DM/d grower feeding rate (3.30 vs 3.45, $P < 0.05$). Even though growth measurements were similar between feeding programs, intake was significantly influenced. The total DMI (sum of daily forage and concentrate intake) was greater for heifers fed grower at 4.1 kg DM/d (pooled across day of study: 5.2 vs 4.6 kg DM/d, $P < 0.01$). The intake of hay was similar for each feeding rate of grower during wk 12 to 14. However, the heifers at the reduced feeding rate of grower consumed more hay over time (treatment by day, $P < 0.01$). At 24 wk of age, heifers at the reduced feeding rate of grower were consuming 2.6 kg of DM/d as hay vs 1.5 kg DM of hay/d. Feeding 3.3 or 4.1 kg DM of AMPLI-Calf Grower per d did not significantly alter body growth performance of dairy heifers. However, the greater feeding rate delayed an increased consumption of the portion of total DMI as hay. The addition of the hay to the diet was great enough quality to maintain growth performance and transition the heifers to greater forage diets.

Key Words: dairy heifer, intake, growth

W131 Effects of milk feeding strategies on performance, ruminal development, and metabolic and hormonal profile of Holstein calves. B. F. Silper,* S. G. Coelho, A. M. Q. Lana, A. U. Carvalho, C. S. Ferreira, A. P. S. Franzoni, H. M. Saturnino, and R. B. Reis, *Universidade Federal de Minas Gerais, Belo Horizonte, Minas Gerais, Brasil.*

Brazilian dairy farms feed calves 4 L/d. Strategies between conventional and accelerated systems show an opportunity to improve development. The effects of milk replacer (MR) feeding strategies on weight gain, starter intake, ruminal development, metabolic/hormonal profile, organs and perirenal fat weights were evaluated (ethical committee - UFMG 44/2009). Male calves (n = 54) were individually bedded on tropical grass. Water and starter were provided at all times. MR (22.5% CP; 17.0% fat; 12.5% solids) was fed in 2 equal portions/d in 3 strategies: 4L-60d (4 L –500 g– MR/d during 60 d), 6L-29d/4L-60d (6 L –750 g– MR/d on the first 30 d and 4 L –500 g– MR/d from 30 to 60 d) and 6L-60d (6 L –750 g– MR/d during 60 d). Weaning was abrupt at 60 d age. Six calves/group were euthanized at 30, 60 and 90 d age. A completely randomized split-plot design was used for statistical analysis, with animals as random and time as repeated measures, means tested with SNK ($P = 0.05$). There were MR refusals in first month in all groups, but none in second month. Starter intake was not different among groups ($P > 0.05$) and increased with age ($P < 0.05$). Weight gain and feed efficiency were higher during first month in groups allowed more MR ($P < 0.05$). From 31 to 60 d age weight gain was equal ($P > 0.05$), after weaning it was higher in 6L-60d ($P < 0.05$). Weight gain increased each week, except on wk 5 in the group which had MR allowance reduced at d 30 ($P < 0.05$). Glucose, NEFA and IGF-1 were not influenced by MR feeding strategy ($P > 0.05$). Insulin was higher in 6L-60d ($P < 0.05$). Glucose and insulin increased and NEFA reduced with age ($P < 0.05$). Forestomach and perirenal fat weights, papillae length, and acetate, butyrate and N-NH$_3$ concentrations were not different ($P > 0.05$). Ruminal pH was higher and propionate concentration lower in 6L-60d ($P < 0.05$). Mitotic index of ruminal mucosa's basal stratum was higher in groups 6L-60d and 6L-29d/4L-60, as were abomasum, pancreas and liver weights ($P < 0.05$). Feeding calves 6 L MR/d during 60 d improved pre and postweaning performance without reducing starter intake or ruminal development. Research supported by FAPEMIG/APQ1839/09.

Key Words: starter intake, milk replacer, papillae

W132 Ontogenic changes of hepatic glucocorticoid and α_1- and β_2-adrenergic receptors in neonatal calves. D. Rohrbeck, J. Steinhoff-Wagner, E. Kanitz, and H. M. Hammon,* *Leibniz Institute for Farm Animal Biology (FBN), Dummerstorf, Germany.*

Neonatal calves, to a greater extent in preterm born, suffer from hypoglycemia after birth and have to adapt glucose metabolism by maturation. Plasma cortisol and catecholamines are elevated around birth and both hormones affect hepatic endogenous glucose production (eGP) by stimulation of glycogen degradation and gluconeogenic activity in liver. We have tested the hypothesis that the number of glucocorticoid (GR) and α_1- and β_2-adrenergic receptors (AR) in neonatal calves change with development and correlate with eGP. Male Holstein calves were born preterm (PT; 9 d before term) or term (T) and slaughtered 26 h after birth or were term born, fed colostrum (TC) and were slaughtered on d 4 (n = 7 per group). TC calves were fed twice daily at 8% of BW/d on d 1 and 10% of BW/d from d 2 onward. For measurement of eGP U-^{13}C-glucose (iv) was infused in PT and T calves directly after birth and in TC on d 3 of life and enrichment of U-^{13}C-glucose in blood plasma was measured. After slaughter, liver samples were snap frozen. For AR measurements membrane suspensions (2 mg protein/ml) were prepared and saturation binding assays were performed with increasing concentrations of (^{3}H)-prazosin and (^{3}H)-CGP-12177 for determination of α_1- and β_2-AR, respectively. For GR measurement the cytosol fraction (8 mg protein /ml) was incubated with increasing concentrations of (^{3}H)-dexamethasone. Maximal binding capacity (B_{max}) and binding affinity (K_D) were calculated. Data were analyzed by General Linear Model (GLM) of SAS with ontogenic stage as fixed. For GR, B_{max} was higher ($P < 0.05$) in TC than T and PT. B_{max} of α_1-AR significantly increased with maturation ($PT < t < TC$; $P < 0.05$). B_{max} of β_2-AR was higher ($P < 0.05$) in TC than in T and PT. K_D for β_2-AR was lowest ($P < 0.05$) in PT. B_{max} of GR and α_1- but not β_2-AR were positively correlated to eGP ($r = 0.61$; $P < 0.01$ and $r = 0.78$; $P < 0.001$). Results demonstrated that hepatic GR as well as α_1- and β_2-AR increase during early development in calves. GR and α_1-AR may be involved in stimulation of eGP by cortisol and catecholamines in neonatal calves. Supported by DFG, Germany.

Key Words: calves, ontogenic maturation, adrenergic and glucocorticoid receptors

W133 L-Arginine regulates expression of myokines and adipokines in myoblast and adipocyte cells.

H. S. Yang, X. Xiong, Y. L. Yin,* and X. F. Kong, *Hunan Provincial Engineering Research Center of Healthy Livestock, Key Laboratory of Agro-ecological Processes in Subtropical Region, Institute of Subtropical Agriculture, Chinese Academy of Sciences, Hunan, Changsha, China.*

It is widely accepted that skeletal muscle and adipose tissue are not only the organs for energy storage and expenditure but also endocrine organs. Factors secreted from muscle (myokines) and adipose (adipokines), have important roles in the regulation of physiological actions in various tissues and organs. This study was conducted to investigate the effect of L arginine (Arg), a functional amino acid, on the expression of myokines and adipokines. Skeletal myoblasts (C2C12) and adipoblasts (3T3-L1) were cultured in high glucose Dulbecco modified high glucose Eagle medium (DMEM) supplemented with 10% fetal bovine serum (FBS). Differentiation was induced by incubation in DMEM containing 2% horse serum (C2C12) or l-methyl-3-isobutylxanthine + dexamethasone + insulin (3T3-L1). The differentiated cells were treated with increasing concentrations of Arg for 12 h and the mRNA expression of myokines and adipokines was measured by reverse transcription (RT)-PCR. Data was analyzed by one way ANOVA. Myokine and adipokine gene expression exhibited time and Arg dose dependence. The expression of IL-15, BDNF, FGF21, EPO, and LIF increased ($P < 0.05$) during C2C12 differentiation. Leptin, adiponectin, TNF, apelin and resistin expression increased ($P < 0.05$) during 3T3-L1 differentiation. When the differentiated C2C12 and 3T3-L1 cells were cultured with Arg, the expression of IL-15, BDNF, Fstl, FGF21, LIF, leptin and adiponectin increased ($P < 0.05$), but the expression of TNF, IL-6 and apelin decreased ($P < 0.05$). Arg-induced expression of IL-15, BDNF, Fstl, FGF21, LIF, leptin, adiponectin, TNF and IL-6 was attenuated ($P < 0.05$) with 100 nM rapamycin or L-NAME. Insulin (100 nM) increased ($P < 0.05$) the effects of Arg on IL-15, BDNF and leptin expression in both cell types. The inhibitory actions of Arg on TNF and IL-6 expression were attenuated ($P < 0.05$) by 100 nM insulin. Results demonstrate that Arg regulates the expression of myokines and adipokines through mechanisms involving mTOR and NO signaling pathways.

Key Words: pigs, amino acids, expression

W134 Role of estrogen receptor-α (ER-α) and insulin-like growth factor receptor-1 (IGFR-1) in estradiol-stimulated proliferation of cultured bovine satellite cells.

E. Kamanga-Sollo, M. E. White, M. R. Hathaway, and W. R. Dayton,* *University of Minnesota, St. Paul.*

Estradiol (E2) enhances muscle growth in several species; however, the mechanism by which E2 enhances muscle growth is not known. Treatment with 10 nM E2 stimulates proliferation of cultured bovine satellite cells (BSC) and this is particularly significant because satellite cells are the source of nuclei needed to support postnatal muscle fiber hypertrophy and are thus crucial in determining the rate and extent of muscle growth. Treatment of BSC with 10 nM E2 significantly ($P < 0.05$) stimulates proliferation and insulin-like growth factor receptor (IGFR)-1β phosphorylation under conditions in which neither IGF-1 nor IGF-2 expression is increased. To further investigate the mechanisms by which E2 stimulates BSC proliferation, we have used small interfering (si) RNA to silence expression of estrogen receptor (*ER*)-*α* and assessed the effects on E2-stimulated proliferation and IGFR-1β phosphorylation in BSC cultures. Additionally, we have assessed the effect of using siRNA to silence *IGFR-1β* expression on E2-stimulated proliferation in BSC cultures. All experiments were repeated at least 3 times using cells from 3 different steers. Treatment of *ER-α*- or *IGFR-1β*-silenced cells with E2 does not significantly stimulate proliferation. Estradiol treatment for 30 min stimulates phosphorylation of IGFR-1β in control BSC cultures but does not stimulate IGFR-1β phosphorylation in *ER-α*-silenced cells. These results indicate that binding of E2 to ER-α results in phosphorylation and activation of IGFR-1β, which results in increased proliferation in BSC cultures. The fact that this occurs under culture conditions in which neither *IGF-1* nor *IGF-2* mRNA expression is increased strongly suggests that E2 activates IGFR-1β via a mechanism that does not involve increased IGF-1 or IGF-2 binding to the receptor.

Key Words: estradiol, satellite cells, bovine

Horse Species

W135 Trends in equine farm management and conservation practices. B. J. McIntosh* and S. A. Hawkins, *The University of Tennessee, Knoxville.*

It is widely recognized that horse farms often have unthrifty, weed infested and overgrazed pastures due to poor grazing management practices, including continuous grazing and overstocking. Poorly managed pastures and lack of appropriate waste management practices on horse farms contribute to surface water pollutant loads of sediment, nutrients, and pathogens. A survey consisting of 48 questions was distributed to participants of the Tennessee Master Horse Owner Program from 2008 to 2011 to identify potential educational needs, demographics and management practices of horse farms. Data are summarized as percentages or mean ± SE. The response rate was 89.0% and surveys (n = 121) were completed by respondents from 18 counties in TN and the states of MS, AR and AL. The respondents consisted of the following age ranges: less than 20 yr (6.6%); 20–29 yr (9.9%); 30–39 yr (6.6%); 40–49 yr (21.5%); 50–59 yr (43.8%); and 60–69 (12.4%). The majority of respondents were female (77.6%) compared with male (23.1%). Most of the respondents indicated involvement in the equine industry for more than 10 years (54.5%). The number of horses per farm was 5.0 ± 0.6 head with a range of 1 to 51. The area designated for pasture was 25.6 ± 0.8 acres. However, 48.8% of farms designated 10 or fewer acres for grazing. Continuous grazing was practiced by 51.5% of respondents. Pasture weeds were reported to be a problem by 78.1% of respondents. Soil testing for nutrient content was not practiced by the majority of respondents (58.4%). Respondents indicated equine were stabled with access to pasture for turnout (62.6%), housed on pasture continuously (36.6%) or stabled continuously (0.8%). The majority of respondents reported that stall waste was stored on bare ground in uncovered piles (89.8%). Mud was reported to be an issue in high animal traffic areas during periods of wet weather on the majority of farms (80.5%). The management practices indicated by the respondents in this study may lead to pollution due to erosion, surface water runoff, or leaching of N or P and volatilization of N from animal waste. This study indicates there is a need for educational programs that target best management and conservation practices for equine farms to reduce adverse environmental impact.

Key Words: equine, management, conservation

W136 The effects of feed-borne *Fusarium* mycotoxins on the presence and severity of equine gastric ulcer syndrome and the efficacy of a glucomannan mycotoxin adsorbent. M. Mortson,* G. Girgis, H. Staempfli, A. Gallastegui, and T. K. Smith, *University of Guelph, Guelph, Ontario, Canada.*

Standardbred racehorses have a high prevalence of ulcer development ranging from 40 to 80%. Consumption of mycotoxin-contaminated diets can have a negative effect on equine health. A study was conducted to determine the effect of feed naturally contaminated with *Fusarium* mycotoxins on the presence of equine gastric ulcer syndrome (EGUS). Feed intake, body weight (BW) gain and serum hematological and biochemical parameters were evaluated as well as and the efficacy of a glucomannan mycotoxin adsorbent (GMA) (Integral, Alltech Inc., Nicholasville, KY). Nine standardbred mares at maintenance, of similar age, were assigned to one of 3 dietary treatments for 28 d with a 21 d recovery, in a replicated 3x3 Latin Square design. Each horse was housed in individual stalls and received limited turnout daily. Dietary treatments included a control, a contaminated diet and a contaminated diet + 0.2% GMA. The 2 contaminated diets ranged from 8.1 to 10 ppm deoxynivalenol and 1.2 ppm zearalenone, along with minor quantities of aflatoxin and fumonisin. Gastroscopies were performed and biopsies collected every 2 weeks during the experimental period. Day 0 ulcer scores ranged from 0 to 1 on a scale of 4 across treatment groups. Histological evaluation of the tissue biopsies showed inflammation of the glandular mucosa across treatments with varying distribution in the contaminated and GMA diets. Data was analyzed using a 2-way ANOVA including horse, diet and day in the statistical model ($P < 0.05$). A slight decrease in feed intake was observed in the contaminated groups compared with the control although the results were not statistically significant. BW gain was not affected by diet. Diet significantly altered serum anion gap ($P = 0.033$) and thymidylate synthase activity ($P = 0.046$) when comparing the control to the contaminated and GMA diets. It was concluded that horses tolerated this level of mycotoxin challenge with respect to BW and feed intake but histological changes in the gastric mucosa were evident.

Key Words: *Fusarium* mycotoxins, horses, equine gastric ulcer syndrome

W137 Comparison of high fat, high fiber, and high starch diets on serum levels of insulin, IGF-1, and glucose in growing horses. C. A. Craige,* S. R. Cooper, L. J. Spicer, and S. T. Kawcak, *Oklahoma State University, Stillwater.*

The objective of this study was to examine the effects of high fat, high fiber, and high starch diets on serum insulin, IGF-1, and glucose levels in growing horses. Yearling Quarter Horse fillies and geldings were randomly assigned into one of 3 treatment groups and individually fed 3 concentrates (each containing 4.0 Mcal/kg DE and 20% CP and fed at 2–3% of BW): 1) high fat (FT; 13% fat, 1% starch; as-fed basis: 90% alfalfa pellets (AF), 10% soybean oil; n = 6), 2) high fiber (FB; 3% fat, 1% starch; as-fed basis: 100% AF; n = 6) or 3) high starch (ST; 4% fat, 20% starch; as-fed basis: 50% AF, 20% ground shelled corn, 20% wheat middlings, 8% soybean meal, 2% minerals; n = 5). Each diet was formulated to contain approximately 20% CP to match the protein level of the FB diet. Diets were fed at 0700 h and 1800 h for 60 d. All horses were allowed 2 h of turn out exercise per day and weighed weekly. After 30 d (feed period 1) and 60 d (feed period 2) of treatment, blood samples were collected starting 15 min before (T-15) and 30 (T30), 60 (T60), and 180 (T180) min after the 0700 h feeding. Serum insulin, IGF-1, and glucose levels were analyzed using MIXED procedure of SAS in a split-split plot design. Main effects of diet, feed period, and time relative to feeding influenced ($P < 0.05$) serum insulin and glucose levels. Within a treatment, glucose concentrations increased postprandially ($P < 0.01$), peaking at T60. A subsequent decrease ($P < 0.01$) in glucose levels was observed until T180. Insulin concentrations were greater ($P < 0.05$) at T60 and T180 in horses fed ST diets compared with FB and FT diets (diet x time, $P < 0.001$). Serum IGF-1 concentrations tended ($P < 0.10$) to be influenced by diet x feed period. Serum IGF-1 levels in horses fed the ST diet tended to increase ($P < 0.10$) from feed period 1 to 2, but did not change in horses fed FT and FB diets. Serum IGF-1 levels did not differ among groups in feed period 1. In feed period 2, horses fed the ST diet tended to have greater ($P < 0.10$) IGF-1 levels (251 ± 25 ng/mL) than horses fed the FT (187 ± 23 ng/mL) or FB (187 ± 23 ng/mL) diets. Overall, the effects of ST diet on serum insulin and glucose were manifested acutely during feeding, whereas the effect of the ST diet on serum IGF-1 took 60 d to develop and was not acutely affected by feeding.

Key Words: equine, IGF-1, insulin

W138 Horses decrease water intake when supplements are added to drinking water. M. E. Gordon,* B. L. Miller, and M. L. Jerina, *Land O'Lakes Purina Feed LLC, Gray Summit, MO.*

The objective of this study was to test the hypothesis that horses decrease water intake when supplements are added to water. Six mature Quarter Horses (564.5 ± 44.0 kg, BW ± SD) were acclimated to drinking water from buckets over a 7 d period, and then offered both plain water (PW) and water with one of 4 different supplements (SW) in a block design. Each treatment period lasted for 5 d, and horses had a 2 d period between treatments when only PW was offered. Supplements included 2 electrolyte preparations (Farnam Apple Dex and Land O'Lakes Calf electrolyte), a vitamin/mineral (Farnam Red Cell) and a joint additive (Finish Line Fluid Action). All supplements were offered at a rate of 28 g per 18.93 L of water. Water intake from buckets was recorded via weight and replenished at 0700 and 1800. Horses were fed 1% BW grass hay and 3.6 kg of commercial pelleted diet daily throughout the trial, split into 2 feedings. Horses had ad libitum access to plain white salt in block form and were housed individually in stalls with attached dry lot paddocks. An incomplete block design was used to test the effect of supplements in water on water intake, utilizing ANOVA with mixed models (SAS 9.2 2010). Least squares means were compared with Fisher's least significant difference ($P < 0.05$). There was an effect of adding supplements to water ($P < 0.0001$), as horses preferred PW with mean daily intake of 11.92 ± 0.893 L versus 4.86 ± 1.785 L for SW. There was no difference within the supplement treatments for water intake ($P < 0.05$). There was a trend for water intake to be affected by time of day ($P = 0.0583$), with the greatest volume consumed overnight. This trend may have been influenced by timing of water weighing and replenishment and/or housing management conditions. In this study, horses drank over twice the amount of PW versus SW. Therefore, adding supplements to water can decrease intake in horses and may cause horses to become dehydrated. This may lead to poor performance or other adverse health effects in horses.

Key Words: equine, water intake, supplements

W139 The effects of coprophagy on the hindgut bacterial community of neonatal foals. L. A. Strasinger*[1], L. M. Lawrence[1], M. D. Flythe[2,1], G. L. Gellin[2], M. Brummer[1], B. E. Davis[1], and L. R. Good[1], [1]*University of Kentucky, Lexington,* [2]*United States Department of Agriculture, Agricultural Research Service, Forage-Animal Production Research Unit, Lexington, KY.*

How and when foals establish their hindgut bacterial community has received little attention from researchers. The aim of this study was to determine if coprophagy of maternal feces is essential for bacterial colonization of the foal′s digestive tract. Eight mare and foal pairs were randomly allocated into 2 treatment groups, allowed access to maternal feces (allowed, n = 4) and restricted access to maternal feces (restricted, n = 4). For at least the first 96 h after parturition, foals in the allowed group were monitored via video surveillance and the number of bouts of coprophagy was recorded. In the restricted group, each pair was constantly observed by an attendant for the 96 h following parturition, and mare feces was removed immediately following defecation. Starting with the passing of the foal′s meconium, fecal samples were taken from the mare and foal during the first 4 d. Samples were immediately frozen then later subjected to PCR-denaturing gradient gel electrophoresis (PCR-DGGE). Comparisons of each mare and foal was made using Dice′s index and cluster analysis, and reported as percent similarity. Foal body weights were measured every day a fecal sample was taken. Foals in the allowed group ate mare feces as early as 27 h after birth. When PCR-DGGE was performed on the meconium of newborn foals (d 0), no bands were observed and % similarity between mares and foals was 0 for both groups. By d 2 and 4 the number of bands had increased ($P < 0.01$), but there was no effect of time × treatment ($P > 0.05$). The average foal to mare similarity increased over time ($P < 0.05$) but there was no time × treatment interaction ($P > 0.05$). The % similarity between foals and their dams was 47 ± 16.8 (mean ± SD) for allowed group and 48 ± 6.3 for restricted group by d 2. The similarity between mare and foals on d 4 was to 62% ± 9.1 for allowed and 55% ± 10.3 for restricted. On d 14 restricted foals had an average daily gain of 2.06kg/d, while the allowed foals gained 1.77 kg/d ($P > 0.05$). Restricting access to maternal feces in the neonatal period did not appear to alter the diversity of the foal′s hindgut bacterial community by d 4.

Key Words: horse, neonates, microbiome

W140 Influence of maternal plane of nutrition and arginine supplementation on mares and their foals: Foaling parameters. K. N. Winsco*[1], J. A. Coverdale[1], C. J. Hammer[2,3], K. L. Gehl[1], A. E. Hanson[1], J. L. Lucia[1], and A. N. Wolford[1], [1]*Department of Animal Science, Texas A&M University, College Station,* [2]*Department of Animal Sciences, North Dakota State University, Fargo,* [3]*Center for Nutrition and Pregnancy, North Dakota State University, Fargo.*

To determine the effect of plane of nutrition and arginine supplementation on foaling parameters, 32 mares (468 to 668 kg BW; 3 to 19 yr) were blocked by expected foaling date and randomly assigned within block to treatments which were arranged as a 2 × 2 factorial with 2 planes of nutrition, moderate (Mod; 0.5% BW AF grain/d) or high (High; 1% BW AF grain/d) and 2 levels of L-arginine supplementation, 0.21 g/kg/d (Arg) or no supplemental Arg (Con; L-alanine to maintain isonitrogenous diets). Treatments began 110 d before expected foaling date and terminated at parturition. Mares were housed by block and allowed ad libitum access to water and coastal bermudagrass (*C. dactylon*) hay, and fed commercial grain 2 × /d in individual stalls. Parturition was observed and the following foaling parameters were recorded: time of water break to birth, time to stand, and time of birth to placenta expulsion. Total length of gestation was calculated and placenta weight was recorded. Additionally, total colostrum volume (CV), specific gravity (SG), and Brix% of colostrum were measured. Physical measurements were also obtained which included mare BW, foal BW, foal wither and hip height, and foal body length. Data were analyzed using PROC GLM of SAS with main effects tested being plane of nutrition (Nutr), amino acid (AA), time, and their interactions. Significance was declared when $P \leq 0.05$ and a trend toward significance declared when $P \leq 0.10$. There was no influence of Nutr or AA on gestation length, foaling parameters, physical measurements, ratio of placenta to mare BW, placenta to foal BW, and ratio of foal BW to mare BW ($P \geq 0.15$). Maternal plane of nutrition tended to influence CV ($P \leq 0.08$) with Mod mares having greater volume compared with High. There was an influence of Nutr ($P \leq 0.03$) on colostrum quality indicated by greater SG in High mares compared with Mod. In summary, these data indicate that maternal plane of nutrition in late gestation affects colostrum volume and quality estimates, while arginine supplementation had no effect on foaling parameters, colostrum, or foal physical characteristics.

Key Words: pregnant mares, parturition, arginine

W141 Mineral concentrations of cool season grasses as affected by specie and season. A. L. Fowler,* L. M. Lawrence, S. H. Hayes, and S. R. Smith Jr., *University of Kentucky, Lexington.*

In pasture-based horse production systems in Central Kentucky the concentrate is the primary source of many minerals imported onto the farm, including phosphorus (P), potassium (K) and copper (Cu). By complementing the minerals in the concentrate with the minerals provided by the pasture, a reduction in mineral importation to the farm might be achieved. To develop a synchronized feeding program, factors affecting the concentration of minerals in the forage must be assessed. To this end, 2 studies were conducted. In experiment 1, replicated plots of 5 cool season grasses were sampled in early May to assess differences in the concentrations of calcium (Ca), P, Cu, K and the Ca:P ratio among species. Multiple samples of perennial ryegrass (n = 12), timothy (n = 12), tall fescue (n = 7), festulolium (n = 4), and orchardgrass (n = 4) were collected from experimental plots seeded the previous fall. Effect of grass specie on mineral content was determined using ANOVA. Ca concentrations ranged from a high of 0.73% in perennial ryegrass to a low of 0.49% in timothy ($P < 0.0001$). Festulolium and perennial ryegrass had the highest concentrations of P (0.46% and 0.46%, respectively), while timothy had the lowest (0.33%; $P < 0.0001$). There were no differences in the Ca:P ratio among species ($P > 0.05$). Timothy had the highest concentration of Cu and perennial ryegrass, festulolium, and tall fescue had the lowest concentrations ($P < 0.0001$). Perennial ryegrass, festulolium, and orchardgrass had higher concentrations of K than tall fescue and timothy ($P < 0.0001$). In experiment 2, samples of 8 tall fescue cultivars were collected from experimental plots in early May and late September to evaluate seasonal differences in the concentrations of Ca, P, Cu, K and the Ca:P ratio. No differences were found in mineral concentrations between spring and fall ($P > 0.05$). When synchronizing mineral content between pasture and concentrate, it might be beneficial to select pasture varieties that contain a higher concentration of necessary minerals to reduce the need for mineral supplementation of the diet and thus reduce the importation of nutrients to the farm.

Key Words: horse, calcium, phosphorus

W142 Effects of late gestation on conformation and movement in mares.

H. Roberts,* J. M. Reddish, and K. Cole, *Department of Animal Sciences, The Ohio State University, Columbus.*

Studies have shown that conformation, soundness and external weight distribution can affect a horse's movement. These factors can also influence the viability of the mare as a breeding animal. The effects of internal weight as opposed to external weight distribution have not yet been evaluated. During pregnancy, mares typically gain approximately 10% of their body weight (BW), with the majority of the weight gain occurring during the last 3 mo of gestation. The objective of this study was to evaluate the effects of increased BW during late gestation on conformation and movement in Quarter Horse mares. Each mare (n = 5) was videotaped in hand at the walk and trot tracking to the left and right on a flat surface on d 270, 285, 300, 315 and 330 of gestation, within 12 h of foaling, and d 15 and 30 postpartum. The camera was positioned at a height of 3.0 m and 8.6 m away from and perpendicular to the line of travel. Each horse was photographed from the left and right lateral view along with a plantar view of the left front and rear hoof. Videos and photographs were analyzed using OnTrack Equine software for hoof width, shoulder and hip angle, maximum knee and hock angle at the walk and trot, and stride length at the walk and trot. Data were analyzed using the PROC MIXED procedure of SAS. A P value of ≤0.05 was considered statistically significant. Average gestation length was 341.8 ± 8.9 d. BW increased by an average of 4.5% in the mares between d 270 of gestation and foaling then decreased after the birth of the foal and passage of the placenta ($P = 0.059$). Conformation of the shoulder and hip were not influenced by increased BW during late gestation ($P > 0.05$). Similarly, BW did not influence conformation of the hoof, as measured by hoof width ($P > 0.05$). Stride length at the walk and trot were not influenced by BW ($P > 0.05$). Knee and hock angles recorded at the walk and trot also were not influenced by BW ($P > 0.05$); however, there was a tendency for these measurements to decrease between d 330 of gestation and 15 d postpartum. In summary, increased BW during late gestation did not influence the conformation or movement of mares in this study.

Key Words: horse, movement, gestation

W143 Exercise response in unfit horses of different selenium status.

M. Brummer,* S. Hayes, B. E. Davis, L. A. Strasinger, S. M. McCown, and L. M. Lawrence, *University of Kentucky, Lexington.*

Glutathione peroxidase (GPx) plays an important role in the neutralization of hydrogen peroxide which can generate hydroxyl radicals known as reactive oxygen species (ROS). Exercise has been shown to increase ROS as well as alter GPx activity post exercise. This study aimed to evaluate the effect of Se status on the response of unfit horses to mild exercise. Twenty 5 mature horses that had received one of 4 dietary Se treatments for 29 wk were used. The 4 dietary treatments were low Se (LS, n = 6), adequate Se (AS, sodium selenite, n = 6), high organic Se (SP; Sel-Plex, Alltech, Nicholasville, KY, n = 7) and high inorganic Se (SS, sodium selenite, n = 6). Total dietary Se for LS, AS, SP and SS was 0.07, 0.14, 0.3 and 0.3 ppm respectively. The basal diet consisted of low Se pasture, hay, cracked corn and a balancer pellet either low (LS, SP, SS) or adequate (AS) in Se. The SP and SS supplements were top dressed on the balancer pellet. Prior to the exercise test blood Se was higher ($P < 0.01$) for SP and SS (255 and 240 ng/mL) than AS and LS (195 and 125 ng/mL). Vitamin E status was adequate and similar between groups ($P > 0.05$). The exercise test, conducted in a 6 horse exerciser (Stratton Equine Enterprise Inc., Lexington, KY), consisted of walking and trotting, covering 4.41 km in 36 min. Blood samples were taken pre-, 0, 4 and 24 h post exercise to evaluate blood GPx activity, serum malondialdehyde (MDA) as indicator of oxidative stress, serum creatine kinase (CK) and aspartate aminotransferase (AST). Data were analyzed as ANOVA with repeated measures (SAS 9.2). There was an effect of treatment ($P < 0.05$) and treatment x time ($P < 0.05$) for GPx. Post exercise GPx decreased in LS and did not recover by 24 h, while remaining unchanged in AS. Post exercise GPx increased in SP and decreased in SS, but both returned to pre values at 24 h. At 24 h MDA was elevated in all groups (time $P < 0.05$). MDA was lower at 4 h in SP compared with AS (treatment x time $P < 0.05$). CK and AST were unaffected by Se status ($P > 0.05$). Overall Se status did not have a substantial effect on response to exercise in unfit horses, but the differences in post exercise GPx response may warrant further investigation.

Key Words: equine, GPx, MDA

W144 The effect of antibiotic administration on fermentative characteristics of equine feces.

B. E. Davis*[1], L. M. Lawrence[1], M. D. Flythe[2,1], S. H. Hayes[1], C. Wilson[1], A. L. Fowler[1], M. Brummer[1], and L. A. Strasinger[1], *[1]University of Kentucky, Lexington, [2]United States Department of Agriculture, Agricultural Research Service, Forage-Animal Production Research Unit, Lexington, KY.*

Horses are often treated with antibiotics in response to wounds or respiratory disease. Antibiotic use is occasionally associated with diarrhea, suggesting a disruption of the normal hindgut microflora. Not all horses receiving antibiotics develop diarrhea, but it is not known whether antibiotic treatment alters fermentation in the hindgut. Therefore, this study was designed to look at the effect of 2 commonly used antibiotics on the functional capacity of the microbial community of the equine hindgut. Horses ranging from 2 to 14 y, were blocked by age and gender into 6 blocks of 3 horses each. Within block horses were randomly assigned to 1 of 3 treatments: CO (no antibiotic; n = 6), ST (trimethoprim-sulfadiazine, oral, 30 mg/kg; n = 6) and CF (ceftiofur sodium, IM, 2.2 mg/kg; n = 6). Each block consisted of a 21 d adaptation, a 7 d treatment, and a 7 d withdrawal period. Feed refusals were weighed back and recorded on the last week of adaptation and during the treatment and withdrawal periods. Fecal samples were collected during each block and were analyzed for pH and DM. In vitro dry matter disappearances (IVDMD) of tall fescue, orchard grass and alfalfa hay were measured using fresh feces from each horse as the inoculum. In vitro gas production (IVGP; mL/g of substrate) from alfalfa hay was also measured using fresh feces as the inoculum. Data were analyzed using repeated measures ANOVA in the mixed procedure of SAS version 9.2. No horses exhibited diarrhea during the study. No differences in feed refusals were found between treatments ($P > 0.05$). There were no treatment or time x treatment effects on fecal DM ($P = 0.51$), fecal pH ($P = 0.78$) or IVGP ($P = 0.30$). Furthermore, treatment did not affect IVDMD of tall fescue, orchard grass, or alfalfa hay respectively ($P = 0.20$; $P = 0.21$; $P = 0.28$). Treatment with CF and ST did not induce changes in the in vitro fermentation associated measurements made in this study, without onset of diarrhea.

Key Words: diarrhea, IVDMD, fermentation

W145 Effects of probiotic supplementation on stress and immune responses in horses.

J. Saul, J. M. Reddish,* K. Barnhart, C. Dyer, and K. Cole, *The Ohio State University, Columbus.*

Today's horse management practices often include restricted access to forage and feeding large quantities of grain in a limited number of meals throughout the day. These practices may create physiological and psychological stress in the horse, leading to increased cortisol production which may alter gastrointestinal microflora and immune responses. In this study, 12 Quarter Horses (1.6 ± 0.6 yr) were used to evaluate the effects of probiotic supplementation on stress and immune response to tetanus toxoid vaccination. Horses were randomly assigned to one of 2 treatment groups: Probiotic or Control. All horses received 0.5% BW of a 14% CP pelleted concentrate, with water and mixed grass hay ad libitum. Horses in the probiotic treatment group were fed a target dose of 10^7 cfu/(45 kg of BW x d) of a mixed culture containing *L. acidophilus*, *L. casei*, *L. plantarum*, and *E. faecium* throughout the study. After 45 d, horses were vaccinated against tetanus toxoid and blood samples were taken on d 0, 7, 14, 21 and 28 d post-vaccination to determine tetanus antibody titers. On d 28 post-vaccination, horses were transported for 15 min and blood samples to determine cortisol concentrations were taken by jugular venipuncture immediately before and after transport. Tetanus antibody titers and cortisol concentrations were analyzed using the PROC MIXED procedure of SAS. A P value of ≤0.05 was considered statistically significant. By d 7 post-vaccination, all of the horses in the study were fully protected against tetanus, regardless of treatment. Although no differences in cortisol production were found across treatment groups, cortisol concentrations increased significantly after transport for 15 min within the control group ($P < 0.05$). Denaturing gradient gel electrophoresis (DGGE) analysis of fecal samples revealed no differences in the microbial profiles of the horses due to probiotic supplementation. However, the microbial profiles of horses of comparable age showed similarities in banding patterns. Overall, probiotic supplementation did not influence gastrointestinal microflora, cortisol response to transport stress, or antibody response in this study.

Key Words: horse, probiotic, antibody response

W146 Biochemical markers of bone metabolism in growing Quarter Horses fed a higher starch versus a higher fat diet.

K. R. Vineyard,* M. E. Gordon, and M. L. Jerina, *Land O'Lakes Purina Feed, Gray Summit, MO.*

The objective of this study was to determine if diet affects serum concentrations of osteocalcin (OC, marker of bone formation) and carboxy-terminal pyridinoline cross-linked telopeptide region of type I collagen (ICTP, marker of bone resorption) in growing Quarter Horses (QH) during the first 2 years of life. Eleven QH foals (5 fillies, 6 colts) housed in dry lot paddocks and individual stalls were fed either Omolene 300 (n = 5) (16% CP, 5% fat, 6.5% fiber, 29.4% starch, 10.6% WSC, 3.4 Mcal/kg) or Ultium Growth (n = 6) (15.5% CP, 9.5% fat, 13% fiber, 16.6% starch, 10% WSC, 3.7 Mcal/kg; analyses by Dairy One, Ithaca, NY). Foals were creep fed beginning at d28, starting with 0.23 kg/d and increased by 0.23 kg every 2 d until intake reached 3.6 kg/h/d, not exceeding 0.45 kg/mo of age before weaning at wk20. Foals consumed grass hay along with their dams and received 1% BW in grass hay post-weaning. Blood serum was collected at birth (d0) and at 6 wk intervals thereafter through wk102 (2 yr) and analyzed for OC (Metra Osteocalcin, Quidel Corporation, CA) and ICTP (ICTP RIA, Orion Diagnostics, Oulunsalo, Finland). A completely randomized factorial split-plot design was used to test the effect of diet, sex, and weaning. Analysis of variance was done with mixed models (SAS 9.2 2010) and least squares means compared with Fishers LSD ($P < 0.05$). There were no differences due to diet or sex for OC ($P = 0.60$, $P = 0.16$) and ICTP ($P = 0.48$, 0.10), but OC was higher in fillies than in colts before weaning ($P = 0.03$). In all horses, both OC and ICTP rose after birth, peaking at wk6 for OC (132.74 ± 11.2 ng/ml) and ICTP (24.26 ± 0.6 µg/L), and were higher before weaning compared with post-weaning levels ($P < 0.0001$). OC returned to d0 levels (86.03 ± 9.4 ng/mL) by wk18 ($P < 0.05$) and fell and remained below d0 levels by wk42 ($P < 0.05$). ICTP returned to d0 levels (21.82 ± 0.6 µg/L) by wk18 ($P < 0.05$) and fell and remained below d0 levels by wk24 ($P < 0.05$). Although feeds higher in starch and sugar have sometimes been implicated in metabolic bone problems in growing horses, these results suggest that bone formation and resorption are not affected by dietary starch and sugar levels in the current study.

Key Words: equine, osteocalcin, ICTP

W147 Anthelmintic resistance testing and training on horse farms in the Southeast.

N. C. Whitley*[1], R. M. Kaplan[2], R. K. Spann[3], A. M. Zajac[4], K. Moulton[1], R. A. Franco[1], C. Swanson[5], A. E. Cooper[1], and V. R. Jackson[1], *[1]North Carolina A&T State University, Greensboro, [2]University of Georgia, Athens, [3]Virginia Tech MARE Center, Middleburg, [4]VA-MD Regional College of Veterinary Medicine, Blacksburg, VA, [5]Virginia Cooperative Extension, Albemarle County, Charlottesville, VA.*

A total of 487 horses on 11 NC farms, 5 SC farms, and 9 VA farms were used for training agricultural professionals in and conducting fecal egg count (FEC) reduction testing for gastrointestinal nematode (GIN) parasite anthelmintic resistance. Horses (249 females, 238 males) of various breeds averaging 519 ± 6 kg BW and 11.3 ± 0.4 yr of age (range 1 to 34 yr) were used. Animals were assigned to treatment to account for preliminary fecal egg count (FEC), sex, breed type and age as possible. Ivermectin (Zimecterin; IVM; n = 246) and pyrantel (Strongid; PYR; n = 241) were used as labeled for BW (measured by equine weigh tape) plus 15% with doses rounded up to the nearest 22.7 kg (50 lb). Ninety horses on 12 farms were used in a switchback design but analyzed as independent data points. At treatment (d 0) and at d 14, fecal samples were collected after defecation for FEC using the Modified McMasters technique with a sensitivity of 8 eggs per gram (epg). Reduction in FEC

(RED) were calculated as ((FEC before trt — FEC after trt)/FEC before trt) x 100% for animals with d0 FEC of at least 40 epg (n = 472). Treatment was considered effective with RED of >80% for PYR and >90% for IVM. On 14 farms, for horses for which treatment was considered effective, fecal samples were collected every 14 d until FEC increased to below effective RED level (egg recovery period; ERP). Using SAS, Chi Square analysis and Wilcoxon Rank Sum testing was conducted. For random samples from 7 farms, individual McMaster chamber FEC was recorded; the CV for those samples averaged 22.1% for all farms. Overall, d0 FEC averaged 639 ± 30 epg. The average RED was greater ($P < 0.01$) for IVM (99.5%) than PYR (63.8%). For individual horses, IVM was effective in 99.2% of the horses tested while PYR was only effective in 57%. The average ERP was 53.4 ± 2.4 d for IVM and 46.0 ± 3.1 d for PYR. As previously reported in other states and livestock species, this study confirms GIN resistance to PYR on NC, VA, and SC horse farms. At least 10 agricultural professionals were trained in equine GIN anthelmintic resistance testing, resulting in overall decreased anthelmintic use on horse farms.

Key Words: anthelmintic resistance, horse, ivermectin

Lactation Biology III

W148 Estradiol enhances apoptosis in bovine mammary epithelial cells in vitro. L. Yart*[1,2], L. Finot[1,2], V. Lollivier[2,1], P. G. Marnet[2,1], and F. Dessauge[1,2], *[1]INRA, UMR1348 Pegase, Saint-Gilles, France, [2]Agrocampus Ouest, UMR1348 Pegase, Rennes, France.*

Previous studies conducted on mid- or late-lactation dairy cows showed that the administration of exogenous estradiol induced a severe decrease in milk yield and accelerated mammary gland involution. However, the effects of estradiol on mammary epithelial cells remained unknown. The aims of this study were to investigate the in vitro effects of estradiol (i) on a bovine mammary epithelial cell line (Mac-T) and (ii) on apoptose-induced bovine mammary epithelial cells. In the first part of this study, the Mac-T cells were treated with increasing doses of estradiol (10^{-6}, 10^{-5}, 10^{-4}, and 10^{-3} M), during increasing times (6h, 12h, 24h and 48h). It appeared that the higher treatment doses of estradiol (10^{-4} and 10^{-3}M) reduced the cell proliferation by 8 and 19% respectively at 24h and by 5 and 10% respectively at 48h, and induced apoptosis of the mammary epithelial cells. In the second part of this study, the Mac-T cells were either treated with estradiol (E_2, 10^{-4}M) or with camptothecin (Ct, 10 μM) to induce apoptosis or with camptothecin combine with estradiol (Ct+ E_2), during increasing times (2h, 6h, 24h and 48h). After 6h of treatment, we observed an increase in apoptotic markers (Caspase 3 activity and Annexin V-positive cell rate) in both Ct and Ct+ E_2 treatment batches. This increase was more important in the Ct+ E_2 treatment batch at 6h (+ 61.5%) and 24h (+ 9.8%) compared with the Ct treatment batch. Taken together, these results suggest that estradiol reduces mammary epithelial cells expansion and enhances apoptosis pathways in vitro.

Key Words: estradiol, mammary epithelial cell, apoptosis

W149 Evaluation of mitogenic properties of colostrum and colostrum replacer (CR) on growth of bovine mammary epithelial cells (BMEC) in vitro. K. E. Stemm,* C. M. Jones, J. L. Collier, and R. J. Collier, *University of Arizona, Tucson.*

Ingestion of colostrum is necessary for neonatal calves to develop a functioning immune system. A viable alternative source of immunoglobulins for management and safety reasons is colostrum replacer (CR). Colostrum has also been implicated in improved milk yield at maturity, possibly due to increased mammary growth. A comparison of mitogenic effects of colostrum versus CR has yet to be established. In this study, pooled whole colostrum (WC) from a commercial dairy was compared with Convert ImmPower Colostrum Replacer supplied by Agrarian Marketing (Middlebury, Indiana). A clonal BMEC cell line (MAC-T), was used to screen potential mitogenic agents in colostrum. Concentrations of DNA were determined by CyQuant DNA Assay (Life Technologies, Grand Island, NY) and by proxy mitogenic activity. Protein concentrations of WC and CR were 187.01 and 181.56 mg/mL, respectively, and therefore treatments were delineated as percentages by weight. Cells treated with 10% WC or CR exhibited a decline in cell numbers ($P < 0.05$). Therefore, only treatments of 1% and 5% WC or CR were utilized. The treatment of MAC-T cells with WC or CR at 1 or 5% produced higher DNA concentrations than cells that were untreated, ($P < 0.05$). The use of WC at 1% provided the best growth results, which was not different from the normal in vitro growth media, containing 10% FBS and insulin. When the comparison was made between the 2 treatments, WC promoted more growth than CR at 1%, ($P < 0.001$). The mitogenic agents epidermal growth factor (EGF) and insulin-like growth factor I (IGF-I) were then added to CR to determine if it improved mitogenesis. The addition of 25 ng/ml EGF and 100 ng/ml IGF-I alone and in combination with 1% CR promoted growth of cells greater than 1% CR alone, ($P < 0.001$), but not different from 1% WC ($P < 0.05$).

Key Words: colostrum replacer, mitogen, mammary cells

W150 Effects of intra-mammary infusions of casein hydrolysate, EGTA, and lactose at drying-off on mammary gland involution. B. Ponchon*[1], P. Lacasse[2], N. Silanikove[3], S. Ollier[2], and X. Zhao[1], *[1]Department of Animal Science, McGill University, Sainte-Anne-de-Bellevue, QC, Canada, [2]AAFC-Dairy and Swine Research and Development Centre, Sherbrooke, QC, Canada, [3]Volcani Center, Bet Dagan, Israel.*

The transition from lactation to the dry period in dairy cows is a period of high risk for acquiring new intra-mammary infections. This risk is reduced when the involution of the mammary gland is completed. Consequently, strategies that accelerate the involution process after drying-off could reduce the incidence of mastitis. The objective of this study was to assess the effect of 3 different treatments on mammary gland involution markers. Each quarter of 8 Holstein cows in late lactation was randomly assigned at drying-off to an intra-mammary infusion of iso-osmotic solutions of a casein hydrolysate (CNH; 70mg), EGTA (5.7g), lactose (5.1g) or saline (control). Milk samples were collected on the last 2 d before and 1, 3, 5, 7, 10 and 14 d after the last milking. Milk somatic cell count (SCC), lactoferrin and BSA concentrations gradually increased ($P < 0.001$) during the first 2 weeks following the last milking whereas milk citrate concentration decreased ($P < 0.001$). The increases in SCC, lactoferrin and BSA concentrations after the last milking were similar in quarters infused with saline and lactose. Intra-mammary infusion of CNH hastened the increase in SCC and BSA and their concentrations were greater ($P < 0.05$) than in milk from control quarters on d 1, 3, 5 and 7. Similarly, the CNH treatment induced a faster rise of lactoferrin concentration, which was greater ($P < 0.05$) than in milk from control quarters on d 1, 3 and 5 after the drying-off. Milk citrate concentration was unaffected by CNH but the citrate:lactoferrin ratio was lower ($P < 0.05$) in CNH-treated quarters at d 3 and 5 than in control quarters. Infusion of EGTA increased SCC on d 1 and 3 but it had no effect on the other parameters. This study suggests that an intra-mammary infusion of CNH at drying-off hasten the involution of the mammary gland.

Table 1. Milk SCC, BSA and lactoferrin concentrations and citrate:lactoferrin ratio 3 days after drying-off

	Control	CNH	EGTA	Lactose
SCC (x 1000)	182	3 162*	436*	323
BSA (g/L)	1.14	2.63*	1.37	1.48
Lactoferrin (G/L)	0.73	1.26*	0.76	0.78
Citrate:Lactoferrin	3.64	1.58*	2.94	2.25

*Different from control ($P < 0.05$).

W151 Expression of amino acid transporter LAT1 and the regulation by prolactin in mammary gland of dairy cow.

L. Feng, Y. Lin, Q. Li,* X. Gao, and N. Zhang, *Key laboratory of Dairy Science, Ministry of Education, Northeast Agricultural University, Harbin, Heilongjiang, China.*

System L-amino acid transport mediates the uptake of aromatic neutral amino acids and nutritionally essential amino acids. This study was to reveal the relationship between the expression of system L-amino acid transporter LAT1 and the development of dairy cow mammary gland, and illuminate the regulation mechanism of prolactin (PRL) to LAT1 expression. We used Western blotting and immunofluorescence triple staining technology to detect the expression of LAT1 and its auxiliary protein 4F2hc at 4 development stages of dairy cow mammary gland tissue, including virgin, pregnant, lactation, involution. The effect of prolactin on the expression of LAT1 was determined by qRT-PCR and Western blotting in dairy cow mammary epithelial cells during mid-lactation. Subsequently, we silenced the prolactin receptor (PRLR) gene by siRNA interference technology in dairy cow mammary epithelial cells, and detected the PRLR gene silencing effect silencing and the expression of LAT1 by qRT-PCR and Western blotting. We also tested Î^{2}-casein in mammary epithelial cells by high performance liquid chromatography (HPLC). Immunofluorescence results showed that LAT1 and 4F2hc co-expressed in the apical and basolateral membrane of duct and acinus epithelium at different stages of mammary gland. The expression of LAT1 and 4F2hc were significantly upregulated during lactation ($P < 0.05$). LAT1 mRNA expression were greatly increased prolactin dose range (5, 10, 20, 40 and 60 Î1/4g/ml), and LAT1 had the highest expression level at 20 Î1/4g/ml prolactin stimulation group. This result conformed to the result of Western blotting. In siRNA-PRLR transfection group, the expression of LAT1 exhibited a differentially reduction ($P < 0.05$). In addition, both secretion of Î^{2}-casein and cell activities were also obviously decreased in transfected cells. These results indicated that PRL-PRLR signaling pathways were most likely to play a major role in the regulation of LAT1 expression during lactation, and LAT1 may play a role during the development and lactation of dairy cow mammary gland.

Key Words: dairy cow, mammary epithelial cells, LAT1

W152 Bzw2 promotes proliferation and lactation of mammary epithelial cell in dairy goat.

R. Sun, Q. Li,* H. Yan, J. Zhao, X. Gao, and N. Zhang, *The Key Laboratory of Dairy Science, Ministry of Education, Northeast Agricultural University, Harbin, Heilongjiang, China.*

Mitosis of mammary epithelial cell is the foundation of mammal lactation. We developed a strategy of combined application of serial analysis of gene expression (SAGE) tags for gene identification (GLGI) to screen and identify genes influenced lactating ability of mammary epithelial cell in the dairy goat. The Bzw2 gene was found as a candidate gene related to lactation by screening Long-SAGE library of mammary gland in the dairy goat. This study was to identify the Bzw2 gene function during lactation in the dairy goat mammary gland. The Bzw2 gene was cloned by SMART RACE from Long-SAGE tag. The mRNA level of Bzw2 was relatively higher in early lactation than in other development stages of the mammary gland. The proliferation of mammary epithelial cell was inhibited by transfecting specific shRNA of Bzw2, The mRNA level of Stat5, Csn2 and Prlr were also downregulated, which would suggest that the productivity of the mammary epithelial cell was attenuated after Bzw2 RNAi. The reduction of mammary cell growth and lactation by Bzw2 RNAi are rescued through overexpression of Bzw2. These results revealed that Bzw2 might play an important role in lactation though the molecular mechanism which was still to be discovered by studies.

Key Words: Bzw2, mammary epithelial cells;, RNAi

W153 CLA and diet induced milk fat depression reduces milk fat across the entire day.

K. Cook[1], K. J. Harvatine*[1], and D. E. Bauman[2], [1]*Penn State University, University Park,* [2]*Cornell University, Ithaca, NY.*

Recently a circadian rhythm of milk and milk component synthesis has been characterized that is partially dependent on the timing of feed intake. Our objective was to determine if inhibition of milk fat synthesis during diet-induced milk fat depression occurred to a higher degree during certain phases of the day. A retrospective analysis was conducted of 2 experiments that induced milk fat depression while milking cows at equal intervals, 3 times per day. The response at each milking was analyzed using the Proc Mixed procedure of SAS with a repeated statement. The model included the fixed effect of treatment, milking time, and the interaction of milking time and treatment and the random effect the cow and period. The subject was cow by period with the ARH1 covariance structure. In Experiment 1, 9 multiparous cows were arranged in a 3 × 3 Latin square design. Treatments were control TMR, control TMR plus 3 d intravenous infusion of 7.5 g/d of trans-10, cis-12 conjugated linoleic acid (CLA), and a low forage and high fat diet for 10 d. In Experiment 2, 10 multiparous ruminally cannulated cows were arranged in a replicated design and milk samples were collected during a control period or after 5 d of abomasal infusion of 10 g/d of CLA. In Experiment 1 there was a significant effect of treatment and milking for milk fat concentration and yield ($P < 0.001$ and $P < 0.05$, respectively), but no interaction of milking time and treatment. In Experiment 2, there also was an effect of treatment and milking time on milk fat concentration ($P < 0.05$) and no treatment by milking time interaction. There was a treatment, but no milking time or treatment by milking time interaction on milk fat yield. Milk fat percent was 0.48 and 0.28 percentage units lower at the morning milking than the afternoon milking in Exp. 1 and Exp. 2, respectively. A daily rhythm of milk fat concentration and yield can be observed in cows milked 3 times a day. However, diet-induced milk fat depression decreases milk fat yield equally over the day.

Key Words: milk fat, CLA, circadian

W154 Dairy cows having various levels of *cis*-9, *trans*-11 CLA de novo synthesis differently express proteins in milk epithelial cells.

H. G. Lee*[1], T. Wang[1], J. N. Lim[1], J. D. Bok[2], J. H. Kim[3], S. B. Lee[1], S. K. Kang[2], J. H. Hwang[1], K. H. Lee[1], H. S. Kang[1], and Y. J. Choi[2], [1]*Department of Animal Science, Pusan National University, Miryang, Gyeongnam, Korea,* [2]*Department of Agricultural Biotechnology, Seoul National University, Seoul, Korea,* [3]*Research and Technology Center, Cargill Agri Purina, Seongnam, Gyeonggi, Korea.*

The objective of this study was to associate cows having various levels of *cis*-9, *trans*-11 CLA to different protein expression profiles of milk epithelial cells. Morning milks were collected individually from 26 multiparous Holstein cows in their third or fourth lactation fed the same diet. Total milk lipids of each sample were extracted following the Folch method and the lipid methyl esters were quantified by GC with a SP-2560 fused silica capillary column. Milk epithelial cells were extracted from the fresh milk by the Boutinaud method. All data were evaluated by GLM of SPSS using ANOVA. On the basis of *cis*-9, *trans*-11 CLA contents, the animals were grouped into group I (0.59% of total lipids;

n = 7), II (0.85% of total lipids; n = 8) and III (1.02% of total lipids; n = 11). Protein aliquots extracted from milk epithelial cells were pooled in each group. Differences in protein expression among these groups were compared with 2-DE. The differently expressed spots (III/I; ≥ 2 or ≤ 0.5) were identified using ESI-Q-TOF and a protein search engine. Although animals were offered the same diet, the content of *cis*-9, *trans*-11 CLA in group III (1.02 ± 0.10%) was twice as high as that in group I (0.59 ± 0.14%) ($P < 0.05$). The groups I, II and III showed significant differences in the protein expression profiles of milk epithelial cells ($P < 0.05$). One upregulated (CATHL5) and 3 downregulated proteins (ANXA1, ZWINT, CSN3) were found and they varied similarly as the pattern of *cis*-9, *trans*-11 CLA contents. In conclusion, the different levels of *cis*-9, *trans*-11 CLA de novo synthesis of dairy cows may associate with these identified proteins expressed in milk epithelial cells.

Key Words: *cis*-9, *trans*-11 CLA de novo synthesis, protein expression profiles, purified milk epithelial cells

W155 Modification of protein synthesis of bovine mammary epithelial cells induced by heat shock. H. Hu, J. Q. Wang,* D. P. Bu, L. Y. Zhou, and P. Sun, *State Key Laboratory of Animal Nutrition, Institute of Animal Science, Chinese Academy of Agricultural Sciences, Beijing.*

The objective of this study was to determine the effect of heat stress on protein synthesis by Chinese bovine mammary epithelial cells (CMEC). The CMEC has been identified to be a normal and available epithelial cell line. The CMEC cultured in vitro were exposed to 42°C for 0.5, 3, 5, 8, 12 h, and controls were exposed to 38°C. Heat shock protein (Hsp) and casein expression of gene and protein were detected by qRT-PCR and ELISA, separately. The mean, SD, and *P* values were calculated from triplicated experiments using SARS (9.0). The Student's *t*-test was used to calculate *P*-values for comparison, and the significant statistics was set at a *P*-value < 0.05. The transcription of Hsp genes (*hsp27*, *70* and *90*) was enhanced ($P < 0.05$) as of 0.5 h of heat stress. The peak of transcription was observed at 3 h after the onset of thermal treatment. Although the transcription rates returned subsequently to baseline values, they were still upregulated ($P < 0.05$) compared with controls at 12 h. The expression of Hsp27, 70 and 90 increased at different rates. The expression of Hsp27 and Hsp70 increased gradually during the first 8 h, and then decreased, yet all values were higher than those of the control over the entire thermal stress period ($P < 0.05$). On the other hand, the Hsp90 expression only increased at 8 h. Among the Hsp, Hsp70 was acutely synthesized, and the transcription and protein expression of Hsp70 were 10 times and 3 times greater than the control group at 0.5 h and 8 h, respectively. The major milk protein genes β-casein (*CSN2*) and butyrophilin (*BTN1A1*), which are markers for the secretion capacity of bovine mammary epithelial cells, were both downregulated with heat stress from 0.5 h to 12 h ($P < 0.05$). Total casein synthesis decreased from 3 to 8 h ($P < 0.05$), corroborating the decline in milk protein secretion. Results suggest that under heat stress, normal biological activities of CMEC are disturbed and the decrease in milk protein synthesis of epithelial cells contributed to synthesize heat shock proteins thereby protecting cells from heat damage. This result might potentially explain the reduction of milk formation induced by heat stress.

Key Words: mammary epithelial cells, heat stress, heat shock protein

W156 Choline and methionine affect oxidative stress in a bovine mammary epithelial cell line. L. Pinotti*[1], E. Skrivanova[2], R. Rebucci[1], E. Fusi[1], F. Cheli[1], and A. Baldi[1], [1]*Department of Veterinary Sciences and Technology for Food Safety, Università degli Studi di Milano, Milan, Italy,* [2]*Institute of Animal Science, Prague, Czech Republic.*

The aim of the present study was to investigate the role of choline and methionine in modulating the oxidative stress induced by hydrogen peroxide in bovine mammary epithelial cells. The BME-UV1 cell line has been used as an in vitro model of the bovine mammary epithelium. Cells were incubated with choline and methionine at 2 different concentrations: LowCM,500 µM and 715 µM for choline and methionine, respectively, or HighCM, 1000 µM and 1430 µM, for choline and methionine, respectively. The ratio between choline and methionine has been established on a molar basis. In both treatments, the cells were cultured in presence of insulin (1 µg/ml). In dose response experiments, cells were exposed to increasing concentrations of hydrogen peroxide (0 to 500 µM) to establish the half lethal concentration (LC50) of hydrogen peroxide for the BME-UV1 cell line. Cell proliferation (MTT test) was measured at different incubation times (24, 48 and 72h), whereas apoptosis (TUNEL) was measured at 48h. Incubation time affected the response to hydrogen peroxide. At the lowest range of hydrogen peroxide concentration tested (15.62 to 62.5 µM) choline and methionine significantly ($P \leq 0.05$) enhanced cell viability on average by 19%, 21% and 25.8% after 24, 48 and 72h, respectively. Supplemental choline and methionine in the medium exerted a dose dependent effect on apoptosis of BME-UV1 cells: percentages of apoptotic cells were 0.42%, 1.35%, in HighCM and LowCM treated cells, respectively, whereas apoptosis in hydrogen peroxide treated cells was 6.81% for the same range of hydrogen peroxide concentration tested. Our results indicate that choline and methionine could play a role in counteracting oxidative damage induced by hydrogen peroxide in bovine mammary epithelial cells, even though the exact mechanism merits further investigations.

Key Words: choline, methionine, bovine mammary epithelial cell

Nonruminant Nutrition: Feed Additives

W157 Effects of dietary Aviplus-S supplementation on growth performance, fecal characteristics, and blood profiles in weanling pigs. J. H. Cho,* L. Yan, and I. H. Kim, *Department of Animal Resource & Science, Dankook University, Cheonan, Choongnam, South Korea.*

A total of 150 weanling pigs [(Landrace × Yorkshire) × Duroc, BW = 6.76 ± 0.61 kg] were used in a 42-d trial to investigate the effects of dietary Aviplus-S supplementation on growth performance, fecal score, fecal moisture, fecal pH, and blood profiles. Pigs were randomly assigned to 1 of 5 treatments according to BW. Dietary treatments were NC, basal diet (without antibiotics); PC, NC + 39 mg/kg tiamulin; AS1, NC + 0.05% Aviplus-S; AS2, NC + 0.1% Aviplus-S; AS3, NC + 0.2% Aviplus-S. Aviplus-S is based on a mixture of citric (25%) and sorbic (16.7%) acids, thymol (1.7%) and vanillin (1.0%). All pigs were housed in an environmentally controlled room and allowed ad libitum access to feed and water. All statistical analyses were conducted in accordance with a randomized complete block design, using the GLM procedures of SAS software package (1996). During d 0–7, ADFI was reduced ($P < 0.05$) in AS1 treatment compared with PC treatment, and G/F in AS1, AS2 and AS3 treatments were higher ($P < 0.05$) than those in NC and PC treatments. During d 7–21, lower ($P < 0.05$) ADFI was noted in AS1 and AS2 treatments than that in PC treatment, and no differences ($P > 0.05$) in ADG and G/F were observed among treatments. During d 21–42, pigs fed the PC diet had a higher ($P < 0.05$) ADG than those fed the NC diet, and the G/F was higher ($P < 0.05$) in PC treatment than those in NC and AS1 treatments. Overall, the ADG and G/F in PC treatment were higher ($P < 0.05$) than that in NC treatment. Fecal scores were reduced ($P < 0.05$) in AS2 treatment compared with NC treatment. Fecal moisture was unaffected ($P > 0.05$) by dietary treatments. Fecal pH was decreased ($P < 0.05$) in AS1 and AS2 treatments compared with NC treatment at d 7, and fecal pH was reduced ($P < 0.05$) in AS1, AS2 and AS3 treatments compared with NC and PC treatments at d 21. No differences ($P > 0.05$) were observed in blood profiles among dietary treatments. In conclusion, Aviplus-S could be used as an alternative for antibiotics in weanling pigs.

Key Words: Aviplus-S, growth performance, weanling pigs

W158 Effects of Alcopro supplementation as energy source on growth performance, nutrient digestibility, and blood characteristics in growing pigs. J. H. Cho*[1], P. Y. Zhao[1], K. D. Yang[2], S. W. Han[2], and I. H. Kim[1], [1]*Dankook University, Department of Animal Resource & Science, Cheonan, Choongnam, South Korea,* [2]*WooGene B&G, Seoul, South Korea.*

A total of 96 growing pigs [(Landrace × Yorkshire) × Duroc, BW = 26.12 ± 1.21 kg] were randomly allotted to 1 of 3 dietary treatments (8 replicate pens per treatment with 4 pigs per pen) to investigate the effects of Alcopro supplementation as energy source on growth performance, nutrient digestibility, and blood characteristics. This experiment lasted for 42 d. All the pigs were housed in an environmentally controlled room with a slatted plastic floor in 24 adjacent pens (1.8 × 1.8 m). Dietary treatments included: 1) CON (basal diet with 4% tallow), 2) A1 (basal diet with 2% tallow + 1% Alcopro + 1% corn), 3) A2 (0% tallow basal diet + 2% Alcopro + 2% corn). Alcopro is based on ethyl alcohol containing energy source (about 10,000 kcal/kg ME) and digestive enzymes for livestock. Data were analyzed using GLM procedures of SAS (1996), with each pen being used as the experimental unit, and the means of the treatments were compared by Duncan multiple range test. No significant difference ($P > 0.05$) was observed on the energy level changed between A1 (1% Alcopro) and A2 (2% Alcopro) diets during 4 d storage at the room temperature. No difference ($P > 0.05$) was observed on ADG, ADFI, and G/f throughout the experiments. However, pigs fed the A1 and A2 diets led to 72g (5%) and 65 g (4%) higher ADFI than those fed the CON diet, although the difference did not reach the significant level. No difference ($P > 0.05$) was observed on the apparent total tract digestibility of DM, N, and energy among treatments. There was no difference ($P > 0.05$) in the concentrations of WBC, RBC, BUN, creatinine, and Lymphocyte percentage during the experimental period. In conclusion, no negative effects were observed when Alcopro® was supplemented as energy source in growing pigs. This study indicated that Alcopro® could be used as an energy source for growing pigs and could partly replace tallow in the pig industry.

Key Words: Alcopro, growing pigs, growth performance

W159 Effects of Calibrin-Z on weanling pigs fed diets with no mycotoxin contamination. F. Chi[1], S. L. Johnston*[1], and D. C. Mahan[2], [1]*Amlan International Inc., Chicago, IL,* [2]*The Ohio State University, Columbus.*

Some clay-based mycotoxin binders have been shown to bind nutrients. However, in previous research Calibrin-Z (CAZ) has been shown to increase nutrient digestibility and has shown a tendency to improve feed efficiency. This would seem to indicate that CAZ either did not bind nutrients or might bind nutrients and release them during passage through the digestive tract leading to higher availability. In the current experiment 160 weanling pigs were used to evaluate the effects of CAZ in diets that had no mycotoxin challenge. The treatments were: 1) control diet; and 2) the control diet with 0.2% CAZ added. Treatment diets were fed from d 0 to d 35 post-weaning (average initial wt = 6.79 kg). There were 16 pens of 5 pigs each on each treatment, pen was the experimental unit. Diets were complex nursery feeds with 3 dietary phases: d 0–7, d 7–21, and d 21–35. The responses to CAZ added at 0.20% of the diet were analyzed in all replicates, the 7 lightest weight replicates, and the 9 heavier weight replicates. There was a numerical advantage ($P = 0.11$) for average daily gain in the 7 to 21 d period when CAZ was fed to all pigs, with values of 513 and 538 g per day for pigs fed the control diet or the control diet + CAZ, respectively. This was mainly due to a numerical advantage ($P = 0.06$) when CAZ was fed to the heaviest pigs. There was no other effect on growth performance with overall values for average daily gain of 525 g or 532 g, for daily feed intake of 783 g or 785 g, or gain:feed of 672 g/kg or 679 g/kg, for pigs fed the control diet or the control +CAZ respectively. At d 21 and 35 of the experiment pigs in 6 replicates were bled and plasma urea nitrogen concentrations were analyzed. There was no difference ($P = 0.19$) between plasma urea nitrogen concentrations on d 21 but it was significantly ($P < 0.01$) higher on d 35 in pigs fed diets containing CAZ, with values of 33.0 and 38.7, mmol/l. These results may indicate that there was higher amino acid availability when pigs were fed CAZ.

Key Words: feed efficiency, Calibrin-Z, plasma urea nitrogen

W160 Bovine lactoferrampin-lactoferricin produced by *Pichia pastoris* fed-batch fermentation improves intestinal microflora in weaned piglets. X. S. Tang and Y. L. Yin,* *Institute of Subtropical Agriculture, the Chinese Academy of Sciences, Changsha, China.*

The chimera of bovine lacroferrampin and lactoferricin, a promising alternative to antibiotics, namely lactoferrampin-lactoferricin (LFA-LFC) has stronger activity than its constituent peptides. In this study, LFA-LFC was produced by fed-batch fermentation in recombinant strain *P. pastoris* (KM71) XS10 constructed by our group. Uniform design U6(64) was used to optimize the fermentation conditions. The target peptide was purified by cation-exchange and size-exclusion chromatography, and identified by antimicrobial activity assay and MALDI-TOF MS. Then the purified sample was added into diet for weaned piglets at 21 d of age. After the following 21 d experimental period, lactobacilli, bifidobacteria and *E. coli* of gut were quantified by real-time PCR. The data were subjected to one-way ANOVA and least significant difference was performed to identify differences among the groups using the SPSS 15.0 program. Results showed that approximately 85 mg of LFA-LFC was secreted into 1 L of medium under the optimized conditions. Purified peptide with a purity of 91% showed antimicrobial activities against all the tested *E. coli* and had the same molecule mass as target peptide. Compared with control group, LFA-LFC group increased the ratio of lactobacilli and bifidobacteria ($P < 0.01$) in gut of piglets including stomach, duodenum, jejunum, ileum, colon and cecum. LFA-LFC group decreased the ratio of *E. coli* in stomach, duodenum and jejunum. These results show that diet supplementation with LFA-LFC can improve gut microbiota in weaned piglets.

Key Words: pig, antimicrobial peptide, microflora

W161 Effects of feeding capsicum oleoresin, garlicon, or turmeric oleoresin on gene expression of ileal mucosa of pigs. Y. Liu*[1], M. Song[1], T. M. Che[1], J. A. Soares-Almeida[1], J. J. Lee[1], D. Bravo[2], C. W. Maddox[1], and J. E. Pettigrew[1], [1]*University of Illinois, Urbana,* [2]*Pancosma SA, Geneva, Switzerland.*

This study was conducted to characterize the effects of 3 plant extracts on gene expression in ileal mucosa of weaned pigs. Weaned pigs (n = 64, 6.3 ± 0.2 kg BW, 21 d old) were housed in individual pens for 15 d: 4 d before and 11 d after the first inoculation (d 0). Treatments were in a 2 × 4 factorial arrangement: with or without an F-18 *E. coli* challenge and 4 diets (a nursery basal diet (CON), 10 ppm of capsicum oleoresin (CAP), garlicon (GAR), or turmeric oleoresin (TUR)). Total RNA (4 pigs/treatment) was extracted from ileal mucosa of pigs at d 5. Double-stranded cDNA was amplified, labeled, and further hybridized to the Affymetrix GeneChip Genome Array. Microarray data were analyzed in R using packages from the Bioconductor project. Differential gene expression was tested by fitting a mixed linear model equivalent to a 2 × 4 factorial ANOVA using the limma package. Bioinformatics analysis was conducted by DAVID Bioinformatics Resources. Three pairwise comparisons were made in the sham group: CAP vs. CON, GAR vs. CON, and TUR vs. CON. Compared with the CON, feeding CAP altered the expression of 490 genes (280 up, 210 down), feeding GAR altered the expression of 35 genes (17 up, 18 down), while feeding TUR altered the expression of 327 genes (232 up, 95 down). Compared with the CON, feeding CAP and TUR increased ($P < 0.05$) the expression of genes related to membrane and tight junctions, suggesting enhanced gut mucosa health, but decreased ($P < 0.05$) the pathway of cell cycle. Feeding GAR and TUR enhanced ($P < 0.05$) the expression of genes associated with immune responses, indicating feeding these plant extracts may stimulate the immune responses of pigs in the normal conditions. These findings may explain, at least partially, why diarrhea was reduced in pigs fed plant extracts in the sham group. In conclusion, plant extracts regulated the expression of genes in ileal mucosa of pigs, perhaps providing benefits by enhancing the gut mucosa health and stimulating the immune system.

Key Words: gene expression, plant extracts, weaned pigs

W162 Productive performance in post-weaned pigs conditioned by pre and postnatal porcine digestive peptides (PDP) exposure through maternal diet. J. Figueroa*[1], D. Solà-Oriol[1], E. Borda[2], S. A. Guzmán-Pino[1], and J. F. Pérez[1], [1]*Universitat Autònoma de Barcelona, Bellaterra, Barcelona, Spain,* [2]*Bioibérica, Barcelona, Spain.*

Piglets present neophobia to unfamiliar ingredients at weaning. Preferences for a novel feed or flavor may be acquired as a result of the transmission of volatile compounds of maternal diet to the amniotic fluid and milk. The aim of the present study was to explore the influence of pre- and postnatal exposure to porcine digestive peptides (PDP) via maternal diet on the productive performance of post-weaned piglets fed a diet containing the same PDP. A total of 240 male/female post-weaned pigs were used in this experiment. Half of animals came from mothers that during late gestation (14d) and lactation (28d) ate 2% PDP in their diets. The other 120 piglets came from mothers fed an iso-caloric and iso-proteic diet but without PDP inclusion in these periods. Piglets were distributed into 4 blocks by initial weight. Within each block, pigs were distributed in pens for a balanced body weight. Each block consisted of 6 pens of 10 animals. All animals received a common weanling diet containing 2% of PDP in the pre-starter (0–14d) and starter (15–35d) specification during the transition period. Feed intake and body weight were weekly measured to calculate average daily feed intake (ADFI), average daily gain (ADG) and feed:gain ratio (FGR). Data were analyzed by using the GLM procedure of SAS. Piglets coming from sow's diets supplemented with PDP tend to showed higher ADFI during the 15–35d period (740 vs. 693g; $P = 0.07$). Similarly results were observed for ADG in piglets coming from PDP-treated sows during the 0–14d period (144 vs. 137g) and during the 15–35d period (502 vs. 471g; $P < 0.06$). No differences were observed for FCR along the experimental period. Therefore the final body weight at the end of the starter phase tended to be higher for those animals coming from mothers fed PDP supplemented diets (20.1 vs. 19.3kg; $P = 0.1$). These results suggest that pre and postnatal exposure to PDP via maternal diet may influence piglet performance in the presence of the same cues probably due to the positive association of the uterine or milk experience with these feed components.

Key Words: pigs, flavors, maternal-transference

W163 Effects of chitosan nanoparticles loaded with chromium ions on growth, blood metabolites, immune traits and tissue chromium in finishing pigs. M. Q. Wang,* C. Wang, H. Li, Y. J. Du, W. J. Tao, S. S. Ye, and Y. D. He, *Animal Science College of Zhejiang University, Hangzhou, Zhejiang, China.*

Nanocomposite materials have a higher surface area and smaller size than typical materials, and they exhibit electrical, magnetic, mechanical and biological characteristics which may enhance mineral absorption. The present study was conducted to investigate the effects of chitosan nanoparticles loaded with chromium ions (CNP-Cr) on carcass characteristics, pork quality and lipid metabolism in finishing pigs. A total of 120 crossbred barrows (66.06 ± 1.01 kg initial BW) were randomly divided into 4 treatment groups, with 4 pens of 10 pigs per group. Pigs were fed a basal diet (corn-soybean meal, 10.5 g/kg of Lys) supplemented without (control), or with 100, 200 or 400 µg/kg Cr from CNP-Cr. All pigs were given free access to feed and water. Eight pigs from each treatment were selected to collect blood and tissue samples after 35 d on trial for analysis of blood metabolites, immune traits, and tissue chromium concentrations. Results suggested no significant differences in growth performance between control and CNP-Cr-treated groups. Supplementation of 200 µg/kg CNP-Cr decreased serum glucose ($P < 0.05$). Serum immunoglobulin A was increased with supplementation of CNP-Cr ($P < 0.05$). Serum immunoglobulins G and M in pigs receiving 400 µg/kg CNP-Cr and serum complement in pigs receiving 100 µg/kg CNP-Cr were increased ($P < 0.05$). CNP-Cr supplementation increased chromium content in blood, longissimus muscle, heart, liver, kidney and pancreas in a linear fashion ($P < 0.05$). These results suggest that dietary supplementation of Cr as CNP-Cr affects serum glucose and immune status, and increases tissue Cr content of muscle and selected organs in finishing pigs.

Key Words: chromium, immune trait, blood metabolite

W164 Effects of fermented chlorella supplementation on growth performance, nutrient digestibility, and blood characteristics in growing pigs.

B. R. Lee*[1], J. Li[1], S. U. Lim[2], and I. H. Kim[1], [1]*Department of Animal Resource & Science, Dankook University, Cheonan, Choongnam, South Korea,* [2]*Ace M&F Ltd., Seoul, South Korea.*

A total of 96 growing pigs [(Landrace × Yorkshire) × Duroc, BW = 26.58 ± 1.41 kg] were used in a 6-week feeding trail to evaluate the effects of fermented chlorella (FC) supplementation on growth performance, nutrient digestibility, and blood characteristics. Pigs were randomly allotted into 1 of 4 dietary treatments with 6 replicate pens per treatment and 4 pigs per pen. Dietary treatments were: 1) NC, basal diet (without antibiotics); 2) PC, NC + 0.05% tylosin; 3) FC01, NC + 0.1% FC, and 4) FC02, NC + 0.2% FC. All diets were formulated to meet or exceed NRC (1998) recommendations for growing pigs. All the pigs were housed in an environmentally controlled room with a slatted plastic floor. Each pen was equipped with a 1-sided self-feeder and a nipple drinker, pigs were allowed ad libitum access to feed and water throughout the experimental period. Pigs fed the PC diet had a higher ($P < 0.05$) ADG than those fed the NC diet. No differences ($P > 0.05$) were observed in ADFI and G/f among dietary treatments throughout the experimental period. The apparent total tract digestibility (ATTD) of DM in PC treatment was higher ($P < 0.05$) than that in NC treatment. However, no difference ($P > 0.05$) was noted in the ATTD of N and energy among treatments. The concentrations of RBC, WBC, IgG, AST, ALT, and lymphocyte percentage were unaffected ($P > 0.05$) by dietary treatments. Fecal moisture content and fecal pH were also not affected ($P > 0.05$) by dietary supplementation with FC. In conclusion, the application of FC had no negative effects on growth performance, nutrient digestibility, and blood profiles in growing pigs, further studies should be conducted to confirm the growth promoting effect of FC in growing pigs.

Key Words: fermented chlorella, growing pigs, growth performance

W165 The efficacy of using the external marker LIPE to predict digestibility values in Nile tilapia (*Oreochromis niloticus*) fed contrasting diets.

R. Jones[1], O. Evans[1], E. A. Teixeira[2], E. O. S. Saliba[2], V. B. Silva[2], K. C. M. Filho[2], J. S. Saliba[2], S. J. Meale*[1], and A. V. Chaves[1], [1]*Faculty of Veterinary Science, University of Sydney, Sydney, NSW, Australia,* [2]*Laboratório de Aquacultura da Universidade Federal de Minas Gerais, Escola de Veterinária, Departamento de Zootecnia, Belo Horizonte, MG, Brazil.*

Measuring diet digestibility of formulate feeds is essential to determining which diets will maximize growth and feed conversion ratios (FCR). Inert dietary digestibility markers are one such method used to determine dry matter digestibility (DMD), organic matter digestibility (OMD), crude protein digestibility (CPD) and the digestibility of digestible energy (DDE) within diets. The main objective of this study was to determine whether the dietary marker LIPE can be successfully utilized as a digestibility marker in fish nutritional studies, by examining its efficacy in predicting digestibility values of juvenile Nile tilapia (*Oreochromis niloticus*) fed contrasting diets. Three treatment diets were formulated (low fat/low starch, high fat, high starch) each containing LIPE and chromic oxide at 0.1 g/kg and 1 g/kg respectively. Diets were randomly assigned to 12 tanks suitable for collection of feces via the Guelph method. Four replicates were used and each tank contained 15 juvenile tilapia. The experiment itself was a split-plot design with diets allocated to the main plots and method of assessing digestibility to the subplots. Data were analyzed using the MIXED model of SAS. Means analysis was used to assess the effect of diet, marker and diet × marker interaction on marker performance. LIPE® and chromic oxide were evaluated against actual values across all treatment groups using 2 statistical methods; linear regression and measures of deviation. Diet x marker interaction was found to be significant ($P \leq 0.05$) for DMD ($P = 0.02$), OMD ($P < 0.01$) and DDE ($P = 0.05$), but was not significant for CPD ($P = 0.06$). CPD was influenced by method ($P < 0.01$). Linear regression showed both LIPE® and chromic oxide predicted values to be weakly correlated with actual values for DMD, OMD, CPD and DDE. Measures of deviation analysis suggested both LIPE® and chromic oxide to overestimate DMD, OMD, CPD and DDE. It can be concluded that both LIPE and chromic oxide were poor markers of apparent energy and nutrient digestibility in juvenile Nile tilapia fed contrasting diets.

Key Words: feed formulation, Nile tilapia, marker performance

W166 Validation of the external marker Nanolipe as an indicator of apparent nutrient and energy digestibility in juvenile Nile Tilapia (*Oreochromis niloticus*).

O. Evans[1], R. Jones[1], E. A. Teixeira[2], E. O. S. Saliba[2], V. B. Silva[2], K. C. M. Filho[2], J. S. Saliba[2], S. J. Meale*[1], and A. V. Chaves[1], [1]*Faculty of Veterinary Science, University of Sydney, Sydney, NSW, Australia,* [2]*Laboratório de Aquacultura da Universidade Federal de Minas Gerais, Escola de Veterinária, Departamento de Zootecnia, Belo Horizonte, MG, Brazil.*

Nanolipe is a new, never before tested, external marker created for use in fish digestibility studies. Nanolipe was evaluated in juvenile Nile Tilapia (*Oreochromis niloticus*) against the traditional methodologies of total collection and titanium(III) oxide. The experiment was a split plot design with 3 contrasting diets (low fat/low starch, high fat, high starch) representing the main plots and 3 different marker methods (total collection, titanium(III) oxide, Nanolipe) representing the subplots, with 4 replicates. Twelve tanks were used, each containing 15 juvenile fish (35 ± 6.6 g). Feces were collected via the Guelph method. Dry matter, organic matter, crude protein and digestible energy digestibilities were assessed. Means analysis was used to assess the effect of diet, marker and diet × marker interaction on marker performance. Nanolipe and titanium(III) oxide were evaluated against actual values using 3 statistical methods; concordance correlation, linear regression and measures of deviation. Nanolipe was found to overestimate digestibility for all dietary components assessed in the low fat/ low starch and high fat diets, but underestimated digestibility for the high starch diet. Titanium(III) oxide was found to underestimate digestibility for all dietary components assessed in the low fat/low starch, high fat and high starch diets. Diet × marker interaction was found to be significant ($P > 0.05$) for both Nanolipe and titanium(III) oxide for all dietary components assessed in all of the low fat/ low starch, high fat and high starch diets. Both Nanolipe and titanium(III) oxide predicted values of estimate digestibility, for all dietary components, were poorly correlated with actual values by concordance correlation. Linear regression showed a significant correlation between Nanolipe and actual values for dry matter digestibility ($R^2 = 0.54$), but a poor correlation between Nanolipe and actual values for digestible organic matter ($R^2 = 0.37$), crude protein ($R^2 = 0.38$), and digestible energy ($R^2 = 0.17$). Measures of deviation analysis showed Nanolipe to over predict the digestibility of dry matter, organic matter, crude protein and digestible energy compared with actual values, while titanium(III) oxide consistently under predicted the digestibility of all dietary components assessed. It can be concluded that both Nanolipe and titanium(III) oxide were poor markers of apparent nutrient and energy digestibilities in feeds utilized by juvenile Nile tilapia. Further studies are evidently needed to understand the exact mechanisms of diet × marker interactions.

Key Words: diet composition, Nile tilapia, markers

W167 Total serum cholesterol and triglycerides concentrations in broilers fed with diets containing different sources of oil associated with conjugated linoleic acid (CLA). V. C. da Cruz*[1], R. F. de Oliveira[1], G. do Valle Polycarpo[2], V. B. Fascina[3], L. H. Zanetti[1], G. A. M. Pasquali[1], R. Crivellari[1], L. C. Carvalho[1], and C. C. do Valle Polycarpo[4], *[1]São Paulo State University, Dracena Campus, Dracena, São Paulo, Brazil, [2]University of São Paulo, Pirassunga Campus, Pirassununga, São Paulo, Brazil, [3]São Paulo State University, Botucatu Campus, Botucatu, São Paulo, Brazil, [4]São Paulo State University, São José do Rio Preto Campus, São José do Rio Preto, São Paulo, Brazil.*

This study was carried out at São Paulo State University, Dracena Campus, Brazil, to evaluate total serum cholesterol and triglycerides concentrations of broilers at 21 and 42-d of age, fed with diets containing 2 levels of CLA (0.5% and 1.0%) associated to 3 oil sources (soybean oil, fish oil and linseed oil). A total of 840 1-d-old male Cobb chicks were distributed in a completely random design with 7 treatments and 4 replications. Broilers received the following treatments: T1- control diet without adding oils and CLA; T2- diet containing soybean oil associated to 0.5% CLA; T3- diet containing fish oil associated to 0.5% CLA; T4- diet containing linseed oil associated to 0.5% CLA; T5- diet containing soybean oil associated to 1.0% CLA; T6- diet containing fish oil associated to 1.0% CLA; T7- diet containing linseed oil associated to 1.0% CLA. At 21 and 42-d of age, 8 birds per treatment were killed for collection of 5 mL of blood through the wing brachial vein. No significant effects of treatments were observed for total serum cholesterol ($P > 0.05$) and triglycerides ($P > 0.05$) concentrations in the periods of 21 and 42 d of age. These results can be explained by the good nutritional quality of oil sources used in this research, which are rich in unsaturated and polyunsaturated fatty acids. The inclusion of CLA in the feeding of broilers seems to have influence on lipid metabolism, with positive effects or not, depending on the supplementation phase and the oil source used. In conclusion, the total serum cholesterol and triglycerides concentrations are not altered by CLA and by dietary lipid sources. The mechanisms of action of CLA about the metabolism of fats are not completely known; therefore further research related to cholesterol and triglyceride levels in broiler diets is needed.

Key Words: poultry, oil sources, serum lipids

W168 Effect of dietary oregano (*Origanum vulgare* L.) essential oil on growth performance of broiler chickens fed with diets of different metabolizable energy levels. **E. van Eerden[1], L. Star[1], P. van der Aar[1], and L. Z. Jin*[2],** *[1]Schothorst Feed Research, Lelystad, the Netherlands, [2]Meriden/Meritech Biotech, Guangzhou, China.*

This study was to investigate the effect of dietary oregano (*Origanum vulgare* L.) essential oil on body weight, feed conversion rate and mortality of broiler chickens fed with diets of the 4 different metabolizable energy levels. A total of 960 one-day-old male Ross 308 broiler chickens were divided into 8 treatments and each treatment had 6 replicates with 20 broilers each. The 8 treatments were arranged to 2 × 4 factorial trial design with supplementation of an oregano essential oil (Orego-Stim, Meriden, UK) at 2 levels (0 and 150 g per ton of feed) and 4 energy levels (standard, standard minus 0.33%, 0.66% and 1.0% fat). During the starter phase (d 0 to 15), all diets had the same energy level. The energy treatments were implemented in the grower phase (d 15 to 30) and the finisher phase (d 31 to 36). All parameters were evaluated by ANOVA using Genstat statistical software. Treatment means were compared by the least significant difference (LSD). The results demonstrated that the addition of oregano essential oil resulted in a significantly ($P < 0.05$) higher body weight gain and lower feed conversion ratio in the starter phase. Feed conversion ratio showed a significant effect of energy level ($P = 0.041$) and a near-significant trend of oregano essential oil ($P = 0.052$) in the grower phase. The lowest energy levels had the highest feed conversion ratios, whereas addition of oregano essential oil tended to result in a lower feed conversion ratio in the grower phase. In the overall production period the result showed that there is no significant differences of body weight gain, feed conversion ratio, final body weight, or mortality between the control group and the treatment group of broilers fed with ME-reduced diet supplemented with the oregano essential oil.

Key Words: oregano essential oil, broilers, energy level

W169 Growth performance, nutrient digestibility, and carcass traits of rabbits fed diets added with DDGS or hemicellulases and glucanases. H. Bernal Barragán*[1,4], J. E. Gallegos Balderas[1], M. A. Liñán González[1], C. A. Hernández Martínez[1], F. G. Ríos Rincón[2,4], M. A. Cerrillo Soto[3,4], N. C. Vásquez Aguilar[1], and A. S. Juárez Reyes[3,4], *[1]Universidad Autónoma de Nuevo León, Fac. de Agronomía, San Nicolás de los Garza, NL, México, [2]Universidad Autónoma de Sinaloa, Fac. de Medicina Veterinaria y Zootecnia, Culiacán, México, [3]Universidad Juárez del Estado de Durango, Durango, México, [4]Red Internacional de Nutrición y Alimentación en Rumiantes, México.*

A trial was conducted to evaluate the effect of 2 levels of DDGS (0 and 30%) and of enzymes hemicellulase+glucanase, (Hemicell, ChemGen, MD, USA; and Porzyme tp100, Danisco, Marlborough, UK), added either at 0 or 0.50 kg/ton of each enzyme, upon growth, nutrient digestibility and carcass traits of rabbits. Twenty-two 53-d old (initial BW = 1.178 kg) crossbred rabbits (California × New Zealand) of both sexes were individually allocated in cages, according to a 2 × 2 factorial arrangement of treatments, in a complete randomized design, with 5 or 6 replicates per treatment. Water and pelleted diets (17.4–18.5% CP, 16.9–25.4% NDF, 3.5–4.9% fat) based on alfalfa hay, grounded sorghum grain, soybean meal and a commercial vit+min mix, were fed ad libitum. During the third week, feces were quantitatively collected for determination of nutrient digestibility. After 28 d, rabbits were slaughtered and carcasses evaluated. There was an interaction ($P < 0.05$) for average daily gain (ADG), since enzymes caused an increase of ADG (26 to 32 g/d) in the diets with DDGS, but a reduction (from 31 to 25 g/d) in the DDGS-free diets. Feed intake and feed conversion rate were not influenced by main factors. No differences ($P > 0.05$) were detected in dry matter digestibility (avg. 71.6%), NDF (avg. 28.4%) and ADF (23.6%). However, enzyme increased lignin digestibility (15–19 percentage units) depending upon DDGS level of the diet (interaction $P < 0.05$). Protein digestibility was higher (74.8 vs. 70.5%; $P < 0.05$) with DDGS inclusion.

Carcass yield nor *Longissimus dorsi* were not different among treatments ($P > 0.05$). Enzyme addition to DDGS-free diets resulted in higher ($P < 0.05$) proportion of carcass forequarter (12.6%) compared with rabbits fed DDGS-diets (11.2%), but forequarter was similar (avg. 12.2%) in both enzyme-free diets (Interaction $P < 0.05$). Rabbits fed diets without DDGS or enzyme had less hindquarter (27.1% of carcass) than other diets (avg. 29.3%; Interaction $P < 0.05$). Results help to understand action mechanisms of hemicellulases and glucanases enzymes added to DDGS containing diets for growing rabbits.

Key Words: rabbits, DDGS, carcass traits

W170 Evaluation of n-3 fatty acid and probiotic supplementation on growth performance, nutrient digestibility, blood characteristics, relative organ weight, and breast meat characteristics in broilers. L. Yan,* S. M. Hong, and I. H. Kim, *Department of Animal Resource & Science, Cheonan, Choongnam, South Korea.*

A total of 720 1-d-old broilers were used in a 28 d experiment to determine the effects of n-3 fatty acid and probiotic supplementation on growth performance, blood characteristics, relative organ weight and breast meat characteristics. Birds were randomly allotted to 1 of 4 treatments in a 2 × 2 factorial arrangement with 2 levels of fish oil (0 or 3%) and probiotics (0 or 0.2%) (1.0×10^{10} viable spores/g of *Bacillus subtilis* endospores and 1.0×10^{9} viable spores/g of *Clostridium butyricum*). Each treatment was fed to 12 replications with 15 broilers per replication. Diets were isolysinic and isocaloric by manipulation of soybean meal and soy oil. In this study, supplementation of salmon oil did not affect ($P > 0.05$) the growth performance and nutrient digestibility throughout the experiment. Dietary probiotic supplementation increased ($P < 0.05$) the body weight gain, feed conversion and apparent total tract of DM digestibility. No difference was observed ($P > 0.05$) in the relative weight of liver, spleen, bursa and breast muscle to the body weight; however, abdominal fat was significantly reduced ($P < 0.05$) with the inclusion of salmon oil or probiotic supplementation. Broiler fed the probiotic supplemented diet had a lower ($P < 0.05$) cholesterol and triglyceride concentration than the non-probiotic diets, whereas the inclusion of salmon oil did not affect the cholesterol and triglyceride concentration. An interactive effect ($P < 0.05$) was observed on the cholesterol concentration. Furthermore, dietary supplementation of salmon oil led to a higher ($P < 0.05$) eicosapentaenoic acid (EPA), docosahexaenoic acid (DHA), total n-3 fatty acid, total polyunsaturated fatty acid but lower n-6:n-3 ratio. The inclusion of probiotics increased ($P < 0.05$) EPA concentration compared with non-probiotic supplemented diets. An interactive effect of probiotic and salmon oil was observed on the EPA concentration. In conclusion, dietary salmon oil supplementation could alter the fatty acid composition in breast muscle of broilers without affecting its growth performance. Dietary probiotics could increase the growth performance and affect the fatty acid concentration in breast muscle. A synergistic effect of salmon oil and probiotic could be observed on the fatty acid composition in broilers.

Key Words: broilers, n-3 fatty acid, probiotic

W171 Effects of YGF-251 extract supplementation on egg production, egg weight, egg quality, blood characteristics, and fecal noxious gas emission in laying hens. S. C. Kim,* S. Zhang, and I. H. Kim, *Department of Animal Resource & Science, Dankook University, Cheonan, Choongnam, South Korea.*

A total of 288 46-week-old ISA-brown laying hens were used in a 6-week trial to evaluate the effects of YGF-251 extract supplementation on the egg production, egg weight, egg quality, blood characteristics, and fecal noxious gas emission. Hens were randomly assigned to 4 treatments with 6 replications (12 layers per replication) per treatment. Dietary treatments were: 1) CON, basal diet; 2) T1, CON + 0.05% YGF-251 extract; 3) T2, CON + 0.1% YGF-251 extract, and 4) T3, CON + 0.15% YGF-251 extract. YGF-251 extract consists of *Phlomis umbrosa* Turez, *Cynanchum wilfordii* Hemsl, *Zingiber officinale* Rosc., *Platycodi Radix* with 5% active ingredient. All diets were formulated to meet or exceed NRC (1994) recommendations for laying hens, protein levels and amino acid compositions were adjusted according to the compositions of YGF-251 at the expense of corn and soybean meal. All statistical analyses were conducted in accordance with a randomized complete block design, using the GLM procedures of SAS software package (1996). Overall, egg production in T3 treatment was higher ($P < 0.05$) than that in CON treatment. No differences ($P > 0.05$) were observed in eggshell color, gravity, shell strength, yolk height, yolk color, haugh unit, shell thickness among dietary treatments. Egg weight was unaffected ($P > 0.05$) by YGF-251 extract treatments. Total protein concentration in blood was higher ($P < 0.05$) in T1 treatment than those in CON and T3 treatments at 2 week. However, there were no differences ($P > 0.05$) in the concentrations of RBC, WBC, IgG, and lymphocyte percentage among dietary treatments throughout the experiment. Supplementation with YGF-251 extract in diets decreased ($P < 0.05$) fecal ammonia emission compared with CON treatment at 6 week. However, hydrogen sulfide, total mercaptans and acetic acid emission were not affected ($P > 0.05$) by dietary treatments. In conclusion, dietary supplementation with 0.15% YGF-251 extract could improve egg production, and decrease fecal ammonia emission in laying hens.

Key Words: egg quality, laying hens, YGF-251 extract

W172 Growth performance and carcass characteristics of Japanese quail fed different levels of zeolite. J. J. Portillo,* J. L. Bolado, A. Estrada-Angulo, B. I. Castro, D. Urías-Estrada, A. Aguilar-Hernandez, C. B. Castro-Tamayo, and F. G. Rios, *FMVZ-UAS, Culiacan, Sinaloa, Mexico.*

This study was conducted to determine the effect of dietary zeolite addition on productive performance of Japanese quail (Coturnix coturnix japonica) during the fattening phase. A total of 256 chicks (1 d of age; unsexed, BW 10.2 g) were allotted to 16 cages (16 quail/pen) in a completely randomized design. Four dietary treatments were based on an isoproteic (28% CP fed d 1 to 14, and 21.5% CP fed d 15 to 35) and isocaloric (2900 ME kcal/kg) basal diet composed of ground corn, soybean meal, soybean oil, sea salt, limestone, orthophosphate, methionine, lysine, Ca, P, vit + min premix. Zeolite was added to the basal diet at 0, 0.5, 1.0 or 1.5% to produce the 4 dietary treatments. After 35 d of feeding, quail were selected based on weight and dressing percentage, with 4 females and 4 males per treatment. ANOVA was performed for a model of completely randomized design with repeated measures for productive response variables, and additionally, slaughter weight was included as a covariate for analysis of carcass variables. Results suggest the inclusion of zeolite in finishing diets does not improve growth performance ($P > 0.50$), although the response changes with time of fattening ($P < 0.01$). Hot carcass weight (127 to 130 ± 2.15 g), dressing percentage (57.6 to 59.3 ± 0.45%) and liver weight per 100 g of quail BW (2.14 to 2.38 ± 0.10 g) were unaffected by the inclusion of dietary zeolite. These results suggest that zeolite supplementation up to 1.5% in fattening diets of quail does not improve growth performance or carcass responses.

Key Words: zeolite, *Coturnix coturnix japonica*, carcass

Nonruminant Nutrition: Management

W173 Appetite stimulants on diets of lactating sows. A. Rodríguez,* A. Pineda, E. Toledo, and A. Borbolla, *Department of Animal Production: Pigs, Facultad de Medicina Veterinaria y Zootecnia, Universidad Nacional Autónoma de México, D.F. México City, México.*

This study evaluated the effect of appetite stimulating ingredients and feed additives on feed consumption and body condition of lactating sows and their litters. Forty-four sows (11 sows/treatment) were randomly assigned to 4 experimental treatments, using a randomized complete block design, with parity as the blocking factor. Four treatments were used in this study: C (control, basal diet for lactating sows), B (basal diet + 1 kg/ton of a phytogenic additive, containing essential oils of oregano, anis and citrus peels mixed with chicory), F (basal diet + 1 kg/ton of homeopathic additive containing natural active substances from plants of the poppy family, such as tetterwort, bloodroot, plume poppy, etc.), and P (basal diet + 5 kg/ton of animal plasma). Diets were fed ad libitum during lactation (22.9 ± 0.2 d). Feed consumption (FC), weight loss (WL) and backfat loss (BL) were measured in each sow. BL was measured at the last rib in the P2 point, upon entering the farrowing room and at weaning, using a Renco® ultrasound (Lean-Meater series 12, Minneapolis, MN, USA). WL was estimated by weighing each sow at entering the farrowing room and at weaning. Weight gain in litters was also evaluated. The resulting data were analyzed using the statistical program SPSS 17.0. There were no differences ($P > 0.05$) for any of the variables evaluated. The FC was similar for all treatments (C = 108.2 kg ± 6.76, B = 114.2 kg ± 5.93, F = 112.7 kg ± 5.93 kg and 112.4 ± P = 6.79). BL showed no differences ($P > 0.05$), among treatments; however, sows receiving both additives and animal plasma had a lower BL, compared with the control group (B = 1.3 mm ± 0.3, F = 1.6mm ± 0.34, P = 1.7 mm ± 0.27 and C = 2.5 mm ± 0.29, respectively). Similarly, the WL did not differ ($P > 0.05$) for any treatment; however, sows receiving the phitogenetic and homeopathic additives, lost the least weight (C = 22.6 ± 3.53 kg, B = 9.9kg ± 3.09, F = 14.9 kg ± 3.53, P = 19.1Kg ± 3.55). The initial weight of all litters was similar ($P > 0.05$) for all experimental groups (C = 18.6 ± 1.27 kg, B = 18.1 ± 1.11 kg, F = 16.4 kg ± 1.06, P = 18.1 kg ± 1.27); and no effect ($P > 0.05$), was observed in this parameter after weaning (C = 60.8 ± 5.16 kg, B = 55.5 ± 4.52 kg, F = 54.7 kg ± 4.52, P = 64.9 kg ± 5.18). These results indicate that under the rearing conditions used in this study, it is not necessary to use these appetite stimulants, although additional studies are needed.

Key Words: feed consumption additives, sows, litters

W174 Reproductive response of sows in lactation anoestrus to additional organic chromium intake and postweaned GnRH-A application. S. A. Félix[1], J. A. Romo[1], J. M. Romo[1,2], H. R. Güemez[1,2], and R. Barajas*[1], *[1]FMVZ-Universidad Autonóma de Sinaloa, Culiacán, Sinaloa, México, [2]Granja Porcina La Huerta, Culiacán, Sinaloa, México.*

Three hundred sixty-eight hybrid multi-parturient sows were utilized to determine the reproductive response of sows in lactation anoestrus to additional organic chromium intake and post weaned GnRH-A application. The study was performed from November 2010 to October 2011 in Culiacan, Sinaloa localized in the Northwest of Mexico. In agreement with a completely randomized experimental design with a 2 × 2 factorial arrangement, Sows were randomly assigned to one of 4 the treatments: 1) Feeding with a lactating corn-soybean meal based-diet, during period of lactation and first 7 d post weaning, and 1 mL-Injection of sterile saline solution 24 and 48 h post weaning (CTRL; n = 96); 2) Diet similar to control and application of 25 µg of GnRH-A at 24 and 48 h post weaning (GnRH-A; n = 84); 3) Diet similar to control plus 400 ppb of additional organic chromium supplementation during lactation time and 1 mL-Injection of sterile saline solution 24 and 48 h post weaning (Cr; n = 85); and 4) Diet similar to control plus 400 ppb of additional organic chromium supplementation during lactation time and application of 25 µg of GnRH-A at the 24 and 48 h post weaning (CrGnRH; n = 103). A GnRH-A x Cr interaction ($P < 0.01$) on interval weaning to estrus was observed, where Cr alone had not effect respect to CTRL, and GnRH-A application lengthened the interval weaning to estrus (5.1 vs. 4.5 d for GnRH and CTRL, respectively), however, when GnRH was applied joint with Cr supplementation (CrGnRH treatment), the length of the interval weaning to estrus was similar to observed in CTRL sows (4.5 vs. 4.4 d for CRTL and CrGnRH treatment, respectively). Treatments had not effect ($P > 0.10$) on the farrowing rate, litter size and the litter weight at the born time. We conclude that postweaned GnRH-A application lengthens the interval weaning to estrus, and the additional intake of organic chromium during lactation time appears to reduce the effect of GnRH-A application on the length of interval weaning to estrus in multi-parturient sows.

Key Words: sows, GnRH-A, reproductive response

W175 Feeding high fiber diet improves productive and reproductive performances of sows. A. Woldeghebriel,* M. Mama-Nodeli, T. Barios, and B. Pope, *North Carolina A&T State University, Greensboro.*

Sows (n = 36) in early gestation were used to determine the effects of feeding different sources of fiber and how these effects may relate to piglet performance. The experimental design employed 4 diets and 9 individually housed sows per diet. The sows were randomly assigned to 1 of 4 diets. Diets included a corn-soybean meal basal diet as the control (CON), and 3 antibiotic-free, high-fiber diets (D1, D2 and D3) each containing 5% sugar beet pulp plus one of the following: 1:2, 1:1, and 2:1 oat to barley ratios. Diets were formulated to contain similar amounts of protein (14% CP) and energy (3.145 Mcal DE/kg), but the fiber content of the CON diet was lower than the average of the high-fiber diets (8.38% vs. 22.40% NDF). All sows were fed the low-fiber diet for the first 84 d of gestation and randomly assigned to 1 of 4 diets for the next 30 d. This means that sows continued receiving either the low fiber (229 g of NDF/d) or high fiber (612 g of NDF/d) diets until farrowing. Each sow received 2.73 kg of feed per day during gestation and 2.73 kg 3 times per day during lactation. Sows were weighed initially, weekly during gestation, after farrowing and when piglets were weaned. Litter sizes and weights were also recorded at birth and weekly for up to 2 weeks post-weaning. Data collected were analyzed using SAS procedure where animals were considered random effects, and diet means were used to compare treatment effects. Results of the study indicated that average litter size at birth in high fiber-fed sows increased by 0.28 pig/sow/y. Litter growth rates were not affected by diet. However, average litter weights at birth and at weaning from high fiber-fed sows were 0.60 and 2.24 kg, respectively, being higher than in CON-fed sows. Average litter weight from high fiber-fed sows was also higher ($P < 0.05$) during the first week of lactation than during the second, but not the third week of lactation. In conclusion, results of the current study indicate that feeding sows with high fiber diet during the last 30 d of gestation had beneficial effects to both the litter and the sow itself.

Key Words: sow, lactation, dietary fiber

W176 Effects of dietary fat and protein quantity from different feedstuffs on litter gain. K. Koch*[1], L. Chu[2], K. Kalscheur[1], R. C. Bott[1], and R. C. Thaler[1], [1]*South Dakota State University, Brookings,* [2]*China Agricultural University, Beijing, China.*

A sow lactation study was performed to evaluate the effects of different quantities of fat and protein inclusion in lactation diets on litter gain and milk composition. Ninety-six sows and 3 dietary treatments were used in a complete randomized design. Sows used were of mixed parity (0–8), and litters were standardized within dietary treatment. Lactation length was standardized to 18 d. Treatments were low fat, high protein (LH, n = 32), comprised of corn and soybean meal; medium fat, low protein (ML, n = 31), comprised of corn and a co-extruded corn and soybean product; and high fat, high protein (HH, n = 33), comprised of corn, soybean meal and added soy oil. Fat quantities were provided at 2.51%, 5.30% and 8.96% of the diet (DM basis) in the low, medium, and high levels, respectively. Protein quantities were 19.36% and 20.50% of the diet (DM) for the LH and HH treatments and 12.14% of the diet (DM) for the ML treatment. Data were analyzed using PROC MIXED of SAS (SAS Inst. Inc., Cary, NC) with diet being a fixed effect. Litter gain was estimated by determining the difference of average litter weight at birth and at weaning, adjusted for the number of piglets. There was an effect on litter gain due to treatment ($P < 0.05$). Litter gain was approximately 4.61, 4.22 and 5.02 kg per piglet, for LH, ML, and HH, respectively. Upon weaning at d 18, 8 sows per treatment were randomly selected to determine if diet affected milk fat concentration. Sows selected had similar body condition scores (2.6 ± 0.1) at the start of the experiment. Milk fat concentration was 6.22 ± 0.51%, 6.70 ± 0.50% and 7.63 ± 0.12% for the LH, ML and HH treatments, respectively. Treatment had no effect on milk fat concentration ($P > 0.198$). Parity was included as a covariate and no effect was demonstrated on litter gain ($P > 0.195$) or milk fat ($P > 0.839$) concentration. Therefore, litter gain may be improved by elevated fat levels in lactation diets, when protein is provided at high level, but there is no effect on milk fat concentration.

Key Words: sow, lactation, fat

W177 The effects of blends of sensory functional ingredients on feed intake and growth in juvenile pigs during a food transition. C. Clouard[1], V. Noirot*[2], M. Champagnac[2], P. Etienne[2], D. Éclache[2], MC Meunier-Salaün[1], and D. Val-Laillet[1], [1]*INRA, UMR1079 SENAH, Saint Gilles, France,* [2]*Laboratoires Phodé, Terssac, France.*

When exposed to a novel diet during food transition, pigs often decrease spontaneously their feed intake, which can lead to impaired growth. The related experiment was conducted by the INRA team of UMR1079 SENAH (Saint Gilles, France). The objective was to identify blends of sensory functional ingredients based on aromatic active principles and plant extracts, formulated by Laboratoires Phodé (Terssac, France), that were likely to improve feed intake during food transitions. The spontaneous feed intake of 24 juvenile female pigs, housed in individual pens, was assessed during a food transition. After 9 d during which they were fed with a familiar starter diet, the pigs were divided into 3 experimental groups and fed with an unfamiliar grower diet added with either the N1 blend, the N3 blend, or without supplementation (control: C). The mean amount of food consumed and the mean body weight of the animals were compared between treatments using non-parametric Kruskal-Wallis tests. After the transition day, no difference in the mean feed intake and in the mean body weight per week was observed between the groups ($P > 0.05$). On d 10 (i.e., the transition day), compared with the consumption of the starter diet on d 9, the consumption of the C diet was 10.31% lower, while the consumption of the N3 diet was only 5.46% lower and the consumption of the N1 diet was 3.77% higher. However, the difference of consumption between d 9 and 10 was not significant ($P > 0.05$), due to high inter-individual variability. Albeit the adjunction of the functional ingredients in the novel diet did not increase feed intake or weight gain in these experimental conditions, N1 was likely to maintain a normal consumption the day of the food transition. Further investigations using an increased number of pigs would have counterbalanced the effects of individual variability and would have been likely to result in more significant results in terms of food intake and preferences.

Key Words: functional feed ingredients, pigs, food transition

W178 Effects of genotype and dietary oil supplementation in pigs. 1. Growth performance and carcass traits. T. M. Bertol*[1], J. V. Ludke[1], R. M. L. de Campos[2], N. N. Terra[3], E. A. P. de Figueiredo[1], A. Coldebella[1], and J. I. dos Santos Filho[1], [1]*Embrapa Suínos e Aves, Concórdia, SC, Brazil,* [2]*Fundação Universidade Federal do Vale do São Francisco, Petrolina, PE, Brazil,* [3]*Universidade Federal de Santa Maria, Santa Maria, RS, Brazil.*

A 42-d study was carried out to evaluate the effect of genotype (GEN): terminal sire line Duroc × F1 (DC×F1); terminal sire line Embrapa MS115 × F1 (MS115×F1); and MS115 × Moura (MS115×MO) and 3 dietary oils (DIET): 3% soybean oil (SBO); 3% canola oil (CAN); and 1.5% canola oil + 1.5% flax oil (CAN+FLX), on pig growth performance and carcass traits. Ninety animals (45 barrows and 45 gilts) averaging 130.7 ± 3 d of age were utilized, 15 barrows and 15 gilts of each GEN per diet. The ANOVA model included block (initial weight), sex, GEN, DIET and interactions of second and third order. Means were compared by protected *t*-test ($P < 0.05$). There was no DIET effect ($P > 0.05$) on growth performance and carcass traits. Final weight (FW), average daily gain (ADG) and daily feed intake (DFI) were higher ($P < 0.001$) in DCxF1, with the lowest values observed in the MS115×MO pigs (FW = 122.4 ± 0.85^a, 112.8 ± 1.38^b, 96.8 ± 1.30^c kg; ADG = 1.090 ± 0.018^a, 0.987 ± 0.019^b, 0.828 ± 0.015^c kg; DFI = 3.415 ± 0.053^a, 3.033 ± 0.056^b, 2.725 ± 0.059^c kg, for DC×F1, MS115×F1 and MS115×MO, respectively). Feed conversion ratio was higher ($P < 0.01$) in the MS115×MO pigs than in the other GEN. The highest ($P < 0.001$) hot carcass weight was found in the DC×F1 and the lowest in the MS115×MO pigs. The MS115×F1 pigs had the lowest ($P < 0.001$) backfat thickness (BF) and the MS115×MO showed the lowest ($P < 0.001$) loin depth (LD) (BF = 22.75 ± 0.71^a, 17.09 ± 0.63^c, 20.46 ± 0.86^b mm; LD = 62.04 ± 0.74^a, 63.35 ± 1.21^a, 54.52 ± 1.11^b mm). The GEN by DIET interaction was significant ($P < 0.05$) for carcass lean percentage (LP), with the highest ($P < 0.05$) LP provided by CAN diet in the DCxF1 pigs and by SBO DIET in the MS115×MO pigs, while no differences were observed ($P > 0.05$) among DIET in the MS115×F1 pigs. For the GEN effect within DIET, the MS115×F1 pigs showed higher ($P < 0.05$) LP than the other GEN, regardless the DIET. In conclusion, the type of oil did not influence growth but did affect carcass traits, depending upon genotype. DC×F1 pigs showed the best growth performance and MS115×MO the worst. The MS115×F1 GEN had the best carcass quality.

Key Words: canola oil, flax oil, soybean oil

W179 Improving feed efficiency in fattening pigs through sensorial stimulation.

G. Tedó[1], D. Torrallardona[2], and I. R. Ipharraguerre*[1], [1]*Feed Additives Division, Lucta S.A., Montornés del Vallée, Barcelona, Spain,* [2]*IRTA-Mas de Bover, Reus, Tarragona, Spain.*

Interest in strategies to improve feed efficiency and prevent excessive fat deposition in fattening pigs is growing. We hypothesized that triggering sensory and gastrointestinal satiety through flavoring compounds may contribute to achieve such a goal by reducing over-consumption of feed without compromising animal growth. To test this hypothesis, an experiment was conducted in which a flavoring composition developed to induce satiety (SAT) was added into the diet of fattening pigs. One hundred and 44, mixed sex (50:50) pigs [Duroc × Landrace (sow line) × Pietrain (boar line); 49 ± 4.55 kg BW] were distributed into 48 pens (3 animals/pen) and 4 blocks of BW, and fed ad libitum either a control diet or the same diet treated with SAT (750 ppm) during the last 49 d before slaughter. Animals were individually weighed on d 0, 21, 35 and 49 and feed intake was recorded every week from d 0 to d 49. Data (BW, ADG, ADFI, GFR) were analyzed as a mixed-effect model with repeated measures in time in which pen was treated as a random effect and diet, block, sex and their interactions were considered fixed effects. Analyses were carried out using the MIXED procedure of SAS. No interactions ($P > 0.5$) were observed for any of the measured parameters. In addition, no differences were observed for BW($P > 0.7$) and ADG (745 vs. 746 g/d;$P > 0.8$) between treatments. The addition of SAT into the diet, however, reduced ($P < 0.02$) ADFI by 6% (2437 vs. 2287 g/d) resulting thereby in a 7% improvement ($P < 0.05$) in GFR (0.30 vs. 0.32). In conclusion, the inclusion of a satiety-inducing flavor in pig finishing diets improved feed efficiency through the reduction of feed intake without affecting body weight gain.

Key Words: efficiency, flavor, satiety

W180 Gene expression of myosin heavy chain isoforms and β-adrenergic receptors induced by ractopamine feeding duration in finishing pigs.

V. V. Almeida*[1], A. J. C. Nuñez[2], A. P. Schinckel[3], M. Ward[3], K. Ajuwon[3], G. Gasparin[1], C. Andrade[1], M. Sbardella[1], L. L. Coutinho[1], and V. S. Miyada[1], [1]*University of Sao Paulo/ESALQ, Piracicaba, SP, Brazil,* [2]*University of Sao Paulo/FZEA, Pirassununga, SP, Brazil,* [3]*Purdue University, West Lafayette, IN.*

Ractopamine (RAC) is fed to finishing pigs to increase muscle mass and decrease fat deposition, to improve feed efficiency and carcass value. To understand how RAC feeding induces skeletal muscle growth, 80 finishing barrows were used to evaluate the time-dependent effect of RAC feeding on myosin heavy chain (MyHC) isoforms (I, IIa, IIx and IIb), β1-adrenergic receptor (AR) and β2-AR mRNA abundance. Pigs were blocked by initial BW (69.42 ± 1.24 kg) and assigned randomly to 5 treatments, with 8 replicates per treatment and 2 pigs per pen. Dietary treatments consisted of corn and soybean meal diets containing no RAC (control) for 28 d and 10 mg/kg RAC for 7, 14, 21, or 28 d before slaughter. Longissimus muscle samples were collected immediately post-exsanguination, snap frozen in liquid nitrogen and stored at −80°C until processed for gene expression analysis. Total RNA was extracted and the mRNA expression was determined by quantitative real-time RT-PCR. Relative gene expression ratio was calculated with the Pfaffl's method, using 18S rRNA as reference gene. Statistical analyses were performed by ANOVA using the GLM procedure of SAS. Linear and quadratic responses were determined utilizing polynomial orthogonal contrasts. Although β1-AR mRNA abundance was not affected ($P > 0.05$) by RAC treatment, increasing RAC feeding duration tended to decrease β2-AR expression (1.39, 1.03, 0.83, 0.83, 0.62 ± 0.15; $P = 0.08$). Expression of MyHC I decreased linearly (1.81, 1.72, 1.53, 0.98, 0.94 ± 0.20; $P = 0.02$), whereas MyHC IIb mRNA expression increased linearly (0.32, 1.05, 1.20, 1.41, 1.79 ± 0.16; $P = 0.001$) as RAC feeding period increased. Conversely, transcript abundance of MHC IIa and IIx did not differ ($P > 0.05$) between treatments. These results suggest that RAC feeding alters the MyHC isoform gene expression profile, and that the responses might be mediated by β2-AR.

Key Words: β-adrenergic agonist, skeletal muscle growth, swine

W181 Influence of pellet size on pellet quality and performance and nutrient utilization of broilers.

M. R. Abdollahi, T. J. Wester,* G. Ravindran, D. V. Thomas, and V. Ravindran, *Institute of Food, Nutrition and Human Health, Massey University, Palmerston North, New Zealand.*

The importance of physical quality of pellets in improving growth is well recognized in the broiler industry. High conditioning temperatures during pelleting increase pellet quality, but decrease nutrient availability. This study tested whether manipulation of pellet diameter and length, at low conditioning temperature, would influence quality of pellets, and performance and nutrient utilization of broilers. total of 192, 10-d old birds were used in a 2 × 2 factorial arrangement to evaluate pellet diameter (3 or 4.76 mm) and pellet length (3 or 6 mm). Wheat-based grower (d 10 to 21) and finisher (d 22 to 42) broiler diets were formulated to meet Ross 308 strain recommendations. Diets were steam-conditioned at 60°C before pelleting. In grower and finisher diets, improvements in pellet durability index and pellet hardness with increasing pellet length were greater ($P < 0.05$) in pellets with 3-mm diameter than those with 4.76-mm. Increasing pellet length from 3 to 6 mm increased ($P < 0.05$) apparent ME value (3322 vs. 3288 kcal/kg DM). Neither main effects of pellet diameter and length nor the interaction were significant for ileal digestibility of nitrogen and starch. During the grower period, birds fed pellets of 6-mm length had greater weight gain ($P < 0.05$; 745 vs. 725 g/bird) and better feed conversion ($P < 0.05$, 1.427 vs. 1.446 feed/gain) than those fed 3-mm long pellets. Feed intake was unaffected. During the finisher phase and over the whole trial (d 10 to 42), neither the main effects nor the interaction were significant for weight gain and feed intake. Pellet length had no effect on feed conversion for 3-mm diameter pellets; however, increasing pellet length from 3 to 6 mm improved ($P < 0.05$) feed conversion at 4.76-mm pellet diameter (1.755 vs. 1.792 feed/gain, finisher phase; 1.675 vs. 1.706 feed/gain, whole trial). Overall, best pellet quality was achieved in 6 mm long and 3 mm diameter pellets, while best performance was in broilers fed 6-mm pellets that were 4.76 mm wide. When low conditioning temperatures are used to optimize nutrient availability, it seems a longer pellet is better, but choice of die size creates a trade-off between pellet quality and bird performance.

W182 Effects of increasing inclusion of supplemental magnesium oxide (MgO) on laying performance and eggshell quality in 72-week-old brown egg-laying hens. C. H. Kim, I. K. Paik, and D. Y. Kil,* *Department of Animal Science and Technology, Chung-Ang University, Anseong-si, Korea.*

In our previous experiment, increasing level of supplemental MgO in diets improved the eggshell quality in 46-week-old laying hens. However, such an effect has not been determined in aged laying hens that may encounter more problems in eggshell quality than young laying hens. The objective of this experiment, therefore, was to investigate the effect of increasing inclusion of supplemental MgO in diets on laying performance and eggshell quality in aged laying hens. A total of 640 Hy-Line Brown laying hens of 72 weeks of age were assigned to 1 of 4 dietary treatments with 4 replicates in a completely randomized design. Each replicate consisted of 40 hens raised in 2 hens per cage. The basal diet contained 0.16% Mg and 3 levels of 0.10, 0.15, and 0.20% MgO (60% Mg) were supplemented to the basal diet. All other nutrients and energy were included to meet or exceed NRC requirement estimates for laying hens. Laying performance was recorded daily and summarized for a 5-week feeding trial. Eggshell quality was measured in 20 eggs collected randomly from each replicate on the last day of each week during 5 weeks and the data were pooled. Results indicated that increasing inclusion of supplemental MgO increased (linear, $P < 0.05$) eggshell strength and decreased (linear and quadratic, $P < 0.01$) broken and shell-less egg production. However, there was no difference in eggshell thickness among treatments. Hunter lightness (L*) and redness (a*) values in eggshell decreased (linear, $P < 0.05$) as inclusion of supplemental MgO increased. Feed intake, feed conversion ratio, hen-day egg production, egg weight, egg yolk color, and Haugh unit were not affected by dietary treatments. The concentrations of Mg in eggshell increased (linear, $P < 0.01$) with inclusion of supplemental MgO, but those of Ca, P, and Fe in eggshell were not influenced by dietary treatments. In conclusion, inclusion of supplemental MgO improves eggshell strength and color with no effect on laying performance in aged laying hens.

Key Words: aged laying hens, eggshell quality, magnesium oxide

W183 Evaluating the impact of pre-weaning calcium and phosphorus supplementation on growth performance and carcass characteristics of low and high birth-weight pigs. P. L. Y. C. Chang*[1], C. H. Stahl[1,2], and E. van Heugten[1], [1]*Department of Animal Science, North Carolina State University, Raleigh,* [2]*Laboratory of Developmental Nutrition, North Carolina State University, Raleigh.*

Neonatal Ca and P deficiencies affect growth performance and the activity of the tissue-specific stem cells responsible for lifetime muscle and bone growth. This study evaluated the effect of direct oral supplementation of Ca and P to nursing pigs on growth performance and carcass characteristics. From commercial sows (n = 52), 2 light-weight pigs (LW, 1.52 ± 0.04 kg BW) and 2 heavy-weight piglets (HW, 2.14 ± 0.04 kg BW) were selected at d 3 of age. Within sow, 1 of the LW and 1 of the HW piglets were orally supplemented once daily with 2 mL of a $CaPO_4$ solution that provided 240 mg Ca and 182 mg P. The remaining LW and HW pig from each litter orally received 2 mL of a placebo. Pigs were weaned at 22.5 d of age and were randomly allotted to pens (3 to 5 pigs per pen) according to sex, supplementation, and birth weight. Pigs were fed 3 diet phases in the nursery (44 d) and 3 diet phases in the finisher (98 d). At the end of the study carcass characteristics were determined using ultrasound. Pigs in the HW group were heavier ($P < 0.001$) at weaning (6.3 vs. 4.7 kg), at the end of the nursery (29.1 vs. 23.7 kg), and at the end of the finisher (121.0 vs. 108.1 kg). Heavy birth weight pigs grew faster ($P < 0.01$; 518 vs. 430; 938 vs. 861; 808 vs. 728 g/d for nursery, finisher, and overall), consumed more feed (0.70 vs. 0.57; 2.44 vs. 2.20; 1.90 vs. 1.69 kg/d for nursery, finisher, and overall) and had greater ($P < 0.01$) loin eye area (19.5 vs. 17.7 cm^2) and daily lean gain (377 vs. 350 g/d). Pre-weaning supplementation with $CaPO_4$ did not affect ADG, ADFI, G/F or any of the carcass traits. In conclusion, increased birth weight of pigs greatly enhanced pig performance to market weight; however, pre-weaning supplementation with $CaPO_4$ did not improve performance of either LW or HW piglets. This work does not support the hypothesis that low birth weight pigs receive inadequate Ca and PO_4 nutrition during the nursing period.

Key Words: nursing pigs, pre-weaning nutrition, $CaPO_4$ supplementation

W184 Bone ash and strength traits of young pigs fed diets with no supplemental vitamin D were compromised within a four-week trial. L. A. Rortvedt,* D. K. Schneider, and T. D. Crenshaw, *University of Wisconsin-Madison, Madison.*

Last year we reported > 30% reduction in growth and whole body skeletal traits in pigs fed diets without supplemental vitamin D (D) during a 4-wk trial. Excess dietary Ca and P did not alleviate D responses. A method to detect kyphosis via DXA was reported, but individual bones were not assessed. The current objective was to evaluate the effect of diets on individual bone traits. In 2 trials (n = 72 ea) pigs were weaned (~3 wk) and fed diets with no supplemental D for 1 wk, then 1 of 8 diets (corn-SBM) for 4 wk. Treatments, arranged as a 2 × 2 × 2 factorial, included diets supplemented with D, 0 (-D) or 280 (+D) IU/kg; Ca, 75% (0.53%) or 150% (1.05%); P, 95% (0.57%) or 120% (0.72%) of requirements. On d 28 pigs (n = 24/trial) were euthanized, femurs and tenth ribs were excised. Femurs were scanned by DXA (GE Lunar Prodigy) to determine bone mineral content (BMC, g/bone) and density (BMD, g/cm^2), then subjected to a 4-point bending test to assess strength. Ribs were dried, de-fatted, and combusted (700°C) to determine ash. Femur BMC was reduced ($P < 0.01$) by > 50% in pigs fed -D vs +D, but responses depended on dietary Ca and P. Additional Ca and P increased femur BMC in pigs fed +D, but not -D ($P < 0.05$). Femur bending moments (BM) and rib ash (g and %) responded in similar patterns as femur BMC. Femurs from pigs fed +D vs -D had decreased ($P < 0.01$) strain, but responses did not depend on Ca or P. In conclusion, individual bone traits responded similarly to dietary D, Ca, and P as whole body DXA responses. Dramatic responses to dietary vitamin D within a 4 wk trial were not expected and may reflect carry-over effects of sow diets.

W185 Estimates of relative bioavailability of monocalcium and dicalcium phosphates based on whole body DXA scans to determine the efficiency of dietary P use by growing pigs.

P. T. Merkatoris,* L. A. Rortvedt, and T. D. Crenshaw, *University of Wisconsin, Madison.*

Monocalcium phosphate (MCP) is a less expensive source of P than dicalcium phosphate (DCP). However, the relative bioavailability of P between the 2 sources may not be equal. The current experiment was designed to access the relative bioavailability of P in MCP and DCP based on a slope-ratio assay using growth, femur ash, and calculations derived from dual energy x-ray absorptiometry (DXA, GE Lunar Prodigy) scans to determine mineral retention and efficiency. Crossbred barrows (n = 35) were fed standard diets until ~10 kg then randomly allotted within weight blocks to 1 of 7 treatments. Treatments included a basal, corn-SBM diet with no supplemental inorganic P (0.39% P) and 3 diets formulated to supply 0.05, 0.10, or 0.15% added P from either MCP or DCP. Pigs were individually housed and allowed continuous access to feed and water except for an overnight fast before DXA scans on d 0 and 20. Skeletal gain (gBMC) was calculated as the difference in d 20 and d 0 whole body bone mineral content (BMC, g) derived from DXA scans. Assuming a distribution of Ca (99%) and P (80%) in the whole body, Ca and P retentions were calculated assuming 38% Ca and 18% P in bone ash. Efficiency of Ca and P retention was calculated as the ratio of nutrient retained to nutrient consumed. Relative bioavailability of MCP vs DCP were based on the ratio of linear slope coefficients calculated for various criteria shown below. Criteria based on assessment of bone traits (femur BMC, gBMC, P efficiency) predicted 9 to 29% higher relative bioavailability for MCP than DCP. However, traits based on growth and feed consumption (ADG, FG ratio) predicted 5 to >35% higher bioavailability of P from DCP vs MCP. Reasons for a discrepancy in relative bioavailability estimates among criteria were not obvious.

Table 1.

Trait	Intercept	Basal	DCP	MCP	R^2	MCP/DCP
ADG	0.0379	0.1432	0.1341	0.1273	0.872	95.0
FG ratio	1.7442	−0.0190	−0.0541	−0.0340	0.090	62.8
gBMC	−1.8927	0.6943	1.3705	1.6362	0.734	119.4
P efficiency	0.0008	−0.0328	0.0529	0.0683	0.598	129.0

Key Words: Ca retention, P retention, slope-ratio assay

W186 Effects of sulfur concentration in diets containing distillers dried grains with solubles on carcass characteristics and tissue mineral concentrations in growing-finishing pigs.

B. G. Kim*[1], D. Y. Kil[2], D. C. Mahan[3], G. M. Hill[4], and H. H. Stein[5], [1]*Konkuk University, Seoul, Korea,* [2]*Chung-Ang University, Anseong-si, Korea,* [3]*Ohio State University, Columbus,* [4]*Michigan State University, East Lansing,* [5]*University of Illinois, Urbana.*

The objective of this experiment was to determine if concentration of S in diets containing distillers dried grains with solubles (DDGS) affect carcass characteristics, loin quality, and tissue S, Se, and Cu concentrations in growing-finishing pigs. A total of 120 growing barrows (34.2 ± 2.3 kg BW) were allotted to 3 dietary treatments with 10 replicate pens and 4 pigs per pen in an 84-d experiment. The control diet was based on corn and soybean meal (0.14% S, 0.19 mg/kg Se, and 15.3 mg/kg Cu). The DDGS diet was formulated with corn, soybean meal, and 30% DDGS (0.16% S, 0.32 mg/kg Se, and 14.0 mg/kg Cu). The DDGS-S diet was similar to the DDGS diet, except that 1.10% CaSO4 (16.2% S) was added to this diet (0.37% S, 0.35 mg/kg Se, and 13.8 mg/kg Cu). Organ weights and loin quality, 24-h pH, drip loss, loin subjective color, marbling, and firmness did not differ among treatments, but loin redness (a*) was greater ($P < 0.05$) for pigs fed the control diet than for pigs fed the DDGS-S diet. Concentrations of S in hair, liver, heart, loin, and all other tissues did not differ among treatments, but urinary S concentration was greater ($P < 0.05$) for pigs fed the DDGS-S diet than for pigs fed the other diets. Pigs fed the DDGS diet or the DDGS-S diet had greater ($P < 0.01$) Se concentrations in hair, liver, heart, and loin than pigs fed the control diet, but liver concentrations of Cu did not differ among treatments. In conclusion, inclusion of 30% DDGS in diets fed to growing-finishing pigs does not influence carcass characteristics or tissue S concentrations regardless of S concentration in the diet, and excess dietary S is excreted in the urine. In contrast, because of the greater concentration of Se in DDGS compared with corn and soybean meal, tissue concentrations of Se are increased if DDGS is included in the diet. However, liver concentrations of Cu are not influenced by dietary DDGS.

Key Words: distillers dried grains with solubles, selenium, sulfur

Physiology and Endocrinology III

W187 Effects of ruminally digested and undigested snakeweed extracts on female Sprague-Dawley rats. R. A. Halalsheh,* D. M. Hallford, and T. T. Ross, *New Mexico State University, Las Cruces.*

Two studies were conducted to examine effects of snakeweed (SW) extracts (evaporate residues) on serum components and reproduction in female Sprague-Dawley rats. In Exp. 1, 36 rats at d 5 (d 1) of pregnancy were offered SW extracts (ethanol and hexane) at 20% and 30% of diet (25g/rat). In Exp. 2, 36 rats at d 5 (d 1) of pregnancy were offered ruminally digested SW extracted (ethanol and hexane) at 20% and 30% of diet (25g/rat). Each rat was assigned a non-SW control rat fed 5001 Rat Chow. Rats were fed for 10 d and BW was recorded on d 1 and 11. Blood samples were collected via heart puncture and rats were euthanized on d 11. Experimental design was completely random with split-plot when appropriate. In Exp. 1, rats consuming 20% ethanol SW extract (20% ESW) had decreased ($P < 0.05$) feed intake on d 1 to 3 and increased ($P < 0.05$) intake on d 10, while those fed the 20% hexane SW extract (20% HSW) had increased ($P < 0.05$) feed intake from d 6 through d 10 compared with control rats. Rats consuming 30% ESW resulted in decreased ($P < 0.05$) feed intake on d 1 to 3 and increased ($P < 0.05$) intake on d 8 to 10. Rats consuming 30% HSW decreased intake on d 1, 2, 3, and 5 and increased intake ($P < 0.05$) on d 7, 9, and 10 compared with controls. Rats consuming 20 and 30% HSW had increased ($P < 0.05$) aspartate and alanine aminotransferase concentrations. Blood urea nitrogen, albumin, and creatinine increased ($P < 0.05$) in treated rats compared with controls. In Exp. 2, rats consuming 20% ethanol extract of digested SW (20% EDSW), 20% hexane extract of digested SW (20% HDSW), and 30% ethanol extract of digested SW (30% EDSW) increased ($P < 0.05$) feed intake compared with controls and 30% HDSW decreased ($P < 0.05$) feed intake on d 1, 2, and 7. Alkaline phosphatase, BUN, globulin and creatinine increased ($P < 0.05$) in rats consuming SW extracts compared with controls. In exp 1 and 2, Serum P4 and number of pups were similar ($P > 0.05$) among treatments. Results indicate that SW, both ruminally digested and undigested may contain potential chemical compounds that cause a mild toxicity and ruminal digestion altered SW hepatotoxicity.

Key Words: snakeweed, Sprague-Dawley rats, toxicity

W188 Effect of niacin on heat shock protein gene expression in transformed bovine mammary epithelial cells. S. Rungruang,* J. L. Collier, and R. J. Collier, *University of Arizona, Tucson.*

Recent studies have indicated a niacin receptor, GPR109A, was differentially distributed in bovine liver, muscle, brain and fat tissues. Objectives of this study were to confirm presence of a niacin receptor in bovine tissues and to examine the effect of niacin on heat shock protein (HSP) gene expression in transformed bovine mammary epithelial cells (MAC-T). In this study,GPR109A was detected by agarose gel electrophoresis and quantified using quantitative real-time reverse transcription-PCR (q-PCR) in tissue samples from 3 cows. Tissues examined were mammary, uterine, ovary, liver, skin, cultured MAC-T and primary bovine mammary epithelial cells (BMEC). Ribosomal protein subunit 9 (RPS9) was used as the reference gene. The receptor was present in all tissues and cells. Expression of the gene for the receptor was highest in skin, the next highest was mammary ($P < 0.01$) and no difference was detected between liver, uterine and ovary receptor gene expression. The receptor in skin and mammary was 26.41 and 4.37-fold higher than liver, respectively ($P < 0.01$). The MAC-T were treated with niacin in different doses (0, 0.01, 0.1 and 1.0 mM) and 2 incubation times (0 and 4 h) at 37 C before incubation in 42 C for 8 h. The expression of genes for HSP27 and HSP70 were analyzed by q-PCR. The expression of HSP27 and 70 genes was increased during heat stress ($P < 0.01$). The data indicated niacin had a dose effect on HSP27 ($P < 0.03$) and HSP70 ($P < 0.02$) expression. The analysis also identified a quadratic relationship in HSP27 ($P < 0.01$), and linear relationship in HSP70 ($P < 0.01$) gene expression. MAC-T supplemented with 0.1 mM niacin had the highest HSP27 and 70 gene expression during heat stress when compared with 0 mM (11.45 vs −2.41-fold, $P < 0.02$ and 77.73 vs 5.26-fold, $P < 0.01$, respectively).Longer incubation times with niacin increased HSP expression ($P < 0.01$). However, we did not detect an interaction between incubation time, dose and temperature. These data indicated that niacin increases HSP gene expression in bovine cells during heat stress.

Key Words: heat shock protein, bovine mammary epithelial cells, heat stress

W189 Effects of betaine on heat induced heat shock protein expression in primary bovine mammary epithelial cells. Y. Xiao*[1,2], J. L. Collier[1], S. Rungruang[1], L. W. Hall[1], F. R. Dunshea[3], and R. J. Collier[1], *[1]University of Arizona, Tucson, [2]Huazhong Agricultural University, Wuhan, Hubei, China, [3]The University of Melbourne, Parkville, Vic., Australia.*

Betaine, an organic osmolyte, is accumulated by cells and stabilizes protein structure and cellular metabolism during physiological stress. Decreased induction of heat shock protein-70 (HSP70) gene expression and anti-apoptotic effects were found in betaine-treated mammalian cell lines (Madin-Darby canine kidney and mouse embryonic fibroblast cells) exposed to a hypertonic environment. To evaluate effects of betaine on heat-shocked bovine mammary epithelial cells (BMEC), we isolated primary BMEC from mammary gland tissue of a pregnant Holstein cow, seeded in collagen for 6 d of culture then determined gene expression of HSP70 and HSP27 in cells treated with 0 mM or 25 mM betaine in thermoneutral (TN, 37°C) and heat stress (HS, 42°C) conditions at 0, 2, 4 and 8 h, using quantitative real-time PCR (qRT-PCR). Hypoxanthine phosphoribosyltransferase served as the reference gene. A one-way ANOVA was conducted on ΔC_t value with the PROC MIXED procedure of SAS. The fold change was calculated by the $2^{-\Delta\Delta C_t}$ method. After 8 h of HS exposure, morphology in 0 mM betaine-treated BMEC indicated distinct cell degradation, which was absent in 25 mM betaine-treated BMEC. The qRT-PCR indicated that, in TN conditions, expression of HSP70 was significantly ($P < 0.01$) decreased in 25 mM betaine-treated cells compared with 0 mM at 2 h and 4 h, and expression of HSP27 decreased significantly ($P < 0.01$) as well at 8 h. In HS condition, HSP70 expression peaked at 2 h in 25 mM betaine-treated BMEC and at 4 h in 0 mM. The expression of HSP70 in BMEC in control media was decreased significantly at 8 h compared with betaine-treated cells (20.80 ± 6.19 *vs.* 57.18 ± 6.19 fold, $P < 0.01$). A continuous increase of HSP27 expression was evident in all HS groups from 0 h to 8 h. Higher expression levels of HSP27 were detected in 25 mM betaine-treated BMEC than 0 mM at 4 h (21.93 ± 2.16 *vs.* 12.93 ± 2.16 fold, $P < 0.01$) and 8 h (61.55 ± 2.64 vs. 33.40 ± 2.64 fold, $P < 0.05$). Collectively, data indicated that betaine had a protective effect in heat-shocked BMEC by increasing expression of heat shock proteins during heat stress.

Key Words: mammary epithelial cells, betaine, heat shock protein

W190 Cloning and responsiveness of bovine glucose-6-phosphatase promoter to cyclic AMP and glucocorticoids.

Q. Zhang,* S. Koser, and S. Donkin, *Purdue University, West Lafayette, IN.*

Gluconeogenesis is an essential process in ruminants. Glucose-6-phosphatase (G6Pase) is a rate-limiting and final step in gluconeogenesis and catalyzes the release of glucose from liver. The objective of this experiment was to clone bovine G6Pase promoter and determine the effects of cyclic AMP (cAMP) and dexamethasone (DEX), on G6Pase promoter activity. Bovine genomic DNA was extracted from liver and used as a template to clone the promoter sequence. A region from −1012 to −17 bp relative to the transcription start site (TSS) and truncated sequences within this region, from −801 to −17 bp, −530 to −17 bp and −312 to −17 bp relative to the TSS were generated by PCR. Amplicons were sequenced and cloned into a eukaryotic expression vector (pGL-3 basic) and linked to a luciferase reporter gene. Each promoter-luciferase construct was transiently transfected into rat hepatoma (H4IIE) cells. Cells were treated with either a combination of 0.70 mM cAMP and 0.10 mM DEX or vehicle. Cells were harvested after 23 h and luciferase activity was determined in the cell homogenate. Basal luciferase activities for all 4 promoter sequences were not different from pGL-3 basic luciferase activity ($P > 0.05$). The activities of all G6Pase promoter sequences were induced ($P < 0.05$) with exposure to cAMP and DEX. The data demonstrate the direct role of cAMP and glucocorticoids in regulating bovine G6Pase expression through promoter activation. Furthermore, the data indicate responsiveness to cAMP and dexamethasone that is within the −312 to −17 bp region of the bovine G6Pase promoter.

Key Words: bovine glucose-6-phosphatase, promoter activity, cAMP and glucocorticoids

W191 Effects of heat stress on insulin production in β-TC-6 pancreatic cells.

M. V. Sanz-Fernandez*[1], R. L. Boddicker[1], J. W. Ross[1], R. P. Rhoads[2], and L. H. Baumgard[1], [1]*Iowa State University, Ames,* [2]*Virginia Polytechnic Institute and State University, Blacksburg.*

Heat stress (HS) decreases feed intake but inexplicably increases plasma insulin and the insulin response to a glucose tolerance test in a variety of animal models. Whether HS directly or indirectly (via an altered hormonal or metabolic profile) alters insulin synthesis/secretion is not known. We utilized murine β-TC-6 pancreatic cells to directly evaluate the effects of HS on glucose stimulated insulin secretion (GSIS). Cells were exposed to 1 of 2 environments: 1) HS (41°C) or 2) thermo-neutral (TN; 37°C). After 2 h of environmental exposure, cells were incubated with 1 of 4 glucose concentrations: 1) 0 mM, 2) 2.5 mM, 3) 5 mM, and 4) 10 mM; and further exposed to their respective temperatures for an additional 2 h. Both HS and TN cells had a similar ($P > 0.10$) maximal GSIS at 2.5 mM glucose. To study the temporal pattern of HS effects on GSIS, β-cells were exposed to HS or TN environments for 0, 2, 6, 12, 24, 48 h; and incubated with either 0 or 2.5 mM glucose. HS decreased ($P < 0.01$) insulin production with time. By 48 h, HS β-cells had a 75% decrease ($P < 0.01$) in GSIS compared with TN cells. Taken together, our results demonstrate that HS decreases insulin secretion in β-TC-6 pancreatic cells. These data suggest that additional mechanisms participate to increase plasma insulin parameters during in vivo HS. This work was supported by USDA NIFA grant #2011–67003–30007.

Key Words: heat stress, insulin, pancreas

W192 Relationship of single nucleotide polymorphisms of the bovine NOS2 and NOS3 genes with disease resistance in feedlot steers.

A. J. Davis,* D. L. Kreider, E. B. Kegley, J. T. Richeson, and D. L. Galloway, *Animal Science Department, University of Arkansas Division of Agriculture, Fayetteville.*

Nitric oxide synthase activity is a key element in the inflammatory process initiated by bovine respiratory disease (BRD). Single nucleotide polymorphisms (SNP) in the promoter region of the endothelial nitric oxide synthase (NOS3) and inducible nitric oxide synthase (NOS2) genes may be related to the etiology of BRD, as well as, the damage and pathology that occurs in the lungs as a result of the inflammatory process associated with BRD. Therefore the objective of this study was to characterize SNP in the promoter region of the NOS3 and NOS2 genes and to determine the relationship of SNP to disease resistance in feedlot calves. Steers were randomly selected from ongoing trials conducted at the University of Arkansas Stocker and Receiving Cattle Research Unit. Health and performance records were used to identify sick (n = 12) and healthy (n = 12) animals. Animals were defined as sick if pulled from their pen for treatment of respiratory disease or suspected respiratory disease. Healthy animals were defined as animals randomly selected from the same pen as the selected sick animals which did not display health related or performance related problems during the feeding period. Upon arrival to the facility, animals were weighed (avg BW = 256.583 ± 16.5 kg) and blood was collected via jugular venipuncture. DNA (n = 24) was extracted from EDTA treated whole blood and SNP identified by sequencing a 5′ region approximately 700 bp upstream from the start of exon 1 for the NOS2 and NOS3 gene promoter region. Eight SNP, 2 deletions, and 1 insertion were observed for NOS3 and 1 SNP for NOS2. Chi-squared analyses did not reveal interactions between SNP and sick feedlot calves ($P \geq 0.12$), although the number of animals used in this study was limited. Additional research is needed to determine the relationship of SNP of the bovine NOS2 and NOS3 genes with disease resistance.

Key Words: nitric oxide, single nucleotide polymorphism, bovine respiratory disease

W193 Hypothalamic and abomasal mRNA expression of regulatory feed intake genes in cows grazing different herbage allowances of native pastures.

V. Bassaizteguy, A. Casal, A. L. Astessiano, A. Kaitazoff, M. Veyga, M. Carriquiry, and A. I. Trujillo,* *Universidad de la Republica. Facultad de Agronomia, Montevideo, Montevideo, Uruguay.*

In extensive rangeland cow-calf systems, annual variability of herbage allowance affects cow energy balance through changes in feed intake. There is scarce information about gene expression of key factors involved in the central and peripheral regulation of energy intake. Thus, the aim of this study was to evaluate the effect of 2 different herbage allowances of native pastures on hypothalamic (NPY, AgRP, POMC, CCK A receptor) and abomasal (ghrelin, CCK) mRNA expression. Pure and crossbred adult beef cows were used in a complete randomized block design and were maintained in the same herbage allowance throughout the year (2.5 vs. 4 kgDM/kgBW; LO vs. HI; n = 8, n = 5 respectively) since May 2007. Cows used in this study gestated and lactated one calf every year from 2007 to 2009. At the end of the third year, all cows were slaughter at 190 ± 15 d postpartum. Samples of hypothalamus and abomasum were collected to measure gene expression by SYBR-Green real time PCR using *RSP9* and β-actin as endogenous control genes. Data were analyzed using a mixed model that include the effect of herbage allowance as a fixed effect and cow genotype as a random effect. Means were considered to differ when $P < 0.05$. Expression of NPY and POMC mRNA did not differ due to herbage allowance. However, hypothalamic expression of AgRP mRNA tended ($P = 0.077$) to be less in HI than LO cows (0.84 vs. 2.3 ± 0.48) and CCK A receptor mRNA was numerically ($P = 0.157$) greater in HI than LO cows (1.91 vs. 1.31 ± 0.26). Herbage allowance did neither affect abomasal expression of CCK mRNA nor ghrelin mRNA expression. Results suggest that rangeland beef cows are sensitive to different nutritional planes and may respond by changing the expression of genes that regulate feed intake in hypothalamus.

Key Words: nutrition, feed intake regulation, mRNA

W194 Identification of short-chain fatty acid (SCFA) receptor transcripts in ruminal papillae and responses to SCFA infusion.

K. Yuan,* L. K. Mamedova, S. H. Li, and B. J. Bradford, *Kansas State University, Manhattan.*

Large quantities of short-chain fatty acids (SCFA) are produced by microbial fermentation in the rumen, but little is known about the mechanisms underlying their regulatory effects in cattle. Recent studies identified SCFA, including acetate, propionate, and butyrate as ligands for G protein-coupled receptor 41 (GPR41) and 43 (GPR43); lactate as a ligand for GPR81; and β-hydroxybutyrate and possibly butyrate as the ligand(s) for GPR109A. The objective of this study was to evaluate the effects of SCFA infusions on the transcript abundance of GPR41, GPR43, GPR81, and GPR109A in ruminal papillae. Six ruminally cannulated lactating Holstein cows were randomly assigned to treatment sequence in replicated 3 × 3 Latin squares and fed a standard lactation diet. Initially, cows were infused with 10 mol/d sodium acetate, sodium propionate, or sodium butyrate for 2 d. However, during period (P) 1, both DMI and calculated energy intake were decreased by infusions ($P < 0.01$) relative to pre-treatment. Therefore, infusion rates were decreased to 5 mol/d for P 2 and P 3. Ruminal papillae were collected immediately after each infusion period, and the mRNA abundance of the GPRs were determined by quantitative RT-PCR relative to the internal control gene RPS9. Data were analyzed using the REML procedure of JMP. Results showed that GPR41, GPR43, GPR81 and GPR109A genes are expressed in ruminal papillae in dairy cows. Transcript abundance of GPR41, GPR43 and GPR109A were not altered by SCFA infusion types or rates ($P > 0.10$), but GPR81 expression was increased by 1.9 ± 0.28 fold ($P = 0.01$) following the 10 mol/d SCFA infusion rate compared with the 5 mol/d infusion (across infusates). Abundance of these transcripts were not correlated with DMI or total energy intake ($P > 0.10$). Interestingly, GPR41 mRNA was positively correlated with GPR43 ($P < 0.001$, $r^2 = 0.71$) and GPR81 ($P < 0.001$, $r^2 = 0.59$), and GPR43 was positively correlated with GPR81 ($P < 0.001$, $r^2 = 0.96$). This study verified the expression of these SCFA receptors in ruminal papillae and indicated possible co-regulation of gene expression across several GPRs. Further research is needed to examine the roles of these GPRs in mediating the regulatory effects of SCFA on rumen function in dairy cows.

Key Words: G protein coupled receptors, rumen, volatile fatty acid

W195 Calibration of a dynamic, mechanistic model of amino acid and insulin effects on protein synthesis in animal tissues to represent liver and skeletal muscle.

E. R. El-Haroun[1,2], J. J. Kim*[1], D. P. Bureau[1], A. R. Willms[1], and J. P. Cant[1], [1]*University of Guelph, Guelph, Ontario, Canada,* [2]*Cairo University, Giza, Cairo, Egypt.*

The objective of the present study was to calibrate a dynamic, mechanistic model of nutritional control of protein synthesis in animal tissues to represent liver and muscle, respectively. The model predicts the fractional synthesis rate (FSR) of protein based on mass action kinetics of translation initiation and elongation, and insulin- and amino acid-mediated regulation of the concentration of bound eukaryotic initiation factor-4E (c4eBp) and the recycling of eukaryotic initiation factor 2 (UF2d, F2d→F2t). Sensitivities of model predictions to 50% changes in each of 16 kinetic parameters were determined. Exponents in the initiation equation and the first-order rate constant for elongation had the greatest effect on tissue FSR and UF2d, F2d→F2t. The steady-state value of c4eBp was highly sensitive to all 5 parameters of factor-4E association and dissociation and lacked sensitivity to any of the other parameters. The strategy for calibration of the model to liver and muscle data was to fit the top 5 parameters to which c4eBp was most sensitive first, followed by fits of the top 5 parameters to which FSR was most sensitive. More than 99% of this error was attributed to random disturbance, indicating a lack of either slope or mean bias. Mean square prediction errors for c4eBp and FSR in liver were 32.9 and 5.0% of their observed means, respectively, with 56 and 99% of the respective errors attributed to random disturbance. Bias in c4eBp prediction was attributed to technical errors in its measurement and did not affect the accuracy or precision of FSR prediction. Sensitivity analysis and accuracy testing suggested that modification of the model structure was not required. Two unique sets of parameters were obtained to describe protein synthesis in liver and muscle in terms of the regulation of c4eBp by insulin and leucine, and of UF2d, F2d→F2t by uncharged tRNA.

Key Words: mechanistic model, amino acid, insulin

W196 Expression of adiponectin and leptin receptors and angiopoietin-like protein 4 (ANGLP4) mRNA differed in the of pure and crossbred beef cows grazing different herbage allowances of native pastures.

M. Carriquiry,* M. Veyga, A. Casal, A. L. Astessiano, and J. Laporta, *School of Agronomy, UdelaR, Montevideo, Uruguay.*

Leptin, adiponectin, and ANGLP4 play important roles in energy expenditure, insulin sensitivity, glucose homeostasis, and lipid metabolism but information in ruminants is scarce. Therefore, the objective of this study was to evaluate the effect of the herbage allowance of native pastures and cow genotype, on hepatic expression of receptors of leptin (LEPRb), adiponectin (ADIPOR1 and ADIPOR2) and insulin (INSR), and ANGLP4 mRNA. Adult cows (n = 24) in a factorial arrangement of herbage allowances (2.5 vs. 4 kgDM/kgBW in average throughout the year; LO vs. HI) and cow genotype (purebred: Aberdeen Angus and Hereford vs. their F1 crossbred; PB vs. CB) were used in a complete randomized block design. Cows were maintained in the herbage allowance treatment since May 2007 and gestated and lactated one calf every year from 2007 to 2009. At the end of the third year, cows were slaughter at 190 ± 15 d postpartum and liver samples were collected to measure gene expression by SYBR-Green real time PCR using hypoxanthine phosphoribosyltransferase and β-actin as endogenous control genes. Data were analyzed using a mixed model and means were considered to differ when $P < 0.05$. Cow body weight and body condition score were greater in HI than LO cows and in CB than PB cows through the gestation-lactation cycle. At slaughter, hepatic ADIPOR2 and INSR mRNA did not differ among groups but ADIPOR1 mRNA tended ($P = 0.09$) to be greater and ANGLP4 mRNA was greater in CB than PB cows (1.21 vs. 1.62 ± 0.26 and 0.54 vs. 1.05 ± 0.27, respectively) and these differences were mainly due to cows in low herbage allowance. In addition, expression of LEPRb mRNA was affected by the interaction between herbage allowance and cow genotype, as its expression was highest in HI-PB, lowest in HI-CB and LO-CB, and intermediate in LO-PB cows (3.58, 1.58, 0.73, and 0.77 ± 0.21, for HI-PB, LO-PB, HI-CR, and LO-CB, respectively). Hepatic LEPRb, ADIPOR1 and ANGLP4 mRNA could play a role in adaptation mechanisms to changes in energy balance through the production cycle of beef cows in rangeland conditions.

Key Words: adipokines, hepatic gene expression, beef cattle

W197 Gene expression analysis of glutathione peroxidase, catalase, and superoxide dismutase (Mn) in white blood cells from dairy cows receiving an apple base nutraceutic supplement. L. E. Escobedo-Morales, J. A. Grado-Ahuir,* C. Rodríguez-Muela, P. Hernández-Briano, and R. M. Villaseñor-González, *Facultad de Zootecnia y Ecología, Universidad Autónoma de Chihuahua, Chihuahua, Chihuahua, México.*

This work was carried out to analyze the gene expression of antioxidant enzymes in white blood cells of cows under a nutraceutical diet based on apple pomace. We studied 8 Holstein cows at fresh stage that were randomly assigned to one of 2 experimental groups, control (T) and supplemented with a nutraceutical feed (M), being both diets isolaloric. Blood samples were obtained from the caudal vein every 14 d for 2 mo. Ribonucleic acid from white blood cells was isolated and real time RT-PCR reactions were performed to measure expression levels of genes coding for superoxide dismutase (SOD2), catalase (CAT) and glutathione peroxidase (GPX) relative to Glyceraldehyde 3-phosphate dehydrogenase (GAPDH). Data were analyzed under a mixed model including treatment, period and their interaction as fixed effects and cow as a random effect. Expression level for CAT and SOD2 genes were higher ($P < 0.05$) in M than in T cows (1.40 and 1.43 times, respectively). There were no difference between groups ($P = 0.4893$) for the enzyme GPX. According to our results, it appears to be a relationship among the antioxidant effects of apple pomace with increased mRNA levels of 2 antioxidant enzymes CAT and SOD2 (mitochondrial), which may explain at the genetic level the synergy of its components to achieve the reduction of reactive oxygen species in dairy cows.

Table 1. Overall fold change in gene expression (least squares means ± standard errors) of genes for antioxidant enzymes

Gene	Apple pomace	Control
Catalase	2.17 ± 0.16^{a}	1.55 ± 0.16^{b}
Glutathione peroxidase	6.26 ± 0.43^{a}	5.83 ± 0.43^{a}
Superoxide dismutase 2	2.72 ± 0.19^{a}	1.90 ± 0.19^{b}

^{a,b}Means with the same letter within a row are statistically similar (P < 0.05).

Key Words: apple pomace, antioxidant enzymes, dairy cows

W198 Measurements of saliva secretion and salivary fluxes of metabolites from jugular–arterial concentration differences, hemoglobin concentration, and jugular blood flow. A. C. Storm*[1], M. Larsen[1], and N. B. Kristensen[1,2], [1]*Aarhus University, Department of Animal Science, Tjele, Denmark,* [2]*Syddanskkvæg, Vojens, Denmark.*

The objective was to assess saliva secretion in lactating dairy cows during resting and rumination by measuring blood flow in right and left jugular vein and the concentration difference of hemoglobin in arterial and jugular blood. Three lactating dairy cows were surgically implanted with permanent catheter inserted into *A. intercostales dorsales* with the tip of the catheter placed in *Aorta*. On sampling days, temporary catheters were inserted 20 cm into *V. auricularis intermedialis* or *V. auricularis lateralis*, for infusion of the blood flow marker *p*-aminohippuric acid (11.17 ± 0.44 mmol/h), initiated 1 h before first blood sampling. Temporary catheters were also placed in the right and left *V. jugularis externa* for sampling of blood. Simultaneous blood samples from the artery and jugular veins were obtained during resting and rumination in 2 subsequent periods. For rumination and resting activity 2–4 and 2–3 repeated samples, respectively, were obtained with 5–10 min frequency. Cows were feed a 50:50 forages to concentrate diet. The difference between periods were dietary Na and K, (period 1 Na = 1.23, K = 1.41; period 2 Na = 0.37, K = 2.81% DM). Means within resting and rumination periods for each cow were analyzed statistically by a mixed model including main effect of activity (rumination and resting), period, and their interaction, considering cow as a random effect. The summed jugular blood flow, saliva secretion, and salivary flux of HCO_3^-, urea, and P were higher during rumination as compared with rest (Table 1), and were not affected by dietary Na or K. In conclusion, the current method for measuring saliva secretion produced reasonable estimates for secretion of selected metabolites in saliva.

Table 1. Jugular blood flow, salivary flow, and salivary flux of P, urea, and bicarbonate in lactating dairy cows during resting and rumination periods

Item	Rest	Rumination	SEM[1]	ACT[2]	Period
Jug. blood flow, L/h	199	430	22.7	<0.001	0.76
Saliva flow, L/h	7.4	13.6	0.77	<0.001	0.14
HCO_3^- salivary flux, mmol/h	870	1879	72	<0.001	0.07
P salivary flux, mmol/h	81	126	8.7	0.003	0.99
Urea salivary flux, mmol/h	22.7	37.8	3.17	0.011	0.13

[1]n = 3.

[2]ACT = rest or rumination.

Key Words: saliva secretion, flux

W199 Is colostrum quality in dairy cows related to postpartum health, production, or fertility? A. R. Dresch*[1], A. H. Souza[1], P. D. Carvalho[1], L. M. Vieira[1,2], J. L. M. Vasconcelos[3], R. A. Cerri[4], M. C. Wiltbank[1], and R. D. Shaver[1], [1]*University of Wisconsin-Madison, Madison,* [2]*University of Sao Paulo-VRA, SP, Brazil,* [3]*Sao Paulo State University Botucatu, SP, Brazil,* [4]*University of British Columbia, BC, Canada.*

Two studies were performed to investigate the relationship between colostrum quality and postpartum health, production and fertility in Holstein cows. In Experiment 1, colostrum samples were from 66 cows housed in a WI tie-stall barn. The DMI and milk yield measurements were daily and milk samples were collected from both AM/PM milkings twice weekly for determination of milk composition from calving to 70DIM. In Experiment 2, colostrum samples (n = 989) were from 2 commercial free-stall/parlor herds in WI. Colostrum was collected from the 1st milking and frozen for later quality analysis (Brix refractometer, 0 to 53% scale). Only cows with at least 3 weeks of dry period were used in the analysis. Data were analyzed using Proc Mixed and Proc Glimmix of SAS. Viscosity (r = 0.75, $P < 0.01$) and color (r = 0.46, $P < 0.01$) were highly correlated to Brix readings. Interestingly, there was no difference ($P > 0.10$) in proportion of primiparous (85%, n = 353) or multiparous (87%, n = 636) cows with Brix > 22%, that was considered to be good quality colostrum. In Experiment 1, cows with lower colostrum quality (LC, n = 18) were not different from cows with greater colostrum quality (GC, n = 48) for DMI, milk yield, fat%, or MUN. In contrast, LC cows tended ($P = 0.07$) to have greater linear SCC score in the first 5 weeks postpartum, with reduced milk protein content (2.9% vs 2.7%; $P < 0.01$) through 70DIM. In Experiment 2, although cows having retained placenta tended ($P = 0.07$) to have lower colostrum quality, but the logistic regression model indicated that cows with LC had similar %RP than GC, respectively (7% vs 4%, $P = 0.13$). In addition, LC cows were more likely to have postpartum metritis (13% vs. 7%, $P = 0.02$). Despite some significant associations between colostrum quality and RP and/or metritis, conception rate to 1st postpartum AI was not related to colostrum quality (LC = 33.8%, n = 133 vs GC = 34.2%, n = 856; $P = 0.90$). In conclusion, measurement of colostrum quality at calving was associated with some important production and health parameters postpartum; whereas, fertility following 1st postpartum AI was independent of colostrum quality. Supported by USDA Grant 2010–85122–20612.

Key Words: colostrum quality, postpartum health, dairy cow

W200 Effect of 17β-estradiol on cGMP-PK1 expression in myometrial longitudinal muscles.

O. Y. Gulay*[1], A. Bulbul[2], M. S. Gulay[1], K. Altunbas[2], and O. O. Akkaya[2], *[1]Mehmet Akif Ersoy University, Faculty of Veterinary Medicine, Burdur, Turkiye, [2]Afyonkocatepe University, Faculty of Veterinary Medicine, Afyonkocatepe, Turkiye.*

The characteristics of spontaneous longitudinal myometrial contractility change due to direct actions of 17β-estradiol (ES) and nitric oxide (NO). NO inhibits the contractility of smooth muscles via guanylate cyclase (GC) where activated GC increases cGMP-PK1 expression and relaxes smooth muscles. Previous studies from our laboratories suggested that ES could inhibit the NO effect in myometrial longitudinal muscle via altering cGMP-PK1 expression. Thus, the aim of this study was to evaluate the effect of injecting different doses and time intervals of 17β-estradiol on cGMP-PK1 expression on myometrial longitudinal muscles of ovariectomized rats. Three to 6 mo old female Sprague Dawley rats (n = 71) were used in the current study. The ovariectomized rats (270 ± 20 g) were randomly assigned to one control (Ov) and 3 17β-estradiol injected groups of 18 rats each. Rats in the Ov group received daily sesame oil (0.2 mL, IM), whereas each rats in the 3 17β-estradiol injected groups were treated with daily 25, 50 and 100 µg estradiol in sesame oil (IM), respectively. Each group was further divided in 3 subgroups: 6 rats in each group were sacrificed by cervical dislocation at 18, 90 and 162 h. Uterus samples removed immediately after sacrifice for immunohistochemical evaluation (streptavidin-biotin-peroxidase method) to determine cGMP-PK1 expression in longitudinal muscles. For statistical evaluation of the data, one-way ANOVA was used. In myometrial longitudinal muscles, cGMP-PK1 scores (expression levels as mean ± SD) at 18, 90 and 162 h for Ov, 25, 50 and 100 µg estradiol groups were 7.33 ± 0.10, 7.41 ± 0.08, 7.00 ± 0.44, and 7.75 ± 0.11 ($P = 0.21$); 6.58 ± 0.53, 6.75 ± 0.11, 7.33 ± 0.27, and 6.50 ± 0.00 ($P = 0.24$); and 7.08 ± 0.08, 6.00 ± 0.89, 7.25 ± 0.11, and 6.16 ± 0.73 ($P = 0.34$), respectively. Our results indicated that effects of estrogen on cGMP-PK1 expression in uterine longitudinal smooth muscles were minimal. Thus, our data suggested that 17β-estradiol did not show its effect through cGMP-PK1 in uterine longitudinal muscles.

Key Words: ovariectomized rats, cGMP-PK1, estradiol

W201 Expression of sex steroid receptors in placental tissues during early pregnancy in sheep.

L. P. Reynolds*[1], P. P. Borowicz[1], M. L. Johnson[1], J. Haring[1], R. Ashley[2], and A. T. Grazul-Bilska[1], *[1]Center for Nutrition and Pregnancy, Department of Animal Sciences, North Dakota State University, Fargo, [2]Department of Animal and Range Sciences, New Mexico State University, Las Cruces.*

Vascularization of the placenta during early pregnancy is critical for the successful establishment of pregnancy and also supports normal fetal growth and development. Sex steroids and their receptors are important regulators of angiogenesis and growth in reproductive tissues, including the placenta. However, little is known about the expression of sex steroid receptors in placental tissues during early pregnancy. To examine mRNA expression of sex steroid receptors, we collected maternal (caruncular, CAR) and fetal (fetal membranes, FM) placental tissues on d14, 16, 18, 20, 22, 24, 26, 28, and 30 of early pregnancy (n = 5–6/day) and on d9–11 after estrus (nonpregnant [NP] controls; n = 5). Placental tissues were snap-frozen, RNA was extracted, and mRNA expression was evaluated using quantitative, real-time PCR. For both CAR and FM, nuclear progesterone receptor (P4R) mRNA was greatest ($P < 0.03$) in NP controls and through d22 of early pregnancy then declined and remained low on d24–30. For CAR, nuclear estrogen receptor (ER) α mRNA was greatest ($P < 0.01$) in NP controls and on d14 but declined on d18 of early pregnancy and remained low thereafter; for FM nuclear ERalpha was greatest ($P < 0.02$) on d20 of early pregnancy. For CAR, nuclear ERbeta mRNA was greater ($P < 0.01$) in NP controls than on any day of early pregnancy; for FM it did not change ($P = 0.33$) across days of early pregnancy. For CAR, membrane P4Ralpha and β were greatest ($P < 0.01$–0.07) in NP controls compared with any day of early pregnancy, whereas membrane P4Rgamma was 2- to 8-fold greater ($P < 0.01$) on d18 and 22 compared with NP controls or any other day of early pregnancy. For FM, membrane P4Ralpha, β, and gamma were elevated ($P < 0.01$–0.10) on d18 or 20 compared with NP controls or other days of early pregnancy. Thus, sex steroid receptors showed distinct patterns of expression in placental tissues during early pregnancy in ewes. These data establish the normal pattern of sex steroid receptor mRNA expression in maternal (CAR) and fetal (FM) placental tissues during early pregnancy, thus providing a basis for understanding the mechanisms by which sex steroids regulate placental growth and vascular development in normal and compromised pregnancies. Supported by USDA-NRI grant 2007–01215 to LPR and ATGB.

Key Words: placental angiogenesis, early pregnancy, sex steroid receptors

W202 Carryover effects on progesterone concentrations and fetal numbers in ewes given human chorionic gonadotropin.

C. M. Richardson,* R. A. Halalsheh, D. M. Hallford, and T. T. Ross, *New Mexico State University, Las Cruces.*

Administration of hCG will increase serum progesterone (P4) and potentially increase number of lambs born. The objective of this study was to determine if a carryover effect of previous hCG administration would alter serum P4 concentrations and increase fetal number in ewes in subsequent years. A single dose of hCG was administered on d 4 post mating with the purpose to increase serum P4 concentrations in ewes and increase number of lambs born. Mixed aged Suffolk ewes (n = 40) received an intravaginal P4-containing insert (CIDR; 0.3 g P4) for 10 d to synchronize estrus. Ewes were mated with fertile rams on the first estrus after CIDR removal and were assigned to 1 of 3 treatments. Ewes that were treated with hCG (600 IU; i.m.) 1 year prior were divided into 2 groups; hCG/hCG and hCG/NO hCG. The hCG/hCG group received hCG (600 IU- i.m.) on d 4 post mating. Ewes that received hCG the year prior and were in the hCG/NO hCG group did not receive hCG and were administered a saline i.m. injection. Control ewes received saline both years. Jugular blood samples were taken from 7 ewes of each treatment group starting on d 1 through 21 d post mating to monitor serum P4. Ovulation rates were determined via laparoscopy on d 44. On approximately d 70, flank ultrasound was used to establish fetal numbers. A treatment x day interaction was observed for serum P4. Ewes in hCG/hCG group had greater ($P < 0.05$) P4 concentrations beginning on d 8 through d 15 than hCG/NO hCG and control treated ewes; whereas, treatments hCG/ NO hCG and controls had similar ($P > 0.05$) serum P4 concentrations. Ovulation rates, CL number ($P > 0.33$)

and fetal numbers ($P > 0.62$) did not differ among treatment groups. In conclusion, administration of hCG in subsequent years does not produce carryover effects allowing multiple year administrations of hCG.

Key Words: human chorionic gonadotropin, progesterone, fetal numbers

W203 Serum testosterone concentrations after feeding in rams treated with GnRH.

M. M. Guardieiro*[1], F. L. M. Silva[1], A. A. Johnson[2], R. S. Gentil[1], P. L. J. Monteiro Jr.[1], D. M. Polizel[1], R. A. Souza[1], I. Susin[1], E. Oba[3], G. B. Mourão[1], and R. Sartori[1], *[1]University of São Paulo, Piracicaba, SP, Brazil, [2]Texas A&M University, College Station, [3]São Paulo State University, Botucatu, SP, Brazil.*

Circulating testosterone (T) is highly variable due to alterations in testicular T production, driven by pulses of luteinizing hormone, and alterations in T metabolism, primarily in the liver. In this study we attempted to develop an experiment to better understand the pattern of T release in male ruminants treated or not with GnRH and after feeding. The hypotheses for this study were: 1) circulating T will rapidly increase in rams following an LH pulse induced by exogenous GnRH treatment, 2) circulating T will decrease following feeding. Eight pubertal Santa Inês rams, weighing 56.6 kg on average, were used in a crossover design to test the first hypothesis and to provide initial observations related to the second hypothesis. Jugular blood samples were collected just before i.v. treatments that were performed 3 times a day (7:00, 11:00, and 15:00 h) with saline (Control group, n = 8) or GnRH (50 µg Gonadorelin, Fertagyl, MSD Saúde Animal; GnRH group, n = 8) and 30, 60, and 120 min after treatments. Rams were fed 1 h after the first i.v. treatment. Serum T concentrations were measured by radioimmunoassay. Data were analyzed using a generalized linear mixed model, considering the first-order heterogeneous autoregressive covariance matrix, due to repeated measures on the same ram at different hours. The model included the fixed effects of treatments, time of blood collection (hour) and treatment × hour interaction. Period and error were included as random effects. There was an effect of treatment ($P < 0.001$), hour ($P = 0.0123$) and treatment by hour interaction ($P < 0.001$). After the first GnRH treatment, T concentrations increased by 30 min with peak concentrations attained by 2 h after GnRH (8.8 ± 1.3 and 2.3 ± 1.3 ng/mL, GnRH vs. Control respectively; $P = 0.004$). There were also increased T concentrations after the second (0.5, 1, and 2 h) and third (1 and 2 h) GnRH treatments, although the peak T concentrations were lower compared with the first GnRH treatment. In the Control group, there was an apparent decrease in circulating T at 3 h after feeding with a subsequent increase in circulating T at 7 h after feeding. Thus, the first hypothesis on GnRH-induced LH pulses driving testicular T production was supported and future studies are needed to validly test whether time of feeding regulates circulating T, possibly through increased T metabolism. Supported by MSD Saúde Animal, FAPESP and CNPq of Brazil.

Key Words: sheep, testosterone, GnRH

W204 The potential effects of dietary nitrate on pregnancy mechanisms in ewes.

K. J. Austin,* R. R. Cockrum, L. E. Speiser, and K. M. Cammack, *University of Wyoming, Laramie.*

Subacute levels of dietary nitrate have been implicated in embryonic loss, abortion and infertility in ruminants. Previous studies have not shown differences in the levels of progesterone or the number of lambs born to nitrate treated ewes compared with control ewes when nitrate was administered for 2 estrus cycles before breeding. However, nitrate toxicity is highly variable in sheep, and tolerance to such toxicity has been observed especially in cases of subacute, chronic exposure. Therefore, we hypothesize that chronic exposure to subacute levels of dietary nitrate may alter pregnancy mechanisms not observed with short-term exposures. Purebred Suffolk ewes (n = 24) were randomly assigned to one of 2 treatment groups, 0 mg/kg KNO_3 /BW (control) or 175 mg/kg KNO_3/ BW (nitrate treated) for 26 d. Ewes were weighed weekly and levels of KNO_3 adjusted according to BW. Ewes were synchronized, monitored for heat, administered KNO_3 for 2 full cycles, and mated to one of 2 intact rams. Ewes were bled daily for 26 d post breeding, then weekly until parturition. Blood was analyzed for progesterone (d 12–14, 50 and 80), *ISG15* and *MX2* mRNA (d 12–14) and circulating levels of PSBP (d 50 and 80). Progesterone levels did not differ in nitrate treated ewes compared with controls on d 12–14 ($P > 0.30$), d 50 ($P = 0.51$) or d 80 ($P = 0.92$) of pregnancy. Message for *MX2* did not differ on d 12 and 13 ($P = 0.24$) but tended to be upregulated (2.6 FC, $P = 0.07$) on d 14 of gestation in nitrate treated ewes compared with controls. Message for *ISG15* tended to be decreased on d 12 (2.3 FC, $P = 0.09$) and 13 (1.6 FC, $P = 0.13$) and upregulated on d 14 (3.8 FC, $P = 0.09$) of gestation in nitrate -treated compared with control ewes. Levels of PSPB in blood tended to be upregulated (1.6 FC, $P = 0.10$) on d 50 but did not differ between control and nitrate treated ewes on d 80 of pregnancy($P = 0.24$). Results imply that although no effects of dietary nitrate were observed immediately following short-term treatment, there may be chronic effects of nitrate in the diet of sheep which may impair the ewe's ability to maintain pregnancy. Perhaps ISG15 and MX2 play some role in protecting pregnancy against this challenge.

Key Words: nitrate, ISG15, MX2

W205 Effects of intravenous glucose infusion and nutritional balance on expression of enzymes responsible for catabolism of progesterone in cattle.

F. Vieira[1], R. Cooke[2], A. Aboin[1], P. Lima[3], and J. L. Vasconcelos*[1], *[1]DPA-FMVZ-UNESP, Botucatu, SP, Brazil, [2]Oregon State University, Burns, [3]IBB-UNESP, Botucatu, SP, Brazil.*

The objective of this study was to evaluate the effects of glucose infusion and energy balance on serum concentrations of glucose, insulin, IGF-1, progesterone (P4), as well as mRNA expression of hepatic GHR1A, IGF-1, CYP2C and CYP3A in nonlactating, ovariectomized cows inserted with an intravaginal device P4 (CIDR). Fifteen Gir × Holstein cows were stratified by BW and BCS on d −28 of the study, and randomly assigned to: 1) negative nutrient balance (NB) and 2) positive nutrient balance (PB). Cows assigned to PB were supplemented individually once a day. From d −28 to −15 of the study, cows received a previously used CIDR, which was replaced by a new CIDR on d −14 and remained until the end of the study (d 1). On d 0, cows within nutritional treatment were removed from pastures and randomly assigned to receive, in a crossover design containing 2 periods of 24 h each (d 0 and 1): 1) intravenous glucose infusion (GLUC; 0.5 g of glucose/kg of BW, over a 3 h period), or 2) intravenous saline infusion (SAL; 0.9% NaCl, over a 3 h period). Cows were fasted for 12 h before infusions, and remained fasted during infusion and sample collections. Blood samples were collected at −12 (beginning of fasting), 0 (before infusion), 3 and 6 h after beginning of infusions via the coccygeal vein. Liver biopsies were performed at 0 and 3 h relative to beginning of infusions. Compared with PB cows, NB cows lost ($P < 0.05$) more BW (−23.1 vs. 16.5 kg) and BCS (−0.20 vs. 0.07). Cows receiving GLUC had greater glucose ($P < 0.01$) concentrations at 3 h relative to infusion compared with SAL cohorts (148.04 vs. 65.5 mg/dL). Cows receiving GLUC infusion had greater ($P < 0.05$) insulin concentrations compared with cows receiving SAL at 3 h, although this glucose-stimulated increase in insulin was greater in NB compared with PB cows (nutritional status x infusion x h interaction; 136.71 vs. 51.3 µUI/mL; $P < 0.01$). In PB cows, glucose infusion reduced the expression of GHR1A and CYP3A, but did not impact serum P4 concentration. In NB cows, glucose infusion increased expression of GHR1A and CYP3A and decreased serum P4 concentration. In conclusion, the effects of glucose infusion on serum insulin, P4, GHR1A and CYP3A mRNA expression were dependent on the cow nutritional status.

Key Words: insulin, CYP3A, progesterone

W206 Ex vivo model for endotoxic laminitis in ruminants. S. Schaumberger,* N. Reisinger, and G. Schatzmayr, *Biomin Research Center, Tulln, Austria.*

It is well known that laminitis in ruminants has a multifactorial etiology. As a key factor feeding of increased fermentable carbohydrate has been identified. If animals are not adapted to these rations, this may lead to rumen acidosis. Coincident with the change in the rumen pH is the release of endotoxin from gram-negative bacteria. An enhanced absorption of bacteria, endotoxin, lactic acid and histamine through the rumen, leads to a direct or indirect disruption in the micro-circulation of the corium and later to the lesions observed in laminitis. Objective of our ex vivo study was to get a better understanding of the direct influence of endotoxins on the lamellar structure of the claw and the separation from the coffin bone. Four normal claws were collected from the slaughter housed. Claw explants consisted of 2 mm of the inner claw wall, 6 intact epidermal lamellae and 2 mm of connective tissue. Explants were cultured with 1 mL culture medium and in 0.9% sodium chloride solution at 37°C and 5% CO2. After 24 and 48 h, explants were studied for lamellar separation. In a second experiment, explants were cultured with different concentrations (200 to 5 µg/mL) of lipopolysaccharides (LPS) from *Escherichia coli* O55:B5 for 24 and 48 h. Explants cultured only in medium were used as a negative control, and those cultured in 0.9% sodium chloride solution as a positive control. After incubation explants were tested for their integrity. Viability was tested with the water soluble tetrazolium (WST)—1 assay. Explants were considered as viable if absorbance of the medium containing 1% WST reagent increased after 2 h of incubation. All explants cultured only in medium for 24 and 48 h remained intact, and all cultured in 0.9% sodium chloride solution separated. Down to 20 µg LPS/mL 100% of the explants seperated. From 10 µg to 5 µg LPS/mL, separation of 33% and 66% of the explants could be detected. Explants still were viable after 24 and 48 h of incubation. Endotoxins of *E. coli* showed a concentration dependent lamellar separation in claw explants. This model may be used to investigate substances which affect the development of bovine laminitis. Further experiments will be carried out to investigate supernatants and explants for their cytokine activity to explain the inflammation process induced by LPS.

Key Words: ruminants, laminitis, endotoxin

W207 Effect of different centrifugation protocols and comparison of four extenders for storage of cooled Caspian horse spermatozoa for 48 hours. H. Nouri[1], A. Towhidi*[1], and M. Bahreini[2], *[1]Department of Animal Science, Faculty College of Agriculture and Natural Resources, University of Tehran, Karaj, Iran, [2]Animal Breeding Center of Iran (A.I. lab), Iran.*

The use of cooled transported equine semen continues to gain popularity among breeders as its acceptance increases among breed registries. Two experiments were conducted to evaluate the impact of 4 extenders and different centrifugation protocols on cooled preservation of Caspian horse semen. In experiment 1, extenders tested included EZ-mixin (Minitube, Germany), Kenney's (Minitube, Germany), INRA96 (IMV, France), and CPE (Caspian horse extender). Semen was collected from 4 adult Caspian horse with artificial vagina and each ejaculate was divided and extended in each of the aforementioned extenders and stored at 4ËšC. Motility measures were determined using computer-assisted sperm analysis at 0, 24, and 48, hours after collection. Samples were evaluated for total motility, progressive motility (PM), straight-line velocity, curvilinear velocity, straight-line distance. Total motility and PM decreased over time in storage ($P < 0.05$). Sperm stored in INRA 96, and CPE retained the most total motility and PM over the 48-h period ($P < 0.05$). CPE had the highest measurements for curvilinear velocity, straight line velocity, and curvilinear distance ($P < 0.05$). In experiment 2: The objectives of this experiment were to determine the effects of centrifugation on Caspian horse sperm progressive motility, viability, and plasma membrane integrity. Ejaculates from 4 Caspian horses were collected, extended (CPE) to a concentration of 50×10^6 cells/mL, and subjected for 4 and 7 min to: 1) no centrifugation (NC); 2) $500 \times g$ (500); 3) $1000 \times g$ (1000); and 4) $2000 \times g$ (2000). Before and after centrifugation (d 0), and after 24 and 48 h of cooling, sperm motility was assessed by computer assisted semen analysis, and samples were stained with Eozin negrosin for viability, and with Hypo-osmolarity swelling test (Host) for membrane integrity. Compared with the other treatment groups the 2000 treatment group showed reduced motility, viability, and membrane integrity ($P < 0.05$). The 500 and 1000 treatment groups centrifugation of semen Compared with uncentrifuged samples resulted in a better sperm quality after chilled storage. The 500 and 1000 treatment groups yielded lower recovery rates than the 2000 treatment group ($P < 0.05$). Centrifugation at $1000 \times g$ for 7 min did not damage Caspian horse sperm.

Key Words: Caspian horse, centrifuge, extenders

W208 Pigs fed camelina meal increases liver CYP8B1 expression. W. J. Meadus*[1], P. Duff[1], T. McDonald[2], and W. Caine[1], *[1]AAFC-Lacombe, Lacombe, AB, Canada, [2]Olds College, Olds, AB, Canada.*

Camelina, also known as false flax, has commercial potential, as an oil seed crop for biofuels and biolubricants grown on marginal lands. Camelina seed has an oil content of >40% and this oil is high in n-3 fatty acids and γ-tocopherol. The oil is not approved for human consumption because as a member of the mustard family (Brassicaceae) and is suspected to contain high levels of erucic acid (C22:1 n-9) and glucoinolates. Camelina meal is the by-product after the oil has been extracted. Pigs (n = 26) were fed 3.7% and 7.4% camelina meal for 20 d starting at weights of 12 kg and finished at 17kg. The livers of the pigs were obtained at slaughter and immediately extracted for total RNA. Total RNA was examined for gene expression changes by microarray analysis using the Rat drug metabolism: phase 1 array and the Human Drug Metabolism: phase 2 enzyme arrays, of SAbioscience. Expression analysis (ΔCt ref-sample) on the rat array identified the cytochrome P450 family 8b1 (Cyp8b1) and aldehyde dehydrogenase 2 (Aldh2); and on the human array, glutathione S-transferase mu 5 (GSTM5), and thiosulfate sulfurtransferase (TST), as being significantly upregulated, relative to the control livers. The porcine version of Cyp8b1 was cloned and confirmed, for significant ($P < 0.05$) upregulation of ~4-fold, by real-time PCR. The Cyp8b1 is associated with hyocholic bile acid formation. The camelina meal must be inducing bile acid formation, possibly due to erucic acids.

Key Words: camelina, gene expression, Cyp8b1

W209 Effect of exogenous testosterone on testes characteristics of large white pigs in a humid enviroment.

A. O. Ladokun*[1], J. R. Otite[2], O. M. Alabi[3], and D. O. Adejumo[2], [1]*University of Agriculture, Abeokuta, Ogun, Nigeria,* [2]*University of Ibadan, Ibadan, Oyo, Nigeria,* [3]*Bowen University, Iwo, Osun, Nigeria.*

A total of 24 pigs were used for the experiment to determine the effect of exogenous testosterone (testosterone enanthate) administered by intramuscular injection on testicular characteristics especially daily sperm production (DSP). Pigs were treated once weekly from birth until 24 weeks of age with vehicle or testosterone enanthate. Testosterone enanthate was given at the rate of 1.2mg/kg body weight. Corn oil was used as the vehicle. At the end of the 24 weeks, the pigs were slaughtered and their testes harvested. The parameters measured include seminiferous tubule diameter, paired testes weight (PTW), testis density, daily sperm production (DSP) from gonadal sperm reserves (GSR) and DSP from quantitative testicular histology (QTH). Data obtained were analyzed using Complete randomized design (one-way ANOVA) of Statistic Analytical System (SAS) package 2001. The results show that testosterone enanthate significantly ($P < 0.05$) increased the values of DSP from QTH (18.12 ± 3.00; 35.28 ± 4.11). The same trend was recorded for Seminiferous tubule diameter (117.73 ± 9.10µ and 148.29 ± 8.70µ respectively for control and testosterone). This present results show that exogenous administration of testosterone to large white male pigs, could be used to accelerate spermatogenesis and thus reproductive efficiency in swine herds especially for boars.

Table 1. Testicular characteristics of boars administered testosterone enanthate

Testicular characteristics	Control (blank injection)	Testosterone enanthate
Paired testes weight-PTW g	101.46^{b}	220.43^{a}
PTW per kg bodyweight	3.27^{b}	3.93^{a}
Testes density	1.10	1.06
DSP from GSR (x109)	4.37^{b}	8.56^{a}
DSP from QTH (x106)	18.12^{b}	35.28^{a}
Seminiferous tubule diameter (µ)	117.73^{b}	148.29^{a}
DSP per unit tubule diameter	28.12^{b}	50.16^{a}
Volume % of round spermatid nuclei	1.74^{b}	3.78^{a}

^{abc}Means in the same row with different superscripts differ significantly ($P < 0.05$).

Key Words: exogenous, testosterone, testes

W210 Effect of heat stress on phosphatidylinositol-3 kinase signaling in gilt ovaries.

J. Nteeba,* E. E. Ullerich, S. C. Pearce, R. Boddicker, J. W. Ross, L. H. Baumgard, and A. F. Keating, *Department of Animal Science, Iowa State University of Science and Technology, Ames.*

Heat stress (HS) negatively affects reproductive performance in swine, but the biological reasons responsible for this impaired fecundity are poorly understood. Paradoxically HS decreases feed intake but unexplainably increases plasma insulin in a variety of animal models including pigs. Insulin influences ovarian phosphatidylinositol-3 kinase (PI3K) signaling, which is important for follicle viability and regulating follicle activation and steroidogenesis. Two downstream mediators of PI3K action are Protein kinase B subunit 1 (*Akt1*), and the forkhead transcription factor subunit 3a (*Foxo3a*). This study investigated the effects of HS on PI3K signaling in the porcine ovary. Crossbred gilts (35 ± 4 kg) housed in constant climate controlled rooms in individual pens with ad libitum feed intake were exposed to thermal neutral (TN) conditions (20°C; 35–50% humidity; n = 3–6) or HS conditions (35°C; 20–35% humidity; n = 3–6) for 7 or 35 d to simulate acute and chronic HS, respectively. Gilts were euthanized, one ovary was stored at −80°C and the other ovary was fixed in 4% paraformaldehyde. Total RNA was isolated and levels of *Akt1* and *Foxo3a* mRNA were quantified by RT-PCR using *GAPDH*, as the internal control gene. The insulin receptor (IR) and phosphorylated (active) AKT (pAKT) proteins were localized by immunofluorescence staining. On d 7, HS decreased (12-fold; $P < 0.05$) mRNA encoding *Akt1*, but environment had no effect on *Foxo3a* mRNA abundance. After 35 d and relative to TN controls, HS increased ($P < 0.05$) *Akt1* (2.0-fold) and *Foxo3a* (2.1-fold) mRNA. Oocyte cytoplasm and cytoplasmic membrane of all stage follicles stained positive for the IR protein. pAKT protein was located in the oocyte cytoplasm of all stage follicles, with apparent greater expression in larger stage follicles. Additionally, theca and granulosa cells of preovulatory follicles were positive for pAKT protein. These data suggest HS leads to altered expression of PI3K signaling pathway members, which could alter dynamics of follicle activation, affect follicle viability and potentially alter ovarian steroid synthesis, thus leading to negative effects on fertility in swine.

Key Words: heat stress/hyperthermia, reproductive physiology, swine/porcine/pig

W211 Acute duration heat stress alters expression of cellular bioenergetic-associated genes in skeletal muscle of growing pigs.

S. G. L. Won*[3], G. Xie[3], R. L. Boddicker[1], J. N. Rhoades[2], T. L. Scheffler[3], J. M. Scheffler[3], M. C. Lucy[2], T. J. Safranski[2], J. T. Selsby[1], S. Lonergan[1], L. H. Baumgard[1], J. W. Ross[1], and R. P. Rhoads[3], [1]*Iowa State University, Ames,* [2]*University of Missouri, Columbia,* [3]*Virginia Polytechnic Institute and State University, Blacksburg.*

Heat stress (HS) causes significant losses to the US swine industry in several production and health areas including efficient lean tissue accretion. Perturbations in skeletal muscle metabolism may participate in this defect. The study objectives were to examine the expression of genes related to cellular bioenergetics in skeletal muscle of piglets subjected to thermal stress in utero and/or during postnatal life. To accomplish this, 48 offspring from 14 first parity gilts were prenatally exposed to 1 of 4 environmental treatments (TNTN, TNHS, HSTN, or HSHS). TNTN and HSHS sows were exposed to thermal neutral (TN, cyclical 18–22°C) or HS conditions (cyclical 28–34°C) for all of gestation, respectively. HSTN and TNHS treatments represent sows heat-stressed for the first or second half of gestation, respectively. At 12 weeks of age, offspring were exposed to one of 2 postnatal thermal environments for 24 h: constant TN (21°C) or HS (35°C). Gestational treatments were randomized across postnatal treatments, with each sow represented equally between the 2 postnatal treatments. Pigs were sacrificed after the 24-h TN or HS treatment and longissimus dorsi skeletal muscle samples collected for total RNA isolation. Real-time PCR was used to measure gene expression of pyruvate dehydrogenase kinase 4 (PDK4), hexokinase 2 (HK2), peroxisome proliferative activated receptor, gamma, coactivator 1 α (PGC-1α), mitochondrial transcription factor A (TFAM), succinate dehydrogenase complex (SDHA), cytochrome C oxidase (Cox5B), and Cytochrome *b* (Cyt B). Data was normalized using eukaryotic translation elongation factor 1 α 1 (EEF1A1) as a control gene and analyzed by the Proc Mixed procedure in SAS. Data analyses did not indicate interactions between gestational and postnatal treatments for the genes studied. Only Cyt B gene expression was altered by gestational HS exposure with HSHS increasing expression up to 2-fold over TNHS, HSTN and TNTN ($P < 0.01$). Neither in utero nor postnatal HS altered Cox5B or PGC-1α mRNA abundance. Postnatal HS significantly increased HK2 by 25%

($P < 0.05$) and tended to increase PDK4 8-fold ($P = 0.076$). In contrast, TFAM, SDHA, and Cyt B gene expression decreased significantly during postnatal HS ($P < 0.05$). These data indicate that acute postnatal HS alters skeletal muscle bioenergetic gene expression, which may favor enhanced glycolysis and a reduction in mitochondrial respiration. This work was supported by USDA NIFA grant #2011–67003–30007.

Key Words: heat stress, skeletal muscle, metabolism

W212 Effect of heat stress (HS) on thermal regulation during pregnancy in first parity sows.

M. C. Lucy*[1], T. J. Safranski[1], J. N. Rhoades[1], J. W. Ross[2], N. K. Gabler[2], R. P. Rhoads[3], and L. H. Baumgard[2], [1]*University of Missouri, Columbia,* [2]*Iowa State University, Ames,* [3]*Virginia Tech, Blacksburg.*

First parity sows suffer from seasonal infertility that is associated with HS. The objective was to test the effects of HS during gestation and assess carryover effects after farrowing in first parity sows. Nulliparous gilts (n = 23) were brought into environmental chambers, inseminated and assigned to one of 4 ambient temperature treatments [TRT; HS (28 to 34°C; relative humidity, RH 80 to 55%) or TN (18 to 22°C; RH 70 to 60%)] that were applied for either the entire gestation [HSHS (n = 4) and TNTN (n = 4)] or for the first (wk 2 to 8) or second (wk 9 to 15) half of gestation [TNHS (n = 4) or HSTN (n = 4)]. There were 3 HSTN and 4 TNHS gilts that were not pregnant after insemination. Rectal, ear and shoulder temperatures (RT, ET, and ST) and respiration rate [RR; breaths per minute (BPM)] were collected twice daily (0900 and 1500h). There was an effect of wk on RT because, regardless of TRT, the RT decreased ($P < 0.001$) in pregnant sows (38.5 ± 0.1 to 38.3 ± 0.1°C; wk 2 to 15). The decrease in RT was not observed in non-pregnant sows (38.4 ± 0.1 to 38.6 ± 0.1°C; wk 2 to 15). There was a TRT by wk interaction for RT because the effects of HS (HSHS, HSTN, TNHS, and TNTN, respectively) were greatest during early gestation (38.4 ± 0.1, 38.5 ± 0.1, 38.2 ± 0.1, 38.3 ± 0.1°C for wk 5), were less in mid-gestation (38.3 ± 0.1, 38.2 ± 0.1, 38.2 ± 0.1, and 38.3 ± 0.1 for wk 10) and increased in late gestation (38.4 ± 0.1, 38.2 ± 0.1, 38.3 ± 0.1, and 38.2 ± 0.1 for wk 15). Effects of HS on RR were greatest during late gestation (53 ± 3, 28 ± 3, 81 ± 3, and 23 ± 3 BPM for wk 15). Changes in ET and ST ($P < 0.001$) were associated with changes in room temperature. Sows moved to a farrowing room (22°C) during the last wk of gestation. The RT, ET, and ST (respectively) increased ($P < 0.001$; 38.3 ± 0.1 to 39.5 ± 0.1°C, 33.1 ± 0.2 to 36.6 ± 0.2°C, 32.1 ± 0.2 to 35.5 ± 0.2°C; d −5 to d 10) after farrowing (during lactation) but there were no carry-over effects of TRT. In summary, sows decreased RT during gestation. The ET, ST, and RR responded to HS. Changes in RT in response to HS were small during gestation. Lactation under non-HS conditions (22°C) was associated with large changes with RT, ET, and ST. This project was supported by USDA NIFA 2011–67003–30007.

Key Words: sow, heat stress

W213 Hair cortisol concentrations—Influence of color and location in Holstein cows.

R. L. A. Cerri*[1], A. M. Tabmasbi[2], and D. M. Veira[3], [1]*Land and Food Systems, University of British Columbia, Vancouver, BC, Canada,* [2]*Fedowsi University of Mashhad, Mashhad, Iran,* [3]*Agriculture & Agri-Food Canada, Agassiz, BC, Canada.*

Cortisol is often used to measure stress. A change in blood cortisol after exposure to a stressor gives an estimate of an acute stress response. However, the episodic daily fluctuations make blood measures of cortisol unsuitable for measuring chronic stress. Cortisol levels within milk or feces reflect circulating levels of cortisol over a longer period than a single blood sample, but still is less than ideal for assessing chronic stress. Recent research in humans and wildlife has shown significant correlations between hair cortisol levels and ill health. Our objective was to determine the potential of extracting and measuring cortisol in hair from cattle and whether its location and color influence cortisol concentrations. We measured the level of cortisol in black and white hair of Holstein cows (n = 18). Cows had both black and white hair shaved from the shoulder, top line and hip; white hair was also harvested from the tip of the tail. The hair samples were cleaned of dirt and dander, washed in water then with isopropanol, dried and then ground in a ball mill or finely cut with scissors. Cortisol was extracted with methanol before being measured using an ELISA kit. Data was analyzed by ANOVA using SAS (significant if $P < 0.05$). Cortisol concentration was similar between locations; however, the white hair had higher ($P < 0.001$) levels than black hair 13.7 ± 1.01 vs. 6.8 ± 1.63 pg/mg, respectively. Primiparous cows had higher ($P < 0.001$) cortisol levels than older cows 21.9 ± 1.80 and 4.37 ± 1.48 pg/mg. Samples processed with a ball mill had higher ($P < 0.006$) cortisol levels than those cut up with scissors 12.6 ± 1.03 vs. 7.9 ± 1.61 pg/mg. Hair from the tail of the Holstein cow is always white and had numerically higher cortisol levels than hair from other locations. It also regrows more rapidly than other sites, allowing sampling as frequently as every 3 wk making it suitable for measuring chronic cortisol levels over extended periods of time. This approach is being used to monitor cortisol levels during lactation and its relationship to health and reproduction.

Key Words: cortisol, hair, cows

W214 Animal and ovarian parameters affect fertilization and embryo quality in high-producing lactating dairy cows.

R. L. A. Cerri*[1], W. W. Thatcher[2], and J. E. P. Santos[2], [1]*University of British Columbia, Vancouver, BC, Canada,* [2]*University of Florida, Gainesville.*

A total of 418 oocytes-embryos from single ovulating lactating Holstein cows were recovered 6 d after artificial insemination (AI). Cows were enrolled in a presynch-ovsynch program starting at 30 ± 3 d in milk. Ovarian responses were evaluated by ultrasonography and blood was analyzed for progesterone (P4) throughout the study. The body condition score (BCS) was measured at enrollment and uterine flush. Responses related to embryo quality were evaluated (tendency $P < 0.10$; significant $P < 0.05$) against parity (primiparous vs multiparous), cyclicity (until 44 ± 3 d in milk), BCS at enrollment (Low < 2.75 > Moderate), BCS change between measurements, ovulation to first GnRH of ovsynch, follicle size at AI (Small < 18mm > Large), and concentrations of progesterone (P4) at PGF (Low < 3 ng/mL > High), AI (Low < 0.2 ng/mL > High) and 6 d after AI (Low < 2 ng/mL > High). Moderate BCS tended to improve embryo quality by increasing proportion of grades 1–2 (73.1 vs 62.4%) and transferable embryos (84.6 vs 77.7%) and decreasing degenerated embryos (22.3 vs 15.4%). Ovulation to the first GnRH of the synchronization protocol improved proportion of embryos grades 1–2, transferable embryos, and live blastomeres, whereas decreased degenerated and unfertilized oocytes-embryos. Large follicles at AI increased fertilization rate (86.5 vs 78.2%) and the mean number of accessory sperm cells attached to the zona pellucida (28.1 ± 3.8 vs 17.8 ± 4.5). High P4 at PGF increased number of blastomeres in embryos (33.4 ± 2.6 vs 26.4 ± 2.3). Low P4 at AI tended to increase fertilization rate (88.0 vs 79.6%), oocyte-embryos grades 1–2 (60.9 vs 52.5%), mean number of cells (35.0 ± 2.3 vs 24.8 ± 2.5) and percentage of live cells (94.7 vs 88.9%), whereas it decreased degenerated and unfertilized oocytes-embryos (36.4 vs 27.1%). High P4 6d after AI significantly decreased proportion of transferable (76.9 vs 83.6%) and increased degenerated embryos (23.1 vs 16.4%). In conclusion, moderate BCS, large follicles with restricted length from emergence to ovulation, and very low P4 levels at AI are associated with greater fertilization rate and embryo quality.

Key Words: embryo quality, fertilization, ovarian dynamics

W215 Relationships between sperm motility and in vivo and in vitro fertility of Holstein and Jersey bulls.

M. D. Utt*[1], M. A. Coutinho da Silva[2], C. A. Messerschmidt[2], J. M. DeJarnette[3], C. E. Marshall[3], F. A. Abreu[1], and M. L. Day[1], *[1]Department of Animal Sciences, The Ohio State University, Columbus, [2]Department of Clinical Sciences, College of Veterinary Medicine, The Ohio State University, Columbus, [3]Select Sires Inc., Plain City, OH.*

Sperm motility has been correlated to bull fertility in the past. Within the last 20 yr, computer-assisted sperm analysis (CASA) has provided a more detailed and objective evaluation of sperm motility. The objective of this experiment was to determine correlations of post-thaw CASA motility data to the following fertility estimates: sire conception rate (SCR; USDA, 2008), heterospermic in vivo (H-VIVO*) and in vitro (H-VITRO) competitive indices, and in vitro embryo cleavage rate (CLV). Extended semen from Holstein (H, n = 3) and Jersey (J, n = 3) bulls was either frozen homospermically or total sperm mixed 1:1 (H:J) to create 9 H/J heterospermic pairings that were later used for in vivo AI (H-VIVO*) or in vitro fertilization (H-VITRO). Frozen/thawed homospermic aliquots were used for determination of CLV or sperm motility parameters by CASA [n = 4 straws per bull; total motility (TM), progressive motility (PM), average path velocity (VAP), straight line velocity (VSL), amplitude of lateral head movement (ALH), tail beat frequency (BCF), and straightness (STR) and linearity of path (LIN)]. In vitro fertilization was performed on approximately 140 or 180 cumulus-oocyte complexes for each for each bull (CLV) or H/J pair (H-VITRO). Competitive indices were calculated for each bull based on mean proportion of calves or cleaved embryos sired by each bull across pairings (21 to 31 random parentage tests per pair; H-VIVO or H-VITRO). SCR data (0.0, 0.0, 0.0, +0.3, +2.0, +2.0) for the 6 bulls were not correlated to any sperm motility parameters. PM was correlated (r = 0.92; $P < 0.05$) only to H-VIVO. LIN, STR, and BCF were positively correlated to H-VIVO (r = 0.87, $P < 0.05$; r = 0.93, $P < 0.05$; and r = 0.78, $P < 0.10$, respectively) but negatively correlated to CLV (r = - 0.82, $P < 0.05$; r = - 0.83, $P < 0.05$; and r = - 0.75, $P < 0.10$, respectively). ALH was correlated to H-VITRO (r = 0.74, $P < 0.10$) and CLV (r = 0.73, $P < 0.10$) but not H-VIVO. In conclusion, correlations of CASA data to fertility differed between both heterospermic methods and between homo- and heterospermic methods in vitro. *Kasimanickam et al., 2006, 2007

W216 Placement of semen in uterine horns failed to improve fertilization rates in superovulated Holstein cows.

P. D. Carvalho*[1], A. H. Souza[1], A. R. Dresch[1], L. M. Vieira[1,2], K. S. Hackbart[1], D. Luchini[3], S. Bertics[1], N. Betzold[4], M. C. Wiltbank[1], and R. D. Shaver[1], *[1]University of Wisconsin-Madison, Madsion, [2]University of Sao Paulo-VRA, SP 05508, Brazil, [3]Adisseo, Alpharetta, GA, [4]U.S. Dairy Forage Research Farm, Prairie du Sac, WI.*

This experiment was designed to test whether depositing the sperm in the uterine horns could improve fertilization rates in superovulated cows with synchronized ovulations. Holstein cows (n = 72), were milked twice daily and housed and fed individually in tie-stalls. Animals were blocked by parity and calving dates and randomly assigned to one of 2 treatments: 1) Semen placed in the uterine body (BAI); and 2) Semen placed in the greatest curvature of the uterine horns (HAI; semen dose split between the 2 horns). All cows had a synchronized superovulation using a modified 5-d Double Ovsynch protocol with 4 d of decreasing FSH (Folltropin, 400mg/cow) treatments. All animals were flushed between 65 to 75DIM, near peak production (39.6 kg/d). Non-sexed frozen semen (15x106 sperm/straw) were produced from single ejaculates of 2 high-fertility sires and cows were inseminated twice (12h and 24h after final GnRH treatment). To avoid variation, a single batch of FSH was used and 2 experienced AI technicians performed all breedings and flushings, which occurred 6d after synchronized ovulations. In addition, a single treatment-blinded technician graded all embryos. The proc GLIMMIX of SAS was used to compare embryo characteristics using cow as a random experimental unit. Site of semen deposit did not change fertilization rate (~78%) or any other measured embryo characteristic, as shown in the table below. In conclusion, placement of semen in uterine horns failed to improve fertilization rates or number of transferable embryos compared with standard body-AI in superovulated, high-producing dairy cows bred twice with high-fertility semen. W217 Influence of sex and breed of the calf on synchronization and pregnancy rates in cows submitted to timed AI.

A. P. Lemes*[1], R. F. G. Peres[2], A. D. P. Rodrigues[3], M. M. Guardieiro[1], E. Oba[3], G. B. Mourão[1], and R. Sartori[1], *[1]University of São Paulo, Piracicaba, SP, Brazil, [2]Agropecuária Fazenda Brasil, Barra do Garças, MT, Brazil, [3]São Paulo State University, Botucatu, SP, Brazil.*

Studies have shown that weight, sex, and breed of calves influence the productive status of cows. This study evaluated the influence of sex and breed of calves on the response of cows to a timed-AI (TAI) protocol. Primiparous and multiparous Nelore (*Bos indicus*) cows (n = 865; 44.3 ± 2.1 d postpartum[DPP]) were submitted to the following protocol: D0 - intravaginal progesterone (P4) device (DIB, Syntex S.A., Argentina), 2 mg estradiol benzoate (Gonadiol, i.m., Syntex S.A.) and 12.5 mg dinoprost tromethamine (Lutalyse, i.m., Pfizer Animal Health); D8 - 12.5 mg dinoprost, 0.8 mg estradiol cypionate (ECP, i.m., Pfizer Animal Health), withdrawal of DIB, and 300 IU eCG (Novormon 5000, i.m., Syntex S.A.) or saline; D10 - TAI using frozen/thawed semen from 3 bulls. Ovaries were evaluated by ultrasound (Mindray 2200 VET DP) 7 and 30 d after AI for presence or absence of CL and pregnancy diagnosis. Data were analyzed using PROC GLIMMIX of SAS and the use of eCG on Day 8, body condition score (BCS), DPP, sex (F: Female; M: Male), and breed (C: Crossbred Nelore × Angus; N: Nelore) of calves were included in the model. Results are presented as least squares means ± SE. Cows being suckled by F or M and C or N calves had similar synchronization rates (F: 86.2 ± 2.1% vs. M: 86.8 ± 2.1%; $P = 0.79$; C: 86.1 ± 2.3% vs N: 87.0 ± 2.1%, $P = 0.74$). Likewise, synchronized cows had no effect of calf sex or breed on conception rate (F: 46.8 ± 5.4% vs. M: 46.3 ± 5.3%; $P = 0.90$; C: 48.9 ± 5.5% vs. N: 44.2 ± 5.4%; $P = 0.33$). Cows with a better BCS had higher synchronization and pregnancy rates ($P < 0.001$). Interestingly, serum P4 concentrations of the synchronized cows were affected by the sex of the calf on d 7 (F: 4.9 ± 0.8 ng/mL vs. M: 4.0 ± 0.8 ng/mL, $P = 0.03$) and 14 (F: 8.1 ± 1.3 ng/mL vs. M: 6.2 ± 1.3 ng/mL, $P = 0.01$), and by calf breed (C: 4.9 ± 0.8 ng/mL vs. N: 4.0 ± 0.8 ng/mL, $P = 0.04$) on d 7 after AI. In conclusion, although there was a relationship between calf sex and breed on circulating P4 of the dam, these variables did not influence the reproductive efficiency of the cow bred by TAI early in postpartum. W218 The requirement of GnRH at the onset of the 5-d Select Synch + CIDR program in beef heifers. F. M. Abreu*[1], L. H. Cruppe[1], M. V. Biehl[3], A. D. P. Rodrigues[2], M. D. Utt[1], G. A. Bridges[4], J. L. M. Vasconcelos[2], and M. L. Day[1], *[1]The Ohio State University, Columbus, [2]Sao Paulo State University, Botucatu, SP, Brazil, [3]University of Sao Paulo, Pirassununga, SP, Brazil, [4]University of Minnesota, Grand Rapids.*

The objective of this study was to investigate whether or not the omission of the GnRH injection at CIDR insertion would affect luteolysis and pregnancy rates to AI in the 5-d Select Synch + CIDR program in beef heifers. Prepubertal (n = 27) and cyclic (n = 124) heifers from 3 locations were randomly assigned to receive either 100µg GnRH (n = 77) or 2 mL saline (SAL, n = 74) at CIDR insertion (d −5); followed by 25 mg PGF coincident with CIDR removal 5 d later (d 0). Blood samples were collected on d −15 and −5 to assess puberty status. Estrus detection was performed twice daily from 0 to 60 h after PGF and AI based on the AM/PM rule. Heifers not detected in estrus were timed AI followed by a GnRH injection 72 h after PGF. In 2 locations, blood samples from heifers with no visual signs of estrus were collected at 72 h to assess progesterone concentrations. Ovarian ultrasonography was performed on d 0 to determine ovulation response to the first GnRH (GnRH treatment) and presence of CL in all heifers. Pregnancy diagnosis was performed on d 35. At CIDR withdrawal, presence of a minimum of one CL in the ovaries tended ($P = 0.09$) to be greater in the GnRH (94%) than SAL (86%) treatment, and was greater ($P < 0.01$) in cyclic than prepubertal heifers (95 and 67%). Size of the largest ovarian follicle on d 0 was greater ($P < 0.01$) for heifers in the SAL (10.6 ± 0.4 mm) than GnRH (8.9 ± 0.3 mm) treatment. The proportion of heifers detected in estrus and time to estrus did not differ (72% and 48.2 ± 0.8 h). For the 2 locations in which blood samples were collected from heifers that did not exhibit estrus (n = 27), incidence of luteal regression was 85.2% and did not differ between treatments. All 4 heifers deemed to have not regressed their CL (not detected in estrus and progesterone concentrations >0.5 ng/ml) were in the GnRH treatment. Synchronization pregnancy rate did not differ between GnRH and SAL treatments (48 and 53%, respectively). In conclusion, administration of GnRH at the onset of the 5-d Select Synch + CIDR protocol did not influence the incidence of luteal regression or benefit pregnancy rates to AI in beef heifers.

Key Words: GnRH, beef heifers, pregnancy rate

W219 Efficacy of the "CoPGF" approach to induce luteolysis in the 5-d CO-Synch + CIDR program in lactating beef cows. M. V. Biehl*[1,3], L. H. Cruppe[1], F. M. Abreu[1], A. D. P. Rodrigues[4], M. L. Mussard[1], G. A. Bridges[2], A. V. Pires[3], and M. L. Day[1], *[1]The Ohio State University, Columbus, [2]University of Minnesota, Grand Rapids, [3]University of Sao Paulo, Piracicaba, SP, Brazil, [4]Sao Paulo State University, Botucatu, SP, Brazil.*

The objective of this study was to determine the efficacy of using 50 mg (2 25 mg doses; CoPGF) of PGF2α (PGF) administered coincident with CIDR removal in the 5-d CO-Synch + CIDR estrous synchronization program in postpartum beef cows. This approach was compared with treatment with 2 25 mg doses of PGF given at an 8 h interval (25 mg at CIDR removal and 25 mg 8 h later; 8hPGF). Lactating multiparous cows (n = 51) were randomly assigned by age and calving date to treatments (CoPGF, n = 27; 8hPGF, n = 24). Blood samples were collected on d −15 and −5 to assess reproductive status at the onset of the program. All cows received 100 µg GnRH (GnRH-1; Cystorelin) at CIDR insertion (d −5). On d 0, the CIDR was removed 2 h before (h −2) the CoPGF treatment or the initial PGF injection of the 8hPGF treatment was given (h 0). Blood samples were collected at h 0, 8, 16, 24, 36, 60, and 84 to assess circulating progesterone concentrations (P4) and luteal regression, and on d 13 to assess function of the subsequent CL. Ovarian ultrasonography was performed on d −5 and 0 to identify the presence of spontaneously formed and GnRH-induced CL, respectively. Estrus detection was performed twice daily from d 0 to 5. Ovulation to GnRH-1 tended to be greater ($P = 0.07$) for the 8hPGF (83.3%) than the CoPGF group (59.3%). Proportion of animals in anestrus at CIDR insertion (33.3%) and presence of at least one CL at CIDR removal (94.1%) did not differ between treatments. The proportion of cows detected in estrus and interval from CIDR removal to estrus did not differ between treatments (8hPGF, 66.7% and 67.0 ± 2.79 h; and CoPGF, 70.4% and 64.6 ± 2.03 h). The incidence of luteolysis did not differ between treatments (8hPGF, 95.2%; CoPGF, 95.7%) and was characterized by P4 below 1 ng/ml by h 36 and thereafter to h 84. Progesterone concentrations on d 13 did not differ (8hPGF, 2.65 ng/ml; CoPGF, 3.03 ng/ml). In conclusion, the CoPGF approach is a highly effective method to induce luteal regression with the 5-d CO-Synch + CIDR program.

Key Words: beef cows PGF, PGFα, 5-d program

W220 Effects of GnRH and administering number of PGF2α doses in the 5-d timed AI program on ovarian responses and fertility of dairy heifers. F. S. Lima*[1], E. S. Ribeiro[1], R. S. Bisinotto[1], N. Martinez[1], L. F. Greco[1], K. N. Galvão[1], C. A. Risco[1], W. W. Thatcher[1], M. Amstalden[2], and J. E. P. Santos[1], *[1]University of Florida, Gainesville, [2]Texas A&M University, College Station.*

Objectives were to determine if GnRH at the initiation of 5-d timed AI combined with 2 doses of PGF2α improve ovarian responses and pregnancy per AI (P/AI) of dairy heifers. Holstein heifers (n = 2,118) received an intravaginal insert (CIDR) containing progesterone (P4) on d0. Inserts were removed on d5 and heifers were treated with PGF2α (25 mg dinoprost). GnRH was administered on d8 concurrently with timed AI. Heifers were allocated randomly to receive no additional treatment (NG1P = 711), a second injection of PGF2α on d6 (NG2P = 696), or an injection of GnRH on d0 and a second injection of PGF2α on d6 (G2P = 711). Ovaries were scanned on d0 and 5. Blood was sampled at AI to measure P4 concentrations. Pregnancy was diagnosed on d 32 and 60 after AI. Data were analyzed using GLIMMIX of SAS. Administration of GnRH on d0 increased ovulation and the proportion of heifers with a new CL on d5 (Table). The proportion of heifers with a CL on d5 (86.8%) did not differ among treatments. The second injection of PGF2α improved luteolysis compared with a single PGF2α despite administration of GnRH on d0. Concentration of P4 at AI was greater for NG1P than NG2P or G2P (0.36 vs. 0.27 vs. 0.30 ng/mL). The P/AI on d 30 and 62 were greater for G2P than NG1P or NG2P, but pregnancy loss did not differ with treatment (NG1P = 7.4%, NG2P = 6.3% and G2P = 4.3%). Heifers with a new CL on d5 that received 2 PGF2α had greater P/AI than those with a new CL but that received a single PGF2α (62.8% vs. 45.7%). Combining GnRH with 2 doses of PGF2α in the 5-d timed AI protocol improved fertility because of greater ovulation associated with adequate luteolysis in dairy heifers.

Table 1. Effect of treatment on reproductive responses [% (no./no.)] of dairy heifers

	Treatment			
	NG1P	NG2P	G2P	*P*-value
Ovulation d0	13.2 (40/303)^{b}	12.8 (38/296)^{b}	27.6 (85/308)^{a}	0.01
New CL d5	20.5 (62/303)^{b}	19.6 (58/296)^{b}	33.8 (104/308)^{a}	0.01
Luteolysis				
P4<0.5 ng/mL	82.5 (151/183)^{b}	92.9 (169/182)^{a}	88.3 (158/179)^{ab}	0.01
P4<0.3 ng/mL	61.2 (112/183)^{b}	74.2 (135/182)^{a}	71.0 (127/179)^{a}	0.03
Pregnant				
d 32	52.9 (376/711)^{b}	55.0 (383/696)^{b}	61.7 (439/711)^{a}	0.01

W221 Comparison between the GGPG and two PGF2α based resynchronization programs on fertility in lactating dairy cows. R. G. S. Bruno*[1,2], A. M. Farias[1], K. J. Lager[1,2], D. E. Hawkins[2], and T. R. Bilby[1], [1]*Texas A&M University, College Station,* [2]*West Texas A&M University, Canyon.*

The objective was to compare the use of either GnRH or PGF as a presynchronization strategy before a resynchronization program on fertility in dairy cows. Lactating cows (n = 2327) from a dairy in TX were assigned to 1 of 3 resynchronization programs at 29 ± 3 and examined for pregnancy at 36 ± 3 d after AI. Resynchronization programs consisted of: GGPG (n = 458), an injection of GnRH at enrollment followed by the Ovsynch protocol initiated at the time of non-pregnancy diagnose (NPD); POV7 (n = 940) an injection of PGF at NPD followed by the Ovsynch protocol 7 d later; and POV11 (n = 929) injection of PGF 3 d after NPD followed by the Ovsynch protocol 11 d later. Cows were AI at any time during the program and, if AI, cows were removed from subsequent injections. Ovaries were scanned and blood sampled for progesterone (P4) levels on day of first GnRH and PGF of Ovsynch. Pregnancy per AI (P/AI) was diagnosed at 36 and 66 d after AI. Overall 64% of cows were diagnosed pregnant 7 d after enrollment. Among non-pregnant cows, GGPG reduced ($P < 0.01$) re-inseminations upon ED (GGPG = 23.3 vs. POV7 = 74.9 and POV11 = 79.6%). Treatment did not affect overall P/AI (35d, GGPG = 29.2, POV7 = 28.7 and POV11 = 31.9%; 66d, GGPG = 25.8, POV7 = 26.6 and POV11 = 30.2%) or pregnancy loss between 36 and 66 d after AI ($P > 0.41$). Cows AI upon ED had greater ($P = 0.02$) P/AI then cows TAI (ED = 32.3, TAI = 25.1%). However, treatment did not affect ($P > 0.31$) P/AI for cows AI upon ED (35d, GGPG = 29.6, POV7 = 29.4 and POV11 = 35.7%; 66d, GGPG = 27.3, POV7 = 28.1 and POV11 = 33.7%) or TAI (35d, GGPG = 29.1, POV7 = 25.0 and POV11 = 16.9%; 66d, GGPG = 25.3, POV7 = 22.1 and POV11 = 16.9%). Treatment affected ($P < 0.01$) the median days between NPD and re-breeding (GGPG = 10, POV7 = 4 and POV11 = 7 d). At beginning of Ovsynch, more GGPG cows had CL (GGPG = 86.8 vs. POV7 = 50.7 and POV11 = 60.0%, $P < 0.01$). However, treatment did not affect ($P = 0.42$) ovulation to the first GnRH of Ovsynch. In conclusion, GGPG reduced re-insemination during resynchronization. Reproductive program did not affect P/AI but starting the resynchronization with PGF at NPD shortened the interval between non-pregnancy diagnose and re-breeding.

Key Words: dairy cow, fertility, resynchronization
