Postmaster: Send address changes to *Journal of Dairy Science*, Elsevier Health Sciences Division, Subscription Customer Service, 3251 Riverport Lane, Maryland Heights, MO 63043.

Customer Service (orders, claims, back volumes, online access, change of address): Elsevier Health Sciences Division, Subscription Customer Service, 3251 Riverport Lane, Maryland Heights, MO 63043. Telephone: 800.654.2452 (US and Canada), 314.447.8871 (outside US and Canada); fax: 314.447.8029; e-mail: journalscustomerservice-usa@elsevier.com (for print support) or journalsonlinesupport-usa@elsevier.com (for online support). Allow 4 to 6 weeks for the change of address to be implemented.

Institutional Subscription Rates: For institutions in the United States and possessions: $879 for print. For institutions in all other countries (prices include airspeed delivery): $991 for print. Current prices are in effect for back volumes and back issues. Electronic access is additional. Please contact customer service for pricing.

ADSA Membership Rates: For individual membership, contact the ADSA office (adsa@assochq.org) to pay dues and obtain access to the journal. For professional members: $110 per year, graduate student membership: $10, undergraduate student affiliate membership: $5. Membership includes electronic version of the journal; additional $56 for paper copy in US, and additional $83 for paper copy in all other countries). Membership in the ADSA is on a calendar year basis from January through December.

Advertising Information: To advertise a position announcement in the News and Announcements section of the journal, please use the FASS Job Resource Center (http://www.fass.org/job.asp); e-mail jrc@assochq.org if you have questions.

For display advertising orders and inquiries please contact Ken Senerth at 609.577.0916; by fax at 212.633.3980; or by e-mail at kensenerth@gmail.com. For non-recruitment classified advertising orders and inquiries please contact John Marmero at 212.633.3657; by fax at 212.633.3820; or by e-mail at j.marmero@elsevier.com.

Author Inquiries: For inquiries relating to the submission of articles, complete Instructions for Authors can be found online at http://www.journalofdairyscience.org. Manuscripts submitted for consideration should be submitted electronically at http://mc.manuscriptcentral.com/jds in accordance with the Instructions for Authors. Need help? Contact shaunam@assochq.org.

Offprints. Authors may place orders for offprints when proof corrections are sent to the editorial office (before the journal is sent for printing). For queries about offprints or order status, e-mail vickip@assochq.org; fax 217.378.4083.

Reprints. To order author reprints after the issue has been printed, e-mail authorsupport@elsevier.com. To order 100 or more reprints for educational, commercial, or promotional use, contact the Commercial Reprints Department, Elsevier Inc., 360 Park Avenue South, New York, NY 10010-1710; fax: 212.633.3820; e-mail: reprints@elsevier.com. Access to single articles available online may be obtained by purchasing Pay-Per-View access on the journal website (http://www.journalofdairyscience.org).

Application for membership in the American Society of Animal Science (ASAS) is invited from persons with interest in animal science and livestock production. In 2013, annual dues including access to the electronic version of the *Journal of Animal Science* are $135 in the United States, Canada, and Mexico and in other countries. For those in the United States, Canada, or Mexico who wish to receive a paper copy of the journal, the additional fee is $100; for those in other countries, the additional fee is $125. Student affiliate membership is granted to those who are certified by a professional member as a regularly enrolled college student who does not hold a full-time position at the time of application for, or annual renewal of, membership. Graduate student memberships ($20 annually) and undergraduate student memberships (free) include access to the electronic version of the *Journal of Animal Science*. Postdoctoral fellows' membership dues are $65. An institutional subscription ($585 annually) entitles an institution Internet access to *e-JAS* within appropriate IP addresses. For an additional $100 fee, institutions within the United States, Canada, and Mexico will receive a paper copy of the journal (an additional $125 fee for all other countries). For corporate subscriptions, please contact the ASAS office for pricing. Individual sustaining membership, $375 per year. Applications for membership with remittance should be mailed to the ASAS Business Office.

ASAS Business Office, PO Box 7410, Champaign, IL 61826

Calendar of American Society of Animal Science Upcoming Meetings

Northeast Section	July 8–12, 2013	Indianapolis, IN
National Annual Meeting (with ADSA)	July 8–12, 2013	Indianapolis, IN
Southern Section (with SAAS)	February 1–4, 2014	Dallas, TX
Midwestern Section (with ADSA)	March 16–18, 2014	Des Moines, IA

Manuscript Submission. Information about manuscript submission is given in *Style and Form* published on the journal website (http://jas.fass.org). All manuscripts submitted to the *Journal of Animal Science* must be accompanied by the JAS manuscript submission form certifying that any research that involves animals has followed established standards for the humane care and use of animals. Manuscripts should be submitted online via http://mc.manuscriptcentral.com/jas.

Address Change and Missing Copies. Notice of change in address should be received by the ASAS Business Office 60 days in advance of change. Claims for missing copies should be received within 30 days (90 days foreign) of publication date to ensure replacement copies at no charge.

Journal of Animal Science (ISSN 0021-8812) is published 12 times per year (monthly) by the American Society of Animal Science. Periodicals postage paid at Champaign, Illinois 61820 and at additional mailing offices. Form 3579 to be returned to the ASAS Business Office. Postmaster: Send change of address to American Society of Animal Science, PO Box 7410, Champaign, IL 61826.

Teaching/Undergraduate and Graduate Education: Teaching and Learning in the Animal Sciences: New Grounds for the 21st Century

1 How to incorporate high-impact practices in the animal sciences curriculum. N. Cockett*[1] and D. Buchanan[2], [1]*Utah State University, Logan,* [2]*North Dakota State University, Fargo.*

The animal sciences curriculum has remained fairly static in relation to changes in the student population, agricultural practice, scientific advances and the place of agriculture in the greater culture. Changes in the curriculum frequently arise by developing new classes or increasing the number of credits for existing classes while the method of teaching frequently remains as standard lecture or lab format. We propose that teaching must rapidly evolve to include high impact practices that are tailored to the demography of the students and the most effective means of conveying the various types of information that will be important for careers of the future. Practices such as first year seminars, learning communities, undergraduate research, global learning, service or community based learning, industry internships and capstone projects need to be ubiquitous in the curriculum instead of operating as isolated pieces. The presentation will include a review of research about the advantages associated with such practices, some examples of high impact practices already being used in animal science and a challenge to "deconstruct" the curriculum and attempt to rebuild it with content that will be relevant, intellectually stimulating and preparatory for careers that our student will likely have. The curriculum should also focus on the most appropriate practices for each component within the Animal Sciences degree.

Key Words: curriculum, undergraduate

2 Courses and high-impact practices to equip students with knowledge, skills, and experiences for the 21st century: Views of animal sciences faculty. M. A. Wattiaux* and P. Crump, *University of Wisconsin-Madison, Madison.*

Our objective was to identify types of courses and high impact practices (HIPs) that animal sciences faculty associated with important knowledge and skills that students should gain during a 4-yr degree program. Data were from a survey of 49 faculty from 33 institutions who attended a June 2012 national conference. Using a scale of 1 (not at all) to 5 (a great deal), participants scored the importance of 17 items describing knowledge and skills (KS) and 16 items describing courses and experiences (CE), seven of which were HIPs. The Kruskal-Wallis test was used to detect differences among professorial ranks and Spearman correlation was used to explore relationships among survey items. The top 8 KS items (scores ranging from 4.81 to 4.45) were in decreasing rank-order: Gain oral and written communication skills (KS1); Demonstrate an ability to apply, analyze, and evaluate (KS2); Gain interpersonal communication skills (KS3); Problem-solving skills as an individual (KS4); Problem-solving skills in team settings (KS5); In depth knowledge of disciplines in the major (KS6); Leadership development skills (KS7); Gain life-long learners' skills (KS8). The top 8 CE items (scores ranging from 4.78 to 4.20) were in decreasing rank-order: Practicum-based courses or courses with hands-on labs (CE1); Courses that include real-world, project-based activities (CE2); In-country internships (CE3); Capstone courses or projects (CE4); Courses that include collaborative assignments and projects (CE5); Undergraduate research experience (CE6); Using the Internet as a learning tool (CE7); Writing intensive courses (CE8). Full professors scored items KS1, KS2, and CE6 (all $P < 0.02$), and item KS4 ($P < 0.06$) lower compared with assistant or associate professors. Items CE2 and CE5 were correlated ($r > 0.4$ and all $P < 0.01$) with 10 and 12 of the 17 KS items, respectively, whereas PowerPoint lecture-based courses (CE15) were not correlated with any KS items. Among the HIPs, items CE3, CE4, CE6 and CE8 were correlated with 7, 10, 2, and 1 KS items, respectively, illustrating that not all HIPs were perceived as of equal relevance.

Key Words: undergraduate curriculum

3 How to incorporate active learning practices in animal sciences classrooms. D. K. Aaron* and C. A. Tilghman, *University of Kentucky, Lexington.*

Most educators agree students retain more knowledge if they are engaged in active learning. Dale's Cone of Experience (Edgar Dale, Audio-Visual Methods in Teaching, 1969) suggests students remember 70% of what they say and 90% of what they both say and do. Conversely, they remember only 20% of what they hear and 30% of what they see. The former is active involvement, the latter is passive. Traditional classroom lecture achieves active involvement by teachers but often restricts students to passive roles. While this may be comfortable for both, it does not maximize learning. Furthermore, changing demographics of students enrolled in animal sciences courses (more students from urban areas with little to no agricultural experience, greater diversity and an increase in nontraditional students) requires both lecture-based teaching and hands-on experiences. This presentation will discuss ways of engaging students in animal sciences courses, from classrooms to labs. It will begin with class attendance. This may seem obvious, but the first step in achieving active learning is making sure students show up to class. It will progress to note taking, which as old-fashioned as it may seem, is an integral part of the learning process because it keeps students engaged. Ways of asking questions and encouraging students to ask questions, thereby turning lectures into conversations, will also be discussed. Finally, some ideas for engaging students through real or simulated experiences and hands-on activities will be presented. Examples of experiential learning opportunities will include those used in an introductory animal sciences course (feeding trials with chicks and lambs, livestock handling and management situations, a livestock judging "contest") and an upper-level course in animal genetics (problem-solving lab exercises, an interactive genetic simulation program). These student-centered, experiential learning activities pave the way for retained knowledge in the subject matter and encourage students to look beyond the planned curriculum to explore continuous learning.

Key Words: teaching, learning, student engagement

Triennial Growth Symposium: Vitamin D—Establishing the Basics to Dispel the Hype

4 Vitamin D: Bones and beyond. H. Deluca* and L. Plum, *Department of Biochemistry, University of Wisconsin-Madison, Madison.*

We now understand that vitamin D is the starting material of an endocrine system primarily devoted to the regulation of serum calcium, serum phosphorus and bone. Vitamin D is normally produced in skin by a photochemical reaction of 7-dehydrocholesterol. It is subsequently converted in the liver to a circulating form (25-hydroxyvitamin D_3) that is then converted by the kidney to a hormonal form, 1a,25-dihydroxyvitamin D_3. The vitamin D hormone acts through a single nuclear receptor in carrying out these functions. The presence of this receptor in a variety of tissues signals functions beyond bone, calcium and phosphorus. This presentation will provide the basic biology of the endocrine system, the current concepts of the molecular mechanisms by which it functions, and a look at the proven and putative functions of the hormone in the various target tissues.

Key Words: vitamin D, 1,25-dihydroxyvitamin D

5 Basics for establishment of 2011 vitamin D guidelines in humans. C. M. Weaver*, *Purdue University, Department of Foods and Nutrition, West Lafayette, IN.*

The 2011 vitamin D recommendations set by the Food and Nutrition Board of the Institute of Medicine was the first time that estimated average requirements (EAR) and recommended dietary intakes (RDA) were given for vitamin D. Previous versions (i.e., 1997 and earlier) used adequate intakes, which implied less certainty of values. Vitamin D is difficult to set requirements for because it behaves more like a hormone than a nutrient and because diet is not the only source of vitamin D. In fact, more vitamin D comes from cutaneous production than from diet for most people. Thus, one cannot use the common factorial approach of estimating daily losses adjusted by absorption and needs during growth to set intake recommendations. The basis for the 2011 vitamin D recommendations was for bone health. Systematic reviews showed vitamin D status levels associated with calcium absorption, bone mineral density, and risk of osteomalacia or rickets. An integrated model was used to set vitamin D status, measured by serum 25(OH)D levels, at 40 nmol/L for the EAR and 50 nmol/L for the RDA. Vitamin D intakes to achieve these levels became the recommended intakes based on a nonlinear model of the relationship of vitamin D intake and achieved serum 25(OH)D levels. The panel assumed all vitamin D intakes should come from diet in their recommendations because many groups are not exposed to UVB light or are elderly or dark skinned which limits cutaneous production. However, intakes are well below recommended levels. Clinical guidelines for patients at risk for vitamin D deficiency were also established in 2011 by the Endocrine Society, which gave physicians more latitude for vitamin D recommendations.

Key Words: vitamin D, humans, dietary reference intakes

6 Novel roles for FGF23 signaling in vitamin D and phosphate homeostasis. B. Lanske*, *Harvard School of Dental Medicine, Boston, MA.*

FGF23 is primarily produced in osteoblasts and osteocytes where it is secreted into the blood stream to act hormonally on specific target tissues. In the kidney, it has been shown to inhibit phosphate reabsorption and vitamin D synthesis by down-regulating the renal sodium phosphate co-transporters NaPi2a and NaPi2c and suppressing the expression of 1a(OH)ase in the proximal tubules. Mutations in the FGF23 gene itself or in genes regulating its expression and activation have been linked to disease processes including autosomal dominant hypophosphatemic rickets (ADHR), oncogenic osteomalacia (OOM) and X-linked hypophosphatemia (XLH), autosomal recessive hypophosphatemia with hyperphosphaturia (ARHR), confirming the role of FGF23 in regulating phosphate and vitamin D metabolism. A new role for FGF23 was discovered when Klotho, a previously described aging-related gene, was found to be a co-factor for FGF23 signaling. Apart from the kidney Klotho expression has also been detected in the parathyroid gland. More recent experiments have established a role for FGF23 in suppressing PTH transcription and secretion. These findings indicate that FGF23 can indirectly affect calcium homeostasis. Furthermore, the high levels of FGF23 found in patients with chronic kidney failure have been associated with increased risk of mortality and morbidity. FGF-23 has also been found to affect bone mineralization independent of its role in systemic phosphate homeostasis, adding significant new data regarding the physiological properties of FGF-23. Although the underlying mechanisms are still unclear, FGF23 appears to regulate the expression of various matrix mineralization inhibitors such as osteopontin, matrix Gla protein and dentin matrix protein. The novel findings that Klotho might also be expressed in bone cells strengthen the observation that FGF23 has paracrine action on bone. In summary, changes in FGF23 activity and the resulting effects on serum phosphate and calcium homeostasis have severe consequences on bone mineralization and ultimately on survival in mice and men.

Key Words: osteoblast, Klotho, FGF23

7 The rise and fall of clinical cases of vitamin D deficiency in commercial swine operations. D. M. Madson*, *Department of Veterinary Diagnostic and Production Animal Medicine, Iowa State University, Ames.*

Hypovitaminosis D is not a new disease; however, in recent years there has been a resurgence of clinical disease within the US swine population. Clinical signs of re-emergence of this disease were first recognized in early 2010 and included lameness, posterior paresis, broken bones, muscle fasciculation/tremors, and sudden death. Morbidity of 50% and mortality in the range of 20% was common. The initial cases of hypovitaminosis D were connected to a particular feed manufacturer supplying a premix devoid of vitamin D which ultimately led to a national recall within five months of the first cases. This recall slowed the number of diagnostic cases and the attention associated with it motivated swine veterinarians and researchers to further investigate this issue. From 2010-present, the Iowa State University Veterinary Diagnostic Laboratory (ISU VDL) diagnosed over 100 cases. Case investigations typically involved determination of serum calcium, phosphorus, and vitamin D levels, assessment of bone quality, and microscopic evaluation of bones and joints. In many of these investigations the ISU VDL worked in collaboration with Heartland Labs in Ames, Iowa. These investigations generally led to the realization that large populations of pigs across the U.S. were either clinically or subclinically deficient in vitamin D. Clinical and diagnostic evidence continues to indicate that subclinical hypovitaminosis D as measured by serum vitamin D status is still occur-

ring. Four companies have introduced oral products for supplementation of pigs, particular aimed at the weaned pig. Supplementation along with increased monitoring of bulk feed vitamin D samples, which have been shown to degrade with time, have reduced the incidence within the swine population. Speculations about alternative feed ingredients, calcium-phosphorus ratios, and even phytase usage have been made as a potential contributor to this recent rise in hypovitaminosis D in pigs. However, the primal underlying cause for these continued cases has not been elucidated at this time.

Key Words: vitamin D, deficiency, lameness

8 Basis for establishment of the 2012 vitamin D requirements in swine. C. Lauridsen*, *Aarhus University, Department of Animal Science, Tjele, Denmark.*

In swine nutrition, little is known about vitamin requirements for reproductive processes and bone health, especially vitamin D. Supplemental vitamin D is usually added to animal feed as cholecalciferol (vitamin D_3), which is transported to the liver and hydroxylated to 25(OH)D_3, which is released into the circulation. Recently, 25(OH)D_3 has become commercially available (Hy-D, DSM Nutritional Products). A dose-response trial with 4 doses of both vitamin D_3 and 25(OH)D_3 was performed. In Exp.1, 160 gilts from first estrus until d 28 of gestation were fed diets containing 4 concentrations of 1 of 2 vitamin D sources [200, 800, 1,400, or 2,000 IU·kg^{-1} from cholecalciferol or corresponding levels of 5, 20, 35 or 50 μg·kg^{-1} from 25(OH)D_3 (Hy-D)]. Concurrently in Exp. 2, the same 8 dietary treatments were fed to 160 multiparous sows from the first day of mating until weaning. In Exp. 1, gilts were killed at d 28 of gestation, the reproductive organs were obtained and number of ovulations was assessed by counting corpora lutea and implanted embryos. In addition, blood samples were obtained at slaughter for plasma separation, and metacarpal bones dissected from the left foot. In Exp. 2, performance data and blood samples were obtained from the sows and the piglets throughout the experiment, and their vitamin D status was assessed by 25(OH)D_3 plasma concentrations. Although no major differences among dietary vitamin D treatments were detected in performance, reproduction and bone status markers of gilts and sows, the observed lower number of still born piglets and the higher vitamin D concentrations may indicate a dietary level around 1,400 IU vitamin D to be recommendable for reproducing swine. The potency of the dietary Hy-D relative to vitamin D_3 depended on the level tested but above 200 IU, Hy-D was more bioavailable than vitamin D_3, and could as such been considered as an equivalent or even more advantageous source of vitamin D.

Key Words: requirements, 25(OH)D_3, reproduction

9 Analytical methods to measure vitamin D in blood, feed and tissues: Application to diagnosis of vitamin D deficiency and excess in livestock. R. L. Horst*, *Heartland Assays LLC, Ames, IA.*

Contemporary views categorize vitamin D_3 (cholecalciferol) not as a vitamin but as a pro-steroid hormone. The significance of vitamin D_3 as a pro-steroid hormone became clear in 1967 when Deluca's lab isolated a new metabolite of vitamin D_3, 25-hydroxyvitamin D_3 (25OHD) which acted more rapidly than vitamin D_3 and was established as the precursor to the active form of vitamin D_3 namely 1,25-dihrdroxyvitamin D_3 [1,25(OH)$_2$$D_3$]. A further complication for analysis is the presence of vitamin D_2. This form and its precursor, ergosterol, are present in plants and is metabolized to vitamin D_3, thus contributing to the overall vitamin D status in mammals. In addition to skeletal benefits, vitamin D has significant roles in extraskeletal health. Too little or too much vitamin D can lead to poor performance and death. Access to reliable analytical methods is, therefore, imperative for monitoring vitamin D and/or vitamin D metabolite concentrations in a variety of matrices. 25-Hydroxyvitamin D, the major circulating form is widely accepted as the best in vivo indicator of vitamin D status. Many methods are available but work only with human sera and do not work properly with sera from livestock. For example, methods used widely in human medicine rely on dissociative methods for detaching 25OHD from its binding protein (VDBP). These methods do not work properly with serum/plasma from livestock. Radioimmunoassays involving protein denaturation to release 25OHD from VDBP work quite well and have been used extensively during the past few years to assist clinicians in uncovering widespread deficiencies of vitamin D in swine and other species. Tissue concentrations of vitamin D and to a lesser extent 25OHD can also be of some diagnostic value (particularly liver and kidney) but limited information is available associating tissue and diet concentrations. Feed analysis of vitamin D can be erratic and accuracy is dependent upon proper mixing and sampling techniques. Challenges in applying analytical procedures to measuring vitamin D will be discussed.

Key Words: serum 25OHD, radioimmunoassay, vitamin D binding protein

10 Novel roles for vitamin D in animal health and immunity. D. R. Barreda*, *University of Alberta, Department of Agricultural, Food and Nutritional Science, and Department of Biological Sciences, Edmonton, Canada.*

Recent years have seen an increased interest in the extra-skeletal roles of vitamin D_3. Pleiotropic effects on the immune system include those on monocyte, macrophage, neutrophil, B and T lymphocyte, and dendritic cell functions. The impacts to cellular immune mechanisms are relevant for host antimicrobial responses, inflammation, hematopoietic cell turnover and others. This presentation will discuss a recent study that examined the modulation of weanling pig cellular immunity in response to diet supplementation with 25-hydroxyvitamin D_3 [25(OH)D_3]. Analysis of functional traits showed that leukocyte cell numbers ($P < 0.05$) as well as proportions of individual granulocyte ($P < 0.01$) and lymphocyte subpopulations ($P < 0.05$) were significantly and differentially affected. There was also positive modulation of leukocyte survival across blood ($P < 0.01$) and bronchoalveolar ($P < 0.05$) compartments, highlighting the potential contributions to systemic and mucosal antimicrobial responses. This was consistent with a parallel upregulation in phagocytic functional responses in Hy-D supplemented pigs ($P < 0.05$). Importantly, challenges remain as we consider the mechanistic basis of these cellular changes. Recent approaches in cellular analysis provide novel alternatives for analysis, particularly in non-classical animal model systems where reagents such as leukocyte antibody-based markers are not as readily available.

Key Words: vitamin D, cellular immunity, animal health

11 The role of vitamin D in skeletal muscle development and growth. J. D. Starkey*, *Texas Tech University, Lubbock.*

The extra-skeletal functions of vitamin D have gained greater attention in recent years. Emerging evidence that vitamin D and its metabolites are indeed involved in the proper development and growth of skeletal muscle in both mammalian and avian species will be the primary focus of this presentation. Recent work conducted in swine suggests that oral administration of 25-hydroxycholecalciferol (25OHD_3) in place

of a majority of dietary vitamin D_3 improves both maternal and fetal vitamin D status as measured by circulating concentrations of $25OHD_3$. These improvements in vitamin D status resulted in enhancement of fetal skeletal muscle fiber number and alteration of fetal skeletal muscle satellite cell proliferation kinetics. These changes in fetal skeletal muscle developmental characteristics may result in improvements in the postnatal growth potential and ultimate red meat yield of these offspring. The cellular and molecular mechanisms by maternal supplementation and vitamin D status improvement augmented fetal development will require further effort. There is a growing body of commercial field research in which up to a 2% increase in breast meat yield has been observed when $25OHD_3$ is included in broiler chicken diets. As is common in the broiler industry, replacement of the greater part of dietary vitamin D_3 with $25OHD_3$ in caged-raised broilers resulted in a classic satellite cell-mediated muscle hypertrophy response in fast-twitch (pectoralis major) muscle. This conclusion is based on observation of increases in satellite cell density on d 14 and 21, nuclear density on d 28, and muscle fiber cross-sectional area at the conclusion of the study on d 49 in $25OHD_3$-fed birds. A mystery remains as to why a similar response was not observed in slow-twitch (biceps femoris) muscles also examined in the study. These findings shed light on the cellular mechanism behind the intriguing results obtained in field studies. Further investigation into the mechanisms by which vitamin D and its metabolites affect both pre- and postnatal development and growth of skeletal muscle is certainly warranted given the large number of questions that remain unanswered at this time.

Key Words: vitamin D, skeletal muscle, satellite cells

12 Practical applications of vitamin D supplements in swine diets. G. Weber*, *DSM Nutritional Products, Basel, Switzerland.*

Vitamin D_3 is an essential micronutrient, which regulates the absorption of calcium and phosphorus. This homeostatic function of vitamin D_3 is important to provide sufficient minerals for incorporation into the bone matrix and to avoid disorders of various origins. To become active, vitamin D_3 has to be metabolized through two subsequent hydroxylation steps, first to the 25-hydroxyvitamin D_3 (25-OH-D_3) in the liver and second to 1,25-dihydroxyvitamin D_3 (1,25-$(OH)_2$-D_3) in the kidney. The major form of vitamin D_3 in blood plasma of animals is 25-OH-D_3. If absorption of vitamin D_3 is hampered or the metabolic function of the liver is impaired by diseases or stress, the released 25-OH-D_3 may not suffice to secure adequate mineral supply. Feeding high-yielding farm animals with 25-OH-D_3 (Hy-D) could therefore optimize mineral homeostasis and improve productivity. Partial or full replacement of vitamin D_3 by Hy-D in swine feeds resulted in higher concentrations of 25-OH-D_3 in blood and in several tissues. In sows 25-OH-D_3 plasma levels are cyclic, being highest in early gestation and lowest at weaning. In a five-parity study, Hy-D supplementation secured that 25-OH-D_3 plasma concentrations never dropped below the threshold to vitamin D insufficiency. The elevated 25-OH-D_3 levels during lactation resulted also in an increased plasma concentration of the active form 1,25-$(OH)_2$-D_3. Higher 25-OH-D_3 levels in milk were measured as well, which improved the vitamin D_3 status of the suckling piglets. In a growth trial 50 mcg 25-OH-D_3/kg improved performance of growing pigs in comparison to a control group with 2000 IU vitamin D_3/kg. Bone strength and bone mineralization were better with Hy-D both in the post-weaning and in the growing-finishing period. Optimum leg confirmation is of particular importance for the selection of gilts for breeding. When supplementing Hy-D during the full growth cycle, the selection rate of gilts was markedly improved under various production systems. Furthermore, the productivity of sows was ameliorated, related to piglets, born alive and litter weight at weaning. In conclusion, Hy-D is a versatile nutritional supplement, improving swine production at different levels.

Key Words: vitamin D, swine, bone strength

13 Practical application for use of dietary vitamin D to promote structural soundness in swine. M. A. Pérez-Alvarado, D. Braña, and J. A. Cuarón*, *Centro Nacional de investigación Disciplinaria en Fisiología Animal, INIFAP, México.*

Even with safety margins of vitamin D (VD), Ca and P, over 8% of growing pigs may either be culled, or experience reduced growth due to structural unsoundness. Structural unsoundness is also a major cause for removal of breeding sows. Recently, the incidence of ostechondrosis (OC) lesions in sows was not linked to bone mineral concentrations. However, diets that provide excess Ca and P may increase mineral density of subchondral bone, possibly creating a rigidity stress on the cartilage preventing chondroblasts differentiation. A deficiency of VD may induce osteomalacia in adults, but bone mineralization in the offspring may also be affected. These responses may be mediated by P through FGF23. Thus, development of dietary inputs to regulate Ca and P homeostasis are necessary to sustain animal wellbeing. Traditional skeletal and extra-skeletal effects of VD are well accepted but an understanding of the non-classical responses within bone, such as effects on cartilage via cell differentiation may expand the practical applications for a role of VD in structural soundness. Epidemiological studies and empirical trials are needed to titrate VD requirements relative to structural soundness, but these trials are hampered by methods used to assess responses beyond those of bone mineralization. Assuming a greater absorption of 25OHVD than VD, our approach has used an assessment of a soundness scores to evaluate apparent OC in concert with measurements of Ca and P balance, particularly in lactating first litter gilts fed diets with varied VD, Ca and P concentrations. Growth performance and fibula ash validated the method of visual appraisal for structural soundness and gilts fed diets with 25OHVD had a greater number of femur osteoblast cells ($P < 0.02$). During lactation, at lower intakes, Ca and P retention were similar or improved ($P < 0.01$) by 25OHVD. Thus provision of greater dietary levels of VD from 25OHVD is a resource to sustain structural soundness of gilts and to protect efficiency of Ca and P use.

Key Words: structural soundness, 25-OH-D_3, osteochondrosis

T1 Effect of supplementation with dehydrated molasses lick blocks on performance of growing dairy-beef steers grazing pasture. J. B. Aveling[1], M. R. Walton[2], and K. Stelwagen*[3], *[1]Ballance Agri-Nutrients, Tauranga, New Zealand, [2]Kaitaringa Farms Ltd., Waiotira, New Zealand, [3]SciLactis Ltd, Hamilton, New Zealand.*

During late summer and in the fall, pasture quality tends to deteriorate. Molasses lick blocks (MLB) offer a convenient way to supplement grazing cattle. A study was conducted to investigate the effect of dehydrated MLB on the performance of growing Friesian cross (Hereford or Angus) steers kept on pasture. The control group (CON; n=25) and MLB group (n = 26) were randomly assigned to adjacent paddocks of similar botanical and nutritional quality (start of trial, CON vs. MLB pastures: DOMD, 65.9 vs. 70.2%; ME, 10.6 vs. 11.2 MJ/kg DM; end of trial: DOMD, 57.4% vs. 61.7%; ME 9.2 vs. 9.9 MJ/kg DM); pasture coverage and quality were at no time during the trial limiting. MLB-steers had ad libitum access to MLB tubs (Crystalyx Forage Plus: ME 12.0 MJ/kg DM, oil 6%, protein 12%, sugar, 35%, minerals and vitamin A, D, E). At the end of the trial a randomly chosen subset of steers (MLB, n = 6; CON, n=6) were subjected to blood sampling to measure plasma selenium, ferroxidase and vitamin B12 levels. The trial was conducted during late summer and fall (22 Jan to 2 May). MLB-steers consumed on average 102 g/d of MLB during the trial. No differences existed between crosses and data were subsequently pooled, with results shown in the Table. MLB-steers gained significantly more BW and faster than those without, resulting in an approximately 15 kg higher final live weight compared to CON steers. MLB steers had significantly higher selenium and vitamin B12 levels, but ferroxidase activity did not differ between groups (respectively, CON vs. MLB ± pooled SE: 230 vs. 475 ± 51 nmol/L, $P < 0.001$; 84 vs.118 ± 10 pmol/L, $P < 0.01$; 19 vs. 16 ± 3 IU/L, $P < 0.25$). In conclusion, MLB can improve performance in growing steers kept on pasture.

Table 1.

	CON	MLB	Pooled SEM	*P* <
Start BW (kg)	128.9	127.5	3.9	0.722
Final BW (kg)	178.8	192.6	5.0	0.001
Weight gain (kg)	49.9	65.1	2.7	0.001
ADG (g/d)	494	644	27	0.001

Key Words: dairy-beef steer, molasses lick block, pasture

T2 Trace minerals: A new approach in nutritional requirements. L. F. C. Silva*, S. C. Valadares Filho, P. P. Rotta, M. I. Marcondes, F. A. Sales, E. C. Martins, A. T. Tokunaga, and D. F. T. Sathler, *Universidade Federal de Vicosa, Vicosa, Minas Gerais, Brazil.*

An experiment was conducted to estimate the trace minerals requirements: chromium (Cr), cupper (Cu), manganese (Mn), iron (Fe) and zinc (Zn) in Nellore bulls. Thirty-seven Nellore bulls with initial shrunk body weight of 259 ± 24.9 kg were used in a comparative slaughter technique. The bulls were randomly divided into 3 groups: 5 bulls to the reference group, whereas 4 were fed at maintenance level and 28 were fed ad libitum. The bulls fed ad libitum were separated into 4 groups, one of which was slaughtered every 42 days. The reference group was slaughtered at the start of the experiment. All the animals were fed with corn silage and concentrate (55:45). Before each slaughter, the digestibility trial was done during 3 d. In each slaughter, the noncarcass components were weighted and a sample was collected for posterior analysis. After 18 hours of slaughter, the half-left carcass was dissected into muscle, fat and bone fractions and they were weighed. The samples were lyophilized, partially defatted and grounded. Feed, urinary, fecal and body trace mineral concentrations were evaluated by atomic absorption spectrophotometer. The net requirements for gain were calculated by the derivative of the allometric equation between body trace mineral concentrations and the empty body weight (EBW). Evaluation of the net requirements to maintenance was performed the regression between each absorbed trace mineral and its intake. After the sum of net requirements for maintenance and gain was divided by the absorption coefficient, the diet requirements were achieve. Data were analyzed using NLIN procedure of SAS. The net requirements for maintenance of Cr, Cu, Mn, Fe, and Zn were, respectively, 9.18; 90.5; 289.3; 856.1 and 266.3 µg/kg of EBW/day. The absorption coefficients for Cr, Cu, Mn, Fe, Zn were, respectively, 0.68; 0.68; 0.45; 0.27 and 0.41. The net requirements for gain (mg/d) to Cr, Cu, Mn, Fe, and Zn were estimated by following equations: Cr = 14.56 × EBW-0.182; Cu = 75.86 × EBW-0.512; Mn = 3.43 × EBW-0.261; Fe = 424.31 × EBW-0.207; and Zn = 151.73 × EBW-0.045. In this study, as the animal gain weight, the trace mineral requirements increase.

Key Words: comparative slaughter, mineral, Nellore

T3 Intake, duodenal flow, and intestinal digestibility of amino acids from canola meal or corn and wheat distillers grains in growing beef heifers. C. Li[1,2], L. Xu[2,4], S. Ding*[2,3], K. A. Beauchemin[2], and W. Z. Yang[2], *[1]College of Animal Science and Technology, Inner Mongolia University for the Nationalities, Tongliao, Inner Mongolia, China, [2]Research Centre, Agriculture and Agri-Food Canada, Lethbridge, AB, Canada, [3]Department of Agricultural, Food and Nutritional Science, University of Alberta, Edmonton, AB, Canada, [4]College of Food Science and Engineering, Inner Mongolia Agricultural University, Hohhot, Inner Mongolia, China.*

The objective of this study was to evaluate the intake, duodenal flows, and intestinal digestibility of amino acid (AA) from canola meal (CM) or type of dried distillers grains with solubles (DDGS) in growing beef heifers. Five ruminally and duodenally cannulated Angus heifers (BW 386 kg) were assigned to a 5 × 5 Latin square design. The diets consisted of 60% barley silage and 40% barley-based concentrate (DM basis) with differing protein supplements: control (CON; no protein supplement), CM, wheat DDGS (wDDGS), corn DDGS (cDDGS) or fractional corn DDGS (fDDGS). The fDDGS was produced by fractionation dry-grinding process where corn kernels are physically separated into high-fiber bran, germ and endosperm prior to mashing and fermentation of the endosperm. Contents of CP were 12.0, 14.1, 14.2, 14.1 and 14.2% (DM basis), respectively, for CON, CM, wDDGS, cDDGS and fDDGS diets. Intakes (g/d) of AA were lower ($P < 0.05$) for CON (631) than the protein supplemented diets (averaged 895), which were not different. Flows (g/d) of EAA and total AA to the duodenum were greatest ($P < 0.05$), respectively, for heifers fed wDDGS (521 and 1168) or fDDGS (534 and 1172), medium for CM (484 and 1069) or cDDGS (475 and 1059), and lowest for CON (385 and 846). The profiles of individual EAA (% of total AA) in duodenal flows were generally not different among treatments except for Lys (DDGS vs. CON and CM; 7.5 vs. 8.2%), Leu (corn DDGS vs. other diets; 9.2 vs. 8.1%), and Met (fDDGS vs. other diets; 1.2 vs. 1.6%). Digestibility of AA in the intestine (% of duodenal flow) generally did not differ (70 to 73% for EAA and 71 to

74% for total AA) except for Leu, Val, and Ala of which the digestibility was greater ($P < 0.05$) for fDDGS than for CON. These results indicate that wDDGS and fDDGS supplemented diets delivered greater amount of AA at the small intestine compared to CM and cDDGS when the diets were formulated to be isonitrogen. Corn and wheat DDGS can be used to replace CM to meet the protein requirements of growing cattle fed diets based on barley grain.

Key Words: beef heifer, duodenal flow of AA, protein supplement

T4 Effects of cottonseed meal and dried distillers grains supplementation on rice straw utilization by Brahman steers. J. C. McCann*, J. E. Sawyer, and T. A. Wickersham, *Texas A&M University, College Station.*

Seven ruminally cannulated Brahman steers were used in a 7 × 4 incomplete block design to determine the effects of cottonseed meal (CSM; 43.9% CP, 82.9% degradable protein) or dried distiller's grain (DDG; 27.5% CP, 43.6% degradable protein) supplementation on rice straw utilization. Treatments consisted of a control (no supplement) and three levels (60, 120, and 180 mg N/kg BW) of either CSM or DDG. Periods were 14 d with 9 d for adaptation and 5 d for data collection. Steers had ad libitum access to rice straw (4.7% CP, 68% NDF) and were fed supplements at 0630 daily. Increased supplementation resulted in a linear increase ($P \leq 0.06$) in forage OM intake from 13.5 g/kg BW (control) to 16.1 and 15.5 g/kg BW for 180 mg N/ kg BW of CSM and DDG respectively, with no difference between sources ($P = 0.84$). Total digestible OM intake was increased by supplementation (linear, $P < 0.01$) from 8.0 g/kg BW (control) to 11.7 and 12.9 g/kg BW for 180 mg N/ kg BW of CSM and DDG respectively. A greater response was observed for DDG ($P = 0.05$) due to greater provision of supplement (g DM/d) to achieve isonitrogenous treatment levels. Total tract OM digestion was linearly increased ($P < 0.01$) by CSM and DDG supplementation. Although CSM and DDG improved NDF digestibility (linear, $P \leq 0.06$) from 49.6% (control) to 53.7% and 54.9% at 180 mg N/kg BW respectively, estimated forage NDF digestibility was not significantly increased ($P > 0.10$). Ruminal ammonia concentrations peaked 4 h after supplementation with the greatest concentration (4.0 m*M*) observed for 180 mg N/kg BW of CSM and the lowest concentration observed in the control (0.8 m*M*). Provision of CSM resulted in a linear increase ($P < 0.01$) in ruminal ammonia in contrast to the quadratic response ($P = 0.02$) observed with DDG supplementation. Total VFA production followed a similar trend with a linear increase for CSM and DDG supplementation, respectively ($P = 0.09$, $P = 0.01$). Protein supplements containing high and low levels of degradable intake protein were effective at improving intake and utilization of rice straw.

Key Words: forage, protein, supplement

T5 Impact of chromium supplementation on lactating beef cows. M. J. Faulkner*[1], P. M. Walker[1], A. L. Wagner[2], R. E. Hall[2], and R. L. Atkinson[3], *[1]Illinois State University, Normal, [2]Cooperative Research Farms, Richmond, VA, [3]Southern Illinois University, Carbondale.*

The trace mineral, chromium (Cr), is required for digestion of carbohydrates, lipids and proteins. Recognized as the active component of the glucose tolerance factor, Cr aids in insulin signaling. When glucose metabolism is increased by production or other stressors, Cr deficiencies can occur. Because glucose metabolism is altered during gestation and lactation, Cr supplementation may be beneficial. Improved pregnancy rates and reduced postpartum BW have been demonstrated when beef cows were supplemented with Cr. The objective of this study was to determine if providing supplemental Cr to lactating beef cows improves calf weaning weights and cow conception rates. Angus × Simmental crossbred cows (n=119) were limit-fed one of two dietary treatments beginning at the birth of the first calf through calf weaning (n = 190 d). Cows were blocked by parity (first parity n = 32, second parity n = 26 and multiparous n = 61) and stratified within parity by BW subject to variation in BCS to 16 pens. Each block was equally represented within treatment. Cows were fed a base diet of corn silage and modified wet distiller's grains with solubles to provide 14.0% CP. Control cows were not fed supplemental Cr (T1) and treatment cows were fed supplemental Cr propionate [4 mg/(cow-d); T2]. All data, excluding reproduction, were analyzed using PROC MIXED of SAS, P=0.05 and the experimental unit = pen. The model statement included TREATMENT and the RANDOM statement included pen within treatment. Pregnancy rates were analyzed using the PROC FREQ procedure with the χ^2 option. No differences ($P > 0.05$) between treatments were observed for calf weaning weight or cow conception rates; mean weaning weight was 290 and 292 kg, and mean cow conception rates were 90 and 87%, for T1 and T2, respectively. No differences ($P > 0.05$) between treatments were observed for mean cow BW change (−76 and −80 kg), mean BCS change (−0.2 and −0.2), mean birth weight (40.7 and 41.1 kg) and mean daily milk production (6.20 and 5.97 kg), for T1 and T2, respectively. Based on the results of this single study, there appears to be no added benefit for supplementing lactating beef cows in optimum BCS with chromium propionate.

Key Words: chromium, lactating beef cow

T6 Effects of two experimental direct-fed microbial products on performance and carcass characteristics of finishing beef cattle. E. M. Domby*[1], U. Y. Anele[1], K. K. Gautam[1], C. H. Ponce[1], J. S. Schutz[1], M. Garner[2], and M. L. Galyean[1], *[1]Texas Tech University, Lubbock, [2]MicroBios Inc., Ithaca, NY.*

Despite reported increases in ruminal pH and nutrient digestion, responses in feedlot performance with direct-fed microbial (DFM) products in small-pen research studies have generally been equivocal. Our objective was to evaluate performance and carcass characteristics of finishing beef cattle fed 2 experimental DFM products. One hundred forty-four single-source steers (average initial BW = 311 ± 2.6 kg) were used in a randomized complete block design experiment. Steam-flaked corn was the basal grain, and treatment diets contained 25% (DM basis) wet corn gluten feed. The 3 treatments (12 pens/treatment) were (1) no DFM; (2) a *Lactobacillus acidophilus*-based DFM fed at a dose of 1×10^7 cfu/(steer·d) during the entire feeding period; and (3) the *L. acidophilus*-based DFM at 1×10^7 cfu/(steer·d) during the first 30 d, followed by a *Propionibacterium freudenreichii*-based DFM fed at a dose of 1×10^8 cfu/(steer·d) for the remainder of the feeding period. Although the DFM treatments numerically increased performance during the first 140 d of the feeding period, no differences ($P \geq 0.11$) for pen-based ADG, DMI, and G:F (averages of 1.52 kg, 8.49 kg/d, and 0.179, respectively) were detected for the overall (average = 187 d) feeding period. Carcass characteristics (HCW, dressing percent, 12th rib fat thickness, longissimus muscle area, calculated yield grade, and marbling score) did not differ ($P \geq 0.36$) among treatments, nor was the distribution of quality grades affected ($P = 0.950$) by treatments. Under the conditions of this study, results suggest neither positive nor negative effects on performance and carcass traits of beef steers associated with feeding the 2 DFM products evaluated.

Key Words: beef cattle, *Lactobacillus acidophilus*, *Propionibacterium freudenreichii*

T7 Influence of organic chromium and tannins extract supplementation on performance of bull calves during the first 50 days in the feedlot. A. Montoya[1], J. J. Bermudez[2], and R. Barajas*[1], *[1]Facultad de Medicina Veterinaria y Zootecnia, Universidad Autonoma de Sinaloa, Culiacan, Sinaloa, Mexico, [2]Ganaderia Integral Vizur, S.A. de C.V., Culiacan, Sinaloa, Mexico.*

Six hundred and seven bull calves (240.9 ± 1.01 kg) were utilized in an experiment to evaluate the influence of organic chromium and tannins extract supplementation on feedlot performance of bull calves during the first 50 d in the feedlot. Calves were individually weighed, and blocked by initial weight. Groups of 48 to 54 the calves were placed in 12 dirt floor pen (15 × 45 m). Pens within a block were randomly assigned to one of four treatments: (1) Basal diet with 87% concentrate (13.7% CP, 2.02 Mcal NE_m/kg DM), formulated with steam-flaked corn and soybean meal (Control); (2) Control supplemented with 0.49 mg Cr/kg DM (CR); (3) Control supplemented with 0.37% (DM basis) tannins extract (TE); and (4) Control supplemented with 0.49 mg Cr/kg DM and 0.37% (DM basis) tannins extract (CRTE). Organic chromium was provided as chromium methionine (MiCroPlex, Zinpro Corporation) and tannins extract was supplied as condensed hydrolysable tannins extract blend (ByPro, Silvateam). Results were analyzed by ANOVA for a randomized complete block design with a 2 × 2 factorial arrangement of treatments, using pen as the experimental unit. Chromium supplementation increased ($P = 0.04$) final weight in 3% (319.86 vs. 310.55 kg), enhanced ($P = 0.05$) ADG 12.3% (1.57 vs. 1.40 kg), and improved ($P = 0.05$) feed/gain ratio 11.4% (4.085 vs. 4.613). Dry matter intake was not affected by treatments ($P = 0.10$). The TE and CRTE treatments had no effect on any of measured variables ($P = 0.18$). As a main factor, TE increased DMI ($P = 0.05$). There was not observed CR × TE interaction for any variables. Supplementation of chromium methionine 0.49 mg Cr/kg DM, is effective for improved performance of bull calves during their first 50 d in the feedlot. Adding TE to diets containing supplemental chromium did not show any additional performance response.

Key Words: bull calves, chromium, feedlot performance

T8 Influence of tannins extract supplementation on feedlot performance and plasma urea nitrogen of nonimplanted growing heifers. B. J. Cervantes[1], A. Camacho[2], J. A. Vazquez[3], M. A. Espino[2], T. J. Heras[2], L. R. Flores[2], J. J. Lomeli[2], and R. Barajas*[2], *[1]Ganadera Los Migueles, S.A. de C.V., Culiacan, Sinaloa, Mexico, [2]Facultad de Medicina Veterinaria y Zootecnia, Universidad Autonoma de Sinaloa, Culiacan, Sinaloa, Mexico, [3]CUALTOS, Universidad de Guadalajara, Tepatitlan, Jalisco, Mexico.*

Forty nonimplanted Brahman heifers (195.8 ± 0.66 kg) were utilized in an 84-d experiment to evaluate the influence of tannins extract supplementation on feedlot performance and plasma urea nitrogen of nonimplanted growing heifers. Heifer were weighed individually, and in groups of five placed in dirt floor pens (6 × 12 m). In accord with initial weight, heifers were grouped in four weight-blocks. Within a block, pens were randomly assigned to one of two treatments: (1) Feeding a 56% roughage diet (15% CP, 1.37 Mcal NEm/kg DM) formulated with corn straw, corn silage without grain, ground sorghum grain and peanut meal (Control); or (2) Similar to control supplemented with 0.28% (DM basis) of tannins extract (TE). In pens assigned to Tannins treatment, daily were offered 87.7 g of tannin extract premix ByPro (Silvateam) premix that contains 72% of a condensed and hydrolysable tannins blend. TE was top-dresed on the diet in the feed bunk. Daily dose was equivalent to 14.54 g TE for each heifer inside the pen. Heifers were weighed on d 1 and d 84. On d 28 and 56, blood samples were taken from jugular vein. Experiment was analyzed by ANOVA for a randomized complete block design. TE improved 2.5% ($P = 0.03$) the final weight (279.2 vs. 272.3 kg), increased 8.88% ($P < 0.01$) ADG (0.993 vs. 0.912 kg/d), and 3.37% ($P < 0.01$) the dry matter intake (6.375 vs. 6.167 kg). TE supplementation enhanced ($P < 0.01$) the gain/feed ratio in 5.4% (0.156 vs. 0.148 kg/kg), and improved 3% ($P < 0.01$) observed/expected NEm and NEg ratio, with values of 1.01 vs. 0.98 for TE and Control heifers, respectively. In d 28, TE have no effect ($P = 0.57$) on plasma urea nitrogen concentration (PUN); however in d 56 TE supplementation diminished 16% PUN value ($P = 0.02$) with mean values of 14.00 and 11.75 mg/dL for TE and Control treatments, respectively. It is concluded; that tannins extract supplementation reduces N wastage measured as PUN and improve feedlot performance of nonimplanted growing heifers

Key Words: feedlot performance, heifer, tannin

T9 Influence of tannins extract and organic chromium supplementation on carcass characteristics of finishing bulls. A. Montoya[1], M. A. Espino[1], B. J. Cervantes[2,1], M. Verdugo[1], and R. Barajas*[1], *[1]Facultad de Medicina Veterinaria y Zootecnia, Universidad Autonoma de Sinaloa, Culiacan, Sinaloa, Mexico, [2]Ganadera Los Migueles, S.A. de C.V., Culiacan, Sinaloa, Mexico.*

Eight hundred and fifty bulls (338.8 ± 3.55 kg) were involved in a 92-d experiment to evaluate the influence of tannins extract and organic chromium supplementation on carcass characteristics of finishing bulls. Bulls were individually weighed and blocked by initial weight. Groups of 51 to 56 bulls were placed in 16 dirt floor pen (15 × 45 m). Pens within a block were randomly assigned to one of four treatments: (1) Finishing diet with 88% of concentrate (14% CP, 1.98 Mcal NEm/kg DM), (Control); (2) Control supplemented with 0.24 mg of Cr/kg DM (CR); (3) Control supplemented with 0.3% (DM basis) of tannins extract (TE); and (4) Control supplemented with 0.24 mg of Cr/kg DM and 0.3% (DM basis) of tannins extract (CRTE). CR was provided as chromium methionine (MiCroPlex, Zinpro Corporation). TE was supplied as condensed hydrolysable tannins extract blend (ByPro, Silvateam). Bulls were harvested after finishing period and hot carcass weight obtained. After 24 h of chilling, carcass characteristics were measured. Results were analyzed by ANOVA for a randomized complete block design with a 2 × 2 factorial arrangement of treatments. TE supplementation increased 2% ($P = 0.05$) hot carcass weight compared with Control (299.8 vs. 293.8 kg). TE augmented ($P = 0.02$) KPH-fat (2.66 vs. 2.30%). Hot carcass weight and KPH-fat of bulls in CR and CRTE treatments exhibits intermediate values and were not different ($P > 0.10$) of Control and TE. Back fat thickness, marbling score, and LM area were not affected by treatments ($P > 0.10$). An interaction CR × TE was observed in KPH-fat ($P = 0.02$). In muscle colorimetric measurements, L values were not affected by treatments ($P > 0.10$). Intensity of color measured as "a" and "b" were increased ($P = 0.01$) by TE supplementation. Interactions CR × TE were detected for "a" and "b" values. It is concluded that supplementation of 0.3% of tannins extract improves hot carcass weight and muscle color intensity, but additional organic chromium supplementation to finishing bulls consuming tannins extract did not produces any additional benefices.

Key Words: bulls, carcass, tannins

T10 Influence of tannins extract and organic chromium supplementation on feedlot performance. A. Montoya*[1], J. J. Bermudez[2], and R. Barajas[1], *[1]Facultad de Medicina Veterinaria y Zootecnia, Universidad Autonoma de Sinaloa, Culiacan, Sinaloa, Mexico, [2]Ganaderia Integral Vizur, S.A. de C.V., Culiacan, Sinaloa, Mexico.*

Eight hundred and fifty bulls (338.8 ± 3.6 kg) were utilized in a 92 d experiment to evaluate the influence of tannins extract and organic chromium supplementation on feedlot performance. Bulls were individually weighted and blocked by initial weight. Groups of 51 to 56 bulls were placed in 16 dirt floor pen (15 × 45 m). Pens within a block were randomly assigned to one of four treatments: 1) Finishing diet with 88% of concentrate (14% CP, 1.98 Mcal NEm/kg DM), formulated with steam-flaked wheat and soybean meal (Control); 2) Control supplemented with 0.24 mg of Cr/kg DM (CR); 3) Control supplemented with 0.3% (DM basis) of tannins extract (TE); and 4) Control supplemented with 0.24 mg of Cr/kg DM and 0.3% (DM basis) of tannins extract (CRTE). Chromium was provided as chromium methionine (MiCroPlex, Zinpro Corporation) and TE was supplied as condensed hydrolysable tannins extract blend (ByPro, Silvateam). Results were analyzed by ANOVA for a randomized complete block design with a 2 × 2 factorial arrangement of treatments. At the end of experiment, bulls in TE were 2.8% heavier ($P = 0.05$), and gained 8.4% more weight ($P = 0.02$) than those in the Control group. Final weight and ADG of bulls in CR and CRTE treatments exhibits intermediate values and were not different ($P > 0.10$) of Control and TE. An interaction CR × TE was observed for ADG ($P = 0.04$). Bulls supplemented with Cr and TE gained less than those fed Cr or TE separately (1.36, 1.41, 1.47 and 1.40 kg/d for Control, CR, TE, and CRTE treatments, respectively). TE supplementation increased HCW by 2% ($P = 0.05$) compared with Control (299.8 vs. 293.8 kg). As a main factor, bulls fed TE ate 3% more DM ($P = 0.05$) than animals that no received tannins (7.8 vs. 8.0 kg/day). Feed/gain ratio was not affected by treatments ($P > 0.10$). It is concluded that supplementation of 0.3% of tannins extract could improves weight gain and carcass weight, but organic chromium supplementation to bulls consuming tannins extract did not produces any additional benefices.

Key Words: bull, feedlot, tannin

T11 Interaction of tannin extract and zilpaterol hydrochloride supplementation on feedlot performance of bulls. R. Barajas*[1], B. J. Cervantes[2], M. A. Espino[1], A. Camacho[1], M. Verdugo[1], L. R. Flores[1], and J. A. Romo[1], *[1]Facultad de Medicina Veterinaria y Zootecnia, Universidad Autonoma de Sinaloa, Culiacan, Sinaloa, Mexico, [2]Ganadera Los Migueles, S.A. de C.V., Culiacan, Sinaloa, Mexico.*

Eighty bulls (341.7 ± 10.1 kg) were utilized in a 108 d experiment to evaluate the interaction of tannin extract and zilpaterol hydrochloride supplementation on feedlot performance of bulls. Bulls were individually weighed and blocked by weight. Groups of five bulls were placed in16 dirt-floor pens (6 × 12 m). Pens within a block were randomly assigned to treatments follows: (1) Finishing diet (14% CP, 1.83 Mcal NE_m/kg) formulated with ground sorghum grain (Control); (2) Control added with zilpaterol hydrochloride (ZH); (3) Control supplemented with 0.3% (DM basis) of tannin extract (TE); and (4) Control added with ZH and TE (ZHTE). Both, ZH and TE treatments were top-dress on the diet in the feed bunk. Zilpaterol hydrochloride was supplied daily as 1.63 g of Zilmax (Merck Animal Health)/bull (which equate to 0.15 mg ZH/kg BW). Zilmax contains 4.8% zilpaterol hydrochloride. Zilmax was withdrawn three days prior harvest. TE was provided feeding daily 35.5 g of condensed hydrolysable tannin blend (ByPro, Silvateam). The experiment was analyzed by ANOVA for a completely randomized design with 2 × 2 factorial arrangement of treatments. Orthogonal contrasts were used to compare ZHTE vs. each one of remainder treatments. TE supplementation increased ($P < 0.05$) final weight, ADG, and hot carcass weight. ZH decreased ($P < 0.05$) DMI as percentage of BW, improved feed/gain ratio, hot carcass weight, and carcass dressing. An interaction ($P < 0.05$) TE × ZH was observed in DMI mean values were 2.8, 2.5, 2.7 and 2.73% of BW for Control, ZH, TE, and ZHTE treatments, respectively. Contrasts indicated that carcass of bulls in ZHTE extract treatment were heavier ($P < 0.05$) than remainder treatments, with means of 324.6, 330.5, 329.8 and 345.4 kg for Control, ZH, TE, and ZHTE treatments, respectively. Results suggest that coupled supplementation of Zilmax and tannin extract contributes to increases in weight gain, final weight, and heavier carcass in finishing bulls.

Key Words: finishing-bulls, tannins, zilpaterol

T12 Influence of zinc methionine and zilpaterol hydrochloride supplementation on feedlot performance and carcass characteristics of yearling-finishing bulls. M. Verdugo[1], B. J. Cervantes[2], M. A. Espino[1], J. A. Romo[1], and R. Barajas*[1], *[1]Facultad de Medicina Veterinaria y Zootecnia, Universidad Autonoma de Sinaloa, Culiacan, Sinaloa, Mexico, [2]Ganadera Los Migueles, S.A. de C.V., Culiacan, Sinaloa, Mexico.*

Eighty yearling-bulls (488.8 ± 4.17 kg) were utilized in a 32-d experiment to evaluate the influence of zinc methionine and zilpaterol hydrochloride supplementation on feedlot performance and carcass characteristics of yearling-bulls fed a finishing diet. Cattle were individually weighed, and groups of 5 were placed in 16 pens (6 × 12 m). Pens were randomly assigned to one of four treatments: (1) Basal diet (CTRL); (2) CTRL plus zilpaterol hydrochloride (ZH); (3) CTRL plus 40 mg Zn/kg DM (ZN); or (4) CTRL plus zilpaterol hydrochloride and zinc-methionine (40 mg Zn/kg DM; ZHZN). The basal diet (14% CP; 1.86 Mcal of NE_m/kg and 60 mg Zn/kg of DM) was supplemented with 57 mg of Zn/kg using zinc sulfate. Both, ZH and ZN were top-dress on the diet in the feed bunk. The ZH was supplied daily as 1.63 g of Zilmax (Merck Animal Health)/bull (which equate to 0.15 mg ZH/kg BW). Zilmax was withdrawn 3 d prior to harvest. The ZN was daily supplemented as 4.6 g Zinpro (Zinpro Corporation)/per bull. The ZINPRO product contains 10% Zn as zinc-methionine complex. The experiment was analyzed by co-variance as a completely randomized design with 2 × 2 factorial arrangement of treatments. Initial weight was the associate co-variable. Feeding ZH increased ($P < 0.05$) final weight (1.9%) and ADG (29.9%), improved ($P < 0.05$) feed/gain ratio 31%, and augmented ($P < 0.01$) hot carcass weight 14.3 kg, and dressing percentage by 1.4%. The ZN has no effect on the measured variables ($P > 0.20$). A tendency ($P = 0.11$) was observed for ZH × ZN interaction on carcass weight, with mean values of 328, 337, 323, and 342 kg for CTRL, ZH, ZN and ZHZN, respectively. A ZH × ZN interaction ($P < 0.05$) was detected for dressing percentage with mean values of 62.8, 63.2, 61.5 and 64.0 for CTRL, ZH, ZN and ZHZN, respectively. Treatments had no effect on carcass characteristics ($P > 0.20$). Results suggest that the ZN supplementation to diets that contains ZH could contribute to increased dressing percentage and heavier hot carcass weight of yearling finishing bulls.

Key Words: yearling bull, zilpaterol hydrochloride, zinc

T13 Effect of direct-fed microbials on ruminal fermentation and lactate utilization in steers consuming a high concentrate diet. N. M. Kenney*, S. M. Wingard, E. S. Vanzant, D. L. Harmon, and K. R. McLeod, *University of Kentucky, Lexington.*

Direct-fed microbials (DFM) have been shown to alter ruminal fermentation and may modulate fermentation during transition to high concentrate diets. To test this hypothesis, 12 ruminally cannulated Angus steers (385 ± 35 kg) were used in split-plot design with the whole plot consisting of control or DFM, and the sub-plot consisting of week of

dietary adaptation. The DFM was a mixed bacterial culture, primarily *Lactobacillus acidophilus* and *Enterococcus faecium*, fed at 1 billion cfu/d. A 90:10 concentrate to forage, corn-based diet was fed twice daily and top-dressed with DFM or lactose carrier. Rumen fluid was sampled on d 14 and 28 at 0, 3, 6, 9 and 12 h post-feeding. Steers were ruminally pulse dosed with a 2 L solution of neutralized DL lactate (0.56 *M*) and CrEDTA 3 h post-feeding on d 15 and 29. Ruminal samples were collected at 10- and 20-min intervals for the first and second hour post-dosing. Total VFA concentration and molar proportions of butyrate were unaffected by DFM ($P \geq 0.19$) or week ($P \geq 0.24$). Molar proportions of acetate exhibited a DFM by hour interaction ($P = 0.04$); however, on average, molar proportion of acetate was 4.4% greater for DFM. Conversely, DFM did not affect propionate ($P = 0.39$). On average, molar proportions of propionate and acetate increased ($P = 0.07$) and decreased ($P = 0.07$), respectively, across weeks. Mean daily ruminal pH was similar for control on d 14 (6.04) and 28 (6.09), whereas mean pH increased from d 14 (6.05) to d 28 (6.35) for DFM (DFM × week; $P = 0.08$). Minimum pH remained unchanged for control over time but increased from d 14 (5.70) to d 28 (6.16) for DFM (DFM × week; $P = 0.10$). Maximum pH decreased from d 14 to 28 in control but increased over time with DFM from 6.31 to 6.53 (DFM × week; $P = 0.05$). Total and L-lactate utilization were unaffected by DFM ($P \geq 0.33$) or week ($P \geq 0.50$). These data indicate that DFM may be beneficial during dietary adaptation, as evidenced by shifts in ruminal VFA profile and pH; however, DFM did not appear to influence ruminal lactate utilization.

Key Words: direct-fed microbial, pH, lactate

T14 Influence of feeding chelated chromium and enzymatically hydrolyzed yeast on growth performance, dietary energetics, and carcass characteristics in feedlot cattle. B. Sánchez-Mendoza*[1], A. Montelongo[1], A. Plascencia[1], R. Ware[2], and R. Zinn[3], *[1]UABC, Mexicali, BC, Mexico, [2]Varied Industries Corporation, Mason City, IA, [3]University of California, Davis.*

Forty crossbred steers (245 ± 0.95 kg) were used in a 222-d feeding trial to assess the effects of a chelated chromium enriched extract of enzymatically hydrolyzed yeast cell wall (EHY) on growth performance, dietary energetics and carcass characteristics. Treatments consisted of a steam-flaked corn-based finishing diet supplemented with 0 or 500 ppb of chelated chromium (Cr) enriched EHY (TruMax, Vi-COR, Mason City, IA). Steers were blocked by weight and randomly assigned to 8 pens (5 steers/pen, 4 pens/treatment). Pens were 43 m^2, with 22 m^2 of shade, automatic waterers, and 2.4-m fence-line feed bunks. Supplemental Cr intake average 4.3 mg/d. During the initial 112-d period, Cr supplementation increased ADG (6.8%, $P = 0.03$) and tended to increase (5.9%, $P = 0.07$) DM intake. However, Cr supplementation did not affect overall (222-d feeding period) growth performance. Nevertheless, Cr supplementation increased LM area (6.8%, $P < 0.01$) and tended to increase retail yield (1.6%, $P = 0.07$), and decrease carcass fat thickness (10%, $P = 0.09$). Results indicate that Cr supplementation has a modulating effect on carcass quality, and may enhance DMI and corresponding ADG of feedlot cattle.

Key Words: chromium chelate, finishing, steer

T15 Influence of feeding yeast cell wall extract on growth performance of feedlot cattle during periods of elevated ambient temperature. M. Montano*[1], A. Plascencia[1], N. Torrentera[1], R. Ware[2], and R. Zinn[3], *[1]UABC, Mexicali, BC, Mexico, [2]Varied Industries Corporation, Mason City, IA, [3]University of California, Davis.*

Eighty crossbred steers (235 ± 0.59 kg) were used in a 229-d feeding trial to assess the effects of an enzymatically hydrolyzed yeast cell wall (EHY) on growth performance and carcass characteristics. Treatments consisted of a steam-flaked corn-based finishing diet supplemented with 0, 1, 2, or 3 g/hd/d of EHY (Celmanax, Vi-COR, Mason City, IA). Steers were blocked by weight and randomly assigned to 16 pens (5 steers/pen). Pens were 78 m^2, with 27 m^2 of shade, automatic waterers, and 4.3-m fence-line feed bunks. There were no effects on growth performance during the initial 84-d period. However, from d 84 to harvest, EHY supplementation increased ADG (10.7%, $P = 0.08$) and gain efficiency (8.6%, $P = 0.09$). From 139-d to harvest, when 24-h temperature humidity index averaged 80, EHY increased DMI (4.8%, $P = 0.03$). Supplementation with EHY had a quadratic effect ($P = 0.02$) on KPH. Otherwise, there were no treatment effects on carcass composition. Enhancements in DMI and ADG during periods of high ambient temperature indicate a potential role of EHY in association with heat stress.

Key Words: cattle, performance, yeast

T16 Effect of level and source of supplemental tannin on growth-performance of Holstein steers during the late finishing phase. C. Rivera*[1], A. Plascencia[1], N. Torrentera[1], and R. Zinn[2], *[1]UABC, Mexicali, BC, Mexico, [2]University of California, Davis.*

Two trials were conducted to evaluate the effects of tannin source and level on feedlot cattle performance during the late finishing phase, when metabolizable protein intake is not limiting requirements for growth. In Trial 1, 96 calf-fed Holstein steers (476 ± 6 kg) were used in a randomized complete block design experiment (4 pens/ treatment) to evaluate level of tannin supplementation. Treatments consisted of a steam-flaked corn-based finishing diet supplemented with 0, 0.2, 0.4, and 0.6% condensed tannin. Across the 84-d feeding period, tannin supplementation increased ADG (1.37, 1.42, 1.48, and 1.50 ± 0.04 kg/d, respectively; $P = 0.05$), gain efficiency (0.122, 0.128, 0.128, and 0.129 ± 0.002, respectively; $P = 0.04$) and observed/expected diet NEm (0.92, 0.95, 0.94 and 0.95 ± 0.01, respectively; $P = 0.06$). In Trial 2, 96 calf-fed Holstein steers (392 ± 4 kg) were used in a randomized complete block design experiment (4 pens/ treatment) to compare the influence of tannin source (condensed vs. hydrolysable) on cattle performance during the late finishing phase. Dietary treatments consisted of a steam-flaked corn-based finishing diet supplemented with 0% supplemental tannin, 0.6% condensed tannin, 0.6% hydrolysable tannin, and a mixture of 0.3% condensed and 0.3% hydrolysable tannin (DM basis). Across the 84-d feeding period, tannin supplementation tended to increase ADG (1.53, 1.64, 1.61, and 1.65 ± 0.06 kg/d, respectively; $P = 0.08$) and DMI (10.0, 10.3, 10.2, and 10.7 ± 0.15 kg/d, respectively; $P = 0.06$). There were no treatment effects on gain efficiency (0.152, 0.159, 0.157, 0.155 ± 0.005, respectively; $P = 0.42$), and observed/expected diet NEm (0.97, 0.99, 0.99 and 0.97 ± 0.02, respectively; $P = 0.38$). It is concluded tannin supplementation may enhance feedlot cattle growth performance during the late finishing phase independently of effects on ruminal metabolism protein (metabolizable protein supply from the basal unsupplemented diet already in excess of requirements for growth).

Key Words: cattle, performance, tannin

T17 Influence of supplemental urea withdrawal during the late finishing phase on growth performance and digestive function in feedlot cattle. D. May*[1], J. Calderon[1], M. Montano[1], A. Plascencia[1], and R. Zinn[2], *[1]UABC, Mexicali, BC, Mexico, [2]University of California, Davis.*

Two trials were conducted to evaluate the influence of supplemental urea withdrawal on characteristics of digestion (Trial 1) and growth performance during the late finishing phase (trial 2). In Trial 1, 6 Holstein steers (160 kg) with cannulas in the rumen and proximal duodenum were used in a replicated 3 × 3 Latin square experiment. Treatments consisted of a steam-flaked based finishing diet, where dietary urea supplementation was adjusted to provide 100, 80 and 60% of expected urea fermentation potential. Daily DMI was restricted to 2.5% of BW. Decreasing supplemental urea decreased (linear effect) ruminal digestion of OM ($P = 0.04$) and NDF ($P = 0.05$), and nonammonia N flow to the small intestine ($P = 0.04$), and tended to decrease ($P = 0.06$) ruminal microbial protein synthesis. There were no treatment effects on total tract digestion of OM, NDF and starch digestion. Decreasing supplemental urea tended to decrease (linear effect) total tract digestion of OM ($P = 0.06$) and NDF ($P = 0.06$), and decreased (linear effect) total tract digestion of N ($P = 0.04$), and DE ($P = 0.05$). Ruminal and total tract starch digestion were unaffected by treatments. There were no treatments effects on ruminal pH. However, decreasing urea supplementation decreased (linear effect, $P = 0.007$) ruminal ammonia N, and increased (linear effect, $P = 0.04$) ruminal acetate:propionate molar ratio and estimated methane production. In Trial 2, 90 crossbred steers (468 kg), were used in a 40 d feeding trial (5 steers/pen, 6 pens/ treatment) to evaluate treatment effects on final-phase growth performance. Decreasing urea supplementation did not affect DMI, but decreased (linear effect, $P < 0.01$) ADG, gain efficiency, and dietary NE ($P = 0.03$). There were no treatment effects on carcass characteristics. In addition to effects on net protein flow to the small intestine, depriving cattle of otherwise ruminally degradable N during the late finishing phase may negatively impact site and extent of digestion of OM digestion and NE value of the diet, as well as ADG.

Key Words: cattle, performance, urea

T18 Evaluation of maternal trace mineral source on cow/calf performance and the subsequent feedlot performance of beef calves. R. L. Stewart Jr.*[1], T. J. Wistuba[2], G. I. Zanton[2], and A. L. Jones[3], *[1]The University of Georgia, Athens, [2]Novus International, St. Charles, MO, [3]The University of Georgia, Tifton.*

A 2-yr study was conducted to assess the effect of trace mineral source (15 ppm Cu, 30 ppm Zn, and 40 ppm Mn; based on a 4-oz mineral intake) on performance of cows and calves and the subsequent feedlot performance and carcass characteristics of beef calves. Each year, the 216 cow herd (BW = 623 ± 21 kg) at the University of Georgia Northwest Georgia Research and Education center was blocked by age (senior cows, junior cows, and first calf heifers) and randomly assigned to receive trace minerals from an inorganic (INORG) or chelated (CHEL; Mintrex, Novus International Inc.) (n=6). A methionine supplement was added to the inorganic source to balance the 2-hydroxy-4-methylthio butanoic acid provided by the Mintrex. Minerals were offered as a component of a free choice mineral, and were offered starting 30 d prior to calving of yr-1 and continuing through weaning of yr-2. Calves were maintained with the dam through weaning. After weaning in yr-1, steers were grouped by treatment and backgrounded for 45 d prior to shipping to a finishing facility. All steers were commingled and fed a common finishing diet for 107 or 142 d, based on estimated final back fat thickness of 1.27 cm. Cow BW at weaning (598 and 610 kg, respectively) and BW change from prepartum to weaning (−20.3 and −9.3) kg, respectively) did not differ ($P \geq 0.15$) between INORG and CHEL treatments. Calf birth weight (34.3 and 34.4 kg, respectively) and adjusted 205-d weaning weight (242 and 249 kg, respectively) did not differ ($P \geq 0.25$) between INORG and CHEL treatments. However, kg of calf weaned per cow exposed to breeding was greater ($P < 0.01$) for CHEL compared to INORG (240 and 228 kg, respectively). During the finishing period, average daily gain was similar ($P = 0.75$) between INORG and CHEL (1.18 and 1.20 kg, respectively). Carcass characteristics were similar between treatments ($P \geq 0.40$), however CHEL tended ($P = 0.07$) to yield more carcasses grading low choice or higher (87.5 and 79.3%, respectively). These data indicate chelated minerals can improve calf production per cow and subsequently improve carcass quality of beef calves.

Key Words: beef, chelated, trace mineral

T19 Influence of abomasal infusion of phenylalanine on characteristics of digestion of a steam-flaked wheat-based finishing diet fed to Holstein steers. A. A. Vite[1], A. G. Alvarez*[1], A. P. Marquez[1], M. F. Montano[1], N. G. Torrentera[1], and R. Zinn[2], *[1]UABC, Mexicali, BC, Mexico, [2]University of California, Davis.*

Four Holstein steers with cannulas in the rumen, abomasum, and proximal duodenum, were used in a 4 × 4 Latin square design experiment to evaluate the influence of abomasal infusion of phenyalanine (PHE, 0, 5, 10 or 15 g/hd/d) on feed intake and digestive function. Steers were allowed ad libitum access to a steam-flaked wheat-based diet (DM basis; 72% steam-flaked wheat, 12% sudangrass hay, 9% sugarcane molasses, 3% yellow grease, 1.9% limestone, 1.3% urea, and 0.5% minerals and vitamins). Chromic oxide was added (0.3% as DM basis) as internal digesta marker. There were no treatment effects ($P > 0.10$) ruminal OM digestion or ruminal microbial efficiency (microbial N/kg OM fermented). However, PHE infusion increased rumen pH (linear component, $P = 0.07$), and ruminal NDF digestion (linear component, $P = 0.09$). There were no treatment effects ($P > 0.10$) on total tract OM and N digestion. However, PHE infusion increased (linear component, $P = 0.03$) total tract NDF digestion (largely attributable to the increased ruminal NDF digestion). Changes in ruminal NDF digestion due to PHE infusion were associated with increased ($P = 0.06$; linear component) rate of ruminal NDF digestion (KdNDF) and decreased rate of ruminal NDF passage (KpNDF). This latter effect may evidence a role for PHE in regulation ruminal emptying and passage of chyme to the small intestine.

Key Words: cattle, digestion, phenylalanine

T20 Effects of postruminal amino acid supply on dietary protein flow from the rumen in forage based diet using a continuous culture system. M. M. Masiero*, J. H. Porter, M. S. Kerley, and W. J. Sexten, *University of Missouri, Columbia.*

Three diets with increasing ruminal undegraded AA, 80% (LO), 100% (MD) and 120% (HI) of the requirements for a 200 kg steer, were fed (50g/d) to continuous culture fermenters (FER) to characterize RUP supplementation (porcine blood meal and Aminoplus) in forage-based diet. We hypothesized increasing diet RUP concentration would increase RUP flow from the rumen without influencing microbial fermentation. Diets were randomly distributed over FER (n = 24), acclimated for 4 d, and sampled over 3 d. FER content was monitored at 0h and 4 h post feeding for pH and analyzed for VFA (m*M*) and ammonia concentration (AM) (m*M*/dL). The pH was greater ($P = 0.005$ and 0.0008) for HI, 6.46 and 6.42, compared to MD, 6.34 and 6.27, and LO, 6.32 and 6.24, for 0 and 4 h, respectively. AM increased as RUP increased (LO 3.18; MD 5.30; HI 8.79) at 0 h, however at 4 h, AM was greater ($P < 0.0001$) for HI (10.58) compared to MD (6.10) and LO (4.26). Acetic, propionic, valeric, total VFA and acetic:propionic did not differ ($P = 0.44$) at 0 and

4 h. Butyric did not differ ($P = 0.37$) at 0 h. At 4 h butyric was greater ($P = 0.036$) for LO (16.9) compared to HI (15.4), however MD (16.5) did not differ between treatments. Isobutyric was greater ($P < 0.0001$) for HI (1.5) compare to MD (1.2) and LO (1.1) at 0 h. At 4 h, isobutyric increased as RUP increased (LO 1.2; MD 1.4; HI 1.6; $P < 0.0001$). Isovaleric was greater ($P < 0.0001$) for HI, 2.9 and 3.0, compared to MD, 2.5 and 2.6, and LO, 2.2 and 2.4, for 0 and 4 h, respectively. OM, NDF and ADF digestibility, microbial efficiency and g of bacterial N/d did not differ ($P = 0.4$). Protein digestibility (%) was greater ($P = 0.042$) for LO (47.2) and HI (46.0) compared to MD (38.3). At the lower RUP inclusion levels RUP was recovered in effluent flow however at greater RUP inclusion levels 34% of added RUP was recovered in effluent flow. In conclusion, RUP supplementation in forage-based diets increased RUP flow from the rumen without influencing microbial fermentation. Reduced RUP for HI compared to MD may be due to microbial adaptation to greater RUP levels.

Key Words: digestibility, fermentation, RUP

T21 Phosphorus excretion in beef steers as affected by increasing levels of corn gluten feed supplementation. D. D. Harmon*[1], E. A. Riley[1], A. L. Zezeski[1], J. K. Smith[1], H. L. M. Tucker[2], S. J. Neil[1], B. D. Dalton[1], and M. A. McCann[1], *[1]Virginia Polytechnic Institute and State University, Department of Animal and Poultry Sciences, Blacksburg, [2]Virginia Polytechnic Institute and State University, Department of Dairy Science, Blacksburg.*

Overfeeding of phosphorus (P) is a contributing factor to P levels in the Chesapeake Bay. The objective of this study was to determine the impact of increasing levels of corn gluten feed as a supplemental organic source of P. Eight Hereford steers (427 ± 79 kg) were randomly assigned to one of four dietary treatments in a 4 × 4 replicated Latin square design. Steers were fed a basal diet of chopped grass hay (0.13% P) and 0, 0.5, 1.0 or 1.5 kg/d of dried corn gluten feed pellets. All steers were supplemented with 0.91 kg/d beet pulp, 0.45 kg/d rumen-inert fat supplement and 18 g/d trace mineral salt. Urea was added to the respective diets at levels of 95.34, 72.64, 49.94, and 31.78 g/d to ensure equal dietary protein across treatments. Steers were housed individually and fitted with total fecal collection bags. Steers were adjusted to each diet for 9 d followed by a 5-d collection period. Following the final collection of each period, a 10 ml jugular blood sample was collected and analyzed to determine serum inorganic P. Feed and fecal samples were dried, ground, subsampled and analyzed for inorganic and total P. Dietary P increased ($P < 0.05$) as level of corn gluten feed increased: 10.14, 14.19, 18.26 and 22.30 g/d. Dry matter digestibility increased linearly ($P < 0.05$) as dietary P increased: 51.15, 52.25, 52.72 and 54.10%. Total P excretion increased linearly ($P < 0.05$) with increasing dietary P content: 9.42, 10.76, 15.51, 16.40 g/d. Inorganic P excretion increased linearly ($P < 0.05$) with increasing dietary P content: 4.26, 6.17, 8.68 and 10.25 g/d. Total P excretion was highly correlated ($P < 0.05$; $r = 0.81$) with inorganic P excretion. Serum inorganic P increased linearly ($P < 0.05$) with increasing dietary P content: 5.61, 5.87, 6.64 and 6.80 mg/dL. Fecal P increased as dietary P increased in steers fed varying dietary levels of P from organic sources. Prevention of overfeeding of P on beef cattle operations is a strategic, managerial practice that can reduce P levels.

Key Words: beef cattle, byproduct feedstuffs, phosphorus

T22 Effect of Bovamine on lactation performance by dairy cows. L. F. Ferraretto* and R. D. Shaver, *University of Wisconsin-Madison, Madison.*

The objective of this study was to evaluate the effect of direct-fed microbial (Bovamine) addition to a TMR on lactation performance by mid-lactation dairy cows. One hundred and twelve Holstein cows (28 primiparous and 84 multiparous; 139 ± 47 DIM at trial initiation) were stratified by parity and DIM and randomly assigned to 14 pens of 8 cows each. Pens were then randomly assigned to 1 of 2 treatments in a continuous-lactation trial consisting of a 2-wk covariate adjustment period with cows fed the basal TMR followed by a 10-wk treatment period with cows fed their assigned treatment diets. The two treatments were: basal TMR plus either 1 g/cow/d Bovamine (BOV, 1×10^9 cfu/g *Lactobacillus acidophilus* NP51 and 2×10^9 cfu/g *Propionibacterium freudenreichii* NP24) or placebo (CON). Data were analyzed as a completely-randomized design with the data from the preliminary period as a covariate using PROC MIXED in SAS. The model included treatment, week and treatment × week interaction as Fixed effects, and pen within treatment as a Random effect. Milk yield was similar ($P > 0.10$) between treatments and averaged 44.9 kg/d. There was a trend ($P < 0.08$) for DMI to be decreased by 0.4 kg/d per cow for BOV overall, and DMI was lower ($P < 0.05$) for BOV than CON during wk 2, 3, 6, 9 and 10 ($P < 0.001$ for week × treatment). However, measures of feed conversion (milk or component-corrected milk yields per unit DMI) were unaffected ($P > 0.10$) by treatment. Milk fat, protein and urea nitrogen concentrations were unaffected ($P > 0.10$) by treatment and averaged 3.75%, 3.11% and 15.2 mg/dL, respectively. Likewise, body weight change and condition score were unaffected ($P > 0.10$) by treatment. Under the conditions of this study, with mid-lactation cows fed a 54% forage TMR (DM basis), there was no improvement in lactation performance from the inclusion of Bovamine in the diet.

Key Words: direct-fed microbial, dairy cow, milk production

T23 Use of plasma lysine to assess postruminal amino acid bioavailability in rumen bypass lysine from Megamine-L. E. Evans*[1], N. Clark[2], and E. Block[3], *[1]Essi Evans Technical Advisory Services Inc., Bowmansville, ON, Canada, [2]Atlantic Dairy and Forage Institute, Fredericton Junction, NB, Canada, [3]Arm & Hammer Animal Nutrition, Princeton, NJ.*

An experiment was conducted to assess the use of plasma Lys to determine post-ruminal absorption. Rumen cannulated, post-peak production cows were housed in stanchion stalls. Cows had ad libitum access to a TMR that met their Lys needs based on CPM Dairy. Four treatments were evaluated in a Latin square design with periods of 14 d. Control was 50g of abomasally infused Lys (63.4g of Lys HCl) and was compared to 37.5, 50 and 62.5 g of abomasally Lys from cows receiving a single rumen dose of Megamine-L (Church & Dwight Co., Inc.). Actual amounts of Megamine-L were calculated to deliver the desired abomasal Lys based on predetermination of soluble protein at 28.6%, a degradation rate of 2.02%/hr, an assumed escape of 50% of the Lys, and 16% free Lys the product. One day prior to application (d 13 of each period) of the test article, blood was drawn via jugular catheter at 0800, 1200, 1600, 2400 and 0400 h to determine baseline plasma Lys levels. At 0800 h on the day of the experiment (d 14 of each period) the Megamine-L treatments were administered as a single dose through a rumen cannula. The control Lys infusion consisted of 63.4g of Lys-HCl (50 g of Lys) dissolved in 3 L of water and was administered over a 2-h period. Blood was drawn at 0745, 1200, 1600, 2400 and 0400 h. Lysine availability was calculated from the area under the curve (AUC). AUC for the control treatment was assumed to represent a digestibility of 98%. Lys bioavailability from Megamine-L increased ($P < 0.05$) with the amount of Lys supplied (57.7, 67.2 and 70.2% calculated absorption

at 37.5, 50.0 and 62.5 g of abomasal Lys). Previously reported trials (digestibility-metabolism trial design) estimated metabolizable Lys in Megamine-L at 46% which is lower than the results in this trial design. Use of plasma Lys to assess Lys status is not accurate, and likely varies with gut and hepatic uptake and utilization. It is likely that compounds exiting the rumen more gradually in normal feeding situations would be disadvantaged relative to the single bolus doses of Lys administered in this trial.

Key Words: metabolizable lysine, rumen bypass lysine, dairy cows

T24 Lactational performance and ruminal fermentation profiles of dairy cows fed different corn silage hybrids ensilaged without or with microbial inoculant. M. N. McDonald[1], M. S. Holt[1], A. J. Young[1], J.-S. Eun*[1], and K. E. Nestor[2], *[1]Department of Animal, Dairy, and Veterinary Sciences, Utah State University, Logan, [2]Mycogen Seeds, Indianapolis, IN.*

A lactation study was conducted to examine the effects of a silage inoculant (SI) applied onto conventional (CCS) or brown midrib corn silage (BMRCS) in lactation diets on lactational performance and ruminal fermentation of dairy cows. Forty multiparous Holstein cows were used starting at 20-58 DIM in a completely randomized design with a 2 × 2 factorial arrangement of treatments. Cows were randomly assigned to 1 of 4 diets: CCS TMR without SI, CCS TMR with SI (CCS+SI), BMRCS without SI, and BMRCS with SI (BMRCS+SI). The experiment lasted a total of 10 wk (2 wk of adaptation and 8 wk of data and sample collection). The SI (Agmaster XV, DuPont, Waukesha, WI) was applied at 1.25×10^5 cfu/g of corn crop to the CCS+SI and the BMRCS+SI. Cows fed BMRCS increased DMI compared to those fed CCS (27.9 vs. 25.6 kg/d; $P = 0.05$), but SI did not affect DMI. Milk yield averaged 45.8 kg/d across treatments, and it was not affected by dietary treatments. In contrast, milk fat concentration and yield increased ($P < 0.05$) due to feeding BMRCS, leading to an increase in ECM yield by feeding BMRCS (47.5 vs. 43.2 kg/d; $P = 0.03$). Dietary treatments did not influence concentrations of milk protein and MUN. Digestibility of DM was similar among treatments, whereas feeding BMRCS increased ($P = 0.05$) digestibilities of NDF and ADF. Ruminal pH averaged 6.29 across treatments and did not differ. Concentration of VFA was not affected by dietary treatments. While feeding BMRCS increased ($P = 0.05$) molar proportion of acetate, it decreased ($P = 0.05$) molar proportion of propionate, resulting in an increase in acetate-to-propionate ratio ($P = 0.05$). Applying SI did not influence VFA profiles. Ammonia-N concentration was similar in response to dietary treatments. The SI tested in this study did not affect lactational performance and ruminal fermentation. However, cows fed BMRCS increased yields of milk fat and ECM due to increased fiber digestion and ruminal acetate production.

Key Words: brown midrib corn silage, silage inoculant, lactating dairy cows

T25 Efficacy of various adsorbents to reduce aflatoxin M_1 levels in milk of lactation cows fed aflatoxin B_1. M. Savari[1], M. Dehghan-Banadaky*[1], K. Rezayazdi[1], and M. Javan-Nikkhah[2], *[1]Department of Animal Science, University College of Agriculture and Natural Resources, University of Tehran, Karaj, Tehran, Iran, [2]Plant Protection Department, University College of Agriculture and Natural Resources, University of Tehran, Karaj, Tehran, Iran.*

The aim of this study was to comparison of various adsorbents including Bentonite, Zeolite, Mycosorb (Alltech) and Biotox (Biochem) on their ability to reduce aflatoxin in milk of Holstein cows. Thirty-five Holstein cows divided into 5 groups (with average 37.3 kg/day milk yield and 114 DIM). Experimental groups were included these treatments: (1) Aflatoxin B_1 (300 µg aflatoxin B_1 dissolved in water) + 40 g Bentonite; (2) Aflatoxin B1 + 20 g Zeolite; (3) Aflatoxin B_1 + 20 g Mycosorb; (4) Aflatoxin B_1 + 20 g Biotox; and (5) aflatoxin B_1 without adsorbent. Milk sampling was performed 4 days (1 day before of treatment and 3 days after that). Data were analyzed using the mixed procedure of the SAS in a completely randomized design with 7 replications. The results of this study showed that milk production was not affected by treatments. In case of milk fat percentage on the second day after treatment, the difference between treatments was significant ($P < 0.05$). As follows the second treatment and the control treatment showed the highest (3.8%) and lowest (3%) percentage of milk fat. On the third day after treatment, respectively treatment 1 and treatment 3 showed the highest (4%) and the lowest (3.2%) percentage of milk fat ($P < 0.05$). In case of the percentage of protein and lactose in milk at the second day after treatment, the second treatment had the highest value ($P < 0.01$). After analysis of the data from ELISA test of AFM1 in milk was determined that most of aflatoxin contamination was observed on the day of treatment and it was related to the control treatment (400.49 ppt) and the lowest contamination in the same day belonged to the first group of cows means consuming 40 g of bentonite (253.89 ppt). According to the results of this experiment the excretion aflatoxin in milk immediately after consumption of toxin by animal in the first milking time was the maximum amount and this amount decreases gradually in the next milking. The sort ascending of efficiency absorption of toxin by absorbent was as follows: Mycosorb, Zeolite, Biotox, and Bentonite.

Key Words: aflatoxin B_1, aflatoxin M_1, mineral and organic adsorbents

T26 Effect of yeast probiotic (*Saccharomyces cerevisiae)* in milk or starter on growth performance, fecal score and rumen parameters of dairy calves. M. Hoseinabadi, M. Dehghan-Banadaky*, and A. Zali, *Department of Animal Science, University College of Agriculture and Natural Resources, University of Tehran, Karaj, Tehran, Iran.*

The objective of this study was to determine how yeast probiotic in milk or starter affects growth performance, fecal score and rumen parameters of dairy calves. Thirty Holstein female calves (14 ± 1 d old) divided to 3 groups, using a completely randomized design with 51-d periods. The treatments included: (1) 2 g yeast probiotic in milk (PM); (2) 2 g yeast probiotic in starter (top dress, PS); (3) control, without probiotic (CON). Animal were individually housed and had free access to water and starter concentrate (21.6% CP and 80% TDN). All calves were offered 6 L/d of milk replacer (22% CP, 19% EE) from birth, which was incrementally reduced after 6 wk to enable weaning by the end of wk 8. The study finished at 65 days old. Fecal scores (fecal scoring: fluidity, 1 = normal, 2 = soft, 3 = runny, 4 = watery) and starter intake were evaluated daily. Calves were weighted at 28, 42, 56, 65 days of age. At 65 d of age, ruminal fluid samples were collected using an oro-ruminal probe and a suction pump for pH and N-NH_3 determination. The results exhibited that experimental diets had not affected body weight changes, average daily gain, and feed efficiency ($P > 0.05$), but dry matter intake was significantly lower in treatment 2 than treatment 3 ($P < 0.01$). pH, N-NH_3 concentration of rumen fluid and blood parameters was not affectd by treatments ($P > 0.05$). Fecal score and health in treatments 1 and 2 were significantly lower than control. Generally using yeast probiotic in milk appeared to be an acceptable alternative than yeast probiotic in starter.

Table 1. Effect of yeast probiotic in milk or starter of Holstein calves

Item	PM	PS	CON	*P*-value	SEM
DMI, g/d	1145[ab]	998[b]	1219[a]	0.006	79.3

T27 Effects of rare earth-chitosan chelate on blood biochemical parameters in lactating dairy cows. R. X. Hu[1,2], J. Q. Wang*[1], D. P. Bu[1], J. B. Cheng[1], F. D. Li[2], H. Y. Zhao[1], S. H. Dong[1], and C. Y. Ren[1,2], *[1]State Key Lab of Animal Nutrition, Institute of Animal Science, Chinese Academy of Agriculture Sciences, Beijing, China, [2]College of Animal Science and Technology, Gansu Agricultural University, Lanzhou, Gansu, China.*

This study examined the effects of different proportion of rare earth-chitosan chelate on blood biochemical parameters in lactating Chinese Holstein dairy cows. Forty-eight lactating cows (days in milk = 130 ± 5; average milk yield = 33.2 ± 5.1 kg/d) were blocked based on days in milk, milk production, and parity and were randomly assigned to 1 of 4 treatments. Dietary treatments were 4 adding levels of RECC (rare earth-chitosan chelate):0 (control), 0.15%, 0.75%, and 1.5%, respectively. The experiment lasted 9 wk including the first week for adaptation. Blood was collected in evacuated tubes via caudal venipuncture at 0, 2, 4, 6, 8 week and placed on ice immediately following collection. In the present study the mean corpuscular hemoglobin and mean corpuscular volume were significantly ($P < 0.05$) affected of the entire hematological indices measured in the 0.15% RECC group vs. control and other groups. Feeding 0.75% or 1.5% RECC resulted in lower white blood cell count and hemoglobin vs. 0.15% RECC group ($P < 0.01$). 0.15% RECC-added in animals thrombocytocrit and platelet were higher than control and 0.75% group ($P < 0.05$). No significant difference in the serum hematocrit, intermediate cell, amylase, alkaline phosphatase and blood urea nitrogen were detected among groups ($P > 0.23$). In general the red blood cell, lymphocyte and neutrophilic granulocyte were consistently enhanced in cows with 0.15% RECC supplemented vs. control, and while the different counts did not follow a particular trend ($P > 0.06$). However, greater intake of RECC (0.75% or 1.5%) decreased red blood cell, lymphocyte and neutrophilic granulocyte vs. control ($P > 0.06$). This suggested that greater intake of RECC have a possible adverse effect of dairy cows, and further confirmed that the tolerable level of RECC adding in dairy cow diet could be 0.75% or 1.5%.

Key Words: rare earth-chitosan chelate, dairy cow, blood biochemical parameter

T28 Effects of rare earth-chitosan chelate on performance and milk composition in dairy cows. R. X. Hu[1,2], J. Q. Wang*[1], D. P. Bu[1], J. B. Cheng[1], F. D. Li[2], H. Y. Zhao[1], S. H. Dong[1], and C. Y. Ren[1,2], *[1]State Key Lab of Animal Nutrition, Institute of Animal Science, Chinese Academy of Agriculture Sciences, Beijing, China, [2]College of Animal Science and Technology, Gansu Agricultural University, Lanzhou, Gansu, China.*

Rare earth-chitosan chelate could improve animal performance supplemented low amount, while increased high level may have a inhibition of production. This study examined the effects of different proportion of rare earth-chitosan chelate on performance and milk content in lactating Chinese Holstein dairy cows. Forty-eight lactating cows (days in milk = 130 ± 5; average milk yield = 33.2 ± 5.1 kg/d) were blocked based on days in milk yield, lactation day, and parity and were randomly assigned to one of 4 treatments. Four dietary treatments were adding levels of RECC (rare earth-chitosan chelate): 0 (control), 0.15%, 0.75% and 1.5% of concentrate feed, respectively. The experimental period was 8 weeks. DMI (dry matter intake), milk yield were recorded daily, and milk composition (fat, protein, and lactose) were analyzed weekly. Data were analyzed by mixed or GLM procedure of SAS software. Feeding 0.15% RECC resulted in greater DMI and milk yield vs. Control and other groups ($P < 0.01$), but greater intake of RECC decreased DMI and milk yield ($P < 0.01$).Milk protein rate was significantly decreased to 3.07% and 2.97% in 0.15% or 1.5% RECC groups vs. control (3.2%) and 0.75% RECC group (3.18%; $P < 0.01$). Compared with control, milk fat was lower while 0.15% or 1.5% of RECC were supplemented, but there was no difference between control and 0.75% RECC-added animals ($P = 0.078$). Adding 1.5% RECC significantly lower total milk solid vs. control and 0.75% RECC group ($P = 0.017$), and the reduction depended on intake of RECC. In addition, feeding RECC have no significant effect on lactose, milk urea nitrogen and milk SCC ($P > 0.31$). It was concluded that add 0.15% RECC could increase milk yield and milk content in dairy cows, but greater intake of RECC (1.5%) have a negative effect of production.

Key Words: rare earth-chitosan chelate, dairy cow, performance and milk composition

T29 Effect of dietary N-carbamoyl glutamate on milk production and nitrogen utilization in high yielding dairy cows. B. Chacher[1,2], W. Zhu*[1,2], J. A. Ye[1,2], D. M. Wang[1,2], and J. X. Liu[1,2], *[1]Institute of Dairy Science, College of Animal Sciences, [2]MoE Key Laboratory of Molecular Animal Nutrition, Zhejiang University, Hangzhou, China.*

High-yielding cows fed diet rich in protein impaired the ureagenesis and decreased feed intake and milk production. Arginine (Arg) played a key role in urea cycle regulation. Due to the high rumen degradation, feeding rumen-protected Arg seemed to be uneconomical. Alternatively, N-carbomyl glutamate (NCG) was of relatively lower rumen degradation rate and known as a potential Arg raiser, but the effect of NCG in dairy cows has not been determined. Thus, the objective of the current study was to determine the effect of NCG on milk production and nitrogen utilization in high yielding dairy cows. Sixty multiparous cows [DIM = 78 (SD 17.3), milk yield = 41.9 (SD 7.90) kg/d] were blocked based on milk yield and DIM, and randomly allocated to receive each of 4 dietary treatments supplemented with 0 (control), 10, 20 or 30 g/d NCG, respectively, for 7 weeks. Milk yield was recorded weekly. Dry matter intake, milk composition, plasma variables and urea N content (plasma, urine and milk) were determined every other week. Data were analyzed using the MIXED procedure of SAS. A statistically significant difference was defined at $P < 0.05$, and trends were declared at $0.05 \leq P \leq 0.10$. Dry matter intake did not change by NCG supplementation of NCG. Compared to the control, cows fed 20 g/d NCG tended to have higher milk yield and milk protein yield (40.01 and 1.12 kg/d vs. 38.09 and 1.04 kg/d). Contents of milk protein and lactose linearly increased ($P < 0.01$) with the supplementing NCG. Cow fed 20 or 30 g/d NCG

enhanced ($P < 0.01$) plasma nitric oxide and decreased ammonia N compared with the control. Plasma Arg concentration increased ($P < 0.01$) by 3.5 and 8.5% in cows fed 20 or 30 g/d NCG, respectively. Supplementation of 20 g/d NCG linearly decreased ($P < 0.01$) the urea N in milk, plasma and urine, while the N utilization (0.283 vs. 0.263) tended to be improved. In summary, supplementation of 20 g/d NCG may alter the plasma metabolite and milk contents, and hence improve lactation performance of high yielding dairy cows.

Key Words: N-carbamoyl glutamate, lactation performance, nitrogen utilization

T30 Predicting prolamin and ruminal starch digestibility in corn silage and high moisture corn using near infrared spectroscopy. K. Foerder* and J. Horst, *Agri-King Inc., Fulton, IL.*

Prolamin levels in corn have been shown to be negatively correlated to starch digestibility in dairy cows. Current analysis methods for prolamin and ruminal in vitro starch digestibility (IVSD) are costly and time consuming. Therefore, it would benefit producers to have a rapid, economic method to more effectively predict prolamin and IVSD of available feedstuffs. The objective was to determine if the use of near infrared spectroscopy (NIRS) could effectively predict prolamin and/or IVSD in corn silage (CS) or high moisture corn (HMC). Samples of CS and HMC were selected to represent regions across the United States and a variety of hybrids. Samples ranged from fresh, unfermented to well fermented and included a wide range of moisture levels. The samples were selected by spectra using WINISI software. A modified turbidimetric zein method developed by Larson and Hoffman (2008) was used to determine the prolamin concentration of each sample. The coefficient of variation (CV) in the prolamin assay is 6.5% using a ground shell corn standard across multiple assays and the results were used to create NIRS calibrations using a 5000 Foss Instrument. The wet chemistry results correlated to the NIRS calibration resulting in an R^2 of 0.91 for CS and 0.78 for HMC. The IVSD was determined on the same set of samples using a standardized 7-h in vitro method with rumen fluid from continuous cultures. The CV across multiple assays for the IVSD assay was 1.89% using a corn silage standard. The NIR spectra were collected and used to determine if NIRS could also predict IVSD. The resultant IVSD calibration resulted in an R^2 of 0.80 for CS and 0.82 for HMC. The development of NIRS calibrations for prolamin and IVSD in both CS and HMC would allow for rapid and economical predictions of starch utilization and better usage of feedstuffs by dairy producers.

Key Words: prolamin, starch digestibility, near infrared spectroscopy

T31 Mineral containing dehydrated molasses lick blocks precalving provide a viable alternative for addressing mineral imbalances during calving in pasture-based New Zealand dairy cows. M. H. Oliver*[1,2], S. Rossenrode[1], and J. B. Aveling[3], *[1]UniServices Ltd., University of Auckland, Auckland, New Zealand, [2]Liggins Institute, University of Auckland, Auckland, New Zealand, [3]Ballance Agri-Nutrients, Tauranga, Bay of Plenty, Tauranga, New Zealand.*

Milk fever and associated conditions occurring in NZ dairy cows around calving are often prevented by dusting pasture or supplementary feed with MgO and also by adding minerals (Mg, Co, Se, Cu, Zn, I) to drinking water up to 2 months before calving. An integrated approach to precalving supplementation using mineral containing dehydrated molasses-based lick blocks (Dry Cow) was evaluated in a trial beside traditional mineral supplementation in a typical NZ Friesian herd with a previous history of milk fever. Cows were recruited in their second or later pregnancy and randomly assigned to traditional mineral supplementation (TM, n = 290) or Dry Cow blocks (DC, n = 207). TM cows had MgO dusted on feed at a rate of 50 g/cow/day and minerals added to water. Dry Cow was provided at a minimum of one 22.5 kg block/20 cows, intake was estimated at 230 g/cow/day. Swedes and silage were fed precalving. Cows entered calving areas 1 week before calving; TM had a mineral additive added to feed at 120 g/cow/day, while DC had continued access to Dry Cow and both treatment groups had minerals added to their shared water supply. Thirty cows per group were blood sampled at the start of the trial before mineral provision, again 6 weeks later and then within 2 weeks following calving. Incidence of milk fever in all cows was low (2.6%) while mastitis (6.2%), retained placenta (8.1%) and assisted calving (8.9%) were moderate. Incident occurrence was not different between treatment groups. Body condition score was slightly higher in DC than TM before the trial (4.6± 0.1/6 vs. 4.8 ± 0.1/6, $P < 0.05$), but was identical following calving (4.5 ± 0.1/6). Serum Mg and B_{12} were not different at any stage while Ca was higher in DC after supplementation and calving ($P < 0.05$). Serum Se and Zn were higher after 6 weeks of supplementation in DC ($P < 0.001$) but not different after calving. In conclusion, mineral containing dehydrated molasses lick blocks offer a convenient method to supply minerals to pregnant cows on pasture, yielding comparable results to traditional methods in common use in NZ.

Key Words: mineral, calving, hypomagnesemia

T33 Milk and milk quality evaluated on a commercial Holstein dairy following an OmniGen-AF dry cow and early lactation feeding strategy. A. E. Holland*[1], J. D. Chapman[1], and L. O. Ely[2], *[1]Prince Agri Products Inc., Quincy, IL, [2]University of Georgia, Athens.*

The goal of this study was to evaluate milk production in multiparous Holstein cows fed OmniGen-AF (OG) during the dry period and into 30 d in milk (DIM). An 8,000 cow dairy farm consisting of 2-4,000 cow side-by-side mirror image units, identified as U1 and U2 were used. Each unit maintained separate dry and lactating herds and both fed the same dry and milk cow diets delivered as TMR. Cows were milked 2x and housed in open free-stall barns. To assess the effect of OG feeding (56 g/h/d) to dry and fresh cows on milk production, 4-90 d periods (P1 to P4) were used. In P1, both U1 and U2 cows received the control diet (no OG). In P2, U2 cows were fed OG and U1 were controls. In P3, both units were fed the control diet, and in P4, U1 cows were fed OG and U2 were controls. Cow groups within period by unit were balanced on parity, previous 305ME, total milk and predicted calving date using Dairycomp305 resulting in 2,337 enrolled cows. Other inclusion criteria were d in the dry period (>45 d) and 3 consecutive test-day milk weights. PROC GLM (SAS) was used to test for differences in first-test (FT), week 4 (W4) and peak (PK) milks and first test log score (LS). In P1, no differences were detected between U1 and U2 for FT (37 kg, 38.3 kg), W4 (39.7 kg, 40.4 kg) and PK (44.2 kg, 44.5 kg) milks. Similar results were observed at U1 and U2 in P3 (FT: 37.2 kg, 37.9 kg, W4: 39.2 kg, 40.6 kg, PK: 42.8 kg, 43.4 kg). In P2, OG was fed to U2 cows and milk yields differed from U1 for FT (37.2 kg, 32.7 kg, $P < 0.001$), W4 (41.5 kg, 38.2 kg, $P < 0.001$), and PK (47.0 kg, 44.6 kg, $P < 0.01$) milks. A similar trend was observed when units fed OG were reversed in P4. Milk yields for cows at U1 were different from U2 cows for FT (36.2 kg, 33.5 kg, $P < 0.01$), W4 (39.6 kg, 37.1 kg, $P < 0.001$), and PK (45.7 kg, 42.8 kg, $P < 0.01$) milks. No differences in LS were observed between U1 and U2 in P1-3; however, differences were detected ($P < 0.01$) in P4 (U1: 4.17, U2: 3.44). In this study the feeding of OmniGen-AF to multiparous Holstein cows during the dry period and into 30 DIM enhanced early lactation.

Key Words: cow, milk, OmniGen-AF

T34 Interaction between forage source and monensin on the formation of biohydrogenation intermediates in continuous cultures. Y. Sun*[1], T. C. Jenkins[2], and A. L. Lock[1], [1]*Michigan State University, East Lansing,* [2]*Clemson University, Clemson, SC.*

A dual-flow continuous fermenter study with a 2 × 2 factorial arrangement of treatments examined the interaction between forage source and monensin on the formation of biohydrogenation intermediates (BHI). Cultures (4 per treatment) were fed diets (50:50 forage:concentrate ratio) for 10 d with the last 3 d for sample collection for fatty acid analysis and samples taken on d 10 at 0, 2, and 4 h after the morning feeding for VFA determination. Treatments were two forage sources: 100% corn silage (100CS) vs. a 1:1 ratio of corn silage and alfalfa haylage (50CS) in combination with two levels of monensin (0 and the equivalent to 350 mg/cow/d). Corn oil was included in all treatments at 2% dietary DM. Data were analyzed as a randomized complete block design. The 100CS diet had higher ($P < 0.05$) propionate and lower ($P < 0.05$) acetate concentrations and acetate/propionate at all sampling times. Monensin did not affect VFA concentrations at the 0 or 2 h sampling times; at 4 h after feeding monensin decreased ($P < 0.05$) acetate/propionate from 1.76 to 1.51. Compared to 50CS, the 100CS diet had a higher ($P < 0.05$) extent of biohydrogenation (BH) for oleic acid (30.6 vs. 44.1%) but lower ($P < 0.05$) BH of linolenic acid (48.7 vs. 34.9%); treatments did not affect extent of linoleic BH. Monensin did not affect extent of BH of oleic, linoleic, or linolenic acid. The 100CS diet had lower ($P < 0.05$) total fatty acid output from cultures than the 50CS diet. Total *trans* 18:1 production was higher ($P < 0.05$) for 100CS than for 50CS (383 vs. 195 mg/d), accounted for mostly by an increase ($P < 0.05$) in the daily production of *trans*-10 18:1 (326 vs. 130 mg/d). There were no differences between the two forage sources on daily production of *trans*-10, *cis*-12 18:2. Monensin had no effect on the formation of BHI. In conclusion, monensin supplementation to continuous cultures caused an expected drop in acetate/propionate but did not increase the production of BHI. Corn silage as the only forage source increased the formation of BHI, particularly *trans*-10 18:1 that is normally associated with increased risk of milk fat depression.

Key Words: continuous culture, fatty acid, monensin

T35 Lysine loss during aerobic exposure of a corn silage based ration with mechanical extracted soybean meal with gums and various rumen-protected lysine products. D. A. Sapienza*[1] and C. A. Macgregor Jr.[2], [1]*Sapienza Analytica LLC, Slater, IA,* [2]*Grain States Soya Inc., West Point, N.*

Lysine loss was evaluated during in vitro aerobic exposure of a ration mixed with either nothing (B, ration blank), mechanical extracted soybean meal (MES) with gums (MESG) (P1), MESG with rumen-protected lysine (RPL) (MESGL) first production run (P2), MESGL second production run (P3), RPL (P4), or MESGL third production run (P5). MESGL was manufactured by inserting RPL into soy gums and drying the gums onto MES. RPL comprised lysine monohydrochloride embedded in a rumen-inert fat matrix. Two ration moisture (M) levels were evaluated: 48% M (L) (as fed 45% corn silage, 55% grain mix) and 58% M (H) (as fed 40% corn silage, 42% grain mix and 18% added water). Free lysine was quantified in water extracts taken from treatments at 0, 6, 18 and 24 hours. Eight replicates were taken for each treatment at each exposure time and lysine reported as microgram lysine per gram of water. Quadratic (orthogonal) polynomials were fitted to characterize the lysine concentration time trends separately for data acquired at L and H. Time trends for MESG runs with (P2, P3, P5) or without (P1) RPL where best characterized as linear trends. Trends for P2, P3, and P5 were not significantly different (F = 0.29 on 6 and 11 df, $P = 0.92$ at 48% M; F = 0.05 on 3 and 11 df, $P > 0.99$ at 58% M). The trend for P1 showed a significantly lower mean concentration at 48% M ($t = -2.52$ on 11 df, $P = 0.03$). Overall linear trends for P2, P3 and P5 were not significantly different from P1 ($P = 0.25$ at L; $P = 0.81$ at H). The concentration time trend for RPL alone (P4) was clearly significantly different from the MESG runs with a highly significant ($P < 1e\text{-}10$) quadratic coefficient, much higher average slope and higher mean concentration (or intercept). The overall linear trend of lysine release from RPL, when RPL was inserted into gums under the conditions of this study, was not different from the linear trend of lysine release from native lysine in MES and was different from the linear trend of lysine release from RPL when it was not in gums.

Key Words: rumen-protected lysine, mechanical extracted soybean meal, soy gum

T36 Consequences of supplementing lactating Holstein cows with an exogenous amylase on milk performance and rumen fermentation. A. Bach*[1,2], E. Azem[3], W. Steinberg[3], and V. Glitsø[4], [1]*ICREA, Institut de Recerca i Estudis Avançats, Barcelona, Spain,* [2]*Department of Ruminant Production, IRTA, Caldes de Montbui, Spain,* [3]*DSM Nutritional Products, Basel, Switzerland,* [4]*Novozymes, Bagsvaerd, Denmark.*

Improving feed efficiency and digestion may increase the economic profitability of dairy herds and minimize the environmental impact of milk production. To evaluate the effects of supplementing cows with an exogenous amylase, 240 lactating Holstein cows (BW = 653 ± 80 kg, DIM = 225 ± 112 kg, and milk yield = 39.2 ± 8.5 kg/d) distributed in 3 pens consuming exactly the same TMR (15.1% CP, 31.4% NDF, 1.69 Mcal of NEl/kg on DM basis) participated in a truncated Latin square experiment with three 29-d periods and 2 treatments: unsupplemented (CTR) and supplemented with 300 Kilo Novo Units of Ronozyme RumiStar CT per kg of TMR dry matter (RS). Within each pen, there were 5 rumen-cannulated cows that were used to determine ruminal degradation kinetics of corn and corn silage. Feed consumption, BW, and milk yield were recorded daily. In addition, during the second period, 2 rumen-cannulated cows from each treatment were used to place in situ bags containing: corn or corn silage to determine DM, NDF, and starch rumen degradation kinetics. The experimental unit for intake and performance data was pen. Data were analyzed using a mixed effects model. Overall, milk production was not affected by treatment. However, there was a significant interaction ($P < 0.001$) between treatment, parity, and stage of lactation. Cows on RS produced more milk ($P < 0.05$) than CTR cows in early stages of lactation (DIM < 150 d), and this increase was more pronounced ($P < 0.05$) in multiparous (42.5 vs. 41.0±1.47 kg/d, respectively) than in primiparous cows (35.1 vs. 34.0 ± 1.52 kg/d, respectively). Primiparous cows on RS gained more BW (16 ± 2.1 kg per period) than CTR cows (12.1 ± 2.1 kg per period), and multiparous cows on RS also recovered more BW than CTR cows after 150 DIM (13.5 vs. 9 ± 1.9 kg per period after 150 DIM, respectively). There was a tendency ($P = 0.07$) for the rate of DM and starch degradation for corn, and NDF for corn silage to increase with RS supplementation. These results suggest that RS supplementation may have increased nutrient availability to cows.

Key Words: digestibility, enzyme, yield

T37 Apparent synthesis of riboflavin and niacin in rumen of lactating dairy cows fed alfalfa or orchardgrass silages. D. S. Castagnino*[1,3], K. L. Kammes[2], M. S. Allen[2], R. Gervais[3], P. Y. Chouinard[3], D. E. Santschi[4], and C. L. Girard[1], [1]*Agriculture and Agri-Food*

Canada, Sherbrooke, Quebec, Canada, [2]Department of Animal Science, Michigan State University, East Lansing, [3]Departement de Sciences Animales, Universite Laval, Quebec, Quebec, Canada, [4]Valacta, Dairy Production Centre of Expertise in Quebec and the Atlantic regions, Ste-Anne-de-Bellevue, Quebec, Canada.

Effects of forage family (legume vs. grass) on apparent ruminal synthesis and post-ruminal supply of riboflavin and niacin were evaluated using 13 ruminally and duodenally cannulated lactating Holstein cows. The experiment was a crossover design with two 18-d treatment periods following a preliminary period during which all cows were fed a diet intermediate in composition between the treatment diets. Treatment diets were formulated to contain 25% forage NDF, 30% total NDF and contained as sole forage, alfalfa (AL, 42.3% NDF) or orchardgrass (OG, 58.2% NDF) silages. Intakes of riboflavin and niacin were greater ($P <$ 0.05) for AL than OG (riboflavin: 1179 vs. 372 ± 32 mg/d; niacin: 1253 vs. 1106 ± 61 mg/d). Alfalfa tended to increase the duodenal flow of riboflavin compared with OG ($P = 0.07$; 1131 vs. 902 ± 85 mg/d) but the duodenal flow of niacin was not affected by treatment ($P > 0.61$; 1993 vs. 1879 ± 154 mg/d for AL and OG respectively). Alfalfa decreased apparent ruminal synthesis of riboflavin compared with OG ($P < 0.01$; −47 vs. 530 ± 79 mg/d) but the apparent ruminal synthesis of niacin was not affected by treatment ($P = 0.87$; 739 vs. 773 ± 144 mg/d for AL and OG respectively). Riboflavin intake was correlated positively with its duodenal flow ($r = 0.44$, $P = 0.02$) but negatively with apparent ruminal synthesis of the vitamin ($r = -0.71$, $P < 0.01$). On the other hand, apparent ruminal synthesis of niacin was correlated positively with its duodenal flow ($r = 0.95$, $P < 0.01$). Forage family affected the apparent ruminal synthesis of riboflavin but had limited effects on the amounts of riboflavin and niacin reaching the sites of absorption.

Key Words: dairy cow, riboflavin, niacin

T38 The effect of a feed additive on the feeding value of a silage-based TMR exposed to air. M. Windle* and L. Kung Jr., *University of Delaware, Newark.*

The objective of this study was to evaluate the effect of feeding a fresh or aerobically spoiling silage-based TMR with or without Omnigen WYC (OWYC, Prince Agri Products Inc., Quincy, IL) on intake and rumen fermentation parameters in heifers. Four Holstein heifers with ruminal cannula were fed 1 of 4 treatments, in a 4 × 4 Latin square design utilizing 14-d periods. The four specific treatments were (A) fresh TMR fed for d 1 to 14, (B) fresh TMR fed for d 1 to 7, spoiled TMR for d 8 to 14, (C) fresh TMR for d 1 to 7, spoiled TMR plus OWYC for d 8 to 14, or (D) fresh TMR plus OWYC for d 1 to 7, spoiled TMR plus OWYC for d 8 to 14. Freshly mixed TMR was prepared daily and fed immediately for all treatments during the first 7 d of each period. To prepare aerobically spoiled feed for the second 7 d of each period, fresh TMR was allowed to spoil for several (2 to 5) d prior to feeding. The TMR exposed to air had a greater pH ($P < 0.01$), more yeasts ($P <$ 0.01), and lower concentrations of lactic acid ($P < 0.01$), acetic acid (P < 0.01), and ethanol ($P < 0.01$) than fresh TMR, and had temperatures 5 to 30°C above ambient (20-22°C) temperatures, indicating that it was spoiling. Feeding spoiled TMR alone during d 8 to 14 resulted in a lower DM intake (treatment B) when compared to feeding fresh TMR alone (treatment A) ($P < 0.05$). Heifers fed OWYC (treatments C and D) had DM intakes that were numerically but not statistically greater than heifers fed treatment B. Heifers consuming spoiled TMR (treatments B, C, D on d 8 to 14 of each period) had more yeasts in their rumen fluid than heifers fed fresh TMR (treatment A) ($P < 0.05$). There was a trend ($P = 0.14$) for heifers that were fed spoiled TMR and who received OWYC for the entire 14 d of each period (treatment D) to have a greater average rumen pH and maximum rumen pH than cows fed fresh TMR (treatment A). There were no differences among treatments in ruminal VFA. Relative to cows fed the fresh TMR, digestion of DM was not affected by feeding spoiled TMR. Feeding a spoiled TMR to heifers reduced intake and supplementing spoiled TMR with OWYC tended to moderate this effect.

Key Words: aerobic stability, spoilage, yeast

T39 Effects of treatment with propylene glycol in fat transition cows. V. Bjerre-Harpøth*, A. C. Storm, T. Larsen, and M. Larsen, *Department of Animal Science, Aarhus University, Foulum, Tjele, Denmark.*

The aim was to investigate the capability of propylene glycol supplementation to impact on the metabolic adaption to lactation in fat transition cows with the object to reduce the risk of fatty liver and ketosis. The experiment was a completely randomized design. Ten ruminal cannulated and intercostal artery catheterized fat Holstein cows (body condition score 2 wk prepartum: mean ± SD = 3.8 ± 0.3) were at parturition randomly assigned to a ruminal pulse dose of 500 g propylene glycol (PGG) or of 500 g water (CON) once a day (at morning feeding) for 4 wk postpartum (pp). All cows were fed the same diet. Milk samples were taken at every milking, 3/d. Two sets of blood samples were collected; weekly blood samples were taken from the tail vein, whereas daily blood sample was collected from the artery ±7 days from parturition. Data were analyzed using PROC MIXED in SAS with treatment (trt), day/week, and the interaction as fixed effects. Cow was considered as random effect, and day/week within cow as repeated measurement. Dry matter intake, body condition score and milk yield were not affected by propylene glycol ($P > 0.38$). The PGG resulted in decreased milk fat concentration ($P = 0.04$). The trt × day interaction revealed higher concentration of milk lactose ($P < 0.01$) and lower concentration of milk protein ($P < 0.01$) with PGG. In d 13-28 pp, the concentration of milk BHBA with PGG was below the concentration with CON (interaction: P = 0.05). In the first 4 wk pp, there was a smaller decline in body weights with PGG (interaction: $P = 0.02$). The PGG displayed highest plasma concentration of glucose during 1 to 7 d pp (P= 0.05) and in the entire 4 wk of allocation ($P < 0.01$). In d 1 to 7 pp, the plasma concentration of non-esterified fatty acids was decreased with PGG compared to CON (P=0.03). The trt × week/day interactions revealed lower concentration of BHBA in plasma with PGG in d 1 to 7 pp ($P = 0.05$) and in the entire allocation period ($P = 0.01$). In conclusion, allocation of propylene glycol to fat transition cows depicted amendments in body weights, metabolism and milk composition suggesting decreased fat mobilization in the fatty cows pp, and thereby implying a reduced risk of fatty liver and ketosis.

Key Words: propylene glycol, transition cow

Ruminant Nutrition: Feeding, Ruminal Fermentation, and Efficiency of Production I

T40 Effects of restricted versus conventional dietary adaptation over periods of 6 and 9 days on rumen papillae of feedlot Nellore cattle. A. Perdigão[1,3], M. D. B. Arrigoni[1], D. D. Millen*[2], C. L. Martins[1], R. S. Barducci[1], M. T. Cesar[1], D. D. Estevam[2], T. V. B. Carrara[2], D. V. F. Vicari[2], and R. F. Pessin[1], *[1]São Paulo State University (UNESP), Botucatu, São Paulo, Brazil, [2]São Paulo State University (UNESP), Dracena, São Paulo, Brazil, [3]Supported by FAPESP, São Paulo, São Paulo, Brazil.*

This study was designed to determine effects of restricting DMI of the final finishing diet (REST) as a means of dietary adaptation compared with diets increasing in concentrate (STEP) over periods of 6-d and 9-d on morphological parameters of rumen papillae of feedlot cattle. The experiment was designed as a completely randomized block with a 2 × 2 factorial arrangement with repeated measures over time, replicated 6 times (5 bullocks/pen), in which 120 22-mo-old yearling Nellore bulls (352.03 ± 19.61 kg) were fed in 24 pens for 84-d according to the treatments: STEP for 6-d, STEP for 9-d, REST for 6-d, and REST for 9-d. The STEP program consisted of ad libitum feeding of two adaptation diets over periods of 6-d or 9-d with concentrate level increasing from 61% to 85% of diet DM. After adaptation one animal per pen (n = 24) was slaughtered for rumen papillae evaluations. The remaining 96 animals were harvested after 84-d on feeding. At harvest, rumenitis incidence (RUM) was determined, on the entire washed rumen, using a scale of 0 (no lesions noted) to 10 (severe ulcerative RUM). Likewise, a 1-cm^2 fragment of each rumen was collected from cranial sac. Manually, the number of papillae per cm^2 of rumen wall (NOP) was determined and 12 papillae were randomly collected from each fragment; scanned, and mean papillae area (MPA) was measured by software for image analysis. The rumen wall absorptive surface area (RASA) in cm^2 was calculated as follows: 1 + (NOP × MPA) – (NOP × 0.002). No significant (P > 0.10) main effects or interactions were observed for NOP and RASA. A significant (P = 0.03) interaction between protocol and days was observed, in which animals adapted for 9-d in STEP protocol and for 6-d in REST protocol had lesser RUM. Moreover, a significant (P = 0.04) interaction between days and harvesting dates was observed, in which animals adapted for 9-d at the end of adaption period had smaller MPA (0.35 cm^2) than animals adapted for: (1) 9-d after finishing (0.48 cm^2), (2) 6-d after adaptation (0.51 cm^2), and (3) 6-d after finishing (0.52 cm^2). For adaptation during 6-d and 9-d, a REST and STEP protocols, respectively, should be used.

Key Words: rumenitis, Zebu

T41 Effects of restricted versus conventional dietary adaptation over periods of 9 or 14 days on total tract digestibility of NDF and TDN of feedlot Nellore cattle. D. H. M. Watanabe[2], A. L. N. Rigueiro[2], R. S. Barducci[1], C. L. Martins[1], M. D. B. Arrigoni[1], M. C. S. Pereira[2], J. Silva[2], T. V. B. Carrara[1], F. Perna Junior[3], M. C. S. Franzói[1], and D. D. Millen*[2], *[1]São Paulo State University (UNESP), Botucatu, São Paulo, Brazil, [2]São Paulo State University (UNESP), Dracena, São Paulo, Brazil, [3]University of São Paulo (USP), Pirassununga, São Paulo, Brazil.*

This study, conducted at the São Paulo State University feedlot, Botucatu Campus, Brazil, had the objective to evaluate step up (STEP) and restriction (REST) protocols to high concentrate diets over periods of 9 or 14 days on total tract digestibility of NDF and TDN of Nellore cattle finished in feedlot. The experiment was designed as a completely randomized block with 2 × 2 factorial arrangement, replicated 6 times (5 bullocks/pen), in which 120 22-mo-old yearling Nellore bulls (361.3±30.2 kg) were fed in 24 pens for 84 days according to the treatments: STEP for 9 days and 14 days, REST for 9 days and 14 days. Measures over time were taken on days 5, 10, 15, and 20 of experimental period. The STEP program consisted of ad libitum feeding of 3 adaptation diets over periods of 9 or 14 days with concentrate level increasing from 55% to 85% of diet DM. The REST program consisted of restricted intake of the final diet (85% concentrate) with programmed increases in feed offered until yearling bulls reached ad libitum access over periods of 9 or 14 days. Fecal samples were collected just before morning (0800) and afternoon (1500) meals, and a composite sample per pen in each day was made. For the NDF and TDN digestibility, it was observed (P < 0.05) interaction between protocols, length of protocols and days. Yearling bulls adapted for 14 days had greater NDF digestibility on the first day of the finishing period (day 15: STEP in 14 days = 70.44%, REST in 14 days = 61.54%) than those adapted for 9 days (day 10: STEP in 9 days = 58.28%, REST in 9 days = 35.04%); however no differences (P > 0.10) between treatments were observed on day 15. Likewise, yearling bulls adapted for 14 days had greater TDN digestibility on the first day of the finishing period (day 15: STEP in 14 days = 78.81%, REST in 14 days = 81.38%) than those adapted for 9 days (day 10: STEP in 9 days = 69.66%, REST in 9 days = 72.33%); however, no differences (P > 0.10) between treatments were observed on day 15. Thus, according to the present data, yearling Nellore bulls should be adapted in 14 days, regardless of the protocol.

Key Words: adaptation, NDF, TDN

T42 Potential proteolytic bacteria adherent to soybean meal in the rumen revealed by PCR-DGGE. D. Jin[2], J. Q. Wang*[1,2], D. P. Bu[2], and S. G. Zhao[2], *[1]Agronomy College of Heilongjiang August First Land Reclamation University, Da qing, Heilongjiang, China, [2]Institute of Animal Science, Chinese Academy of Agricultural Sciences, Beijing, China.*

Rumen bacteria metabolize dietary protein to provide enough N for animal health and production. Soybean meal is widely used as protein source in ruminant feeds and protein degradation by the adherent bacteria is the first essential step for rumen N metabolism. In order to get the information of bacteria involved in protein degradation, denaturing gradient gel electrophoresis (DGGE) was used to reveal the potential proteolytic bacteria adherent to soybean meal in the rumen of Holstein dairy cows. Three healthy Chinese Holstein dairy cows fitted with rumen cannula and similar body weight were selected (n = 3). Soybean meals were placed into nylon bags and then incubated in the rumen for 0, 12, 24, 48 h. Rumen degradability of DM was estimated, and N concentration was determined by Kjeldahl N apparatus. Bacteria adherent to soybean meal were eluted with phosphate buffer saline. Patterns of bacterial composition were compared by DGGE profiling and some special bands from different incubation time were selected and sequenced. Results showed that DM was degraded at 55.5, 70.1, and 96.3%, whereas CP was degraded at 36.9, 58.4, and 95.7%, respectively, after incubation for 12, 24, and 48 h. The DGGE profiles showed the number and intensity of bands from varying samples were different, and the dendrogram of the PCR-DGGE fingerprint showed that they were

assigned to different clusters by different incubation time. The amounts and types of special strains increased significantly after incubating for 12 h and these may be closely related to protein degradation. Shannon-Wiener index of different time differed ($P < 0.01$). Sequencing results derived from 16S rDNA analysis for the DGGE bands showed that most of them belonged to *Prevotella* sp. and uncultured bacteria. The results showed that more proteolytic bacteria were from uncultured bacteria. In future, metagenomic analysis should be applied to these uncultured bacteria for key proteolytic enzyme exploration.

Key Words: PCR-DGGE, rumen bacteria, soybean meal

T43 Effect of changing ratios of corn silage and alfalfa on ruminal fiber digestion in high producing lactating cows. F. Lopes*, D. E. Cook, and D. K. Combs, *Department of Dairy Science, University of Wisconsin, Madison.*

The aim of this study was to compare ruminal fiber digestion and passage of alfalfa and corn silage in lactating cows. Alfalfa silage and corn silage with similar NDF content (33.2%) and in vitro 48-h NDF digestibilities of 44.2 and 38.4% respectively, were used. Eight rumen-cannulated dairy cows (110 ± 5 d in milk) were utilized in a 4 × 4 Latin square design with 21 d period to test 4 rations of corn silage:alfalfa silage; 100:0 (A), 66:33 (B), 0:100 (C) or 33:66 (D). Total mixed rations contained approximately 55% of DMI as forage, with 28.8, 29.1, 32.9 and 29.7% of NDF for ration A, B, C and D, respectively. Intake and milk production were measured during d 14 to 21. Ruminal contents were evacuated manually 4h after and 2 h before feeding on d 20 and 21 to evaluate rumen nutrient pool sizes and turnover. Ruminal contents were analyzed for OM, NDF and iNDF content. Data were analyzed with MIXED-SAS with fixed effect of square, diet, period, and cow within square was the random effect. Milk production was 39.2, 37.6, 36.9 and 37.7 kg/d for A, B, C, and D, respectively, with significantly ($P < 0.05$) higher yield for ration A. Dry matter and NDF intake were lower ($P < 0.05$) for diet D than other treatments. Indigestible NDF intake was greater for diets C and D than diets A and B (Table 1). Ruminal digesta volume did not differ by treatment; but ruminal mass was greater for diets with more corn silage compared to alfalfa silage. Rumen pools and turnover of NDF and iNDF were affected by different rations of corn:alfalfa silage. Fiber turnover rates increased as more alfalfa was included in the diets.

Table 1.

	CS:ALF				
Item	A (100:0)	B (66:33)	C (0:100)	D (33:66)	SEM

T44 Dry matter intake and nutrient intake of crossbred cattle ¾ Zebu x ¼ Holstein fed different levels of calcium and phosphorus in the diet. L. F. Prados*, S. C. Valadares Filho, S. A. Santos, D. Zanetti, A. N. Nunes, L. D. S. Mariz, F. C. Rodrigues, P. M. Amaral, A. S. F. Veiga, E. Detmann, and F. A. S. Silva, *Universidade Federal de Viçosa, Viçosa, Minas Gerais, Brazil.*

This study aimed to evaluate the intake of dry matter and nutrient intake of crossbred bulls. A total of 36 ¾ Zebu × ¼ Holstein crossbred bulls with an initial weight of 214 ± 4 kg and a mean age of 11 ± 0.2 mo were used in the study. The animals were fed ad libitum and distributed in a completely randomized design with a 3 × 3 factorial arrangement for treatments, with 3 levels of calcium and phosphorus and 3 periods of feedlot (56, 112 or 168 d). The 3 levels of calcium and phosphorus were: low = 0.18 and 0.22%, medium = 0.30 and 0.24%, normal = 0.42 and 0.26%, respectively for calcium and phosphorus on a dry matter basis. The diets were isonitrogenous (12.6%) and consisted of corn silage and concentrate (60:40). The amount of feed supply was recorded daily, and samples were collected from corn silage and orts of each animal. Samples of feed and orts were measured for dry matter (DM), mineral matter (MM), crude protein (CP), neutral detergent fiber (NDF), ether extract (EE), calcium (Ca) and phosphorus (P). Intake of DM was not affected ($P > 0.05$) by the level of Ca and P in the diet. Intake of DM, CP, EE, organic matter (OM) and non-fiber carbohydrates, when expressed as kg/d, were higher ($P < 0.05$) for animals in feedlot for longer periods. Intake of DM as a function of body weight (BW) decreased ($P < 0.05$) in animals confined for longer periods. This decrease in the ratio of intake of DM to BW can be explained by the reduction in maintenance requirements because of a decrease in organ tissue as a proportion of overall BW. Differences were observed ($P < 0.05$) in Ca intake with increasing levels of Ca in the diet and for different feedlot periods. There were no significant differences in P intake ($P > 0.05$) by the level of Ca and P in the diet. We observed higher intake of Ca and P ($P < 0.05$) for animals in feedlot for longer periods this can be explained by a higher intake of DM of these animals. It was concluded that reductions in the levels of Ca and P in cattle diets did not change DMI and nutrient intake of animals, and the periods of feedlot influenced DMI.

Key Words: calcium, nutrient intake, phosphorus

T45 Relationship of residual feed intake with heart rate and heat production in Nellore steers. A. S. Chaves*[1], M. L. Nascimento[1], R. R. Tullio[2], M. M. Alencar[2], A. N. Rosa[3], and D. P. D. Lanna[1], *[1]University of Sao Paulo/ESALQ, Piracicaba, SP, Brazil, [2]Embrapa Cattle Southeast, Sao Carlos, SP, Brazil, [3]Embrapa Beef Cattle, Campo Grande, MS, Brazil.*

The objective of this work was to examine the relationship between RFI, heart rate (HR) and heat production (HP) of Nellore steers. The animals (n = 39) were individually fed twice daily with 5% of orts, for 84 days. BW was measured at 14-d intervals. HR was recorded during a 4 day period with measurements at 60 seconds intervals. HR and O_2 consumption (VO_2) were collected at the same time during 15 minutes using a face mask open-circuit respiratory system (Exhalyzer). These measurements were used to calibrate the volume of O_2 per heart beat. O_2Pulse (O_2P) was calculated as the VO_2 per beat. Daily HP (kcal/kg$^{0.75}$) was calculated multiplying O_2P by the average HR obtained during the 4 days, assuming 4.89 kcal/L de O_2. Daily gain (DG) was estimated by slope of the individual regression between BW and days on feed. RFI was obtained using mixed models in which metabolic BW and DG were included to predict the feed

intake. The animals were classified as low, medium and high RFI (mean ± 0.5 SD), and then high and low RFI classes were compared using Proc GLIMMIX (SAS). During oxygen calibration, HR was similar to the daily average measurement when the animals were in the stalls, 101 ± 6.2 and 102 ± 2.7 bpm, respectively. This suggests animals were not stressed and O_2P values probably are not biased. Furthermore, HR was 19.4% lower ($P = 0.019$), and the average daily HR tended to be lower for efficient animals ($P = 0.092$). O_2P did not differ between classes ($P > 0.05$), but there was a trend ($P = 0.0956$) toward higher VO_2 in efficient animals. These results suggest that efficient animals, have a slower heartbeat rate, and maybe able to pump a greater amount of oxygen per heart beat. No significant relationships were observed between RFI and HP in efficient and inefficient animals ($P > 0.05$).

Key Words: energy expenditure, feed efficiency

T46 Does the processing method affect cell wall and dry matter degradability of wheat grain. H. Karkhaneh*, K. Rezayazdi, M. Dehghan-Banadaki, and A. Zali, *University of Tehran, Tehran, Iran.*

Four Holstein cattle with rumen fistula were used according to a Latin square design with 4 treatments and 4 periods of 21 days and 4 cows. Treatments include ground wheat (control), dry rolled wheat, steam flaked wheat and wheat processed with formaldehyde 0/4 percent. Cell wall and dry matter degradability of processed wheat were measured at 2, 4, 8, 12, 24 and 48 hours according to the method of Vanzant et al. (1998). Effective degradability of dry matter of different treatments in passage rate r = 0.05, respectively, 87/62, 87/95, 76/50 and 80/62 percent were significantly different ($P < 0.05$). Also effective degradability of cell walls of wheat grain processed with different methods in passage rate r = 0.05, respectively, 64/30, 68/25, 52/85 and 53/97% of which were also significant differences between them. So it can be concluded that treating with formaldehyde and steam rolling can cause a significant reduction in dry matter and cell wall degradability of wheat.

Key Words: processed wheat grain, dry matter degradability, cell wall degradability

T47 The effect of three different dietary starch concentration on some reproductive parameters in lactating dairy cows. G. Y. Mecitoglu[1], E. Karakaya[1], I. Cetin[2], C. Kara[2], A. Orman[3], H. Gencoglu*[2], A. Keskin[1], A. Gumen[1], and I. Turkmen[2], *[1]Department of Obstetrics and Gynecology, Faculty of Veterinary Medicine University of Uludag, Bursa, Turkey, [2]Department of Animal Nutrition and Nutritional Diseases, Faculty of Veterinary Medicine. University of Uludag, Bursa, Turkey, [3]Department of Zootechnics, Faculty of Veterinary Medicine University of Uludag, Bursa, Turkey.*

The aim of this study was to determine the effect of three different dietary starch concentrations on first postpartum (PP) and following induced estrous ovulation times, follicular and luteal size in dairy cows. Primiparous dairy cows (n = 22) were randomly assigned to 1 of the 3 treatment groups at PP 6 d. Cows were fed with low (LS, 16.2% starch, n = 8), medium (MS, 19.8% starch, n = 6) or high-starch (HS, 24.1% starch, n = 8) diets as TMR (DM basis). To determine the time of PP first ovulation, all cows were scanned three times a week until PP 50 d. In order to detect ovulation time after estrus, cows were synchronized. Cows received GnRH and intravaginal progesterone device (CIDR) at PP 60 d and 7 d later CIDR was removed and $PGF_{2\alpha}$ was administered. Cows were scanned 8 h apart as from 48 h after $PGF_{2\alpha}$ administration to determination of ovulation. Furthermore, cows were also scanned 7 d after ovulation to detect luteal size. Data were analyzed according mixed models procedure. Times of PP first ovulations were did not differ among the groups (19.9 ± 5.04 d in LS, 26.3 ± 5.81 d MS and 24.3 ± 4.84 d HS). The size of ovulatory follicle before PP first ovulation was lower ($P = 0.05$) in LS (13.31 ± 1.10) than in HS (14.83 ± 0.51) but did not differ from MS group (14.62 ± 1.91). In addition ovulation time after induced estrous tended to be shorter ($P = 0.09$) in MS group (75.33 ± 13.68h) than in HS (100.33 ± 4.88 h) and LS (100.17 ± 12.96 h) groups. Ovulatory follicle size tended to be lower ($P = 0.08$) in LS (14.70 ± 0.62 mm) than MS (16.67 ± 1.20 mm) and HS (16.25 ± 0.42 mm). Luteal size measured 7 d after ovulation was lower ($P = 0.04$) in LS group (21.92 ± 1.12 mm) than MS (27.67 ± 1.88 mm) and HS (26.33 ± 1.34 mm) groups. Thus, although the ovulation times in both first PP and following induced estrous did not differ among the groups, follicular size in synchronized estrous and luteal size were lower in LS than MS and HS groups.

Key Words: cow, reproductive parameter, starch

T48 Use of simple static models to estimate in vitro methane production. A. Woldeghebriel*, A. Duncan, and M. Worku, *North Carolina A&T State University, Greensboro.*

A two-stage static model developed for ruminant animals was used to determine the amount of carbon dioxide (CO_2) and methane (CH_4) produced in the study. Concentration of CO_2 calculated in the first-stage was then used to determine concentration of CH_4 in the second-phase. Molar concentration of the three VFAs (acetate, propionate and butyrate) used in the model was determined by GC. Feed grab samples from a TMR was oven-dried, coarsely pulverized in a regular kitchen blender for one minute, and separated into three particle-sizes (PS; 0.85, 1.00 and 1.40 mm). The experimental design was a 3 × 4 factorial (3 PS and 4 feed additives at 1:4 feed ratios). The treatments used were: (1) feed only, as control (CON); (2) CON+ nitrate; (3) CON + fumarate; (4) CON + a 50/50 nitrate-fumarate mix. A 4-g sample from each particle-size for each treatment was weighed in triplicates and transferred into a pre-labeled 500 ml flask. Each flask received 400 mL of rumen fluid-buffer mixture according to the Tilley and Terry procedures and CH_4 gas in the over-head space of each flask was directly measured using the G2301Picarro Gas Analyzer (Picarro, CA). While the VFA data obtained from the study was used in the model to estimate CO_2 and CH_4 production, the direct measurements of CH_4 by the Picarro Gas Analyzer were used for comparison using the t-test statistics at 5% probability. Results obtained show that the model underestimated ($P < 0.05$) the amount of CH_4 produced for all PS and feed additive by as much as 15%. However, CH_4 gas concentration data obtained from the model seem to closely follow the same patterns as the direct measurements of the gas by the Picarro Gas Analyzer. It seems therefore the model can appropriately be used to estimate production of methane using VFA data.

Key Words: methane, nitrate, model

T49 Development of equations to estimate microbial contamination in ruminal incubation residues of tropical forage using ^{15}N as a marker. P. A. S. Machado, S. A. Santos, S. C. V. Filho, E. Detmann, L. F. Prados, P. M. Amaral*, L. F. C. Silva, A. C. B. Menezes, F. A. C. Villadiego, and P. P. Rotta, *Universidade Federal de Vicosa, Vicosa, MG, Brazil.*

The objective was to use ^{15}N to label microbial cells to allow development of equations for estimating the contamination in ruminal incubation residues of tropical forage. A total of 24 forages were divided into 3 groups, and each group was incubated in a different steer per period, in a 3 × 3 Latin square design. Ruminal bacteria were labeled with ^{15}N by continuous infusion 60 h before the first incubation and continued until

the end of incubation period. The digesta was collected for the isolation of bacteria before the first infusion of ^{15}N and after the infusion of ^{15}N. Three collections were made on each day, being the first before feeding and two at an interval of 4 h. To determine the contaminated fractions of CP degradation, the restricted model was compared with the full model using the model identity test. Values of the corrected fraction "A" (ACPC) were estimated from its values without correction (ACPWC) by the equation: ACPC= 1.99286 + 0.98256 × ACPWC. The corrected fraction "B" was estimated from its value without correction (WC) and from CP, NDF, neutral detergent insoluble protein (NDIP), and indigestible NDF (iNDF) using the equation BCPC = −17.2181 – 0.0344 × BCPWC + 0.65433 × CP + 1.03787 × NDF + 2.66010 × NDIP – 0.85979 × iNDF, where BCPC = the potentially degradable B fraction of CP corrected for microbial contamination and BCPWC = the fraction WC. The corrected "kd" (kdCPC) was estimated using the equation kdCPC = 0.04667 + 0.35139 × kdCPWC + 0.0020 × CP – 0.00055839 × NDF – 0.00336 × NDIP + 0.00075089 × iNDF, where kdCPWC = the rate of degradation without correction. The equation obtained to estimate the contamination (C) using CP of the feeds was: %C = 79.21 × (1-e-0.0555 × t) × e-0.0874 × CP, where: t = incubation time. It was concluded that A and B fractions and kd of CP would be biased by microbial CP contamination, thus these corrected values could replace the use of microbial markers. The contamination and the corrected apparent degradability of CP could be obtained from values of CP and time of incubation for each feed, which could reduce cost involved when using ^{15}N.

Key Words: degradability, protein fraction

T50 Influence of offering hay free-choice concurrently with total mixed ration on residual feed intake rank differences of beef bulls. E. El-Haroun[1,3], M. Abo-Ismail*[3], H. Salim[2], G. Vander Voort[3], M. McMorris[1], and S. Miller[3], *[1]Beef Improvement Opportunities, Guelph, Ontario, Canada, [2]Department of Animal and Poultry Science, Cairo University, Giza, Egypt, [3]Centre for Genetic Improvement of Livestock, Department of Animal and Poultry Science, University of Guelph, Guelph, Ontario, Canada.*

Individual feed intake data has been collected on growing bulls on a moderate energy pelleted diet, while the bulls had free access to chopped hay as a roughage source, where the hay was not recorded. The objectives of this study were to offer bulls hay free choice in addition to a moderate energy total mixed ration (TMR) and determine if measurement of the hay influenced the bulls ranking for residual feed intake (RFI). The study collected feed intake and BW data from 102 crossbred bulls on a post-weaning growth test over a 2-yr period where individual feed intake was measured using the Insentec Roughage Intake Control (RIC) system. The RFI was calculated using different models, which included ADG, mid-metabolic BW, marbling and backfat. The principal RFI determination in this study RFI_{Koch} was calculated as the residuals from the regression of total DMI (DMI_{hay}+ DMI_{TMR}) on BW and ADG. The RFI_{hay} and RFI_{TMR} were calculated as the residual from the regression of DMI_{hay} and DMI_{TMR}, respectively on BW and ADG. The RFI_{Koch} had the lowest coefficient of determination (R^2; 0.75), and highest, less desirable, Bayesian information criterion (BIC; 286.4). The RFI_{TMR} had the highest R^2 (0.87) and the best BIC (230.1) among the other models, while, RFI_{hay} had a moderate R^2 (0.77) and BIC (283.6). The RFI including carcass traits had the same R^2 (0.76) and BIC (285.6 and 283.6) for marbling and backfat, respectively. The rank correlations among the RFI calculated from different models were obtained. The RFI_{Koch} was highly correlated with RFI_{hay} 0.97%, indicating that the 2 RFI were similar and the relative re-rankings of the bulls were similar regardless of the model used. The rank correlation between RFI_{Koch} and RFI_{TMR} was 74%, thus, the 2 RFI were somewhat different and bulls ranked differently when hay intake was accounted for RFI_{Koch}, compared to when hay intake was not included RFI_{TMR}. These results suggest that when measuring feed intake in young growing bulls, it is important to measure all sources of energy consumption, including hay that has been overlooked in previous studies and test designs.

Key Words: beef, reranking, residual feed intake

T51 Model for estimating enteric methane emissions from black goat. Y. Na*, W. Jeong, O. Yi, S. Hwang, and S Lee, *Department of Animal Science and Technology, Konkuk University, Seoul, Republic of Korea.*

The objective was to develop mathematical models for estimating enteric CH_4 emissions from black goats. Methane production and digestibility of diets were measured using respiration-metabolism chamber with different feeding conditions: different concentrate to roughage ratio (40:60, 50:50, and 60:40), oil sources (soybean oil, coconut oil and palm oil) and roughage sources (timothy, rice straw, corn silage, alfalfa pellet and tall fescue). One hundred and thirty-five observations from these experiments were used for the estimation of model parameters. Dry matter intake, OM intake (OMI), CP intake (CPI), NDF intake (NDFI), digested DMI (DDMI), digested OMI (DOMI), digested CPI (DCPI) and digested NDF intake (DNDFI) were considered for the development of models. Cook's distance tests were performed to identify outliers and SAS PROC REG was used for the calculation of single and multiple simple linear regressions. Root mean square prediction error (RMSPE) and R^2 were used as a measure of prediction accuracy. For the simple linear regression, an equation using OMI as an independent variable most accurately predicted CH_4 emission: CH_4, L/d = 0.1092 + 0.0414 × OMI, g/d (RMSPE = 5.49, R^2 = 0.44) among equations using nutritional intake as an independent variable. An equation using DOMI as an independent variable was the most accurate: CH_4, L/d = 4.5051 + 0.0410 × DOMI, g/d (RMSPE = 5.11, R^2 = 0.52) among equations using digested nutritional intake as an independent variable. For the multiple linear regression, an equation using nutritional intake as independent variables CH_4, L/d = 1.1605 + 0.0078 × DMI, g/d + 0.0250 × OMI, g/d + 0.0167 × CPI, g/d + 0.0037 × NDFI, g/d resulted in the lowest RMSPE value (5.55) and the highest R^2 value (0.45). And an equation using digested nutritional intake as independent variables, CH_4, L/d = 9.2184 – 0.0081 × DDMI, g/d + 0.0133 × DOMI, g/d + 0.0057 × DCPI, g/d + 0.0227 × DNDFI, g/d resulted in the lowest RMSPE value (5.01) and the highest R^2 value (0.55). Therefore, digested nutritional intake (DDMI, DOMI, DCPI, and DNDFI) is better independent variables than nutritional intake (DMI, OMI, CPI, and OMI) for the prediction of CH_4 emissions.

Key Words: black goat, methane, modeling

T52 Effects of forage sources on the gene expression related to milk protein synthesis in the mammary gland of lactating Holstein cows. X. Zhang[1], C. Ao*[1], M. Gao[2], E. Khas[1], H. Zhang[1], L. Song[1], and R. Du[2], *[1]Inner Mongolia Agricultural University, Hohhot, Inner Mongolia, China, [2]Inner Mongolia Academy of Agricultural & Animal Husbandry Sciences, Hohhot, Inner Mongolia, China.*

The objective of this study was to determine the effects of forage sources on gene expression related to milk protein synthesis in the mammary gland of lactating cows. Twenty multiparous Holstein cows (BW = 566 ± 19.6 kg, DIM = 95 ± 24 d) were assigned to a single factor block design with 30 d period. Cows were fed diets with different forage. Diets (on DM base) were: (1) corn straw (35%) and 65% of concentrate (CS; CP: 17.14%, NDF: 41.58% and NEL: 1.58 Mcal/kg); (2) hay (4%), corn silage (27%) and alfalfa (23%) with additional 46% of concentrate (MF; CP: 17.45%, NDF:

38.33% and NEL: 1.6 Mcal/kg),.Nutrient level in the two diets were similar. Mammary gland tissue (500 mg/animal) biopsies were randomly performed for half numbers of cows in each group after milking on the last day of experiment. Statistical analysis was performed using the PROC MIXED procedure of SAS 9.0. We hypothesized that forage sources will affect gene expressions in three aspects : (1) milk protein synthesis (CSN1S1 CSN3); (2) hormone receptors in the cytomembrane of mammary epithelial cells (PRLR GHR1A); and (3) the cell signal regulators involved in milk protein synthesis (mTOR JAK2 STAT5); Results showed that the level of CSN1S1 CSN3 PRLR GHR1A and mTOR mRNA were significantly increased ($P < 0.05$) by the MF treatment, but the mRNA expression of JAK2 and STAT5 were not significantly affected by treatment ($P > 0.05$). In conclusion, forage quality affects the efficiency of milk protein synthesis in lactating Holstein cows. High quality forage can promote PRLR GHR1A and mTOR genes expression, resulting in increased milk protein synthesis.

Key Words: mammary gland, protein synthesis, gene expression

T53 Relationship of flight speed, rectal temperature and infrared thermography of eye with feed efficiency of Nellore beef cattle. A. M. Mobiglia[1], F. R. Camilo[1], V. R. M. Couto[1], E. G. Moraes[2], H. F. Oliveira[1], L. F. N. Souza[2], J. T. Neves Neto[1], T. S. Almeida[1], J. C. Pimenta[1], and J. J. R. Fernandes*[1,2], *[1]Escola de Veterinaria e Zootecnia da UFG, Goiânia, Goiás, Brazil, [2]Nelore Qualitas, Goiânia, Goiás, Brazil.*

The objective of this study was to correlate flight speed (FS), rectal temperature (RT) and eye temperature (ET), measured by infrared thermography, with residual feed intake (RFI), feed efficiency (FE), and feed conversion (FC) of Nellore beef cattle. The bulls (n = 120, 393.04 ± 47.3kg of BW), with an average of 20 mo of age, were housed outdoors in individual pens and weighted at beginning and end of trial. All the animals were fed sorghum silage (27%), sugarcane bagasse (10%) and concentrate (63%). Animals were classified as follows: high RFI (SD >0.42 - less efficient; n = 32), medium RFI (SD ± 0.42; n = 52), and low RFI (SD <0.42 - more efficient; n = 36). We evaluated eye temperature using an infrared portable camera (FLIR I7 of Flir Systems Inc.). In all photographs, we considered a specific shape (circle) in order to keep a constant sub-area (eye surface), and the average was computed. We measured RT and ET simultaneously with a digital thermometer. We measured FS by infrared sensors placed in exit of the crush. The data were analyzed by Pearson using statistical software R (2010). Mean ET and RT were 35.63 ± 1.60°C and 38.39 ± 0.61°C, respectively, ranging between 39.30°C and 31.50°C for ET, and 40.30°C and 37.20°C for RT. In addition, the values of FS were 2.78 ± 1.53m/s (BFS, beginning of feedlot), 1.75 ± 0.6 m/s (EFS, end of feedlot) and −1.02 ± 1.68 m/s (DFS, difference between BFS and EFS). The data of correlation are showed in Table 1 (*$P < 0.05$). Therefore, the RT, ET, and FS did not correlate with feed efficiency. However, the ET showed medium correlation with RT of Nellore beef cattle.

Table 1. Correlation among variables.

	RFI	FE	FC	BFS	EFS	DFS	RT	ET
RFI	—							
FE	−0.38*	—

T54 Bone morphometry and densitometry of goats of different genders subjected to feed restriction. N. C. D. Silva*[1], K. T. Resende[1], M. H. M. R. Fernandes[1], H. C. Bonfá[2], D. C. Soares[1], R. F. Leite[1], F. O. M. Figueiredo[1], M. M. Freire[3], B. R. S. M. Oliveira[4], and I. A. M. A. Teixeira[1], *[1]Unesp Univ Estadual Paulista, Jaboticabal, São Paulo, Brazil, [2]Universidade Federal de Viçosa, Viçosa, Minas Gerais, Brazil, [3]Universidade Federal de Alagoas, Maceió, Alagoas, Brazil, [4]Unesp Univ Estadual Paulista, Araçatuba, São Paulo, Brazil.*

The objective of this study was to evaluate the effect of gender and feed restriction on bone morphometry and bone mineral densitometry (BMD) of 54 Saanen goat kids (18 intact males, 18 castrated males and 18 females) with initial BW of 15 kg. The animals of the same gender were randomly distributed into 6 groups (blocks) of 3 animals subjected to different levels of feed restriction (ad libitum or 0%, 25% and 50% of feed restriction). Then in total there were 18 blocks. A whole group was slaughtered when the kid subjected to 0% of feed restriction reached 30 kg BW. After slaughter and evisceration, the carcasses were weighed and femur of the right leg of each animal was removed for subsequent analyses. Morphometric evaluations were accomplished by measuring femur weight, total length (TL), perimeter proximal epiphysis (PEP) and distal (PED), perimeter of diaphysis (PD), breadth of diaphysis-laterolateral position (LDLL) and craniocaudal position (LDCC). The evaluation of BMD was performed by image generated by X-rays of femur using Lunar DPX equipment. Data were analyzed as a randomized complete block design with a 3 × 3 factorial arrangement, using mixed model of SAS. Gender did not affect TL, PD, LDLL and LDCC, but, femur weight, PEP and PED were lower ($P < 0.05$) in females (100.9 ± 2.6g, 11.8 ± 0.1cm and 15.2 ± 0.2cm, respectively) than intact males (109.4 ± 4.0g, 11.5 ± 0.1cm and 15.9 ± 0.2cm, respectively) and castrated males (116.7 ± 2.3g, 12.4 ± 0.1 cm and 16.1 ± 0.2cm, respectively). Regarding feed restriction level, animals subjected to 50% feed restriction showed lower values ($P < 0.05$) of all morphometric variables compared to the kids subjected to 0% and 25% feed restriction. Bone mineral densitometry was higher ($P < 0.05$) for females fed ad libitum (0.644 ± 0.04 g/cm^2) compared to intact males and castrated fed ad libitum. We concluded that bone morphometry was influenced by gender and feed restriction. Bone mineral densitometry and bone morphometry can be important tools for understanding bone mineral metabolism in goats.

Key Words: bone metabolism, density, nutrition

T55 The National Animal Nutrition Program (NANP): Modeling Subcommittee goals and progress. M. D. Hanigan*[1], C. R. Angel[2], C. F. M. de Lange[3], E. Kebreab[4], J. P. McNamara[5], L. O. Tedeschi[6], N. L. Trottier[7], and M. J. VandeHaar[7], *[1]Virginia Tech, Blacksburg, [2]University of Maryland, College Park, [3]University of Guelph, Guelph, ON, Canada, [4]University of California, Davis, [5]Washington State University, Pullman, [6]Texas A&M, College Station, [7]Michigan State University, East Lansing.*

The NANP is a research-support activity established as National Research Support Project 9 (NRSP-9; http://www.ca.uky.edu/nrsp-9/index.htm). The NRSP are funded from Hatch funds administered by the U.S. Department of Agriculture and drawn from federal allocations prior to formula distribution to experiment stations. The objective of the NANP Modeling subcommittee is to facilitate the use of predictive technologies, tools, and platforms, and to support the efforts of the National Research Council (NRC). The goals are to provide maintenance of the nutrient requirement models and software between NRC releases, to collect user feedback, to provide guidelines and tools for scientists and instructors using modeling to address nutrition problems, and to facilitate knowledge development and dissemination. Two calculation errors in the 2001 Dairy NRC model

were corrected and the installation program was recompiled to support 64-bit Windows installations. We also created an installation program to allow the 2000 Beef NRC to be operated on modern Windows based computers. Both are available on the website. We are working to develop a review of techniques used to evaluate models, an article listing guidelines for reporting dietary information in publications, and an article describing a software platform that could be used across NRC species requirement models. We are also developing a database to store observational data collected by the NRC committees which can be downloaded and used for model development. Future work includes development of a web based mechanism to provide access to the model source code for use by the animal nutrition research community, collection of feedback from model users to help identify software problems and prediction problems, summarization of evaluations of the current NRC models, and an assessment of supply and requirement model subcomponents that could be used across species. These changes will facilitate the use of NRC models in diet formulation, update NRC models more rapidly as new information becomes available and at lower cost, and improve efficiency of feed use and sustainability in animal agriculture.

Key Words: NRC, nutrient requirements, nutrition model

T56 Effects of stage of gestation and diet on maternal fat deposition. P. P. Rotta*[1], S. C. Valadares Filho[1], T. R. Santos[1], L. F. Costa e Silva[1], M. I. Marcondes[1], B. C. Carvalho[2], A. A. G. Lobo[1], J. V. F. Souza[1], M. A. S. Novaes[1], M. F. L Ferreira[1], and J. S. A. A. Santos[1], *[1]Universidade Federal de Vicosa, Vicosa, Brazil, [2]Empresa Brasileira de Pesquisa Agropecuaria, Brazil.*

The objectives were to evaluate the maternal nutrient intake and stage of gestation on mesentery, kidney, pelvic and heart (KPH) fat and fat thickness growth rate in Holstein × Gyr cows. Sixty-two multiparous cows were inseminated with the same Gyr semen and in the d 30 the gestation was confirmed in 44 cows. Six cows non-pregnant were previously slaughtered as reference group. The 44 pregnant cows were randomly distributed in four time of gestation: 140, 200, 240 and 270 days. Thus, 11 cows were slaughtered in each time. These eleven cows were randomly allocated in two different diets: maintenance level (n = 6; 1.1% of body weight) and ad libitum (n = 5). The cows that achieved the time of gestation were slaughtered and necropsied. The mesentery was removed of the viscera and weighted. The KPH fat was removed and weighted. The fat thickness was measured using an electronic caliper rule 18 h after the slaughter. The values are given in function of final body weight. Data were analyzed using MIXED procedure of SAS. Data of non-pregnant cows were used considering as initial time. The growth rate of mesentery for cows fed ad libitum was exponential and the estimated equation was: $y = 2.7808 + 3.9181 \times [1 - \exp(-0.00726 \times \text{days})]$. However, the growth rate of mesentery for cows fed at maintenance level was linear and the estimated equation was: $y = 2.8351 + (0.00484 \times \text{days})$. In the same way, the KPH fat was exponential to cows fed ad libitum: $y = 1.0812 + 6.5984 \times [1 - \exp(-0.00172 \times \text{days})]$ while the estimated equation to cows fed at maintenance level was linear: $y = 1.1236 + (0.002572 \times \text{days})$. The fat thickness was also exponential to cows fed ad libitum: $y = 0.8033 + 0.0111 \times [\exp(0.0186 \times \text{days})]$ in comparison to cows fed at maintenance level, which estimated equation was linear: $y = 0.757 + (0.002986 \times \text{days})$. Thus, cows fed ad libitum present exponential growth rate of fat deposition, while cows fed at maintenance level present linear growth rate. This can be explained by the high dry matter intake observed to this group and the higher average daily gain. In this way, the excess of energy and protein are being deposited as fat.

Key Words: fat thickness, KPH fat, mesentery

T57 Effects of different diets on the gene expression of enzymes related to fatty acid synthesis in the mammary gland of lactating dairy cows. H. Zhang, C. Ao*, L. Song, E. Khas, and X. Zhang, *Department of Animal Science of Inner Mongolia Agricultural University, Huhhot, Inner Mongolia, China.*

The objectives of this study were to determine the effects of three different diets on the genes expression of key enzymes involved in fatty acid synthesis in the mammary gland of dairy cows. Thirty multiparous Holstein cows (BW = 566 ± 19.6 kg, DIM = 95 ± 24d) were assigned to a single factor block design with 30 d period. Animals were fed diets with different roughage and same concentrate profiles, the concentrate-roughage ratio in the treatments were different. Diets (on DM base) were: (1) hay (4%), corn silage (27%) and alfalfa (23%) with additional 46% of concentrate (MF; CP: 17.45%, NDF: 38.33% and NEL: 1.6 Mcal/kg); (2) corn straw (35%) and 65% of concentrate (CSA; CP: 17.14%, NDF: 41.58% and NEL: 1.58Mcal/kg); (3) corn straw (54%) and 46% of concentrate (CSB; CP: 13.80%, NDF: 55.59% and NEL: 1.36 Mcal/kg). Mammary gland tissue (500 mg/animal) biopsies were randomly performed for half numbers of cows in each group after milking on the last day of experiment. Gene expressions for key enzymes involved in fatty acids synthesis were determined by RT-PCR. Statistical analysis was performed using the PROC MIXED procedure of SAS 9.0. Results showed that mRNA abundance for ACACA and FASN which involve in de novo fatty acid synthesis was higher ($P < 0.05$) in MF compared to CSA and CSB. Gene expression for fatty acid desaturase SCD was significantly increased ($P < 0.01$) by MF treatment and gene expression for fatty acid uptake and intracellular trafficking enzymes LPL, ACSL1 and CD36 were increased ($P < 0.05$) also by MF. However, no effects were observed for milk fat synthesis regulator genes PPARA, PPARG, SREBF1 ($P > 0.05$). No effects on the gene expressions for all above enzymes and regulators between CSA and CSB were found. The data indicated that diet with high quality roughage and the same concentrate-roughage can increase the gene expression of enzymes related to fatty acid synthesis and desaturation, but with the same roughage and different concentrate-roughage ratio had no effect on milk fat synthesis key genes in the mammary gland of dairy cows.

Key Words: dairy cow, mammary gland, fatty acid synthesis

T58 Effects of stage of gestation and diet on dairy cow placentomes. P. P. Rotta*[1], S. C. Valadares Filho[1], T. R. Santos[1], L. F. Costa e Silva[1], M. I. Marcondes[1], M. M. Campos[2], F. A. S. Silva[1], J. R. Oliveira[1], A. C. B. Menezes[1], E. C. Martins[1], and F. A. C. Villadiego[1], *[1]Universidade Federal de Vicosa, Vicosa, Brazil, [2]Empresa Brasileira de Pesquisa Agropecuaria, Brazil.*

The objectives were to evaluate the maternal nutrient intake and stage of gestation on caruncular, cotyledon and placentoma growth and number rate in Holstein × Gyr cows. Sixty-two multiparous cows were inseminated with the same Gyr semen and in the d 30 the gestation was confirmed in 44 cows. Six cows non-pregnant were previously slaughtered as reference group. The 44 pregnant cows were randomly distributed in four time of gestation: 140, 200, 240 and 270 days. Thus, 11 cows were slaughtered in each time. These eleven cows were randomly allocated in two different diets: maintenance level (n = 6; 1.1% of body weight) and ad libitum (n = 5). The cows that achieved the time of gestation were slaughtered and necropsied. The gravid uterus was removed and the uterus was separated from placenta. In the uterus, all carunculars were removed, counted and weighted. In the placenta, all cotyledons were removed, counted and weighted. Except for placentomas number, that consider 140 days of pregnancy at minimum, the

other equations consider the time 0 to time of pregnancy. Data were analyzed using MIXED procedure of SAS. Data of non-pregnant cows were used considering as initial time. For all parameters evaluated, the growth rate observed was exponential, except to placentomas number, which was linear. The weight of caruncular was similar ($P > 0.05$) between diets and the estimated equation was: y = −0.5018 + 0.3992 × exp(0.008658 × days). However, the higher ($P = 0.0007$) value to cotyledons weight was observed to cows fed at maintenance level: y = −0.0698 + 0.07697 × exp(0.01249 × days) in comparison to cows fed ad libitum: y = −0.0698 + 0.07697 × exp(0.01115 × days). Placentomas weight were higher ($P = 0.0144$) to cows fed at maintenance level: y = −0.568 + 0.4597 × exp(0.009739 × days) in comparison to cows fed ad libitum: y −0.568 + 0.4597 ×exp(0.009303 × days). The number of placentomas was linear and higher ($P < 0.0001$) to cows fed at maintenance level. The estimated equation to maintenance was: y = −53.8325 + (1.219 × days) and to cows fed ad libitum: y = −53.8325 + (0.9717 × days).

Key Words: caruncular, cotyledon

T59 Rumen epithelial adaptation during the transition period is associated with structural changes and transcriptomic signatures. M. A. Steele*[1], O. AlZahal[1], C. Zettler[1], J. C. Matthews[2], and B. W. McBride[1], *[1]University of Guelph, Guelph, Ontario, Canada, [2]University of Kentucky, Lexington.*

The structural and functional adaptations of the rumen epithelium during the transition period are largely undescribed. To characterize the adaptations of the rumen epithelium during transition, multiparous dairy cattle (n = 12) fed a low energy dry cow diet (1.45 Mcal/kg NE_L) were transitioned abruptly to a high-energy lactating cow diet (1.60 Mcal/kg NE_L) immediately after parturition. Dry matter intake and ruminal pH were monitored at -3 wk, +1 wk, and +6 wk relative to calving. To uncover changes in the ruminal epithelial structure and function, rumen papillae were biopsied at -3 wk, +1 wk, and +6 wk relative to calving. Histomorphometrics of rumen epithelial structure was examined under a light microscope and mRNA profiling was performed using Affymetrix GeneChip. Data pre-processing was conducted using Robust Multichip Average method and detection of significant genes was conducted using ANOVA. Dry matter intake was 13.1 ± 0.84 kg/d at -3 wk and 12.8 ± 0.84 kg/d at +1 wk, and increased ($P < 0.05$) to 21.0 ± 0.84 kg/d at +6 wk. Ruminal pH was reduced ($P < 0.05$) during the onset of lactation from 6.38 ± 0.07 at -3 wk to 5.81 ± 0.07 and 5.85 ± 0.07 at +1 and +6 wk, respectively. Microscopic examination of rumen papillae revealed an increase in epithelial sloughing during early lactation as sloughing scores increased ($P < 0.05$) from 1.7 ± 0.2 at -3 wk to 4.1 ± 0.3 and 3.4 ± 0.2 at +1 and + 6 wk, respectively. A total of 1,144 and 535 differentially expressed genes (False discovery rate of 0.01, $P < 0.01$) were uncovered from -3 wk to +1 wk and +6 wk relative to parturition, respectively. Analysis of microarray results using Ingenuity Pathway Analysis revealed that metabolic and transport genes were regulated during early lactation, including mitochondrial dysfunction being the top pathway identified ($P < 0.01$) between -3 wk and +1 wk and +6 wk. These results suggest that the structure and function of the rumen epithelium is altered during early lactation and is associated with the differential expression of genes involved with metabolic functions.

Key Words: transition cow, rumen, epithelium

T60 Effects of stage of gestation and diet on maternal and fetal growth in dairy cows. P. P. Rotta*[1], S. C. Valadares Filho[1], T. R. Santos[1], L. F. Costa e Silva[1], M. I. Marcondes[1], F. S. Machado[2], L. H. R. Silva[1], B. C. Silva[1], F. A. C. Villadiego[1], M. V. Pacheco[1], D. E. C. Marquez[1], and R. H. M. Ortega[1], *[1]Universidade Federal de Vicosa, Vicosa, Brazil, [2]Empresa Brasileira de Pesquisa Agropecuaria, Brazil.*

The objectives were to evaluate the maternal nutrient intake and stage of gestation on gravid uterus, uterus, fetus and placenta growth rate in Holstein × Gyr cows. Sixty-two multiparous cows were inseminated with the same Gyr semen and in the d 30 the gestation was confirmed in 44 cows. Six cows non-pregnant were previously slaughtered as reference group. The 44 pregnant cows were randomly distributed in four time of gestation: 140, 200, 240 and 270 days. Thus, 11 cows were slaughtered in each time. These eleven cows were randomly allocated in two different diets: maintenance level (n = 6; 1.1% of body weight) and ad libitum (n = 5). The diet was based on corn silage and concentrate at 93:7. The cows that achieved the time of gestation were slaughtered and necropsied. The gravid uterus was removed and weighted. After the opening of gravid uterus, uterus, placenta and fetus were removed and weighted separately. Data were analyzed using MIXED procedure of SAS. Data of non-pregnant cows were used considering as initial time. For all parameters evaluated, the growth rates observed were exponential. The gravid uterus presented a similar ($P > 0.05$) growth rate to cows fed ad libitum or at maintenance. The estimate equation was: y = −1.104 + 1.7406 × exp(0.0132 × days). In the same way, the growth rate of uterus was similar ($P > 0.05$) between diets. The estimated equation was: y = −0.591 + 0.9817 × exp(0.008836 × days). The growth rate of fetus was similar ($P > 0.05$) between diets and the equation was: y = −1.2426 + 0.4939 × exp(0.01589 × days). However, the growth rate of placenta was higher ($P = 0.0125$) to cows fed at maintenance level: y = −0.1324 + 0.1665 × exp(0.0118 × days) in comparison to ad libitum: y = −0.1324 + 0.1665 × exp(0.01144 × days). Placenta is the organ most related to gestation and its growth rate is positively affected by maintenance level. This suggests that the organism tried to develop mechanisms to be more efficient in nutrient transfer to cows fed at maintenance level. In conclusion, the effect of stage of gestation is exponential and cows fed at maintenance level present higher growth rate to placenta.

Key Words: fetus, gravid uterus, placenta

T61 Determination of particle size distribution and physically effective fiber in total mixed ration from 14 dairy farms in the Comarca Lagunera, Mexico. P. A. Robles Trillo*[1], E. Vazquez-Martínez[1], F. G. Veliz-Deras[1], C. A. Meza-Herrera[2], and P. Cano-Ríos[1], *[1]Universidad Autonoma Agraria Antonio Narro, Torreon, Coahuila, Mexico, [2]Unidad Universitaria de Zonas Aridas. Universidad Autonoma de Chapingo., Bermejillo, Durango, Mexico.*

In order to determine the particle size distribution (PSD) and physical effectiveness factor (PEF) in totally mixed ration (TMR) in dairy cattle farms, a cross-sectional study was conducted in 14 stables from the Comarca Lagunera, Mexico (25°N, 103°W). Farms were randomly selected and visited in summer in order to collect two freshly served samples of TMR; both the PSD and PEF were determined by the Penn State Particle Separator technique. The amount of PSD and PEF differed among farms ($P < 0.05$). In nine farms and using a 19 mm-sieve (S) PSD ranged from 4.85 to 8.86%, the remainder ranged from 12 to 23%. Above a S-8 mm the PSD ranged among 32 to 54%, although seven stables had lesser than 40%. Regarding PSD using S 1.18 mm, the variation between farms was 16% (30 to 46%). When analyzing the plastic bottom pan, four farms had less than 10% of food collected while the rest ranged from 12-19%. The PEF 8 mm showed great variation, ranging from 38 to 61%, although eight stables were above 50%. Finally, with the PEF1.18 mm, the range was 81 to 93% for all the stables. In

conclusion, both the PSD and PEF showed differences between farms; moreover the PSD and PEF were in line with some research reports, which can cause variations in DMI, milk production and composition.

Key Words: dairy, feeding, fiber

T62 Relation between ultrasound and carcass measurements in Girolando steers fed spineless cactus. R. A. S. Pessoa*[1], J. R. C. Silva[1], A. S. C. Veras[1], M. A. Ferreira[1], I. Ferraz[2], and P. C. Vasconcelos[1], *[1]Universidade Federal Rural de Pernambuco, Recife, Pernambuco, Brazil, [2]Instituto Agrono de Pernambuco, Recife, Pernambuco, Brazil.*

The objective of this study was to evaluate the correlations between the measurements obtained by ultrasound and from the carcass of the ribeye and back fat thickness in Girolando steers (5/8 Holstein-Zebu). Eighteen animals, no castrated, with average initial body weight of 320 kg and 24 mo of age were used, kept in feedlot system and assigned to a randomized block design, established in accordance with the weight of animals, being 3 treatments and 4 blocks. The experimental period lasted 84 d divided into 3 periods of 28 d. The treatments were 3 urea levels (0.0, 1.5 and 3.0%) in substitution of cottonseed meal (23.0, 11.5 and 0.0%) in diets based on spineless cactus with approximately 12.0% of crude protein and 65.0% of total digestible nutrients. The control diet was composed of 60.0% of spineless cactus, 15.0% of sorghum silage, 0.0% of urea:ammonium sulfate mixture (9:1), 23.0% of cottonseed meal and 2.0% of mineral mixture, in dry matter basis. The animals were slaughtered at 84 d of feedlot. The measurements taken by ultrasound when the steers reached the slaughter point and from the carcass after the slaughter were ribeye and back fat thickness. The fat thickness was evaluated using a paquimeter and the ribeye was evaluated by using a quadrant grade ruler. The data were submitted to ANOVA and correlation of Pearson using the SAS. The replacement of cottonseed meal by urea did not alter the ribeye and back fat thickness ($P > 0.05$) (average of 58.25 and 2.65, respectively). The correlations measured by ultrasound and from the carcass were 0.72 for ribeye and 0.60 for back fat thickness. The characteristics of the measurements taken by ultrasound correlated well with measurements at the time of slaughter in Girolando steers. FACEPE process number: 2008/0979.

Key Words: nitrogen, *Opuntia ficus indica,* ribeye

T63 Effects of grain source and alfalfa hay particle size on feed sorting, feeding behavior, and chewing activity in mid-lactation Holstein dairy cows. S. M. Nasrollahi[1], G. R. Ghorbani[1], M. Khorvash[1], W. Z. Yang[2], and Z. He*[2], *[1]Isfahan University of Technology, Department of Animal Sciences, Isfahan University of Technology, Isfahan, Iran, [2]Lethbridge, Agriculture and Agri-Food Canada, Research Centre, Lethbridge, AB, Canada.*

This study investigated the effects of grain source and alfalfa hay (AH) particle length on feed sorting, feeding behavior, and chewing activity of lactating dairy cows. Eight Holstein dairy cows (175 ± 21 DIM) were used in a replicated 4 × 4 Latin square design with four 21-d periods. The experiment was a 2 × 2 factorial arrangement of treatments with 2 grain sources (barley grain alone or equal blend of barley and corn grains) combined with 2 particle lengths of alfalfa hay (short = 15 mm and long = 30 mm). Diets were fed ad libitum as TMR with a concentrate to forage ratio of 60:40. The TMR and orts were sampled at 0, 1.5, 3, 6, and 24 h post morning feeding for determining particle size distribution. Data were analyzed using Mixed Procedures of SAS with linear models consisting of fixed period, grain source, hay particle size, and grain source × hay particle size effects, plus cow and residuals random effects. Interactions between grain source and AH particle length on feed particle distributions, sorting index, chewing activity, and milk production were minimal ($P > 0.05$). Partially replacing barley grain with corn in the diet generally did not change diurnal distributions of particles retained on the sieves of Penn State Particle Separator ($P > 0.05$) but reduced the proportion of particles on 1.18-sieve and increased that of particles on pan ($P < 0.05$). Grain source did not affect feed sorting index and chewing activity ($P > 0.05$). However, feeding long AH increased intakes of long particles (i.e., 19- and 8-mm), prolonged eating time, and lowered eating rate ($P < 0.05$). Interestingly, cows fed with long AH ate more coarse particle during critical-early time after feeding (i.e., 1.5 h after feeding), which increased eating time and decreased eating rate in the similar moment ($P < 0.05$). The increased eating time as well as decreased eating rate with marginally increasing AH particle length would be beneficial to improve ruminal pH and milk composition because of any undesirable effect on feed sorting.

Key Words: alfalfa hay particle length, dairy cow, feeding behavior

T64 Effect of level and source of supplemental protein on rate of ruminal methane production and methanogen concentration in *Bos taurus* and *Bos indicus* steers fed low-quality forage. N. L. Bell*[1], R. C. Anderson[2], S. L. Murray[1], J. C. McCann[1], K. K. Weldon[1], A. D. G. Wright[3], J. E. Sawyer[1], and T. A. Wickersham[1], *[1]Texas A&M University, College Station, [2]USDA/ARS Southern Plains Agricultural Research Center, College Station, TX, [3]University of Vermont, Burlington.*

The adaptive response of ruminal methanogen populations to substrate availability is not well defined. In this study, 10 ruminally cannulated steers (5 each: *Bos taurus*, Bt, 303 ± 10 kg initial BW and *Bos indicus,* Bi, 323 ± 28 kg initial BW) were used to quantify differences in source and level of protein on rate of ruminal methane (CH_4) production and methanogen concentration. Breeds were assigned to separate 5 × 5 Latin squares and fed low-quality forage (4.5% CP). Treatments were arranged as a 2 × 2 factorial plus a control (no supplement): the first factor was level of protein, 60 or 120 mg N/kg BW daily; and the second was source, DIP (degradable intake protein; 72% DIP) or UIP (undegradable intake protein; 72% UIP). Rumen fluid collected immediately after feeding and 4 h later was processed according to standard laboratory protocols. There was a main effect of time after feeding ($P < 0.01$) for both Bt and Bi steers with CH_4 production being lower at 4 h after feeding versus 0 h (1.75 ± 0.45 and 2.32 ± 0.95 μmol CH_4/mL per h; respectively). There was a protein source by level interaction for Bt ($P = 0.03$) and Bi ($P = 0.07$) steers. In both cases, steers fed 60 or 120 mg N/kg BW UIP had lower levels of in vitro CH_4-producing activity (1.93 ± 0.74 and 1.90 ± 0.91 μmol CH_4/mL per h for Bt and Bi, respectively) than steers fed 60 or 120 mg N/kg BW DIP (2.25 ± 0.88 and 2.20 ± 0.74 μmol CH_4/mL per h for Bt and Bi, respectively). Contrary to our hypothesis, main effects of breed, treatment, or time, and the interactions were not observed ($P > 0.35$) for methanogen concentrations measured by most probable number (MPN) or quantitative PCR. Methanogen concentrations averaged 6.52 ± 1.13 and 7.08 ± 0.86 $\log_{10}$/mL rumen fluid when measured by MPN and PCR methods, respectively. These results suggest that while methanogen concentrations remained unchanged, the population may favor slow growing methanogens expressing high substrate affinity during periods of limiting reductant and favor more rapid growing species with lower substrate affinity when reductant is abundant.

Key Words: protein supplementation, methane

T65 Whole cottonseed can replace barley straw in TMR fed beef heifers at finishing period. S. P. Iraira[1], J. L. Ruíz de la Torre[1], M. Rodríguez-Prado[1], M. Pérez[2], X. Manteca[1], S. Calsamiglia*[1], and A. Ferret[1], *[1]SNiBA, Universitat Autònoma Barcelona, Bellaterra, Spain, [2]Unitat de Qualitat i Carn-IRTA, Girona, Spain.*

To study the effect of whole cottonseed (WCS) on performance and meat quality, and to compare the results with those provided by the use of barley straw (BS) offered either separately or mixed with the concentrate, 27 Simmental heifers (initial BW 265.1 ± 20.4 kg) were assigned to three treatments in a randomized complete block design. Treatments consisted of (1) concentrate and BS, both offered as free-choice in separate feedbunks (CH-BS), (2) concentrate and BS offered as total mixed ration (TMR) with a concentrate to BS ratio of 92 to 8 (TMR-BS), and (3) TMR in which 16% of WCS (DM basis) was used as an alternative fiber source (TMR-WCS). All diets were offered ad libitum and formulated according to NRC (2000) to be isoenergetic (3.0 Mcal ME/kg DM), and isonitrogenous (14% on DM). Animals were allotted to roofed pens with 3 animals per pen, and 3 pens per treatment. Intake, ADG and G:F ratio were registered. Dressing percentage was calculated from hot carcass weight and the BW recorded before transfer to the abbatoir. The Longissimus thoracis (LT) muscle was excised from the 6th rib, and was used for measurements of meat quality. Intake of DM, ADG, and G:F ratio were no different among diets, being on average 8.1 ± 0.34 kg/d, 1.4 ± 0.08 kg/d, and 0.18 ± 0.01, respectively. The concentrate to BS ratio in heifers fed CH-BS was 96 to 4. Intake of CP was greater ($P = 0.013$) in TMR-WCS than in CH-BS and TMR-BS, and NDF intake was greater ($P = 0.05$) in TMR-BS than in TMR-WCS. There were no differences in the carcass characteristics and meat quality among diets, but there were differences in the percentage of some fatty acids. The percentage of C17:0 ($P = 0.005$), and C18:1 *trans*-10, *trans*-11, *trans*-12 ($P = 0.012$) was greater in heifers fed TMR-WCS than heifers fed BS diets, but lesser in the case of C18:1 *cis*-9 ($P = 0.002$). The n-6:n-3 ratio was greater in TMR-WCS than in the other two diets ($P = 0.001$). In summary, these results suggest that WCS can replace BS in finishing beef heifers without affecting DM intake, ADG, G:F ratio, carcass characteristics, and meat quality, although it can cause some changes in the fatty acid profile of the LT muscle.

Key Words: beef cattle, whole cottonseed

T66 Effects of basal diet and degradable intake protein level on the growth response to slow release urea in beef steers. V. B. Holder*[1], J. S. Jennings[2], K. M. McLeod[1], J. M. Tricarico[3], and D. L. Harmon[1], *[1]University of Kentucky, Lexington, [2]Alltech Inc., Brookings, SD, [3]Innovation Center for the U.S. Dairy, Rosemont, IL.*

This experiment was conducted to determine the effects of basal diet, DIP level and urea source on the growth and efficiency of beef cattle. The experiment utilized 240 Angus crossbred steers (BW: 287 ± 1.4 kg) over a 70-d growth period. Steers were blocked by weight and, within block, randomly assigned to treatment. Each treatment combination had 6 replicate pens with 5 head per pen. Treatments were arranged as a 2 × 2 × 2 factorial structure with two concentrate levels (70% vs. 40%), two DIP levels (90% vs. 120% of requirements) and two sources of DIP (urea vs. slow release urea, OptigenII, Alltech Inc.). The basal diet was achieved by the addition of either wheat straw and corn stalks (40% concentrate) or high moisture shelled corn (70% concentrate) to a corn silage-based diet. Feed was offered once per day throughout the experiment and bunks were managed for ad libitum intake. The 70% concentrate diet increased DMI (9.38 vs. 7.76 kg/d, $P < 0.0001$), ADG (1.77 vs. 1.21 kg/d, $P < 0.0001$) and feed efficiency (189.1 vs. 156.4 g/kg, $P < 0.0001$). Similarly, the 120% DIP diets increased DMI (8.82 vs. 8.31 kg/d, $P < 0.0001$), ADG (1.61 vs. 1.38 kg/d, $P < 0.0001$) and feed efficiency (181.2 vs. 164.2 g/kg, $P < 0.0001$). There was an interaction between basal diet and DIP source where slow release urea increased ADG (1.80 vs. 1.75 kg/d, $P = 0.04$) and tended to improve feed efficiency (192.2 vs. 185.9 g/kg, $P = 0.07$) of 70% concentrate diets but tended to decrease these variables in 40% concentrate diets (ADG: 1.18 vs. 1.25 kg/d; efficiency: 154.6 vs. 158.2 g/kg). If provided when DIP is limiting, providing DIP as slow release urea instead of urea may increase performance and feed efficiency of animals on higher concentrate diets but not for the low quality high forage diets used in this experiment.

Key Words: N efficiency, N pollution

T67 In situ disappearance in lactating beef cows of dried distillers grains subjected to different levels of heat damage. K. P. Coffey*, A. N. Young, E. B. Kegley, D. Philipp, P. Hornsby, and J. Hollenback, *University of Arkansas Division of Agriculture, Fayetteville.*

Distillers dried grains (DDG) may be subjected to varied levels of heat damage during processing and transport. Our objective was to determine in situ DM disappearance of conventional (CDDG) or a lower-fat DDG (LFDDG) subjected to varied levels of heat damage. Both CDDG and LFDDG were mixed 80:20 with water, placed in Al pans, covered with foil, and heated for either 3 or 5.5 h at 150C. Contents from the center of each pan were retained separately from the exterior 2 cm of each pan. The exterior 2 cm from the 5.5-h heating was charred excessively and retained to represent excessive heat damage (5.5CHR). Ruminally cannulated beef cows (n=4; 533±14.0 kg BW) were offered bermudagrass hay with either no supplement or 0.45% of BW from either CDDG, LFDDG, or heated LFDDG (3 h at 150°C) in a 4 × 4 Latin square experiment. Nylon bags containing unheated CDDG and LFDDG, those heated for 3 or 5.5 h, and those from 5.5CHR were incubated in the rumen for multiple times up to 108 h. Dry matter remaining was fit to a non-linear model, resulting in estimations of immediately-soluble (A) and potentially degradable (B) fractions, along with disappearance rate (k_d). Cow diet did not affect ($P > 0.29$) in situ parameters. Fraction B was greater ($P < 0.05$), and k_d was less ($P < 0.05$) from CDDG vs. LFDDG. Fraction B was greater ($P < 0.05$) from 5.5CHR and DDG heated for 5.5 h, and k_d was slowest ($P < 0.05$) from 5.5CHR followed by DDG heated for 5.5 h. Neither measure differed ($P > 0.05$) between unheated DDG and DDG heated for 3 h. Linear relationships were strongest ($R^2 > 0.77$) between acid-detergent insoluble N (ADIN, % of total N) and fraction A within DDG type. Linear and quadratic relationships between ADIN and other kinetic parameters were observed ($P < 0.05$), but those relationships were lower ($R^2 \leq 0.41$) than for fraction A, and were even less ($R^2 = 0.06$ to 0.32) when analyzed across types of DDG. Therefore, moderate heat damage had little impact on ruminal DM kinetic measurements, and use of ADIN analyses to assess ruminal DM disappearance characteristics should be viewed with caution, even within DDG processing method.

Key Words: distillers dried grain, in situ disappearance, heat damage

T68 Raw soybeans in a whole corn diet for feedlot heifers. A. J. Pordomingo, N. A. Juan, G. Volpi Lagreca*, and R. Beierbach, *National Institute Agricultural Research (INTA), Anguil, La Pampa, Argentina.*

Small-scale beef producers often use raw soybeans as protein source. Ruminants have the ability to denature in the rumen the antitrypsin factors present in soybeans, but levels are not conclusive and require further elucidation. Ninety-six 285-kg Angus heifers were distributed in 24 feeding pens. Pens were allocated to 8 diets, a factorial combination of processing (raw or roasted) and 4 levels (0, 10, 16 and 22%) of soybeans. Diets were whole corn based and included 5% alfalfa hay, a mineral premix and monensin. Soybean were ground before feeding. Sunflower meal and urea were used to adjust the crude protein content to 14%. Animals were fed in excess to voluntary intake (DMI) over a 90 d period. Processing by level interactions were detected ($P < 0.05$) for final weight, ADG and intake. Increased roasted soybean concentration in the diet tended to improve ADG and final weight (linear trend; P = 0.06) No treatment effects were detected ($P > 0.05$) in DMI for roasted soybeans. A similar response was observed for raw soybeans up to the 16% level in the diet. Treatments with 10 or 16% raw or roasted soybean resulted in similar ($P > 0.627$) ADG, final live weight and intake. On the contrary, the diet with 22% raw soybean resulted in the lowest ADG and feed intake ($P < 0.001$) compared with the other treatments, which elicited the lowest final live weight. This treatment had also the poorest feed efficiency ($P < 0.034$). Increased performance with increasing soybean content could be attributed to the increased oil content of the diet and the quality of protein of soybeans versus sunflower meal. The lower ADG for the 22% raw soybeans vs. the other treatments could be at least in part explained by the presence of antitrypsin factors in the soybeans.

Key Words: antitrypsin factors, feedlot heifers, raw soybeans

T69 Effect of supplemental protein amount and degradability on intake and digestion in *Bos indicus* and *Bos taurus* steers fed rice straw. K. K. Weldon*, J. C. McCann, J. E. Sawyer, and T. A. Wickersham, *Texas A&M University, College Station.*

We evaluated effects of amount and degradability of supplemental protein on utilization of low-quality forage in 5 Angus steers (*Bos taurus*, Bt, BW = 303 ± 10 kg) and 5 Brahman steers (*Bos indicus*, Bi, BW = 323 ± 28 kg). Steers fitted with ruminal and duodenal cannulas were used in concurrent 5 × 5 Latin squares. Treatments were arranged as a 2 × 2 factorial plus a control (CON; no supplementation). Isonitrogenous (27% CP) supplements were formulated to provide different proportions of ruminally degradable protein (DIP; L = 28% DIP or H = 72% DIP). Each type of supplement was fed to deliver 60 or 120 mg of N/kg BW. Steers had ad libitum access to rice straw (4.4% CP, 72.8% NDF). Experimental periods were 15 d; 9 d adaptation and 6 d sample collection. Forage OM intake (FOMI) was greater for Bt than Bi ($P = 0.05$). Supplementation increased FOMI in both Bt and Bi ($P < 0.05$); Bi FOMI was increased from 13.5 g/(kg BW·d) to 14.8 g/(kg BW·d) and Bt from 16.5 g/(kg BW·d) (CON) to 17.6 g/(kg BW·d). Neither protein source, amount, nor their interaction affected FOMI within Bi or Bt ($P > 0.20$). OM digestibility (OMD) was greater in Bi than Bt ($P < 0.01$). Supplementation did not affect OMD in Bt ($P = 0.53$; 54.4% vs. 53.6% for CON vs. supplement), but increased OMD for Bi ($P = 0.02$) from 53.4% (CON) to 57.0% (supplemented). There were no source, amount, or source × amount effects ($P > 0.37$) within Bi or Bt for OMD. Total digestible OM intake (TDOMI) was similar between breeds ($P = 0.12$), and increased ($P < 0.01$) with supplementation. A 14% increase in TDOMI was observed from CON for Bt ($P = 0.04$); TDOMI increased 29% from CON for Bi ($P = 0.05$). There were no source, amount, or source × amount effects ($P > 0.22$) within either breed for TDOMI. While Bt had significantly higher FOMI, an increase in OMD for Bi with supplementation resulted in similar overall TDOMI between breeds.

Key Words: digestion, intake, straw

T70 Effect of degradability and level of protein supplementation on ruminal fermentation in *Bos indicus* and *Bos taurus* steers fed rice straw. K. K. Weldon*, J. C. McCann, J. E. Sawyer, and T. A. Wickersham, *Texas A&M University, College Station.*

We evaluated the effects of amount and degradability of supplemental protein on ruminal fermentation of different breeds of cattle fed low quality forage. Five Angus steers (*Bos taurus,* Bt) and 5 Brahman steers (*Bos indicus*, Bi) with ruminal cannulas were used in concurrent 5 × 5 Latin squares. Treatments were arranged as a 2 × 2 factorial plus a control (CON; no supplementation). Isonitrogenous (27% CP) supplements were formulated to provide different proportions of ruminally degradable protein (DIP; L = 28% DIP or H = 72% DIP). Each type of supplement was fed to deliver 60 or 120 mg of N/kg BW. Steers had ad libitum access to rice straw (4.4% CP, 72.8% NDF). Experimental

periods were 15 d; 9 d adaptation, and 6 d sample collection. Total digestible OM intake (TDOMI) was similar between breeds ($P = 0.12$), and increased ($P < 0.01$) with supplementation. Ruminal ammonia (NH_3-N) concentrations increased with supplementation ($P < 0.01$) versus CON in both breeds. *Bos indicus* steers had greater NH_3-N concentrations than Bt ($P < 0.01$). Supplement amount × source affected NH_3-N in Bt and Bi ($P < 0.01$). In Bt, increasing from 60-L to 120-L had minimal effect; increasing from 60-H to 120-H increased NH_3-N 58%. In Bi, increasing from 60 to 120 increased NH_3-N by 45% for L, but only 26% for H. Plasma urea nitrogen (PUN) was greater for Bi than Bt ($P < 0.01$) for all treatments and at both 0 and 4 h after feeding. Supplementation tended ($P = 0.06$) to increase PUN versus CON in Bt, but not Bi ($P = 0.82$). Increased amount of supplement tended to increase PUN in Bi ($P = 0.08$), while both increased supplement amount and proportion of DIP increased PUN in Bt ($P < 0.01$). *Bos taurus* steers had numerically ($P = 0.19$) greater total volatile fatty acids (VFA) across treatments than Bi steers. Increased amount of supplementation to Bt increased total VFA ($P < 0.01$) from 74.1 m*M* (60) to 76.3 m*M* (120), but did not change VFA in Bi ($P = 0.32$). Overall, Bi had higher ruminal and plasma nitrogen concentration than Bt; these concentrations increased as amount and DIP proportion of supplements increased in both breeds.

Key Words: forage, ruminal, fermentation

T71 Effect of amount and degradability of protein supplements on nitrogen metabolism in *Bos indicus* and *Bos taurus* steers fed rice straw. K. K. Weldon*, J. C. McCann, J. E. Sawyer, and T. A. Wickersham, *Texas A&M University, College Station.*

We evaluated effects of amount and degradability of supplemental protein on nitrogen metabolism in 5 Angus steers (*Bos taurus*, Bt, BW = 303 ± 10 kg) and 5 Brahman steers (*Bos indicus*, Bi, BW = 323 ± 28 kg). Steers fitted with ruminal and duodenal cannulas were used in concurrent 5 × 5 Latin squares. Treatments were arranged as a 2 × 2 factorial plus a control (CON; no supplementation). Isonitrogenous (27% CP) supplements were formulated to provide different proportions of ruminally degradable protein (DIP; L = 28% DIP or H = 72% DIP). Each type of supplement was fed to deliver 60 or 120 mg of N/kg BW. Steers had ad libitum access to rice straw (4.4% CP, 72.8% NDF). Experimental periods were 15 d; 9 d adaptation, and 6 d sample collection. Total nitrogen (N) intake was greater for Bt than for Bi steers ($P = 0.06$). As expected, supplementation increased total N intake vs. CON ($P < 0.01$), and higher amounts of supplemental N increased total N intake within both breeds ($P < 0.01$). Higher DIP supplements increased total N intake for Bt ($P < 0.01$); no effect of supplemental N source was observed in Bi ($P = 0.19$). Fecal N was higher in Bt than Bi ($P < 0.01$). Supplementation increased ($P < 0.01$) fecal N vs. CON for both breeds. Increased amount of N supplementation elevated fecal N in Bi ($P = 0.02$), but not Bt ($P = 0.13$). Urinary N tended to be higher for Bi than Bt ($P = 0.10$). Supplementation increased ($P < 0.05$) urinary N for both breeds. Increasing N amount increased urinary N excretion in Bi ($P = 0.02$), and Bt ($P = 0.06$). Retained N was greater for Bt over Bi ($P = 0.07$). In both breeds, N retention increased with supplementation vs. CON ($P < 0.01$). More N supplement increased N retained ($P < 0.01$). Increased supplementation raised N excreted and N retained for both breeds; fecal N was greater in Bt, while urinary N was greater in Bi. Total N intake tended to be greater in Bt, while total excretion was similar for Bt and Bi, resulting in greater amount of N retained by Bt.

Key Words: forage, nitrogen, balance

T72 Effect of different substitute levels of ground corn by coarsely ground wheat on ruminal fermentation, milk yield and composition in dairy cows. Y. Guo*, Y. Zou, X. Xu, Z. Yang, S. Li, and Z. Cao, *State Key Laboratory of Animal Nutrition, College of Animal Science and Technology, China Agricultural University, Beijing, China.*

Eight multiparous Holstein cows (569 ± 47 kg of BW; 84 ± 17 DIM) were used to evaluate the effects of different levels of coarsely ground wheat (CGW, 3-mm screen, geometric mean particle sizes: 1,139 μm) as replacements for ground corn (GC, 3.5-mm screen, geometric mean particle sizes: 666 μm) in diets on ruminal fermentation, milk yield and composition in dairy cows. The cows were settled in a replicated 4 × 4 Latin square design with 3-wk treatment periods; four cows in one of the replicates were fitted with rumen cannulas. The four diets contained 0, 9.6, 19.2, and 28.8% CGW and 27.9, 19.2, 9.6, and 0% GC (DM basis), respectively. The cows were fed a TMR, with a 47:53 forage to concentrate ratio, where forage was 27% corn silage, 14% alfalfa hay, and 6% Chinese wild rye. The cows were fed and milked twice daily. Substituting CGW for GC had no effect on daily mean ruminal pH, but tended to reduce minimum ruminal pH and increase pH range when the cows were fed the 28.8% CGW diets. Increasing the dietary concentration of CGW resulted in a linear increase in ruminal propionate and ruminal NH_3-N concentration, while ruminal acetate: propionate tended to decrease in cows fed the 28.8% CGW diets. Daily DM intake averaged 19.7kg and tended to increase quadratically. Milk production was not affected by diets; however, percentage and yield of milk fat, 3.5%FCM, and ECM decreased linearly, and milk urea nitrogen increased linearly, when the level of CGW was increased. Dietary treatments had no effect on feed efficiency (milk/DMI), while 3.5%FCM/DMI decreased linearly with increasing levels of CGW. The data indicate that CGW is a suitable substitute for GC in diets of dairy cows and that it may be included up to a level of 19.2% of dry matter without adverse effects on ruminal fermentation, feed intake, milk yield and composition, if the cows are fed fiber-sufficient diets and the levels are adjusted gradually. However, high inclusion levels of CGW, such as in the case of 28.8% CGW diets, could increase the risk of subacute ruminal acidosis, and milk-fat depression.

Key Words: wheat, dairy cow, rumen fermentation

T73 Effects of feeding a corn straw or mixed forage diet to lactating cows on rumen fermentation parameters using a wireless data logger. C. F. Qin[1,2], D. P. Bu[1], J. Q. Wang*[1], P. Sun[1], P. H. Zhang[2], X. W. Zhao[1], J. N. Li[1], and P. Zhang[1], *[1]State Key Laboratory of Animal Nutrition, Institute of Animal Science, Chinese Academy of Agricultural Sciences, Beijing, China, [2]Hunan Provincial Key Laboratory for Genetic Improvement of Domestic Animal, College of Animal Science and Technology, Hunan Agricultural University, Changsha, Hunan, China.*

The objectives of this study were to evaluate the effects of feeding two different diets on ruminal pH, temperature and oxidation reduction potential (ORP) and their rhythms for 24 h through real-time monitoring. Eight primiparous lactating Holstein cows fitted with rumen cannula were blocked by milk yield and body weight and then randomly assigned to high forage diet (HF; forage:concentrate = 60:40) with Chinese wildrye, alfalfa hay and corn silage as the forage source or low forage diet (LF, forage:concentrate = 40:60) with corn straw as the forage source. Ruminal pH, temperature and ORP were real-time monitored by a wireless data logger during a trial period of 14 d. Data were analyzed using the PROC MIXED procedure of SAS. Cows fed LF diet had higher ruminal pH compared to those fed HF diet (6.32 and 6.12; $P < 0.01$),

whereas temperature (38.57 and 38.86 °C; $P < 0.01$) and ORP (−384.25 and −361.88 mV; $P < 0.01$) were lower in LF group. The pH values were higher in LF group compared to those fed HF diet at the minutes when morning (6.33 and 6.17; $P < 0.05$) and evening (6.57 and 6.42; $P < 0.05$) ingestion began and at the minutes when night rumination (6.22 and 6.02; $P < 0.01$) proceeded and when morning (6.30 and 5.99; $P < 0.01$) and evening (6.29 and 6.02; $P < 0.01$) ingestion finished. Cows fed LF diet had less minutes for ruminal pH < 6.0 (161.55 and 449.74 min/d; $P < 0.05$) and pH < 5.8 (79.45 and 230.50 min/d; $P < 0.05$) compared to those fed HF diet, and ruminal pH < 5.6 (31.86 and 79.53 min/d; $P = 0.07$) tended to be less in LF group. However, minutes for pH < 5.2 were not affected by diets. Ruminal pH and ORP rose to their peaks when feeding began but reduced to the minimums when feeding finished. Ruminal temperature reduced to minimum after feeding at noon. The results indicated that rumen fermentation parameters were affected by forage-to-concentrate ratio in the diets, and the wireless data logger system can accurately and precisely measure rumen fermentation parameters.

Key Words: forage pattern, wireless data logger, rumen fermentation parameter

T74 Effect of feeding a corn straw or mixed forage diet on mixed-rumen bacterial fatty acid profiles in lactating cows. C. F. Qin[1,2], J. Q. Wang[1], D. P. Bu*[1], P. Sun[1], P. H. Zhang[2], M. Yi[1], S. K. Jiang[1], and J. N. Li[1], *[1]State Key Laboratory of Animal Nutrition, Institute of Animal Science, Chinese Academy of Agricultural Sciences, Beijing, China, [2]Hunan Provincial Key Laboratory for Genetic Improvement of Domestic Animal, College of Animal Science and Technology, Hunan Agricultural University, Changsha, Hunan, China.*

Rumen microbial matter is a vital source of nutrients for the host animal and it may be affected by diet systems. Our objective was to determine the effect of different forage sources on fatty acid (FA) composition of mixed-rumen bacteria. Twelve primiparous, lactating and ruminally fistulated Holstein cows were used in this study. Cows were randomly assigned to high forage diet (MF, forage:concentrate = 60:40) with Chinese wildrye, alfalfa hay and corn silage as the forage source or low forage diet (CS, forage : concentrate = 40 : 60) with corn straw as the forage source. This study lasted for 9 weeks with 2-week of preliminary period and 7-week of trial period. Rumen samples were collected 4 times daily in the last 3 excessive days to insure each sample was obtained with 2-hour intervals inter. All samples were composited for each cow and kept at -20°C for further analysis. Data were analyzed using the PROC MIXED procedure of SAS 9.1. Compositions of C14:1 (5.53 and 6.09%), C15:0 (3.01 and 3.38%), *trans*-9 C18:1 (0.23 and 0.26%), *trans*-11 C18:1 (1.42 and 1.50%), *cis*-9, *cis*-12 C18:2 (2.66 and 2.85%), *cis*-9, *tran*-11 CLA (1.33 and 1.18%), *trans*-10, *cis*-12 C18:2 (0.33 and 0.37%), C20:0 (0.32 and 0.31%), mono unsaturated FA (11.93 and 11.80%), poly unsaturated FA (4.75 and 4.75%), saturated FA (83.32 and 83.44%) and unsaturated FA (16.68 and16.57%) were not affected by forage sources ($P > 0.05$). Proportions of C18:0 (49.17 and 42.92%; $P < 0.05$), *cis*-9 C18:1 (4.50 and 3.66%; $P < 0.01$), > C16:0 (61.61 and 55.02%; $P < 0.01$) and long chain FA (16.68 and16.57%; $P < 0.01$) were increased in cows fed with CS. Percentages of C16:0 (25.23 and 30.28%; $P < 0.01$), C18:3 (0.20 and 0.36%; $P < 0.01$) and medium chain FA (33.22 and 44.84%; $P < 0.01$) were lower in CS group. The CS diet tended to have a negative effect on proportion of C12:0 (0.80 and 0.99%; $P = 0.09$), C14:0 (3.33 and 3.97%; $P = 0.08$) and C22:0 (0.26 and 0.39%; $P = 0.09$). In conclusion, different forage patterns influenced mixed-rumen bacterial FA synthesis and caused the alteration of rumen microbial FA profiles in cows.

Key Words: forage source, lactating cow, mixed-rumen bacterial fatty acid

T75 Effect of fed a corn straw or mixed forage diet on fatty acid extraction in mammary gland of lactation dairy cows. H. Y. Chen[1,2], D. P. Bu*[1], F. D. Li[2], X. M. Nan[1], X. W. Zhao[2], and H. Hu[1], *[1]Institute of Animal Science, Chinese Academy of Agricultural Sciences, Beijing, China, [2]Gansu Agricultural University, Lanzhou, Gansu, China.*

Changing the fatty acids (FA) profile of plasma might affect FA metabolism in the mammary gland of dairy cows. This study was conducted to evaluate the effect of feed type on the FA profile of plasma, blood parameters and fatty acids extraction in mammary gland of dairy cows in lactation. Twenty lactating Holstein cows (BW = 558 ± 40 kg, DIM at the beginning of the experiment = 83 ± 10 d, n = 10) were randomly assigned to high forage diet (MF, forage : concentrate = 60 : 40) with Chinese wildrye, alfalfa hay and corn silage as the forage source or low forage diet (CS, forage : concentrate = 40 : 60) with corn straw as the forage source. The experiment lasted for 49 d with a 14 d adaptation period for cows to adjust to the treatment diets. On the 48 d and 49 d of the experiment, blood samples were taken from the coccygeal artery (representing mammary arterial supply) and milk vein at 3 hr after morning feeding. Extraction (%) of each FA was assessed via arterial-rectificative venous concentration (AC-RVC) differences. Data were analyzed using the MIXED models of SAS, with treatment as fixed effect. The results showed that MF increased the contents of C14 (0.71 and 0.69, $P < 0.05$), C16:1 (0.72 and 0.55, $P < 0.05$) and PUFA (68.88 and 67.81, $P < 0.05$) in the blood, while the content of c9c12C18:2 in MF was lower than the CS (59.29 and 60.85, $P < 0.01$), A nonsignificant increase of other FA was observed in our trial. Compared to the CS, MF did not affect most of the fatty acids extraction in mammary gland ($P > 0.05$), except C18:3 (24.26 and 42.10, $P < 0.05$). The MF increased content of NEFA in plasma (0.92 and 0.85, $P < 0.05$) and tended to increase the content of TC and LDL. These results indicated that different diet can changed the plasma fatty acid profile, which can cause the fatty acid extraction rate to change. Moreover, the results suggest that when FA taken up from arterial plasma by mammary gland tissues, there is a relationship between them. Changing the type of diet affects FA metabolism in the mammary gland of dairy cows.

Key Words: blood parameter, fatty acid extraction rate, feed type

T76 Effect of replacing timothy silage with alfalfa silage in dairy cow diets on enteric methane production. F. Hassanat*[1], R. Gervais[2], P. Y. Chouinard[2], H. Petit[1], D. Massé[1], and C. Benchaar[1], *[1]Agriculture and Agri-Food Canada, Dairy and Swine Research and Development Centre, Sherbrooke, QC, Canada, [2]Département des Sciences Animales, Université Laval, Québec, QC, Canada.*

The objective of this study was to determine the impact of replacing timothy silage with alfalfa silage (AS) in dairy cow diets on enteric CH_4 emissions. Nine lactating, multiparous Holstein cows (DIM = 92 ± 19; BW = 696 ± 71 kg; milk yield 46.2 ± 4.3 kg) used in a replicated 3×3 Latin square (32-d periods, 14-d adaptation) were fed (ad libitum) a TMR (60:40, forage:concentrate ratio) with the forage portion being either timothy silage (0% AS), alfalfa silage (100% AS) or a 50:50 mixture (50% AS). Diets were formulated to contain 16.5% CP and 1.64 Mcal/kg NE_L. Production of CH_4 was determined (3 consecutive days) using respiration chambers. Digestibility and milk performance were determined over 6 consecutive days. Linear and quadratic contrasts (MIXED Procedure; SAS) were used to determine the effects of increasing AS proportions on response variables. Significance was declared at $P \leq 0.05$ and tendencies at $0.05 \leq P \leq 0.10$. Dry matter (DM) intake (22.5, 23.7, and 24.6 kg/d for 0, 50 and 100% AS, respectively) increased linearly while DM digestibility did

not change as the proportion of AS increased in the diet. Yields of milk, fat-corrected milk (FCM) and energy-corrected milk (ECM) were not affected by increasing dietary AS proportions. Daily CH_4 emission tended ($P = 0.10$) to increase with increasing proportions of AS in the diet (476, 483 and 491 g/d for 0, 50 and 100% AS, respectively). Methane production adjusted for DM (average 19.8 g/kg) or gross energy intake (average 5.83%) was not affected by increasing AS inclusion in the diet. When expressed on FCM or ECM yield bases, CH_4 production increased linearly ($P = 0.03$) with increasing AS proportions in the diet. In conclusion, under the experimental conditions of this study, CH_4 energy losses (% gross energy intake) were not affected by replacing timothy silage with alfalfa silage in dairy cow diets.

Key Words: alfalfa silage, timothy silage, methane

T77 The optimal ratio of canola meal and dried distillers grain proteins in high producing Holstein cow diets. N. Swanepoel*[1,2], P. H. Robinson[1], and L. J. Erasmus[2], [1]*Department of Animal Science, University of California, Davis,* [2]*Department of Animal and Wildlife Sciences, University of Pretoria, Pretoria, South Africa.*

Limited data is available on dairy cow performance when feeding canola meal (CM) and distillers dried grains with solubles (DDGS) as main supplemental crude protein (CP) sources. Our objective was to determine the optimal ratio of CM to DDGS CP in a contemporary California dairy ration by feeding combinations of CM and high protein (low oil) DDG (HPDDG) to high producing dairy cows. The design used 4 pens of 320 high-producing cows/pen in a 4 × 4 Latin square crossover with 28-d periods. Treatments varied in the amount of CM and HPDDG added on a dry matter (DM) basis: (1) 0 CM, 200 g/kg HPDDG, (2) 65 CM, 135 g/kg HPDDG, (3) 135 CM, 65 g/kg HPDDG, (4) 200 CM, 0 g/kg HPDDG. DM intake was not affected (avg: 24.4 kg/d) by the CM/HPDDG ratio. Milk (44.9, 47.4, 47.9, 47.4 kg/d for 0, 65, 135, 200 g/kg CM respectively; $P < 0.01$) and true protein yield (avg: 1.37 kg/d) increased quadratically with the higher CM/HPDDG ratio, peaking at 135 g/kg CM. Milk fat yield (avg: 1.61 kg/d) and true protein (TP) % (avg: 2.93) responded quadratically ($P < 0.01$), peaking at ~120 g/kg CM. Milk fat % (avg: 3.44) had a linear decrease ($P < 0.01$) with lowest values at 200 g/kg CM. Body condition score (BCS) change responded quadratically (0.001, 0.034, 0.08, 0.029 units/28 d for 0, 65, 135, 200 g/kg CM respectively; $P < 0.01$), with highest BCS gain at ~120 g/kg CM. Results suggest the optimum level was 120 to 135 g/kg of supplemental protein from CM. The urine purine derivative to creatinine index increased linearly ($P < 0.01$) with higher CM level, suggesting microbial protein production (MCP) was limited at 0 g/kg CM and progressively stimulated by higher feeding levels of CM. Plasma amino acid (AA) levels suggest a reduction in lysine from dietary protein, with the decreased MCP production, resulted in substantial reduction in lysine available to support milk production, limiting performance in higher HPDDG rations. The only essential plasma AA to linearly decrease ($P < 0.01$) with higher CM were Phe, Leu and Met. The additional quadratic response ($P < 0.01$) of Met and Phe at the 200 g/kg CM treatment suggests that Phe and/or Met limited production in the highest CM ration.

Key Words: urine purines, amino acids

T78 Intake, milk yield, and blood acid-base balance of cows in response to marine algae meal. N. M. Lopes[1], R. A. N. Pereira[2], and M. N. Pereira*[1], [1]*Universidade Federal de Lavras, Lavras, MG, Brazil,* [2]*Empresa de Pesquisa Agropecuaria de Minas Gerais, Lavras, MG, Brazil.*

The skeleton of the marine algae *Lithothamnium calcareum*, a source of calcium carbonate, has been fed to dairy cows as an alkalizer, despite the lack of strong evidence for its effectiveness and for the mode of action. This experiment evaluated the performance, diet digestibility, and venous acid-base balance of cows supplemented with algae meal (Algarea, Brazil) or sodium bicarbonate. Twenty Holsteins (248 DIM) received treatments in 4 × 4, 21-d period, Latin squares. Treatments were: Control (C), 1% of DM of algae meal (A), 0.5% algae meal+0.5% sodium bicarbonate (AB), or 1% sodium bicarbonate (B). Diets had (% of DM): 52.7 corn silage, 2.2 Tifton hay, 21.7 soybean meal, and 20 high moisture corn. On days 19 to 21, acidosis was induced by abrupt replacement of 12.4% DM units of corn silage by high moisture corn. Jugular vein gasometry was performed 9.5h post-feeding on day 19. Pre-planned contrasts were: C vs. A, A vs. B, and AB vs. (A+B). Total tract digestibility, determined by total collection of feces, was not affected by treatments ($P > 0.64$). Milk yield was (kg/d): 21.5 for C, 20.6 for A, 21.5 for AB, and 22.3 for B, and DMI was 18.1, 17.5, 18.0, and 18.8, respectively. There was a trend for decreased DMI when algae meal was added to the control diet ($P = 0.06$), and a linear decrease in DMI ($P < 0.01$) and milk yield ($P = 0.10$) when it replaced bicarbonate. During acidosis induction, the response across treatments in DMI and milk yield followed that same pattern. Satiety, measured as the duration of the first meal, was shortest in C, while the proportion of daily DMI between 7AM and 12AM was smallest in A. Across treatments, the response in satiety paralleled the response in blood gasometry. Treatment A had the strongest measures of blood hypoxia, although a similar, but weaker response, was also elicited by bicarbonate. The net Ca^{++} and Na^{++} absorption apparently induced hypoventilation for the maintenance of blood pH at 7.41. Algae meal was a potent manipulator of acid-base balance, but at 1% of diet DM it did not improve performance or digestibility of cows in late lactation.

Key Words: blood acid-base balance, algae meal, *Lithothamnium calcareum*

T80 Starch digestion variation between in vitro and in situ digestion techniques. C. R. Heuer*[1,2], J. P. Goeser[1], and R. D. Shaver[2], [1]*Rock River Laboratory Inc., Watertown, WI,* [2]*University of Wisconsin, Madison, Madison.*

Starch digestion (starchd) of grains and forages is important to dairy cattle nutritionists. By being able to accurately predict the starchd they are able to maximize milk production and milk fat. Our objective was to determine if different starchd techniques, rumen in vitro (IV) and in situ (IS), generate comparable results and are repeatable across weeks. Corn silage (n = 2), snaplage (n = 2), TMR (n = 2), high moisture corn (n = 2), and dry corn (n = 2) were dried and ground (4 mm). For the IV technique samples were weighed (0.5 g) into 125-mL flask, rumen fluid was collected from 2 lactating dairy cows and went through a standardization procedure. Samples were analyzed in triplicate for 3 and 7 h time points. IS samples were weighed (6 g per bag) in triplicate to be placed in 3 lactating dairy cows consuming a commercial diet for 3 and 7h. Residue bags were rinsed until effluent was clear. Bags were dried and weighed to determine the dry matter digestion. Residue samples were composited and ground to 1mm. Starch content was then determined by the use of an YSI 2700 to determine glucose (g/L). Starch was calculated as 100 × [(volume/weight) × (glucose) × (0.9)/1000]. Starchd was calculated as 100 × [($Starch_{0h}$ − $Starch_{residue}$) / ($Starch_{0h}$)]. Each of these techniques was evaluated 2 weeks to assess repeatability. We analyzed the data set using SAS 9.3 and linear models. Both starchd and technique modeled as response variables, with fixed effects of week and hour in both

and technique in the starchd model and ID as a random effect in both. When comparing techniques, IS was used as the response variable. Means were compared by Tukey's test. IV results yielded greater estimates than IS results (69.2% vs. 56.4%, $P < 0.04$). When comparing the variation IV samples averaged a numerically higher standard deviation than IS samples (7.80 vs. 2.01). The IV results tended to be related to IS results ($P < 0.07$). Results suggest that the IV technique of determining starchd causes elevated digestion levels compared to IS starchd. The tendency in relationship between techniques suggest IV may be an acceptable predictor of IS starchd.

Key Words: starch digestion

T81 Geometric mean diameter fails to reflect diversity in size of particles in processed maize grain. L. J. Nuzback, W. J. Seglar, M. Laubach, T. Hageman, and F. N. Owens*, *DuPont Pioneer, Johnston, IA.*

For feeding livestock, most maize grain is processed to reduce particle size and increase the surface area exposed for digestion. This in turn increases rate of ruminal digestion and total tract digestion of maize starch by lactating cows. Geometric mean diameter (GMD) of feed particles is appraised through measuring the mass retained on stacked sieves of different pore sizes. For forages, 5 sieves are used but for cereal grains a stack of 14 screens commonly are used and samples typically are dried prior to screening. We tested whether fewer screens might be used and the impacts of drying and processing method on GMD. Using dry processed and high moisture maize grain (12 and 7 samples) gathered from various Midwest dairies, GMD by the 14 screen system was determined at a commercial lab. These same samples were appraised through a simpler 4 screen system (Tyler 4, 8, 16 and 30 sieves). With the 4 screen system, GMD was determined with samples that differed in moisture content. For dry (rolled or hammer milled) maize grain samples, GMD was determined as received (85 to 88% DM). For high moisture rolled maize (HMC; 70 to 77% DM), GMD was determined either as received or after being air dried at least 48 hours or being oven dried at 50 C for 24 hours. Correlations of GMD determined at a commercial lab with GMD determined with 4 screens for the 5 sets of samples were high, being 0.99 (dry maize), 0.91 (as received HMC), 0.97 (air dried HMC), and 0.99 (oven dried HMC) with RMSE being 95, 137, 220, and 102 microns, respectively. For field use, GMD determined with the shorter stack system appears suitable. Although the GMD for the rolled and hammer milled dry grain samples did not differ, the standard error of the GMD was greater for hammer milled samples reflecting a wider distribution in particle sizes. GMD values alone fail to reflect this particle size diversity, a factor of interest nutritionally because very small particles may induce acidosis while larger particles likely are digested less extensively.

Key Words: grain, particle size, processing

T82 Performance and digestion of dairy cows in response to exogenous amylase. A. S. R. Andreazzi[2], N. N. Morais Junior[1], R. F. Lima[1], A. C. S. Melo[1], R. B. Reis[2], R. A. N. Pereira[3], and M. N. Pereira*[1], *[1]Universidade Federal de Lavras, Lavras, MG, Brazil, [2]Universidade Federal de Minas Gerais, Belo Horizonte, MG, Brazil, [3]Empresa de Pesquisa Agropecuária de Minas Gerais, Lavras, MG, Brazil.*

Exogenous amylase supplementation of dairy diets may increase the nutritive value of corn, especially when floury endosperm hybrids are not available. Twenty-eight Holsteins (171 ± 80 DIM at day 1) were paired blocked and assigned to a treatment for 70 days, after a two-week standardization period. Treatments were: Control or Amylase (Ronozyme RumiStar, DSM Nutritional Products). The enzyme was mixed to ground corn and added to a mixer to achieve 0.5g of enzyme per kg of TMR DM (300 KNU/kg of DM). Cows were individually fed in tie stalls. The diet contained (% of DM): 32.1% starch, 39.4% corn silage, 11.2% re-hydrated and ensiled mature corn, and 11.7% finely ground mature corn. Corn hybrids were semi-dent or flint type. Milk yield and DMI were recorded daily, milk solids weekly, and BW and BCS at 14-day intervals. On week 10, total tract digestibility and allantoin excretion were determined by total collection of feces and urine, PUN was measured at 0, 1, 2, 3, 6, 9, 12, and 18h post-feeding, and rumen pH and plasma glucose at 12h post-feeding. Eating and rumination pattern was visually evaluated for a 24h period. Data was analyzed with Mixed of SAS as a covariate adjusted randomized block design with repeated measures over time, except when data was obtained once along the experiment. Amylase increased milk yield (33.0 vs. 32.3kg/d, $P = 0.02$) and reduced DMI (19.7 vs. 20.7kg/d, $P < 0.01$), increasing feed efficiency ($P < 0.01$). Body weight and condition score did not differ ($P > 0.44$). Milk lactose production was increased by Amylase ($P = 0.01$) and there was a trend for increased plasma glucose content ($P = 0.07$). Amylase decreased PUN (13.6 vs. 14.7, $P = 0.05$), and induced numerical increase in the relative rumen microbial yield and reduced the duration of the first daily meal and rumen pH, all suggestive of increased ruminal OM fermentation. Total tract digestibility of DM, OM, NDF, and starch were not responsive to the enzyme ($P > 0.41$). Exogenous amylase supplementation increased feed efficiency of dairy cows. The decrease in PUN suggests that the enzyme increased ruminal starch degradation, without affecting total tract nutrient digestibility.

Key Words: amylase, starch, corn

T83 Effects of single or pulse dose of sugar on in vitro DMd and NDFd digestibility of corn silage. D. N. Lobão da Silva*[1], R. S. Younker[2], and N. B. Litherland[1], *[1]University of Minnesota, Saint Paul, [2]Milk Specialties, Eden Prairie, MN.*

DaisyII incubator, (Ankom Technology, Fairport, NY) rotating jar-in vitro system is an inexpensive technique to measure feedstuff digestibility and has potential to serve as a screening tool to evaluate ruminant feeds and feed additives; however, in vitro systems may better mimic natural feeding conditions through pulse dosing of test compounds. The objectives of this study were to evaluate the usage of rotating jar system using one or three pulse doses, and determine the effects of supplementing in vitro rumen culture with commercially available sugar supplement, on 30 h %IVDMd and %IVNDFd of corn silage (CS) with 38.0% NDF, 8.1%CP and 31.6% starch. In the first experiment, 1.3 g of RUMIN8 (R) per 400ml of rumen fluid using a single dose (R1) or three pulses doses (R3) and no sugar supplementation (C1) were evaluated. In the second experiment, 2.1g of 6 types of sugars (R), lactose (L), sucrose (S), molasses (M), whey permeate (W) and corn syrup solids (CSS) were evaluated. Amounts of 1.3g and 2.1g of sugar were calculated to represent in vivo diet inclusions of 0.7% and 1.0% of diet DM /cow/day. In both experiments, replicate samples were placed in Dacron bags and incubated in two Daisy II incubators. Data was analyzed using the MIXED procedure of SAS as completely randomized design. In the first experiment, IVDMD was similar ($P = 0.37$) among treatments and averaged 78.6, 79.5 and 77.76 ± 0.8% and IVNFDd was similar ($P = 0.45$) 39.4, 42.3, and 37.6 ± 2.7% for C1, R1, and R3, respectively. In the first experiment, results suggest that increased dosing frequency of Rumin8 did not increase %IVDMd or %IVNFDd of CS compared to C1. In the second experiment, L and S improved IVDMd ($P < 0.01$) by 4

and 3.5%, respectively compared with C, R, M, W and CSS (75.1, 75.0, 74.8, 76.8, 75.0 ± 0.7%). Also, L and S increased ($P < 0.01$) IVNDFd by 12.7 and 10.8% respectively compared with C, R, M, W and CSS (32.5, 32.1, 31.4, 34.3, 31.4 ± 2.0%). In vitro incubations of CS with sugar supplementation suggested that L and S greatly improve digestibility of DM and NFD compared with C, R, M, W and CSS.

Key Words: fiber digestibility, sugar, corn silage

T84 Feeding of a sugar alcohol during summer months to Holstein cows during transition phase to support subsequent lactation performance. J. A. Davidson*, C. M. Klein, and B. L. Miller, *Purina Animal Nutrition Center, Gray Summit, MO.*

The objective was to determine if a sugar alcohol (Rally) improves milk and component yield of transition cows during the summer months. Holstein cows (44 multiparous and 18 primiparous) were blocked by calving date (June 22 to Sept 4, 2010 and June 20 to Aug 28, 2011) and randomly assigned to dietary treatments of control (C) or sugar alcohol (R) from d -28 to 30 relative to parturition. Individual cows were fed with Calan doors once a day, ad libitum, and diets were formulated to be iso-nitrogenous and iso-caloric. On d 30 postpartum, all cows were fed the same diet. Within the free-stall housing, cows were provided with thermostat-controlled fan cooling only. During the treatment period of d -28 to 30 d, cows experienced environmental temperature humidity index readings greater than 68 for 91.1% of the time. During the prepartum, dry matter intake (DMI) and body weight (BW) were not different. From 0 to 30 DIM, milk yield was greater for R fed cows compared with C (32.5 vs 30.2 kg/d, SE = 0.78, $P < 0.05$). Cows fed R had greater DMI of 1.26 kg relative to C fed (SE = 0.39, $P < 0.05$). Cows fed R had lower milk fat (%) during the first 30 d postpartum than C fed cows with the greatest difference occurring during the first week postpartum ($P < 0.01$). However, component yields were not significantly different. Multiparous cows had greater improvement in milk yield compared with primiparous cows. For 0 to 21 DIM, multiparous cows fed R had lower plasma non-esterified fatty acid concentrations than C fed cows (0.79 vs. 0.93 meq/L, SE = 0.05, $P = 0.07$). Additionally, plasma β-hydroxybutyrate concentrations were also lower (7.6 vs 10.5 mg/dL, SE = 0.61, $P < 0.01$). From d 0 to 60 postpartum, multiparous cows fed R during transition phase produced an additional 2.9 kg/d of milk and consumed an additional 1.6 kg/d of DMI compared with C. When feeding R, cows had lower circulating metabolites and milk fat (%) immediately postpartum may be indicative of changes of metabolism by peripheral tissues. Feeding R during warm seasons improved transition cow milk yield and DMI which may lead to better performance for the entire lactation during the cooler seasons.

Key Words: Rally, cows, lactation

T85 Relationships between circulating plasma amino acid concentrations and milk protein production in lactating dairy cows. R. A. Patton*[1], H. Lapierre[2], and C. Parys[3], *[1]Nittany Dairy Nutrition Inc., Mifflinburg, PA, [2]Dairy and Swine Research and Development Centre, Agriculture and Agri-Food Canada, Sherbrooke, Quebec, Canada, [3]Evonik Industries AG, Hanau, Germany.*

Better understanding of the relation between amino acid (AA) supply and milk protein output may increase protein efficiency. Direct measurements of the digestive AA flow require invasive, expensive experiments. Plasma AA concentrations ([AA]) might be used as surrogates to investigate relationships between AA supply, requirement and milk protein output. A database was developed after a literature search to identify studies in lactating dairy cows reporting circulating plasma [AA], production data, and adequately described rations. A total of 105 studies representing 420 diets were used. Using the AminoCow ration program, duodenal AA flow and metabolizable protein (MP) were estimated. Relationships were evaluated using multi-factorial regression (JMP 10 version of SAS) including study as a random factor. Plasma [Arg] was greater for first parity compared with greater parities. Plasma [AA] was most significantly related to predicted duodenal AA flow: Arg, Ile, Lys, Thr, and Val were related quadratically whereas His, Met and Phe were related linearly to their respective duodenal flow. Highest correlation between duodenal and plasma [AA] was for Arg ($R^2 = 0.90$) and the lowest was for Met ($R^2 = 0.69$). Associations of [AA] with milk protein % (MlkP%) or milk protein yield (MlkPY) were similar whether AA were expressed as plasma [AA], AA duodenal flow (duo: g/d or % of MP).

MlkP% (mean: 3.15%)

= 2.77 + (0.083 × Metduo, %MP) + (0.032 × Lysduo, %MP); RMSE = 0.136; $R^2 = 0.81$

= 3.3437 + (0.0036 × Metduo, g/d) – (0.0028 × Thrduo, g/d); RMSE = 0.139; $R^2 = 0.81$

= 3.17 + (0.0016 × [Lys], μ*M*) – (0.0028 × [Phe], μ*M*); RMSE = 0.140; $R^2 = 0.81$

MlkPY (mean = 0.908 kg/d)

= 0.942 – (0.071 × Thrduo, %MP) + (0.050 × Hisduo, %MP) + (0.029 × Argduo, %MP) + (0.015 × Lysduo, %MP); RMSE = 0.050; $R^2 = 0.94$

= 0.5270 + (0.0018 × Thrduo, g/d) + (0.0007 × Lysduo, g/d); RMSE = 0.050; $R^2 = 0.95$

= 0.8072 + (0.00081 × [Lys], μ*M*) + (0.00016 × [Val], μ*M*); RMSE = 0.050; $R^2 = 0.94$.

Relationships were stronger for MlkPY than for MlkP%. These preliminary results suggest that circulating [AA] could be useful in adequately modeling AA requirements.

Key Words: amino acid, concentration, milk protein yield

T86 Hepatic gene expression and post-ruminal protein supply in lactating dairy cattle. H. Tucker*[1], M. Hanigan[2], and S. Donkin[1], *[1]Purdue University, West Lafayette, IN, [2]Virginia Polytechnic Institute and State University, Blacksburg.*

Metabolizable protein supply limits milk production in dairy cows. Amino acid (AA) availability to extrahepatic tissues, including mammary tissue, is a combined function of the quantity of metabolizable protein supplied and hepatic AA catabolism. The latter is determined by nutrient supply and physiological status. This experiment evaluated the effect of post-ruminal protein infusion on key genes for ureagenesis and amino acid catabolism. Six multiparous early-lactation Holstein cows were utilized in a replicated cross-over design. Cows were fed a TMR (14.5% CP) and given postruminal infusion of either 0 or 600 g/d of milk protein isolate. Periods were 21 d in length consisting of a 14-d washout phase followed by 7 d of protein infusion. On the last day of each infusion, liver samples were collected for mRNA analysis and explant culture, milk samples were collected for mRNA analysis and blood samples were collected for plasma metabolite analysis. Postruminal infusion of protein increased ($P < 0.05$) milk yield by 10.5%, milk fat yield by 12.5%, milk protein yield by 20%, milk lactose yield by 11%, and total solids by 15.5%. Postruminal infusion of protein increased ($P < 0.05$) milk urea N by 23.5%, blood urea N by 18.6%, and abundance

of ornithine transcarbamoylase mRNA by 52.8%. Postruminal infusion of protein did not alter ($P > 0.1$) abundance of argininosuccinate synthase, aminoadipate semialdehyde synthase, cysteine sulfinic acid decarboxylase, cystathionase, and associated milk protein synthesis mRNA. Postruminal protein infusion increased ($P < 0.05$) metabolism of L-[U ^{14}C] Lys to CO_2 by 127% (0.14 vs. 0.063 ± 0.05 nmol substrate converted to CO_2 · mg tissue^{-1} · h^{-1}) while metabolism of L-[U ^{14}C] Ala to CO_2 tended ($P < 0.1$) to be greater (0.52 vs. 0.37 ± 0.06 nmol product · mg tissue^{-1} · h^{-1}) compared with control. These data indicate increased ureagenesis matched by up-regulation of non-essential AA catabolism and a disproportional increase in Lys oxidation in response to increased postruminal protein infusion in lactating dairy cows.

Key Words: protein, gene expression, postruminal protein infusion

T87 Kelp meal (*Ascophyllum nodosum*) did not improve milk yield but increased milk iodine in early lactation organic Jersey cows during the winter season. N. T. Antaya*, A. F. Brito, N. L. Whitehouse, N. E. Guindon, and S. Werner, *University of New Hampshire, Durham.*

Kelp meal (KM) made from dry and ground *Ascophyllum nodosum*, a brown algae, is often fed as a mineral supplement on northeastern organic dairy farms. Sixteen (4 primiparous and 12 multiparous) organic Jersey cows with initial BW of 444 kg (SD ± 46) and DIM of 49 (SD ± 30), were blocked by DIM and parity and randomly assigned to 4 replicated 4 × 4 Latin squares to investigate the effects of incremental dietary levels of KM (0, 57, 113 or 170 g, as fed) on milk yield and composition. Periods lasted 21 d with 14 d for diet adaptation and 7 d for data and samples collection. Data were analyzed using the MIXED procedure of SAS with linear and quadratic contrasts. Cows were fed a TMR containing: (DM basis) 64% alfalfa/grass baleage and 36% of a cornmeal/barley/soybean meal-based concentrate. TMR averaged: 16% CP, 49% NDF, and 34% ADF. To ensure complete consumption, KM was mixed with 227 g concentrate and fed after the a.m. milking, cows on the control treatment (0 g KM) received concentrate only. Feeding incremental levels of KM to early-lactation cows did not affect milk yield, DMI, or concentrations and yields of milk components. However, concentration of milk iodine increased lineally in response to incremental levels of KM, possibly explained by high content of iodine (820 mg/kg DM basis) in this brown algae supplement. Kelp meal did not improve animal performance or milk composition but increased milk iodine to levels that may be of concern to human health, particularly children. Results also suggest that KM may not be a cost effective supplement for organic dairy farms.

Table 1. Effects of kelp meal on milk yield and composition.

	Kelp meal					*P*-value	
	0 g	57 g	113 g	170 g	SED	Linear	Quadratic
Milk yield, kg/d	16.3	16.2	16.4	15.8	0.37	0.27	0.24

T88 Influence of maize kernel maturity on chemical characteristics, prolamin content, and in vitro starch digestion. . W. J. Seglar*, M. Pauli, A. Patterson, L. Nuzback, and F. N. Owens, *DuPont Pioneer, Johnston, IA.*

As an indicator of starch digestion, commercial laboratories measure in vitro starch disappearance of ground grain incubated for 7 hours (7HSD). As kernels mature, this index has been reported to decrease while prolamin content has been suggested to increase. Both presumably are correlated with kernel density. In trials in 2011 and 2012, we examined the relationships between kernel maturity (half-milk line, near black layer, and at full maturity) and density by gas pycnometer, chemical composition, and 7HSD using grain from 5 (2011) or 6 (2012) commercial Pioneer hybrids grown at 79K/hectare at each of two locations (central and southern Wisconsin). 7HSD and chemical composition were determined at a commercial laboratory. Differences among hybrids and years were detected ($P < 0.01$) for all chemical measurements except for NDF and ash; year by hybrid interactions were detected for 7HSD, prolamin, and starch. With kernel maturation, kernel weight increased stepwise (by 32 and 10% in 2011; 19 and 1% in 2012) while 7HSD percentages decreased slightly in 2011 (73% vs. 75%; $P < 0.05$) but increased slightly in 2012 (70% vs. 65%; $P < 0.05$). At the growing location with higher N fertility, protein and prolamin content of kernels were greater ($P < 0.05$). Within individual years, specific gravity was correlated with prolamin in 2011 (r = 0.63; $P < 0.01$) but not in 2012 (r = −0.15); 7HSD was poorly correlated with prolamin (r = −0.11 in 2011; r = −0.03 in 2012) across all samples but these two factors were correlated more strongly within kernel maturity groups (r = −0.3 to −0.51). The factor related most closely related ($P < 0.01$) to prolamin content was crude protein content of grain (r = 0.91 in 2011; r = 0.55 in 2012). For the hybrids, locations, and kernel maturities tested, kernel maturation failed to increase prolamin content or the prolamin:starch ratio. Neither reliably predicted 7HSD indicating that factors beyond hybrid and maturity were altering these measurements.

Key Words: prolamin, starch digestion, maize

T89 Range in starch content and digestibility of common starch sources in US and Japan and their effect on in vitro microbial biomass production when incorporated into total mixed rations. K. W. Cotanch*[1], H. M. Dann[1], J. W. Darrah[1], R. J. Grant[1], Y. Koba[2], and K. Hirano[2], *[1]William H. Miner Agricultural Research Institute, Chazy, NY, [2]ZEN-NOH National Federation of Agricultural Cooperatives, Tokyo, Japan.*

New methods have been developed to assess fermentability of starch sources including enzymatic digestion at 7 h (Cumberland Valley Analytical Services, Hagerstown, MD) and in vitro measurement of ruminal microbial biomass production (MBP; Fermentrics, Dairyland Labs, Arcadia, WI). The objective of this project was to evaluate the range in starch content, starch digestibility (starch-D), and MBP when common starch sources fed in the US and Japan are incorporated into total mixed rations (TMR). Descriptive statistics were applied to the database to evaluate mean values and ranges. Samples of grains were obtained from across the US, Canada, and Japan (rice only) that included: fine/medium corn (n = 20), flaked corn (n = 12), barley (n = 13), wheat (n = 12), and rice (n = 9). The mean and range of starch content (% of DM) plus 7-h enzymatic starch-D (% of starch) were determined (table). Rations based on corn silage (24.6% corn silage and 30.3% haycrop silage, DM basis), haycrop silage (49.7% haycrop silage), and dry hay (19% alfalfa hay, 16% timothy hay, and 7.6% oat hay) were formulated to contain similar starch content using

each starch source. For corn silage and hay-based TMR, ground rice grain resulted in highest MBP (182 and 188 mg/g, respectively, with range across diets of 137-182 and 130-188 mg/g) whereas for haycrop silage-based TMR fine ground corn resulted in the greatest MBP (141 mg/g with range across diets of 121-141 mg/g). These in vitro measures indicate that starch sources influence fermentation differently depending on the forage base. Existing feed databases used in ration formulation models may be updated with these starch digestibility and in vitro MBP values.

Table 1.

	Starch, % of DM		Starch-D, % of starch		MBP,
Grain	Mean	Range	Mean	Range	mg/g
Fine/medium corn	73.2	71.4 – 75.8	51.3	44.9 – 56.4	186
Flaked corn	74.5	72.2 – 77.3	52.7	40.3 – 63.0	266
Ground barley	59.7	55.3 – 63.9	57.4	46.2 – 62.4	248
Whole rice	79.7	77.3 – 82.2	16.8	13.5 – 18.0	332
Ground wheat	67.7	66.4 – 69.8	59.7	55.4 – 62.5	238

Key Words: digestibility, forage, starch source

T90 Kelp meal (*Ascophyllum nodosum*) did not improve milk yield or mitigate heat stress but increased milk iodine in mid lactation organic Jersey cows during the grazing season. N. T. Antaya*[1], A. F. Brito[1], K. J. Soder[2], N. L. Whitehouse[1], N. E. Guindon[1], A. D. B. Pereira[1], and C. C. Muir[1], *[1]University of New Hampshire, Durham, [2]USDA-ARS, Pasture Systems and Watershed Management Research Unit, University Park, PA.*

Kelp meal (KM) made from dry and ground *Ascophyllum nodosum*, a brown algae, is often used as a mineral supplement on northeastern organic dairy farms. Twenty (12 primiparous and 8 multiparous) organic Jersey cows with an initial BW of 410 kg (SD ± 39) and DIM of 135 (SD ± 52) were blocked by milk yield and parity. Cows were randomly assigned to treatments (0 or 113 g KM as fed) to examine the effects of KM supplementation on milk yield, milk components, plasma metabolites, and indicators of heat stress. The study lasted from June to October 2012 with 4, 28- d periods with the last 7 d used for data and sample collection. Data were analyzed using the MIXED procedure of SAS with repeated measures over time. Cows had access to mixed mostly cool-season grass pasture for 16 h daily, which was managed using rotational strip grazing. Cows were supplemented a TMR made (DM basis) of 51% grass-legume baleage, 47% concentrate, and 2% liquid molasses fed via Calan doors. Kelp meal had no impact on milk yield, components or heat stress indicators. However, concentration of milk iodine was 77% higher in KM fed cows than those fed no KM, which is explained by the high concentration of iodine (i.e., 820 mg/kg DM basis) found in brown algae. No KM effects were seen for plasma cortisol, NEFA, and thyroxine (T_4); a trend for lower plasma triiodothyronine (T_3) was found in KM cows, likely as a result of higher iodine intake. Kelp meal did not improve milk yield or mitigate heat stress but increased milk iodine, which may be of concern to human health, particularly children.

Table 1. Effects of kelp meal on milk yield, plasma metabolites, and heat stress indicators

	Kelp meal			
	0 g	113 g	SED	*P*-value
Milk yield, kg/d	12.4	13.0	0.90	0.56

T91 Effects of partial replacement of corn grain with alkaline pretreated corn stover on production of lactating dairy cows. D. E. Cook*[1], M. J. Cecava[2], P. H. Doane[2], M. B. Hall[3], and D. K. Combs[1], *[1]University of Wisconsin-Madison, Madison, [2]ADM Research, Decatur, IL, [3]USDA-ARS, US Dairy Forage Research Center, Madison, WI.*

The fiber digestibility of corn crop residues can be improved by pretreatment with calcium oxide (CaO). The objective of this study was to evaluate how intake and milk production was affected when corn grain was replaced with CaO-treated corn stover. Corn stover was pretreated with CaO (50 g CaO kg^{-1} stover DM in 500 g H_2O kg^{-1} stover DM) at ambient conditions. Sixty-three Holstein dairy cows (101 ± 29 DIM, 39.2 ± 2.4 kg milk d^{-1}) were fed diets containing treated corn stover at 0, 40, 80, 120 g stover DM kg^{-1} TMR. The design of the study was a randomized complete block utilizing a 14-d covariate period, followed by a 6 wk experimental period. Cows were blocked by DIM and parity. Body weight change was not affected by treatment. DMI decreased linearly ($P < 0.01$) with each level of stover inclusion, (Table 1). Milk production as well as fat and protein production ($P < 0.01$ for all) also declined linearly with increasing levels of stover inclusion. Energy-corrected milk (ECM) decreased linearly ($P < 0.01$) from 47.6 kg d^{-1} to 40.7 kg d^{-1}. Stover inclusion had no effect ($P > 0.6$) on feed conversion rate as measured by ECM divided by DMI (1.766 ± 0.14). Overall, in high producing dairy cows, replacement of corn grain with treated stover caused a decline in DMI and milk yield.

Table 1.

	Stover inclusion (g stover DM kg^{-1} TMR DM)				
	0 (n = 16)	40 (n = 16)	80 (n = 16)	120 (n = 15)	SEM
DMI (kg d^{-1})	26.7	25.8	24.3	23.5	0.2
Milk (kg d^{-1})	42.2	40.8	39.4	36.9	0.4
Fat (kg d^{-1})	1.79	1.71	1.60	1.51	0.04
Protein (kg d^{-1})	1.32	1.24	1.17	1.11	0.02

Key Words: calcium oxide, stover, treated stover

T92 Effects of dietary starch content and NDF source on intake and milk production by dairy cows. S. M. Fredin*, L. F. Ferraretto, M. S. Akins, and R. D. Shaver, *University of Wisconsin, Madison, WI.*

An experiment was conducted to evaluate the effects of dietary starch concentration and source of NDF on intake, ruminal fermentation, and milk yield, composition and component yields. Eight ruminally-cannulated multiparous Holstein cows (193 ± 11 d in milk at trial initiation) were randomly assigned to treatments in a replicated 4 × 4 Latin square design with 21-d periods. Treatment TMR were high corn grain (HCG; 38% corn silage, 19% dry ground corn and 4% soy hulls), high soy hulls (HSH; 38% corn silage, 11% dry ground corn, 13% soy hulls), high corn silage (HCS; 50% corn silage, 6% dry ground corn, and 4% soy hulls) and low corn silage (LCS; 29% corn silage, 15% corn, and 19% soy hulls). The HCG, HSH, HCS, and LCS diets contained 29, 23, 24, and 22% starch, 27, 32, 30, and 32% NDF, and 21, 21, 25, and 17% forage NDF, respectively. During each period milk samples were obtained from a.m. and p.m. milkings on d 16 and 17 and rumen fluid four times daily at 2-h intervals on d 18-20 such that the samples represented a 24-h feeding cycle. Data were analyzed using the MIXED procedure of SAS. Mean DMI (24.9 kg/d) and milk yield (36.0 kg/d) were unaffected by treatment. Cows fed LCS had reduced milk fat percentage (3.54%; $P = 0.02$) compared with HSH and HCS (3.85 and 4.00%, respectively). Mean milk fat yield (1.33 kg/d), milk protein percentage (3.29%), and protein yield (1.16 kg/d) were unaffected by treatment. Milk urea nitrogen concentration was greater for HCS (19.8 mg/dL; $P = 0.0001$) compared with the other treatments (mean = 16.1 mg/dL). Rumen ammonia concentration was lower for HCG and LCS (9.6 and 8.0 mg/dL; $P = 0.001$) compared with HCS (12.1 mg/dL). Rumen pH was greater for cows fed HCS (6.25; $P = 0.007$) compared with cows fed LCS (6.04). Feeding a diet with corn silage NDF partially replaced by soy hulls NDF reduced milk fat percentage and rumen pH.

Key Words: dairy cow, NDF, starch

T93 Metabolic profile and onset of puberty of growing dairy heifers fed increased dietary fat from dried distillers grains. J. L. Anderson*[1], K. F. Kalscheur[1], J. A. Clapper[1], G. A. Perry[1], D. H. Keisler[2], A. D. Garcia[1], and D.J. Schingoethe[1], *[1]South Dakota State University, Brookings, [2]University of Missouri, Columbia.*

The objective of this trial was to determine if feeding increased dietary fat from dried distillers grains with solubles (DDGS) to growing dairy heifers affects metabolic profiles and onset of puberty. Thirty-three Holstein heifers (133 ± 18 d old) were fed one of three diets in a 24-wk randomized complete block design. Diets were: 1) control (C) that contained 15.9% (DM basis) ground corn and 17.9% soybean products, 2) low-fat (LFDG) that contained 21.9% reduced-fat DDGS and 11.9% ground corn, and 3) high-fat (HFDG) with 33.8% traditional DDGS. All diets contained 39.8% grass hay, 24.8% corn silage, and 1.5% vitamins and minerals. Although, diets were isonitrogenous and isocaloric, HFDG was formulated to contain 4.8% fat versus 2.8% in C and LFDG. Every 4 wk, jugular blood samples were collected for metabolites and metabolic hormones analysis. When heifers weighed between 200 and 300 kg of body weight (BW), coccygeal vein blood samples were taken two times per wk for progesterone analysis to estimate puberty. Plasma NEFA was similar among treatments ($P = 0.63$) and over time ($P = 0.67$). Plasma BHBA, insulin, IGF-1 and leptin were similar ($P > 0.10$) among treatments, but increased ($P < 0.05$) over time. Serum glucose tended ($P = 0.06$) to be less in heifers fed HFDG compared to C. Plasma urea nitrogen (PUN) was less ($P = 0.03$) in LFDG-fed heifers compared to other treatments and increased ($P < 0.01$) over time in all. Plasma total cholesterol was greater ($P < 0.01$) in heifers fed HFDG compared to other diets. Because cholesterol increased markedly in heifers fed HFDG, but remained more stable in the LFDG and C fed heifers, there were effects of time ($P < 0.01$) and treatment × time ($P = 0.02$). Based on progesterone analysis, 81.8% of heifers fed HFDG were pubertal at < 300 kg of BW compared to 36.4 and 27.3% in C and LFDG, respectively ($P = 0.03$). These findings provide evidence that dietary fat from DDGS can be used in replacement of starch from corn in diet of growing dairy heifers and maintain energy status. Feeding increased fat from DDGS may decrease the body weight at puberty.

Key Words: dairy heifer, distillers grains, metabolic profile

T94 Lactation performance of cows fed soybean meal or canola meal supplements. F. E. Contreras-Govea*[1], S. Bertics[1], G. A. Broderick[2], A. Faciola[3], and L. E. Armentano[1], *[1]University of Wisconsin-Madison, Department of Dairy Science, Madison, [2]US Dairy Forage Research Center, Madison, WI, [3]University of Nevada, Department of Agriculture, Nutrition, and Veterinary Sciences, Reno.*

Performance of mid lactation-Holstein cows fed diets with 17.3% CP based on soybean meal (SBM) or canola meal (CM) was determined. Sixty four cows were housed in a free stall barn equipped with 32 Insentec electronic feeding gates (RIC systems; Insentec BV, Marknesse, the Netherlands). Each gate allows access by one or more selected cows and record individual daily DMI. The SBM diet was assigned randomly to 16 gates, and 32 cows (16 multiparous and 16 primiparous) were assigned randomly to these 16 gates. The additional 32 cows were assigned to the other 16 gates and fed CM. Cows within a diet had access to all 16 gates with that diet, and cow was considered the experimental unit. For 21 d, all cows received a common diet and covariate measurements were obtained. Cows were then fed their treatment diet for the next 63 d. Treatment diets (dry matter basis) were 25.7% alfalfa haylage, 31.6% corn silage, corn grain (24.0% for CM diet, 27.2% for SBM diet), and either 16.5% CM or 13.3% SBM. Cows were milked twice daily and yields were recorded for 84 d. Cow were weighed weekly. Milk composition was determined for two consecutive milkings weekly. Covariately adjusted data were analyzed as a complete randomized block design with cow within treatment and parity as the subject for weekly repeated measurements. Cows fed CM had greater intake (28.4 vs. 23.6 kg DM/d), and yield of milk (39.0 vs. 36.2 kg/d), milk fat (1.44 vs. 1.36 kg/d), milk protein (1.24 vs. 1.15 kg/d), and milk lactose (1.93 vs. 1.78 kg/d), but observed feed efficiency was lower for cows fed CM (1.38 vs. 1.55 kg milk yield/kg intake; all $P < 0.05$). Body weight increased across weeks ($P < 0.05$), but diet by week interaction was not significant ($P = 0.678$) and condition score observations did not reveal an obvious energy balance difference due to diet. The predicted undiscounted TDN for the CM and SBM diets were 71% and 73%, and energy allowable 3.5% fat corrected milk was 47.2 and 39.4 kg/d for CM and SBM. The measured intake differences are larger than expected even considering the greater milk yield and lower predicted energy density of the CM diet.

Key Words: canola, protein, soybean

T95 Utilization of byproducts from human food production as feedstuffs for dairy cattle and relationship to greenhouse gas emissions and environmental efficiency. K. L. Russomanno, T. F. Christoph, R. J. Higgs, and M. E. Van Amburgh*, *Cornell University, Ithaca, NY.*

The objective of this study was to use survey data collected from nutritionists representing significant regions of dairy production to evaluate the methane (CH_4) and carbon dioxide (CO_2) production per unit of dietary byproducts fed. The data included a complete set of diet ingredients, including chemical analysis of individual ingredients and a complete diet summary. In addition, values for group average body weight (BW), dry matter intake (DMI), milk yield (kg), and milk fat and protein concentrations were provided. Ninety-one diets from seventy different farms representing ten different states were compiled, and included a range of different byproducts (e.g., soy hulls, distillers grains, almond hulls), forages, protein feeds, and minerals. The average byproduct concentration in the diets was 31.3% DM with a range of 12.7% and 56.7%, DM. Data were evaluated in the Cornell Net Carbohydrate and Protein System v6.1 (CNCPS; Tylutki et al., 2008, Van Amburgh et al., 2010). Equations for enteric CH_4 and CO_2 emissions were incorporated into the CNCPS from Mills et al., (2003) and Casper and Mertens, (2010), respectively. Total emission of CO_2 per cow was positively related to total milk yield ($R^2 = 0.69$). However, CO_2 emissions per kg of milk yield (kg CO_2/kg milk) resulted in a negative relationship, ($R^2 = 0.81$). The average CO_2 emission per unit of milk yield was 0.353 kg CO_2/kg milk, with minimum and maximum values of 0.283 kg and 0.423 kg, respectively. The mean prediction of CO_2 (kg) per kg of byproducts was 0.05 and the correlation between CO_2 emission and inclusion of byproduct as a proportion of the total DMI was high ($R^2 = 0.81$). CH_4 emissions per kg DMI ranged from 0.021 kg to 0.027 kg with a mean of 0.024 kg CH_4/kg milk. Total CH_4 emissions were positively correlated with milk yield (slope = 0.004; $R^2 = 0.68$) but CH_4 kg/kg milk was negatively correlated (slope = −0.26; $R^2 = 0.88$) similarly to CO_2. Use of byproducts in diets for dairy cattle reduces the environmental impact of human food production and enhances the efficiency of the dairy industry.

Key Words: byproduct, dairy, greenhouse gas

T96 The effects of different ratio of metabolizable protein to metabolizable energy on dry matter intake, average daily gain, and nutrient digestibility in Holstein heifers. H. R. Motalebei, M. Dehghan-Banadaky*, K. Rezayazdi, and H. Kohram, *Department of Animal Science, University of Tehran, Karaj, Tehran, Iran.*

The purpose of this study was to investigate the effects of different ratio of metabolizable protein (MP) to metabolizable energy (ME) on dry matter intake (DMI), average daily gain (ADG), feed efficiency and nutrient digestibility in Holstein heifers. In present experiment 24 Holstein heifers with a mean age of 7 months and the average weight of 217 kg were used. Heifers were randomly assigned to 3 rations: 1) ration which includes 10% metabolizable protein less than NRC (2001) (−10% NRC) 2) control ration which metabolizable protein based on NRC (2001) (NRC). 3) Ration with includes 10% metabolizable protein more than NRC (2001) (+10% NRC). Rice hull and soybean meal used for adjusting diets. Metabolizable energy in all rations was based on NRC requirements. DMI, ADG and feed efficiency were measured once every 14 days and digestibility once every 28 days. The nutrients digestibility was affected by rations ($P < 0.05$) and the nutrients digestibility were higher in ration 1 than rations 2 and 3, but no significant differences were observed in DMI, ADG and feed efficiency between rations. The results showed that by increasing the ratio of protein to energy metabolizable, nutrients digestibility decreased.

Table 1. Effects of different ratio of metabolizable protein to metabolizable energy on DMI, ADG, feed efficiency, and nutrient digestibility

	MP/ME (g/Mcal)				
Item	−10% NRC (31.14)	NRC (34.57)	+10%NRC (38)	*P*-value	SEM
DMI (kg)	6.18	6.20	6.19	NS	0.017
ADG (g)	827	842	817	NS	0.027
Feed efficiency	7.98	8.31	8.22	NS	0.31
Digestibility %					
Dry matter	67.79[a]	64.41[b]	60.31[c]	0.01	1.761
Crude protein	67.74[a]	63.25[b]	60.60[c]	0.007	1.592
Organic matter	69.39[a]	66.10[b]	61.41[c]	0.01	1.865

Key Words: heifer, digestibility, metabolizable protein

T98 Feeding 5-hydroxy-L-tryptophan (5-HTP) to transition rats increases serum serotonin (5-HT) and calcium and down-regulates mRNA expression of calcium transporters in the gut. C. Cronick*, J. Laporta, S. Weaver, and L. L. Hernandez, *University of Wisconsin, Madison.*

The absorption of calcium (Ca^{2+}) and role of serotonin (5-HT) in the gut are independently well-understood processes. Less clear is the effect of 5-HT on the absorption of Ca^{2+} by the gut during the transition from pregnancy to lactation. In order to better understand 5-HT's effect on Ca^{2+} dynamics in the gut during lactation we fed female rats two different diets: a control diet (CON, n = 15) and a diet supplemented with 5-hydroxytryptophan (5-HTP, 0.2% of total diet, n = 15), the immediate precursor for 5-HT synthesis, from d13 of pregnancy through d9 of lactation. We collected serum on d1 and 9 of lactation to measure circulating 5-HT and Ca^{2+} concentrations, and also measured Ca^{2+} concentration in the milk. Rats were euthanized on d9 of lactation and gut samples were collected. mRNA expression of tryptophan hydroxylase 1 (TPH1), 5-HT reuptake transporter (SERT), plasma membrane Ca^{2+} ATPase 1 (PMCA1), Na^{+}-Ca^{2+} exchanger 1 (NCX1), transient receptor potential cation channel, subfamily V, member 6 (TRPV6), voltage-dependent Ca^{2+} channel ($Ca_v1.3$), and Ca^{2+} binding protein calbindin-D_{9K} (CalbD9k) were measured by real-time RT-PCR. Serum 5-HT was elevated on d 1 (4.7± 0.39 ng/mL vs. 1.83 ± 0.26) and d9 (8.3 ± 0.7 vs. 3.4 ± 0.25 ng/mL) of lactation in the 5-HTP compared to CON dams. On d 1 of lactation 5-HTP dams had increased serum Ca^{2+} concentrations compared to CON ($P = 0.0085$), while no significant changes in milk Ca^{2+} were observed. On d9 of lactation 5-HTP dams had similar serum Ca^{2+} concentrations to the CON dams, but demonstrated increased milk Ca^{2+} concentrations ($P = 0.032$). Gut mRNA expression of SERT and TPH1 was decreased in 5-HTP dams compared to CON ($P < 0.041$). Gut mRNA expression of all Ca^{2+} transporters evaluated were decreased in 5-HTP dams compared to CON ($P < 0.05$). It is probable that during lactation the gut decreases 5-HT synthesis and reuptake as well as expression of Ca^{2+} transporters, because the mammary gland is increasing production of 5-HT and transport of Ca^{2+} into the milk to provide adequate nutrition to the neonate.

Key Words: serotonin, gut, calcium

T99 Mammary clock regulation and function. E. Erickson*, J. Crodian, M. Schutz, T. Casey, and K. Plaut, *Purdue University, West Lafayette, IN.*

Most physiological processes, including lactation, are controlled by the circadian system, which coordinates growth, development, and metabolism to optimal times of day through generation of circadian rhythms. Approximately 10% of genes expressed show circadian rhythms that are generated by interactions of molecular clock genes (e.g., *Clock*, *Bmal1*, *Per1*). BMAL1-CLOCK heterodimers function as a transcription factor that binds E-box sequences in promoters of clock controlled genes. Little is known about how mammary clock is regulated or what genes it controls. We hypothesize mammary clock is regulated by lactogenic hormones and it regulates genes important to mammary development and milk synthesis. Our objectives were to (1) Determine effects of lactogenic hormones on circadian rhythms of molecular clock genes *Bmal1* and *Per1* in mouse mammary epithelial cells, HC-11; and (2) knock down CLOCK to measure effects on *Per1* and cell cycle gene, cyclin D1 (*Ccnd1*) expression. HC-11 cells were grown to confluence, treated for 2h with RPMI media + 10% calf serum ± lactogens (5 µg/mL insulin, 2 µg/mL prolactin, 40 ng/mL dexamethasone), after which RNA was collected every 4 h for 48 h to capture circadian gene expression. Q-PCR analysis showed lactogens induced 24-h rhythms of *Bmal1* and *Per1* expression and a 2.5-fold increase in *Bmal1* rhythm amplitude (i.e. peak-trough); 2-way ANOVA revealed significant time and treatment effects ($P < 0.05$). For the second objective, HC-11 cells were transfected with shRNA plasmids with insert mouse *Clock* sequence I [AAACCCACATTCCTTAGTAAT] or II [ATCAAACCCTGGATTGAATTT]; a negative control was transfected with plasmid insert sequence: ggaatctcattcgatgcatac. Eighteen clonal cell lines were created through dilution and lines with sequence I or II insert were selected based on greatest *Clock* knockdown. Cells were synchronized by RPMI + 10% calf serum media change and RNA was isolated 4 h later. Q-PCR analysis revealed the 40% knock down of Clock by sequence I and the 42% knock down by II was associated with 70% and 35% knock down of Per1 and a 2.3-fold or 1.8-fold induction of *Ccnd1,* respectively. Data suggest lactogens regulate mammary clock, and mammary clock may regulate *Ccnd1*.

Key Words: lactation, mammary, circadian

T100 Potential for compost bedded pack barns in sustainable organic dairy farming systems. H. A. Mussell*[1], J. L. Taraba[2], and J. M. Bewley[1], *[1]University of Kentucky, Department of Food and Animal Sciences, Lexington, [2]University of Kentucky, Agricultural Engineering, Lexington.*

When managed properly, compost bedded pack barns (CBP) are an excellent housing alternative for dairy cows. Although most CPB barns have been constructed for conventional dairies, these barns fit within the spirit of organic dairy farming by relying on a natural process (composting) to produce a comfortable environment for lactating dairy animals that maximizes cow comfort and longevity and minimizes mastitis and other health problems. These barns provide more freedom for cows to move around or lie down as compared to stall based dairy facilities. The composting process increases the bedding temperature to control disease-causing microorganisms and decreases the bedding moisture by increasing the drying rate. Additionally, CBP barns serve as an area for manure storage and reduce the volume and frequency for manure application to fields. The objective of this study was to examine cow and pack performance metrics within three Kentucky organic dairy farms housing cows in CBP barns. Temperatures (0.1, 0.2, and 0.3 m below pack surface) and bedding samples were collected three times from nine different locations within each barn. Samples were collected at each farm for moisture content and nutrient analysis. Forty cows per farm were scored for hygiene and locomotion at each visit. Mean pack temperature at 0.30 below the pack surface was 27.79 °C ± 12.03. These temperatures were lower than the recommended range of 43 to 65°C. Two of the three farms were not consistently tilling their packs, which may have contributed to the lower temperatures observed during these visits. Mean moisture was 57 ± 7%, within the recommended range of 50 to 60%. Mean C:N ratio was 32:1, higher than the ideal range of 25:1 to 30:1. Mean locomotion and hygiene scores were 1.54 ± 0.28 and 1.72 ± 0.55, respectively, demonstrating that cows managed in organic

dairy compost bedded pack barns can be sound and clean. Compost bedded pack dairy barns could meet the farmer, land and cow needs of organic dairy operations.

Key Words: compost bedded pack barns, cow comfort, organic

T101 Effects of microbial fermentation products on milk production in dairy cows during heat stress. R. M. Wagner*[1], S. I. Kehoe[1], and D. DuBourdieu[2], *[1]University of Wisconsin-River Falls, River Falls, [2]R&D Lifesciences, Menomonie, WI.*

Heat stress is a problem that reduces milk production for dairy producers. The objective of this research was to determine the production benefits of feeding a combination microbial product containing fermentation products from *Bacillus subtilis*, *Trichoderma viride*, and *Aspergillus oryzae* (Lactomace; R & D Lifesciences, LLC, Menomonie, WI) during a summer heat wave. Two pens of lactating dairy cattle were matched in DIM and assigned to either a Control treatment with no microbial product (C) or a Microbial treatment (M) fed 5 gm/hd/day for the first 30 days and 10 gm/hd/d for the second 30 days. Daily milk yield and DMI and calculated 3.5% fat-corrected milk (FCM) and FCM:DMI ratio were recorded. Milk fat and protein % were collected from bulk tank samples after the first 30 d and 60 d. During data collection, heat index (HI) rose to an average of 32°C thereby causing significant heat stress. Data were analyzed using a paired TTest. During periods of high HI, from 29°C to 45°C, least squares means of FCM were significantly higher for the M group compared with C (42.41 ± 1.71 kg and 38.45 ± 1.71 kg, respectively). During this heat time frame, milk yield from C cows was reduced by 15% and M cows by 5% although least squares means were significantly higher for the C group (41.54 ± 1.85 kg and 39.25 ± 1.58 kg for C and M, respectively). The M group had significantly higher FCM:DMI ratios (0.78 ± 0.05 and 0.67 ± 0.05 kg FCM/kg DMI for M and C, respectively). Dry matter intake was not different between treatments (24.60 ± 1.62 kg and 25.26 ± 4.56 kg for M and C, respectively). During the high HI time frame, milk fat % increased in the M treatment compared with a decrease in C cows (+0.56% compared with −0.46% for M and C, respectively). Results of this study conducted on a commercial dairy farm in WI during summer months indicate that FCM is significantly increased with an increased FCM efficiency. These results indicate that supplementation of these fermentation byproducts may improve digestion and utilization of feedstuffs in the diet thus abating the effects of heat stress and supporting production.

Key Words: microbial product, heat stress, milk fat

T102 Effect of micellar casein concentrate fortification on the acidification, physical and rheological properties of nonfat Greek-style yogurt. D. D. Bong* and C. I. Moraru, *Department of Food Science, Cornell University, Ithaca, NY.*

The rising popularity of Greek-style yogurt (GSY) in recent years was one of the most remarkable changes in food production and sales in recent history. One factor that may limit growth of GSY is the production of large quantities of acid whey during the centrifugation step. The objective of this work was to develop and optimize an alternate make process for GSY, in which the desired level of protein is reached by fortification with micellar casein concentrate (MCC) instead of whey removal. The acidification, physical and rheological properties of GSY made by these two methods were evaluated and compared. MCC preparations with 2 levels of serum proteins (SP) (65% SP reduced and 95% SP reduced) obtained from milk by microfiltration were used as sources of protein. GSY with 9.80% protein made from unfortified skim milk using straining at 4°C was the control. Skim milk fortified with 65% and 95% SP reduced MCC to 9.80% protein was used in the alternate process. All samples were inoculated with GSY culture and fermented until pH 4.5.The experiment was repeated three times. Acidification was significantly faster ($P < 0.05$) for MCC fortified GSY than the control. Physical, rheological and acidification properties of MCC fortified GSY were determined after 24 hours storage at 4°C. Water holding capacity of MCC fortified GSY was significantly lower ($P < 0.05$) than the control, due to higher casein-to-whey protein ratio. Dynamic rheological analysis showed a weak frequency dependency of G′ for all samples, with G′ > G″ over the range of frequency tested, indicating that a weak gel network was formed in all samples. Differences ($P < 0.05$) in the magnitude of viscoelastic parameters between the two types of GSY were found, with G′ control > G″ fortified, which indicates a different magnitude of protein interactions in the two types of GSY. The apparent viscosity of all samples decreased as a function of increasing shear rate, indicating shear-thinning behavior, which fitted well the power law model. This study provides a basis for potential adoption of an alternate make process for GSY by the yogurt industry.

Key Words: Greek yogurt, micellar casein, rheology

T103 The effect of feed solids concentration and inlet temperature on the flavor of spray-dried whey protein concentrate. C. W. Park*[1], E. Bastian[2], B. E. Farkas[1], and M. A. Drake[1], *[1]North Carolina State University, Raleigh, [2]Glanbia Nutritionals Inc., Twin Falls, ID.*

Off flavors in whey protein negatively influence consumer acceptance of whey ingredient applications. Previous research has demonstrated that unit operations in whey protein manufacture, such as liquid storage and bleaching, promote off-flavor production in dried whey protein. The objective of this study was to determine the effects of feed solids concentration in liquid retentate and spray drier inlet temperature on the flavor of the resulting whey protein concentrate (WPC). Cheddar cheese whey was manufactured, fat-separated, pasteurized, bleached (250 ppm hydrogen peroxide), and ultrafiltered (UF) to obtain WPC80 retentate that was 25% solids (wt/wt). The liquid retentate was then diluted with deionized water to one of the following solids concentrations: 25%, 18%, or 10%. Each of the treatments was then spray dried at one of the following temperatures: 180°C, 200°C, or 220°C. Experiments were replicated three times. Dried WPC80 were evaluated by sensory and instrumental analyses. Particle size and surface free fat were also analyzed. Both main effects (solids concentration and inlet temperature) and interactions between solids concentration and inlet temperature were investigated. A decrease in feed solids concentration resulted in increased surface free fat, intensities of overall aroma, cabbage and cardboard flavors and increased concentrations of pentanal, hexanal, heptanal, decanal, (E)2-decenal, DMTS, DMDS, and 2,4-decadienal ($P < 0.05$). A decrease in inlet temperature also resulted in increased surface free fat, cardboard flavor and increased concentrations of pentanal, (Z)4-heptenal, nonanal, decanal, 2,4-nonadienal, 2,4-decadienal, and 2- and 3-methyl butanal ($P < 0.05$). Mean particle size was higher for powders from increased feed solids concentration and increased inlet temperature ($P < 0.05$). These results demonstrate that an increase in feed solids concentration in the liquid retentate and inlet temperature within the parameters tested decreases off-flavor intensity in the resulting WPC80 powder.

Key Words: WPC80, flavor, processing step

T104 Enzyme hydrolysis of lactose in milk and dairy co-products. X. E. Li* and M. A. Drake, *North Carolina State University, Raleigh.*

Interest in dietary sugar reduction has led to a search for natural alternatives to sweeten dairy beverages such as chocolate milk. We recently demonstrated that parents were interested in sugar reduction in chocolate milk for their children but that desirable flavor and natural sources of sweet taste reduction were desired. The naturally existing milk sugar lactose has a lower relative sweetness compared to its monosaccharide constituents glucose and galactose. As such, lactose hydrolysis of milk or a dried dairy ingredient may be a natural and label friendly method to reduce added sugar in chocolate milk. The objective of this study was to evaluate and compare enzymatic hydrolysis of lactose from different dairy matrices with different lactase sources. Four commercial lactase enzymes were evaluated. Lactose hydrolysis of whole raw and pasteurized milk, skim pasteurized milk, fresh liquid whey and milk permeates, five rehydrated commercial spray dried whey permeates [5 and 10% (w/w) solids], and two different commercial rehydrated lactose sources [5 and 10% (w/w) lactose in phosphate buffer] were compared at 4°C. Following 12 or 24 h, an aliquot of solution was removed and subjected to 100°C for 5 min to inactivate lactase. Hydrolysis was determined by measurement of lactose in control and treated solutions by high performance liquid chromatography (HPLC). Experiments were conducted in duplicate. Lactose was efficiently hydrolyzed in skim and whole milk, liquid permeates, and lactose solutions by three lactases in 24h (>95%), however the degree of hydrolysis varied in different rehydrated spray dried whey permeates (4 to 90%) and also varied by lactase source ($P < 0.05$). These results provide a better understanding of lactose hydrolysis in milk and dairy co-products which could be applied to naturally enhance the sweetness of dairy beverages such as chocolate milk.

Key Words: lactose hydrolysis, permeate, milk

T105 Impact of gravity separation of raw milk on shelf-life of pasteurized fluid milk. S. L. Beckman* and D. M. Barbano, *Cornell University, Ithaca, NY.*

The objective of this research was to use gravity separation (GS) of raw milk to increase the microbiological shelf-life of pasteurized 2% fat milks. Raw whole milk (experiment 1), and cold (6°C) centrifugally separated (CS) raw skim (experiment 2) milk were GS (4°C, 22 h) to remove bacteria and spores prior to production of standardized 2% fat pasteurized (72 and 80°C, 25 s), homogenized milks. A standard plate count (SPC) was conducted on raw milks (d = 0), and on pasteurized milks initially and every 7 d during 70 d storage at 6°C, with a shelf-life limit of 20,000 cfu/mL. Mesophilic spores were enumerated on raw and initial pasteurized milks. Each experiment was replicated 3 times with different lots of milk. In CS raw skim milk (experiment 2), bacteria ($P < 0.05$), spores ($P < 0.05$), and fat ($P < 0.05$) GS into the top 4% (wt/wt) layer of a column of milk. When used on raw CS skim milk, GS reduced SPC and spores by 0.8 and 0.6 log cfu/mL, respectively. Both GS of raw whole milk (experiment 1) and raw CS skim milk (experiment 2) improved the shelf-life of high-temperature short-time pasteurized milks. Lower SPC ($P < 0.05$) and spores ($P < 0.05$) in GS milks prior to pasteurization created fluid milks that had microbial shelf-lives extending beyond 70 d of storage at 6°C (experiment 1 and 2). The extended shelf-life of pasteurized GS milks compared to CS (conventionally processed) milks can be attributed to the partitioning of vegetative bacteria and heat-resistant psychrotolerant sporeformers into the cream layer during GS. There was an interaction ($P < 0.05$) of day of storage by pasteurization temperature on the shelf-life of GS and CS milks, with milks pasteurized at 72°C increasing in bacteria count faster than 80°C (experiment 1 and 2). Future work should focus on determining the chemical and biological basis for the mechanism of GS (i.e., rising) of bacteria and spores in raw and minimally pasteurized whole and skim milk. Once this mechanism is understood, it may be feasible to design a continuous-flow technology for removal of bacteria and spores from raw milk that can be done at low temperatures.

Key Words: gravity separation, shelf-life, pasteurized milk

T106 The influence of solids concentration and bleaching agent on bleaching efficacy and flavor of sweet whey powder. M. G. Jervis* and M. A. Drake, *North Carolina State University, Raleigh.*

Recent studies have demonstrated the impact of bleaching and bleaching agent on flavor and functional properties of whey protein ingredients. Fat had minimal effects on bleaching, but protein concentration at bleaching significantly impacted bleaching efficacy and flavor effects of different bleaching agents. It is not known if these parameters influence manufacture of sweet whey powder (SWP). The purpose of this study was to determine the effects of solids concentration and bleaching agent on the flavor and bleaching efficacy of SWP. Colored Cheddar whey was manufactured, fat separated and pasteurized. Subsequently, the whey (6% solids) was bleached, concentrated using reverse osmosis (RO) to 14% solids and then spray dried, or whey was concentrated prior to bleaching and then spray dried. Bleaching treatments included: Control (CT) (no bleaching, 50°C, 60 min), hydrogen peroxide (HP) (250 mg/kg, 50°C, 60 min), benzoyl peroxide (BP) (50 mg/kg, 50°C, 60 min), lactoperoxidase (LP) (20 mg/kg, 50°C, 30 min), and Maxibright (MB) (2 dairy bleaching units/ml, 50°C, 30 min). The experiment was repeated in triplicate. Sensory properties and volatile compounds of SWP were evaluated by a trained panel and gas chromatography mass spectrometry, respectively. Bleaching efficacy (norbixin destruction) and benzoic acid were measured using high performance liquid chromatography. Differences in bleaching efficacy, sensory and volatile compound profiles and benzoic acid were observed with different bleaching agents ($P < 0.05$) consistent with previous studies. Solids concentration impacted bleaching efficacy of HP ($P < 0.05$) but not other bleaching agents. SWP from whey bleached with HP or LP following RO had increased cardboard and fatty flavors and higher concentrations of lipid oxidation compounds compared to SWP from whey bleached prior to RO. These results indicate that solids concentration impacts bleaching efficacy of HP and influences off flavors associated with specific bleaching agents in SWP.

Key Words: sweet whey powder, bleaching, flavor

T107 Detection of fat and protein differences between mid-infrared instruments used for milk producer payment testing. M. C. Adams* and D. M. Barbano, *Cornell University, Ithaca, NY.*

The USDA Federal Milk Marketing Orders are responsible for ensuring milk component testing accuracy for producer payment. Currently, there are 2 ways this can be achieved: through split-sampling or statistical analysis of routine testing data. The former is ideal, as the same sample can be measured in 2 labs. However, this is not always practiced due to duplicate sampling costs. Our objective was to determine the least significant differences (LSD) necessary to detect differences in mid-infrared (MIR) spectrophotometric payment results at various confidence levels ($P = 0.0001$ to 0.10). This robust statistical method could be used when split-sampling is not practical. Two MIR instruments' fat and protein results from 4 months (153 to 197 producers in a month) were analyzed. Models for each component during each month were constructed (i.e., Fat_{July} = producer + instrument + instrument × producer + error) using the general linear model statement (PROC GLM) of SAS software. The analyses of variance indicated that "producer" was significant ($P < 0.0001$) in all 8 models, "instrument" was significant ($P < 0.05$) in most models, and "instrument × producer" was not significant ($P > 0.05$) in any of the models. "Instrument" LSD values for fat ranged from 0.0108% to 0.0148% for the 4 months ($P = 0.05$). "Instrument" LSD values for protein ranged from 0.0045% to 0.0089% for the 4 months ($P = 0.05$). In addition to these models, the differences between instruments for each producer were plotted as function of fat or protein concentration and regression was used to estimate the slopes of the best-fit lines. Surprisingly, the slopes of the best-fit lines were different ($P < 0.001$) from 0 for all 4 months for both fat and protein. This indicated that systematic differences in the MIR calibrations across component concentrations could lead to underpayment or overpayment to producers at the extremes of the concentration range, even though the means for the 2 instruments may not be different. Given the present trend toward fewer farms producing larger volumes of milk, small errors in test values could amount to large payment errors over time.

Key Words: mid-infrared, payment, statistics

T108 Measuring consumer emotional response to flavored and unflavored milk. E. Arnade*, S. Duncan, J. Dunsmore, R. Rudd, and S. O'Keefe, *Virginia Tech, Blacksburg.*

Flavored milk in school food service settings has received significant media attention because of higher caloric content, mostly from high fructose corn syrup, and questions about contributions to childhood obesity. The goal of the experiment was to characterize emotional response to unflavored (white) vs. flavored (chocolate) milk as compared to reported behavior and hedonic preference for a young adult population to better understand the current sentiment and/or disconnect between intake and liking. Panelists consumed chocolate and white milk (1% fat) and selected emotional terms from a list (n = 43 terms) describing the way they felt immediately post-consumption of each product sample. Panelists completed demographic, knowledge and

attitudes, and beverage consumption questionnaires, and rated each sample using a 9-point hedonic scale. Frequency, similarities (shared) and differences (unique) in emotional terms selected across and between samples were compared. Chocolate milk received a statistically higher ($P = 0.0017$) mean acceptability score than white milk, 7.0 ± 1.5 and 5.7 ± 2.4, respectively (overall; n = 52). Gender segmentation showed a statistically higher ($P = 0.0047$) mean acceptability score for chocolate milk than white milk within females (n = 34); no statistical difference in acceptability scores were shown within males (n = 18). Emotional term analysis identified 14 frequently used terms as well as shared terms (calm, good) across samples. Unique terms were identified between the chocolate (satisfied, happy, warm, nostalgic, and joyful) vs. white (disgusted) milk. Gender segmentation showed that females (n = 31) differentiated between the samples with many more unique terms than males (n = 17), while males had a greater number of shared terms among the samples than females, suggesting that female and male emotional response may differ. Emotional response may provide an added value understanding for the acceptability of flavored and unflavored fluid milk, suggesting an opportunity to foster the current positive response to flavored milk by providing rationale for promotion and continued access to low-fat flavored milk options.

Key Words: milk, emotion

T109 Oxidative stability evaluation of milk from cow fed with dried distillers grains with solubles by sensory and chemical analysis. G. Li*, E. Testroet, S. Clark, and D. Beitz, *Iowa State University, Ames.*

Feeding dried distillers grains with solubles (DDGS) to dairy cows has been loosely implicated in formation of oxidized off flavors in milk. The purpose of this study was to examine the impact of feeding DDGS to dairy cows on the oxidative quality of the milk by sensory and chemical analysis. Twenty-four cows were divided into 2 groups, fed a total mixed ration, with 3 incorporation levels of DDGS (0%, 10%, 25%). Each group received each of the diets, such that they served as their own controls. Milk was collected 3 times (on days 14, 21, 28) during the feeding periods. For each treatment, pooled fresh milk was divided into 3 fortification options (no vitamin, 0.06% vitamin E, 0.06% vitamin C) then HTST pasteurized. Milk fat (%), SNF (%), and protein (%) were measured by LactiCheck. A 10-member descriptive analysis panel evaluated the milk samples on seven specific descriptors on days 1, 3, and 7 of storage. Chemical analyses [peroxides, free fatty acids (FFA)] were taken from the same milk with SafTest kits. Milk fat decreased significantly ($P < 0.0001$) from 3.3% to 2.7% in both 10% and 25% DDGS groups, while SNF and protein increased ($P < 0.1$), storage day effect ($P > 0.1$), or fortification effect ($P > 0.05$) on oxidized off-flavors. However, for the 25% diet treatment milk with vitamin C, higher light oxidized ($P < 0.05$) and metal oxidized ($P < 0.0001$) flavor scores were found. Though statistically significant, the milks did not exhibit definite oxidized flavor; the scores were lower than 1.5 on a 15-cm line scale. All peroxide and most of the FFA measurements were below detection level, with the exception of a couple of samples that had slightly elevated FFA; the elevated results were not observed in their replicates. With no apparent oxidation in any milk from any treatment, the sensory and chemical analyses support the conclusion that feeding of DDGS at 10% and 25% levels did not decrease the oxidation stability of milk. Spontaneous oxidation is a complex process that cannot be blamed on DDGS alone.

Key Words: milk, dried distillers grains with solubles, sensory evaluation

T110 Role of exopolysaccharide-producing starters in biofilm formation on dairy separation membranes. N. Garcia-Fernandez*, A. N. Hassan, and S. Anand, *Midwest Dairy Foods Research Center, Dairy Science Department, South Dakota State University, Brookings.*

The objective of this research was to evaluate the role of exopolysaccharides (EPS) produced by lactic starters in biofilm formation on dairy separation membranes. Exopolysaccharides are thought to play a role in biofilm formation and stability. We hypothesized that EPS-producing starters used in cheese making would increase the risk of biofilm formation on whey separation membranes. Two different EPS^+ starters and their isogenic EPS^- variants were used to study attachment of bacterial cells in the absence of growth (at 4ºC) and biofilm formation on Reverse Osmosis (RO) membranes. M17 broth and whey protein concentrate 35 solution (10% w/w) were used as growth media for biofilm formation under static conditions. *Streptococcus thermophilus* ST3534 (EPS^+) and ST5842 (EPS^-) were provided by Chr. Hansen. *Lactococcus lactis* ssp. *cremoris* JFR^+ (EPS^+) was isolated from a retail dairy product and an EPS^- mutant (JFR^-) was selected in our laboratory. Plasmid profile analysis revealed the absence of a plasmid in JFR^-. Five (2 × 2 cm) pieces of RO membrane were used in each experiment. Bacterial cells were allowed to attach and form biofilm on the retentate side only. A stomacher was used to recover cells attached to the membrane and the viable cell counts were estimated. Each experiment was repeated three times. Results showed significantly greater ($P < 0.05$) counts (cfu/cm^2) of ST3534 cells in biofilm than those of ST5842 whilst counts of cells attached to the membrane in the absence of growth did not differ ($P > 0.05$) between the isogenic pair. Interestingly, JFR^+ counts were significantly lower ($P < 0.05$) than those of JFR^-. These findings indicate that EPS produced by ST3534 may have a role in building up the three dimensional structure of the biofilm rather than assisting in the attachment to the membrane at the initial steps of biofilm formation while EPS produced by JFR^+ interfered with both cell attachment and biofilm formation. In conclusion, EPS produced by starter cultures vary in their role in bacterial attachment and biofilm formation, likely, due to variations in their molecular characteristics and interactions with the membrane.

Key Words: biofilm, exopolysaccharide, membrane

T111 Solubility and antihypertensive activity of whey protein hydrolysate subjected to Maillard-induced glycosylation. K. Ruud*, Q. Wang, and B. Ismail, *University of Minnesota, St. Paul.*

The interest in the utilization of biologically active whey protein hydrolysates (WPH) in functional foods and beverages, specifically, has significantly increased over recent years. While bioactive WPH potentially may impart physiological benefits such as antihypertensive activity, maintaining quality and shelf-life stability is a major hurdle that hinders its application in beverages. We have recently demonstrated whey protein solubility and thermal stability enhancement upon partial Maillard-induced glycosylation over a broad pH range. Our objective was to evaluate the effect of limited and controlled Maillard-induced glycosylation on the solubility, thermal stability, and antihypertensive activity of WPH. Whey protein hydrolysate (DH 5.2%) was reacted with dextran (10 kDa) at $a_w = 0.49$ and at 60°C for up to 60 h to produce partially-glycosylated WPH (PGWPH). Extent of glycosylation was assessed by monitoring absorption at 304 nm and by determining % amino-groups blockage. Extent of browning was monitored at 420 nm. The antihypertensive activity was determined by measuring the angiotensin converting enzyme (ACE) inhibitory activity following an in vitro assay. For determination of solubility and thermal stability, PGWPH samples and their controls were prepared in solutions (5% wt/

vol) at various pH values and subjected to heat treatment at 80°C for 30 min. Difference UV spectroscopy confirmed that glycosylation was initiated after 48 h of incubation. Partial glycosylation with only up to 2% amino-group blockage and minimal browning were maintained after 60h of incubation. Solubility and thermal stability of PGWPH were enhanced especially around the pI of whey protein. The antihypertensive activity of PGWPH was preserved maintaining an IC_{50} similar to or greater than that of WPH. Our results indicated that partial glycosylation has the potential to improve the solubility and thermal stability of WPH over a wide range of pH, while maintaining its bioactivity.

Key Words: whey protein hydrolysate, Maillard-induced glycosylation, antihypertensive activity

T113 Effect of dietary unsaturated fatty acids on ruminal fermentation in dairy cows. J. E. Freitas Jr.*[1], M. D. S. Oliveira[2], B. C. Venturelli[1], E. F. Jesus[2], R. Gardinal[1], G. D. Calomeni[1], J. R. Gandra[1], V. G. C. Lacuna[1], V. P. Bettero[2], C. S. Takiya[1], R. V. Barletta[1], and F. P. Rennó[1], *[1]University of São Paulo, Pirassununga, São Paulo, Brazil, [2]State University Julio de Mesquita, Jaboticabal, São Paulo, Brazil.*

The aim of this study was to evaluate the ruminal fermentation in dairy cows supplemented with unsaturated fatty acids sources. Eight Holstein cows in the mid lactation (80 ± 20 d in milk; mean SD) cannulated in the rumen and abomasums (580 ± 20 kg of weight; mean ± SD) with milk yield of 25 kg/d were assigned randomly into two 4 × 4 Latin squares, fed the following diets: (1) control (C); (2) refined soybean oil (inclusion of 3% in the total dry matter); (OS); (3) whole soybean raw (WS) (inclusion of 16% in the total dry matter); and (4) calcium salts of unsaturated fatty acids (CSFA) (inclusion of 3% in the total dry matter). Data were analyzed using PROC MIXED of SAS 9.1 according with the orthogonal contrasts (C vs SO + WS + CSFA); (SO vs WS + CSFA) and (WS vs CSFA). Dietary treatments did not affect total molar proportions of ruminal volatile FA. However, cows fed WS, SO and CSFA had a slow molar proportion of butyrate than those fed the CO diet. Cows fed SO had a higher ruminal pH than those fed the WS and CSFA diets (5.76; 5.87; 5.78 and 5.76 to diets CO, SO, WS and CSFA respectively). However, cows fed CO had a higher NH_3-N concentration than those fed the WS, SO and CSFA diets (43.1; 36.4; 36.9 and 33.3 mg/dL to diets CO, SO, WS and CSFA respectively). Unsaturated fatty acids increased ruminal molar proportions of acetate and propionate (1.2 and 3.3% respectively) and decreased ruminal molar proportions of butyrate in 10.1%. It is concluded that the supplementation of unsaturated fatty acids, alter ruminal fermentation and have positive effect on ruminal energetic efficiency

T114 Effects of nutritional prepartum supplementation upon maternal-kid behavior (1). N. E. Hernandez-Macias*[1], V. Contreras-Villarreal[1], O. Angel-Garcia[1], J. M. Guillen-Muñoz[1], P. A. Robles-Trillo[1], G. Arellano-Rodriguez[1], R. Rodriguez-Martinez[1], M. Mellado[1], C. A. Meza-Herrera[2], and F. G. Veliz[1], *[1]Universidad Autonoma Agraria Antonio Narro, Torreon, Coahuila, Mexico, [2]URUZA-UACh, Bermejillo, Durango, Mexico.*

This study aimed to evaluate the effect of either 15 or 30 d of prepartum nutritional supplementation upon maternal-kids behavior under grazing-semiarid rangeland conditions in northern México (26 N). A total of 23 goats with similar body weight and condition were divided in three experimental groups: (1) Control Group (CG; n = 7) was non-supplemented, (2) G15 Group (G15, n = 8) was supplemented from 15-d pre- up to 7-d postpartum; goats were supplemented prior grazing (0800) with a 500 g of a mixture of 20% manure, 37% rolled corn, 37% bran, 4% treacle and 2% salt); (3) G35 group (G35, n = 8) received the same supplement as G15 but from 35-d pre- up to 7-d postpartum. To evaluate kids' ability to differentiate their mother from an alien kid's at 8 h postkidding, a discrimination test was carried out, which is a double election test to evaluate their preference for his mother. The test lasted 5 min. Recorded behaviors included: high and low bleating per kid, number of visits to the "Contact Zone" and time spent in each zone. Data were subjected to the Student t-test (MYSTAT). Table 1 shows the behavioral variables considered. No differences ($P < 0.05$) were observed among experimental groups for the studied behavioral doe-kids variables. The last may have occurred because does depicted a intermediate body condition and were facing similar management conditions. Therefore, results suggest that does-kids facing such physiological and environmental scenarios do not require any additional supplementation to enhance or stimulate a closer relationship between does and their kids.

T115 Use of estradiol to induce reproductive activity in anestrous goats. V. Contreras-Villarreal*[1], O. Angel-Garcia[1], J. M. Guillen-Munoz[1], P. A. Robles-Trillo[1], M. A. de Santiago-Miramontes[1], G. Arellano-Rodriguez[1], R. Rodriguez-Martinez[1], M. Mellado[1], C. A. Meza-Herrera[2], and F. G. Veliz[1], *[1]Universidad Autonoma Agraria Antonio Narro, Torreon, Coahuila, Mexico, [2]URUZA-UACh, Bermejillo, Durango, Mexico.*

Use of estradiol for sexual activity induction was evaluated in anestrous goats. Mixed breed anovulatory adult goats (n=16) were divided into 2 groups (n=8) with homogeneous body condition score and body weight; four mixed-breed bucks were also used. Does grazed from 1000h to 1600h. Group 1 (IM+E2) received 25 mg i.m. progesterone and 24h later received 1 mg i.m. estradiol (estradiol cyclopentil propionate). Group 2 (Spo+E2) was treated during 7 days with an intravaginal sponge impregnated with 20 mg cronolone; at sponge removal, goats received 1 mg i.m. estradiol; does were penned and kept there during 5-d, and were fed with alfalfa hay ad libitum, 200 g commercial mix (14% CP, per animal/d) while trace mineral salt blocks and water ad libitum. Estral activity was evaluated by introducing a male in each experimental group 15 min (morning) and 15 min (afternoon). Females depicting signs of heat were moved to a different pen with two males. Follicular activity was evaluated with a transrectal ultrasonographic scanning (TUS) from -7 d up to +7 d from estradiol administration. Forty-five days after estrus detection, goats were evaluated for pregnancy by TUS. Number and size of ovulatory follicles and size of the corpus luteum for each group were compared with a Student T; the percentage of females depicting estrus, ovulation and pregnancy were compared with a chi^2. Reproductive response from both experimental groups is presented on Table 1. Mixed-breed anestrous goats from northern Mexico (26°N) treated with estradiol positively responded to estral activity induction although depicted a reduced ovulation rate. Therefore, estradiol may have not been able to stimulate follicles enough for oocyte maturation and ovulation.

Table 1. Reproductive response of mixed-breed anestrous goats receiving either an i.m. progesterone or intravaginal sponges impregnated with progesterone and estradiol.

	Group

T117 Effects of tamoxifen on estrogen and progesterone receptor expression in prepubertal female calves. H. L. M. Tucker*[1], C. L. M. Parsons[1], S. Ellis[2], and R. M. Akers[1], *[1]Dairy Science Department, Virginia Polytechnic Institute and State University, Blacksburg, [2]Animal and Veterinary Sciences Department, Clemson University, Clemson, SC.*

We have reported that ovariectomy (OVX) of prepubertal calves reduces mammary development in the period before puberty would have occurred. This was accompanied by increases in expression of estrogen receptor (ER), IGF-I axis molecules and expression of extracellular matrix proteins. Our purpose was to determine if the effects of OVX were dependent on expression of estrogen and/or progesterone (PR) receptors by use of the anti-estrogen tamoxifen. Sixteen Holstein calves were randomly assigned to one of two treatment groups: tamoxifen-injected (TAM) or control (CON). Calves were injected daily from 28 d to 120 d of age with 0.3 mg/kg tamoxifen or carrier. At 120 days calves were sacrificed and udders removed. Weight of trimmed parenchymal tissue (left rear quarter) was dramatically lower ($P < 0.0003$; 16.1 vs. 34.8 g) in TAM calves. Parenchymal samples from three regions of the left rear quarter (lower, middle and outer regions) were processed for immunohistochemical staining for ER and PR. Ductal areas within parenchymal sections were identified as stratified or unstratified. Epithelial cells were classified as ER positive, PR positive, dual labeled or unlabeled. The orientation of labeled cells was also characterized based on position within the epithelial layer (luminal, medial, or basal). Overall, the proportion of neither ER nor PR labeled cells was impacted by treatment but the percentage of dual labeled cells was higher (38.4% vs. 34.1%) in CON calves ($P < 0.05$). However, imaging analysis indicated a markedly higher intensity of ER expression in CON calves but no difference for PR staining intensity. The proportion of both ER and PR labeled cells was different when comparing stratified vs. unstratified ductal regions ($P \leq 0.001$). While treatment with the anti-estrogen tamoxifen reduced mammary parenchymal mass similarly to OVX, the mechanism(s) involved appear to differ. This suggests that the impacts of ovariectomy are only partially explained by alterations in ER expression. Ongoing analysis is focused on determining intensity of ER expression as well as effects of tamoxifen on other mammogenic pathways.

Key Words: tamoxifen, ovariectomy, estrogen receptor

T118 Effect of fatty acids n-3 and n-6 supplementation on blood parameters of Holstein cows during transition period and early lactation. R. Gardinal*[1], J. R. Gandra[1], G. D. Calomeni[1], L. C. Verdurico[1], R. D. Mingoti[1], R. V. Barletta[1], J. E. Freitas Jr.[1], C. E. Araújo[1], T. H. A. Vendramini[1], E. Ferreira de Jesus[2], and F. P. Rennó[1], *[1]Department of Nutrition and Animal Production, Faculty of Veterinary Medicine, University of São Paulo, Pirassununga, São Paulo, Brazil, [2]Department of Animal Science, State University Julio de Mesquita UNESP, Jaboticabal, Jaboticabal, São Paulo, Brazil.*

The aim of this study was to evaluate effect of n-3 and n-6 supplementation on blood parameters of Holstein cows during transition period and early lactation. Forty-eight Holstein cows were divided in 4 experimental groups in randomized design. Animals were assigned to receive 1 of 4 treatments: (1) control (C; n = 12), without fat sources in pre and postpartum; (2) flaxseed (FS; n = 12), fed 60 and 80 g/kg of DM of flaxseed in pre and postpartum; (3) whole raw soybeans (WS; n = 12), fed 120 and 160 g/kg of DM of whole raw soybeans in pre and postpartum; (4) calcium salts of unsaturated fatty acids (CSFA; n = 12; Megalac-E), fed 24 and 32 g/kg of DM of calcium salts of unsaturated fatty acids in pre and postpartum. Experimental diets were fed from 35 d before the estimate calving until 84 d of lactation, formulated to meet nutritional requirements of each period. Blood samples were

taken −21, −14, −7 days in relation to prediction of birth, at birth and +7, +14, +21, +28, +35, +42, +84 days postpartum. Glucose (GLU), total cholesterol (CHOL), triacylglycerides (TRI), non-esterified fatty acids and β-hydroxybutyrate concentrations were measured. Data were analyzed using the PROC MIXED of SAS 9.1 with fixed dietary effect, time effect, interaction between diet and time. Data were analyzed by orthogonal contrasts C vs. WS+CSFA+FS (C1); FS vs. WS+CSFA (C2); and WS vs. CSFA (C3). In the prepartum, animals supplemented with fatty acids had higher ($P < 0.05$) concentration of TRI (C1) (25.0 vs. 40.4, respectively). Concentration of GLU was higher ($P < 0.05$) in group FS, C2 (70.7 vs. 62.4, respectively). WS group had higher concentration ($P < 0.05$) of CHOL compared to CSFA group (C3) (137.9 vs. 103.1, respectively). In the postpartum, animals supplemented with fatty acids had higher ($P < 0.05$) concentration of CHOL (C1) (142.0 vs. 165.1, respectively). Concentration of GLU was higher ($P < 0.05$) in group FS (C2) (67.2 vs. 58.4, respectively). Blood parameters of Holstein cows fed with source of n-3 and n-6 in the transition period and early lactation were positively influenced.

Key Words: fat source, blood parameter, transition period

T119 Ruminal dynamics and neutral detergent fiber digestibility of dairy cows fed with different sources of unsaturated fatty acids. R. Gardinal*[1], J. E. Freitas Jr.[1], M. D. S. Oliveira[2], B. C. Venturelli[1], E. F. Jesus[2], G. D. Calomeni[1], L. C. Verdurico[1], V. G. C. Lacuna[1], V. P. Bettero[2], T. H. A. Vendramini[1], R. V. Barletta[1], and F. P. Rennó[1], *[1]Department of Nutrition and Animal Production, Faculty of Veterinary Medicine, University of São Paulo, Pirassununga, São Paulo, Brazil, [2]Department of Animal Science, State University Julio de Mesquita – UNESP, Jaboticabal, Jaboticabal, São Paulo, Brazil.*

The aim of this study was to evaluate the ruminal dynamics, NDF concentrations and digestibility of dairy cows fed with different sources of unsaturated fatty acids. Eight Holstein cows in mid-lactation (80 ± 20 d in milk, mean SD) cannulated in the rumen and abomasums (580 ± 20 kg of weight, mean ± SD) with milk yield of 25 kg/d were randomly assigned into two 4 × 4 Latin squares, fed the following diets: (1) control (C); (2) refined soybean oil (inclusion of 3% in the total dry matter); (SO); (3) whole raw soybean (WS) (inclusion of 16% in the total dry matter); and (4) calcium salts of unsaturated fatty acids (CSFA) (inclusion of 3% in the total dry matter). Milk yield and dry matter intake were measured daily throughout the experimental period. The marker NDFi was used to determine the abomasal dry matter flow. Ruminal contents were evacuated manually through the ruminal cannula at 4.5 h after feeding on d 20, and at 2.0 h before feeding on d 21 of each period. Fractional rates of fatty acids biohydrogenation and passage by the rumen were calculated utilizing the model that accounts for transfer of fatty acids among ruminal pools. The potentially digestible neutral detergent fiber (pdNDF) was calculated by the difference (1.0 − NDFi). Data were analyzed using PROC MIXED of SAS 9.1 according with the orthogonal contrasts (C vs. SO + WS + CSFA) (SO vs. WS + CSFA) and (WS vs. CSFA). Animals fed with WS diet showed higher NDF intake ($P < 0.05$) than those fed with CSFA diet (5.25 vs. 4.65 kg/d, respectively). There was a lower pdNDF intake ($P < 0.05$) by the animals fed with WS diet relative to the animals fed with CSFA diet (2.41 vs. 2.70 kg/day, respectively). The cows fed with C diet had lower ruminal digestibility of pdNDF ($P < 0.05$) compared to the cows fed with SO, WS and CSFA diets, contrast one (1.41 vs. 1.79; 2.02; 1.88, respectively). The use of diets containing raw soybean and calcium salts provided better ruminal digestibility of pdNDF (kg/d) in dairy cows in mid-lactation.

Key Words: linoleic acid, whole raw soybean, ruminal fermentation

T120 Follicular dynamics of Holstein cows fed with supplemental sources of n-3 and n-6 fatty acids during transition period and early lactation. G. D. Calomeni*[1], J. R. Gandra[1], R. Gardinal[1], J. E. Freitas Jr.[1], L. C. Verdurico[1], E.F. Jesus[2], C.S. Takiya[1], R.D. Mingotti[1], T. H. A. Vendramini[1], R. V. Barletta[1], and F. P. Rennó[1], *[1]Department of Nutrition and Animal Production, Faculty of Veterinary Medicine, University of São Paulo, Pirassununga, São Paulo, Brazil, [2]Department of Animal Science, State University Julio de Mesquita – UNESP Jaboticabal, Jaboticabal, São Paulo, Brazil.*

The aim of this study was evaluate the effect of supplemental sources of n-3 and n-6 fatty acids in follicular dynamics of dairy cows fed during the transition period and early lactation. Forty-eight Holstein cows were assigned into 4 experimental groups in randomized designed. The animals were randomly assigned to receive one of 4 treatments: (1) control (C), without fat sources in the pre and postpartum, (2) flaxseed (FS), 60 and 90 g/kg of DM of flaxseed in the pre and postpartum, respectively; (3)whole raw soybeans (WS), 120 and 160 g/kg of DM of whole raw soybeans in the pre and postpartum; (4) calcium salts of unsaturated fatty acid (CFSA; Megalac-E), 24 and 32 g/kg of DM of calcium salts of unsaturated fatty acid in pre and postpartum. The experimental diets were fed from 35 d before the estimate calving, and provided until 84 d of lactation, formulated to meet the nutritional requirements of each period. Ovaries of all cows were examined daily by ultrasonography beginning on day 14 and continuing until day 72 postpartum. Were examined by scanning: the total number of follicles (TNF), size of follicles, number and area (mm^2) of corpus luteum. Follicles were classified by size into 5 classes: (1) <3mm (CLA1), (2) 3-5mm (CLA2), (3) 6-9 mm (CLA3), (4) 10-15 mm (CLA4) and (5) >15 mm (CLA5). Data were analyzed using PROC MIXED of SAS 9.1, with the effect of treatment, period and interaction as fixed effects, and animal has random effect. The data were analyzed by orthogonal contrasts C vs. WS+CSFA+FS (C1); WS vs. CSFA (C2); and FS vs. WS+CFSA (C3). We observed an effect ($P < 0.05$) of treatment only for TNF and number of CLA1. Effect of period was observed for TNF, number of CLA3 and CLA5. There was interaction ($P < 0.05$) between the fatty acids sources and period for TNF, number of CLA2 e CLA3. Analyzing the orthogonal contrasts effect of C1 was observed for TNF (10.4 vs. 14.5) and number of CLA1 (1.27 vs. 4.21). The supplemental sources of n-3 and n-6 fatty acids influenced follicular dynamics of dairy cows fed during transition period and early lactation.

Key Words: fat source, follicular dynamics, transition period

T121 Ruminal dynamics of dairy cows fed with different sources of unsaturated fatty acids. G. D. Calomeni*[1], J. E. Freitas Jr[1], R. Gardinal[1], M. D. S. Oliveira[2], B. C. Venturelli[1], E. F. Jesus[2], C. S. Takiya[1], V. G. C. Lacuna[1], V. P. Bettero[2], T. H. A. Vendramini[1], R. D. Mingoti[1], F. Zanferrari[1], R. V. Barletta[1], and F. P. Rennó[1], *[1]Department of Nutrition and Animal Production, Faculty of Veterinary Medicine, University of São Paulo, Pirassununga, São Paulo, Brazil, [2]Department of Animal Science, State University Julio de Mesquita – UNESP Jaboticabal, Jaboticabal, São Paulo, Brazil.*

The aim of this study was to evaluate the ruminal dynamics of dairy cows fed with sources of unsaturated fatty acids. Eight Holstein cows in the mid lactation (80 ± 20 d in milk; mean SD) cannulated in the rumen and abomasums (580 ± 20 kg of weight; mean ± SD) with milk yield of 25 kg/d were assigned randomly into two 4 × 4 Latin squares, fed the following diets: (1) control (C); (2) refined soybean oil (inclusion of 3% in the total dry matter); (OS); (3) whole soybean raw (WS) (inclusion of 16% in the total dry matter); and (4) calcium salts of unsaturated fatty acids (CSFA) (inclusion of 3% in the total dry matter). Milk yield and the dry matter intake were measured daily throughout the experimental

period. The marker iNDF was used to determine the abomasal dry matter flow. Ruminal contents were evacuated manually through the ruminal cannula at 4.5 h after feeding on d 20, and at 2.5 h before feeding on d 21 of each period. Turnover rate in the rumen, passage rate from the rumen, and ruminal digestion rate of each component (%/h) were calculated. Data were analyzed using PROC MIXED of SAS 9.1 according with the orthogonal contrasts (C vs. SO + WS + CSFA); (SO vs. WS + CSFA) and (WS vs. CSFA). There was no effect of unsaturated fatty acids sources on dry matter and NDF digestions rates. Although, cows fed with WS diet submitted lower ($P < 0.03$) digestion rate of potentially digestible NDF (pdDNF) than cows fed with CFSA diet (1.21; 1.30; 0.89; 1.34%/h, to diets CO, SO, WS and CSFA respectively). Ruminal turnover rate for pdNDF ($P < 0.01$) was greater for animals fed the WS diet than did cows fed the CFSA diet (2.13; 2.48; 2.82; 1.91%/h, to diets CO, SO, WS and CSFA respectively). There was no effect of the diets on the passage rate, ruminal turnover rates of dry matter, organic matter, NDF and iNDF and rate of passage of dry matter, NDF, and iNDF. The supplementation of unsaturated fatty acids alter the ruminal dynamics of dairy cows

Key Words: ruminal turnover rate, dairy cow, unsaturated fatty acids

T122 Effect of different fatty acid profiles on milk fat depression in dairy cattle fed diets below 4% fat. C. M. Stoffel* and L. E. Armentano, *Department of Dairy Science, University of Wisconsin-Madison, Madison.*

High dietary C18:2 (linoleic acid) levels can result in incomplete biohydrogenation of fatty acids (FA) in the rumen leading to reduced milk fat secretion. The goal of this study was to identify the effect of different dietary FA profiles at FA levels below 4% of TMR dry matter (DM). Twenty-four primiparous and 36 multiparous lactating cows were paired (within parity) to form 30 experimental units. Pairs were fed 6 diets in five 6 × 6 balanced Latin squares with 21-d periods, using data from the last 5 d. There were two control diets: a corn control diet (CC; 29% corn silage, 16% haylage, 19% corn grain, 8% distillers grain, DM basis) containing 3% ether extract; and a low oil control (LOC; 9% corn silage, 35% haylage, 20% corn starch, and 8% corn gluten meal, DM basis) containing 2% ether extract. Starch in LOC was replaced with 1.75% diet DM of a 50/50 blend of corn oil and high linoleic safflower oil (CO), high oleic sunflower oil (OO), palm oil (PO), or 1.84% diet DM MegaLac (ML, Church and Dwight Company, Inc., Princeton, NJ) to create 4 treatment diets. Milk fat yield and concentration was significantly lower for CO than for PO. Milk yield was significantly lower for LOC than all other diets except ML. There were no treatment by parity or treatment by production effects on any of these parameters. The underperformance of the LOC versus the other diets suggests that it is useful to feed some fat in the diet. However, while adding free oils to the LOC diet increased milk yield, only palm oil increased milk fat yield.

Table 1.

Item	CC	LOC	CO	OO	PO	ML
C18:2 from oil, % Diet DM	—	—	1.15	0.18	0.16	0.11
Milk, kg/d	43.5^{ab}	39.7^{c}	42.7^{ab}	43.1^{ab}	43.5^{a}	40.7^{bc}

T123 Increasing dietary cation-anion difference improves feed efficiency in lactating dairy cows. M. E. Iwaniuk* and R. A. Erdman, *University of Maryland, College Park.*

Feed costs in the dairy industry have doubled during the last five years and dairy producers are keenly interested in factors that will improve dairy feed efficiency (FE). The most common index of dairy FE is 3.5% fat-corrected milk (FCM) per unit of dry matter intake (DMI). Increasing dietary cation-anion differences (DCAD) has been shown to increase milk production, FCM, and FE while optimizing DMI. However, the optimal DCAD concentration for maximum production and dairy FE has yet to be determined. The objective of this experiment was to determine the optimal DCAD concentration for maximal FE in early lactation dairy cows. Eight primiparous and 12 multiparous Holstein cows averaging 89 (±25) days in milk were used. Cows were individually fed a basal diet consisting of 60% corn silage and 40% concentrate (dry matter basis). Experimental treatments consisted of 250 (basal), 300, 350, and 400 mEq/kg DCAD which were applied in a 4 × 4 Latin square design with 3-week experimental periods. Potassium carbonate was added to the basal diet to provide the respective DCAD concentrations. DCAD had no effect on milk production or DMI. However, milk fat percent was increased linearly ($P = 0.014$) by DCAD resulting in an increased ($P = 0.054$) FCM. This resulted in a 0.08 unit increase in dairy FE ($P = 0.027$). As the maximum FE occurred at the highest DCAD concentration, the optimal DCAD could not be determined, but it would be at least 400 mEq/kg DM. The results confirm earlier studies suggesting that altering DCAD could be used to increase FE in dairy cows and reduce feed costs.

Table 1.

	DCAD, mEq/kg					$P <$	
Item	250	300	350	400	SEM	Linear	Quadratic
Milk, kg/d	38.9	38.4	39.2	38.7	1.560	0.943	0.917
Fat, %	2.58	2.82	2.75	2.89	0.179	0.014	0.529

Key Words: dairy cow, DCAD, potassium carbonate

T124 Sodium bicarbonate is more effective than potassium carbonate as a DCAD source for improving feed efficiency in lactating dairy cows. M. E. Iwaniuk* and R. A. Erdman, *University of Maryland, College Park.*

Increasing dietary cation-anion differences (DCAD) has been shown to increase milk production (MP), 3.5% fat-corrected milk (FCM), and feed efficiency (FE) while optimizing dry matter intake (DMI) in lactating dairy cows. Either sodium (Na) or potassium (K) can be used to increase DCAD in lactating dairy cow diets; however, cation supplementation with potassium carbonate (K_2CO_3) is 4× more expensive than cation supplementation with sodium bicarbonate ($NaHCO_3$). The objective of this study was to determine the relative efficacy of K_2CO_3 versus $NaHCO_3$ on dairy FE. Eight primiparous and 12 multiparous Holstein cows averaging 95 (±75) days in milk were used. Cows were individually fed a basal diet consisting of 65% corn silage and 35% concentrate (dry matter basis). Experimental treatments consisted of a basal diet containing 250 mEq/kg DCAD, and the addition of 150 mEq/kg DCAD using four ratios (mEq/kg basis) of K:Na: 100:0, 67:33, 33:67, and 0:100 using K_2CO_3 and $NaHCO_3$, respectively. Treatments were applied in a 4 × 4 Latin square design with 3-wk experimental periods. Cation source had no effect on DMI, MP, or FCM production. However, cation source had

a significant effect on milk fat where replacement of K with Na resulted in a linear increase in milk fat percent ($P = 0.005$). Dairy FE, defined as FCM/DMI, was highest ($P = 0.04$) when Na was the sole cation source. This change was primarily a result of increased milk fat percent that increased FCM. These results suggest that Na was more effective than K as a cation supplement to improve dairy FE.

Table 1.

	K:Na[1]					$P <$	
Item	100:0	67:33	33:67	0:100	SEM	Linear	Quadratic
Milk, kg/d	37.5	37.3	36.3	37.9	1.280	0.903	0.219

FCM/DMI	1.56	1.58	1.55	1.67	0.040	0.036	0.125

[1]All diets contained an overall DCAD concentration of approximately 400 mEq/kg.

Key Words: dairy cow, DCAD, feed efficiency

T125 Quality of corn silage inoculated with *L. buchneri* and *P. pentosaceus*. K. N. Kaletsch*[1], S. H. Ward[1], J. K. Ward[2], J. D. Davis[2], and A. J. Geiger[1], *[1]Department of Animal and Dairy Sciences, , Mississippi State, [2]Department of Agriculture and Biological Engineering, Mississippi State.*

Corn was harvested on July 21–22, 2012, using a 1.9-cm forage chopper with kernel processor. Corn was 35% DM and treated with 5×10^5 cfu/g of *Lactobacillus buchneri* and *Pediococcus pentosaceus* (B500) or not (CON). Treatment was applied as silage was loaded into bags using a Kelly Ryan Bagger with a 2.74 m tunnel. 22,959 and 25,290 kg of wet silage was loaded into CON and B500 bag, respectively. Temperature sensors were placed in the bags and data was logged every 4 h for 120 d. Samples were collected every 6 h for 48 h, every 24 h for 5 d, then weekly for 5 wk, and again at 90 and 120 d. Samples were analyzed for pH then subjected to proximate analysis. Samples were pooled by week (1-6), 90 and 120 d, analyzed for mold and mycotoxins. MIXED procedure of SAS (Cary, NC) was used to analyze the main effects of treatment, day, and their interaction. Significance was declared at $P < 0.05$. Interaction of treatment and day was significant for all measures of proximate analysis and pH. DM was lower in B500 compared to CON (39.1 vs. 40.2%, respectively; $P < 0.01$). DM increased in CON from 40% on d 60 to 45% on d120 and decreased in B500 from 35% on d 60 to 25% on d120. Ash content was greater in CON compared to B500 (5.0 vs.4.9%, respectively; $P < 0.04$). IVDMD was greater in CON compared to B500 (72.7 vs. 60.9%. respectively, $P < 0.01$). On d7, 8, and 50 CON had greater NDF (53.6, 52.3, 52.7%, respectively) and ADF (25.9, 29.3, 28.8%, respectively) than B500 (NDF: 43.5, 50.1, 46.9%, respectively; ADF: 17.1, 24.3, 27.3%; respectively; $P < 0.01$), otherwise B500 had greater NDF and ADF content. CP was lower in B500 than CON on d7, 40, and 50 (7.0 vs. 7.3%; 7.5 vs. 7.8%; 8.5 vs. 9.6%; respectively, $P < 0.01$), but greater on other days. In 24h, pH of CON decreased faster compared to B500 (4.5 to 3.9 vs. 3.9 to 3.8, respectively; $P < 0.01$). B500 had lower pH on d1, but the reverse was observed in subsequent days. Greater spoilage was noted in B500 as time progressed. Mold count exceeded 6×10^6 cfu/g by d 120 in B500 compared to CON (<50,000 cfu/g). Inoculation was more effective in nutrient preservation than CON, but after d60 data indicated increased spoilage of inoculated silage.

Key Words: silage, inoculant, dairy

T126 Effect of stocking density in the prepartum period on innate immune parameters and hemogram of dairy cows. A. Dresch*[1], J. Moraes[1], P. Silva[2], H. Hooper[1], C. Spies[1], P. Lau[1], K. Lobeck[2], K. Machado[1], M. Ballou[3], M. Endres[2], and R. Chebel[1], *[1]Department of Veterinary Population Medicine, University of Minnesota, St Paul, [2]Department of Animal Science, University of Minnesota, St Paul, [3]Department of Food and Animal Sciences, Texas Tech University, Lubbock.*

Objectives were to evaluate the effect of prepartum stocking density on innate immune parameters and hemogram of Jersey cows. Within each replicate (n = 4), 2 pens were assigned to 80% stocking density (80D, n=38) and 2 pens were assigned to 100% stocking density (100D, n=48). Nulliparous and parous animals were housed separately. Pen was considered the experimental unit (n=8/treatment). A sub-sample of animals randomly selected to represent each pen (n=48/treatment) had blood sampled weekly from 14 d prepartum to 14 d postpartum. Polymorphonuclear leukocyte (PMNL) phagocytosis (PHAGO) and oxidative burst (OB) and expression of CD18 and L-selectin were determined by flow cytometry, and complete blood count was performed. Animals were examined for metritis at 4, 7, 10, and 14 d postpartum. Dichotomous data were analyzed by logistic regression using the PROC GLIMMIX and continuous data were analyzed by ANOVA using the PROC MIXED procedure. Pen was included as the random effect. Treatment was nested within pen and replicate and cows were nested within treatment. Stocking densities were 74.0 and 94.3% (±0.3) of headlocks and 80.7 and 102.8% (±0.4) of stalls for 80D and 100D, respectively. The incidence of metritis was 33.3 and 11.8% for nulliparous animals and 16.7 and 22.2% for parous animals in the 80D and 100D treatments, respectively. Treatment did not affect percentage of PMNL PHAGO+ ($P = 0.71$) and the intensity of PHAGO ($P = 0.79$). Similarly, treatment did not affect percentage of PMNL OB+ ($P = 0.84$) and intensity of OB ($P = 0.84$). Treatment tended to affect percentage of PMNL CD18+ (80D = 98.8 ± 0.3 vs. 100D = 99.5 ± 0.3%; $P = 0.12$). Intensity of CD18 expression by PMNL, however, was not affected by treatment ($P = 0.47$). Percentage of PMNL L-selectin+ was not ($P = 0.93$) affected by treatment. Similarly, intensity of L-selectin expression by PMNL was not ($P = 0.66$) affected by treatment. The ratio of granulocyte:lymphocyte was not ($P = 0.96$) affected by treatment. Stocking density did not affect innate immune parameters, indicating that 100% stocking density during the prepartum period may not affect health of dairy cows.

Key Words: stocking density, dairy cow, immune response

T127 Effects of residual feed intake classification on feed efficiency, ultrasound, and feeding behavior traits in growing Santa Gertrudis heifers. J. A. Ramirez*[1], G. E. Carstens[1], J. G. Moreno[1], L. O. Tedeschi[1], J. C. Bailey[1], J. Jorgenson[2], and D. D. DeLaney[2], *[1]Texas A&M University, College Station, [2]King Ranch, Kingsville, TX.*

Objectives of this study were to evaluate the effects of residual feed intake (RFI) classification on performance, efficiency, carcass ultrasound and feeding behavior traits in growing heifers. Santa Gertrudis heifers (n = 220) with initial BW of 282.3 ± 98 kg were used in this study. Feed intake and feeding behavior traits were collected for 70 d using a GrowSafe system while consuming a forage-based diet (ME = 2.04 Mcal/kg DM). RFI was computed by regression of DMI on mid-test $BW^{0.75}$ and ADG, and heifers classified into low and high RFI (± 0.05 SD) groups. A 2-population distribution model was fit to $\log_{10}$-transformed non-feeding interval lengths to estimate meal criterion (MC) and compute frequency and duration. RFI was positively correlated ($P < 0.001$) with DMI (r = 0.77) and F:G (r = 0.68), but not with initial BW or ADG. RFI was positively correlated ($P < 0.05$) with bunk visit

(BV) frequency (r = 0.50) and duration (r = 0.44), and meal frequency (r = 0.13) duration (0.32). RFI was negatively correlated with meal criterion (r = −0.33). The R^2 of the base RFI model (ADG, mid-test $BW^{0.75}$) was 0.42, which increased to 0.65 with the inclusion of feeding behavior traits (BV frequency and duration, MC, meal frequency and duration). Low RFI heifers had 25 and 26% lower ($P < 0.0001$) DMI and F:G compared to high RFI heifers. Heifers with low RFI had lesser ($P < 0.001$) BV frequency (60.5 vs. 75.4 ± 1.7 events/d) and duration (80.2 vs. 99.5 ± 4.1 min/d) and higher ($P < 0.01$) MC (11.65 vs. 9.45 ± 0.61 min) compared to high-RFI heifers. Between-animal variation in RFI was not associated with differences in ultrasound measurements of carcass composition in this study. However, variation in feeding behavior traits account for 23% additional variance in DMI beyond that associated with ADG and mid-test $BW^{0.75}$. The longer MC observed in low-RFI heifers suggests that these heifers take longer to initiate a subsequent meal compared to high-RFI heifers, and demonstrate the heifers with divergent RFI have distinctive feeding behavior patterns.

Key Words: feeding behavior, residual feed intake

T129 Hepatic gluconeogenesis in dairy cows as affected by dietary starch level and supplementation with monensin during early lactation. M. M. McCarthy*[1], T. Yasui[1], S. H. Pelton[1], C. M. Ryan[1], G. D. Mechor[2], and T. R. Overton[1], *[1]Cornell University, Ithaca, NY, [2]Elanco Animal Health, Greenfield, IN.*

The objectives of this study were to determine the effects of postpartum dietary starch level and supplementation with monensin (M) on rates of in vitro hepatic gluconeogenesis and oxidation from propionate. Primiparous (n = 17) and multiparous (n = 37) Holstein cows were fed a high starch (HS) or low starch (LS) early lactation diet with 0 or 450 mg/d M by topdress in a 2 (starch) × 2 (M) factorial arrangement. Prior to parturition all cows received a common controlled energy diet ad libitum with a daily topdress of either 0 or 400 mg/d M, depending on early lactation treatment assignment. From parturition until d 21 cows were fed HS TMR (26.2% starch, 34.3% NDF, 22.7% ADF, 15.5% CP) or LS TMR (21.5% starch, 36.9% NDF, 25.2% ADF, 15.4% CP) with a daily topdress of 0 or 450 mg/d M. Biopsies were obtained on d 7 (± 4) postpartum and liver slices used in an in vitro incubation system to determine liver capacity to convert [1-^{14}C]propionate to CO_2 and glucose. Interactions of starch × M were not significant. There was no effect of starch or M treatment on liver capacity to oxidize propionate to CO_2, and effects of starch on gluconeogenesis were not significant. Cows fed M tended (P=0.14) to have greater capacity to convert propionate to glucose than controls. Primiparous animals had greater capacity for oxidation and gluconeogenesis from propionate than multiparous animals (P = 0.04 and 0.01, respectively). In vitro incubation with insulin (10 n*M*) tended to decrease propionate oxidation to CO_2 (P = 0.10) but had no effect on propionate conversion to glucose. The ratio of rates of conversion of radiolabeled propionate to glucose and CO_2 provide an index of the efficiency of propionate utilization for gluconeogenesis; M supplementation increased the ratio of glucose to CO_2 (P = 0.05), which indicates that cows fed M have a greater propensity to convert propionate to glucose. Overall, primiparous cows had greater capacity to both oxidize and convert propionate to glucose than did multiparous cows and M increased hepatic capacity to convert propionate to glucose relative to CO_2.

Key Words: early lactation, gluconeogenesis, monensin

T130 Effect of postruminal propionate infusion on expression of key genes for gluconeogenesis in the liver of lactating dairy cows. Q. Zhang*, H. A. Tucker, K. E. Boesche, J. E. Sibray, S. L. Koser, and S. S. Donkin, *Purdue University, West Lafayette, IN.*

Propionate is the major precursor for gluconeogenesis in ruminants. Glucose demand during lactation is met through increased availability of gluconeogenic precursors, including propionate, as a consequence of greater feed intake. This experiment evaluated the effect of increased postruminal propionate supply on hepatic expression of phosphoenolpyruvate carboxykinase-cytosolic (PEPCK-C), phophoenolpyruvate carboxykinase – mitochondria (PEPCK-M) and glucose-6-phosphatase (G6P), three rate-limiting enzymes for gluconeogenesis in bovine liver. Six multiparous mid-lactation Holstein cows were utilized in a replicated 3 × 3 Latin square. Periods consisted of a 6-d acclimation and washout phase followed by 8-h infusion. Solutions delivered 1.67 mol propionate, 0.84 mol glucose, or an equivalent volume of water over 8-h period. On the day of infusion, blood samples were collected at 0,2,4,6, and 8-h relative to the start of infusion for blood propionate, glucose, and insulin analysis and liver biopsy samples were collected at the end of infusion for mRNA analysis. Plasma propionate tended to increase at 8-h relative to start of infusion with propionate infusion (0.059 m*M* vs. 0.044 m*M* vs. 0.037 m*M* for propionate, glucose and water, respectively; P = 0.07). Plasma glucose was not affected by treatments (P > 0.1). Serum insulin was increased (P < 0.05) 1.47-fold by glucose and1.74 fold by propionate compared to water infusion. There was a tendency for PEPCK-C expression to differ (P = 0.1) among treatments (1.45 vs. 0.65 vs. 1.33 arbitrary units, for propionate, glucose and water, respectively). Propionate tended to increase PEPCK-C expression compared to isocaloric glucose infusion (P = 0.1). Expression of PEPCK-M and G6P mRNA were not affected by treatments (P > 0.1). These data indicate in vivo effects of propionate to alter hepatic gene expression in mid-lactation dairy cows that is tempered by a commensurate increase in serum insulin concentration.

Key Words: propionate, gluconeogenic gene expression, lactating dairy cow

T131 Regulation of pyruvate carboxylase expression by fatty acid cocktails in Madin-Darby bovine kidney cells. K. E. Boesche*, S. L. Koser, and S. S. Donkin, *Department of Animal Sciences, Purdue University, West Lafayette, IN.*

Pyruvate carboxylase (PC) catalyzes oxaloacetate synthesis, a key reaction for both gluconeogenesis and fatty acid oxidation. Activity of this enzyme is linked to PC mRNA and is increased during feed restriction and transition to lactation, metabolic states when non-esterified fatty acids (NEFA) are elevated in blood. Saturated fatty acids, including C18:0, decrease expression of PC while intracellular signals related to unsaturated fatty acid metabolism act to increase PC expression in Madin-Darby bovine kidney (MDBK) cells. The objective of this study was to determine dominance of control of PC mRNA expression in MDBK cells with copresence of saturated and unsaturated fatty acids. MDBK cells were cultured to 80% confluence and exposed to fatty acid treatments for 24h. Single fatty acid treatments consisted of 1.0 m*M* of either C16:0, C18:0, or C18:3n-3 *cis*. Fatty acid cocktails (1 m*M* total) were supplied as increasing concentrations of C18:3n-3 *cis* (0.25 m*M*, 0.5 m*M*, 0.75 m*M*) combined with decreasing concentrations of either C16:0 (0.75 m*M*, 0.5 m*M*, 0.25 m*M*) or C18:0 (0.75 m*M*, 0.5 m*M*, 0.25 m*M*). Saturated fatty acid treatments of either 1.0 m*M* C16:0 or 1.0 m*M* C18:0 decreased (P < 0.05) PC expression by 72.2% and 92.9%, respectively. Cells exposed to 1.0 m*M* C18:0 had significantly lower (P < 0.05) PC expression when compared to C18:0 treatment combined, at any level, with C18:3n-3 *cis*. While the lowest evaluated concentration (0.25 m*M*) of C18:3n-3 *cis* proved enough to ameliorate PC expression with exposure to 0.75 m*M* C18:0, only the highest inclusion level of C18:3n-3 *cis* (0.75 m*M*) with C16:0 (0.25m*M*) could recover PC expression to levels similar to control. Data indicate that C18:3n-3 *cis* is a more potent alleviator of PC depression caused by C18:0 than similar effects resulting from C16:0 exposure. The activation of PC mRNA by unsaturated fatty acids may play a critical role in setting the capacity for fatty acid oxidation.

Key Words: fatty acid, gluconeogenesis, pyruvate carboxylase

T132 Lying time, lameness and leg injuries on freestall farms in China. Y. Liang*[1,2], Y. Wang[3], G. I. Zanton[2], M. A. Vazquez-Anon[2], D. M. Weary[1], and M. A. G. von Keyserlingk[1], *[1]Animal Welfare Program, University of British Columbia, Vancouver, Canada, [2]Novus International Inc., St. Louis, MO, [3]Novus International Inc., China.*

The aim of the study was to describe variation in lying time, lameness, and leg injuries among Holstein herds in two prominent dairy regions in China: Beijing (14 herds) and Huadong (25 herds). One trained individual evaluated one group of high production cows in each of the herds. Cows were gait scored using a 5-point Numerical Rating System where 1 and 2 are considered non-lame, ≥3 clinically lame, and ≥4 severely lame. Hock injuries were scored on a scale of 1 to 5 (1=healthy and 5=severe swelling or severe lesion). Knee injuries were based on a 1 to 3 scale (1=healthy, 2=hair loss and 3=evident swelling). The analyses were descriptive and all results are presented as means ± standard deviation. Herd size in the Beijing region averaged 807 ± 701 milking cows (range 184 to 2444) and 1737 ± 2115 cows (range 160 to 8873) in Huadong. Lying times and lameness were similar in the two regions: lying time averaged 11.3 ± 0.54 h/d (range 10.3 to 12.3 h/d) and 11.4 ± 1.01 h/d (range 9.1 to 13.1 h/d); prevalence of clinical lameness averaged 29 ± 10.5% (range 15% to 46%) and 29 ± 13.7% (range and 6% to 51%); and prevalence of severe lameness averaged 10 ± 7.7% and 8 ± 6.0% in Beijing and Huadong, respectively. Knee and hock injuries were less prevalent in Beijing versus Huadong: prevalence of swollen knees averaged 4 ± 4.1% versus 16 ± 9.2%; prevalence of hock injuries (≥2) averaged 37 ± 11.3% and 41 ± 24.6; and prevalence of severe injuries (score ≥4) averaged 1 ± 1.2% and 7 ± 10.7% in Beijing and Huadong, respectively. Previous work on North American farms has demonstrated that the use of deep bedding is highly protective for leg injuries. We therefore suggest that the lower rates of knee and hock injuries in Beijing were likely associated with most farms in this region using deep-bedded stalls, but more work is now required to identify farm management factors associated with injuries and other indicators of cow comfort on farms in these regions of China.

Key Words: lying time, hock injuries, knee injuries

T133 Colostrum replacer feeding regimen, addition of sodium bicarbonate, and milk replacer: The combined effects on absorptive efficiency of IgG in neonatal calves. R. G. Cabral*[1], M. A. Cabral[1], C. E. Chapman[1], D. M. Haines[2], and P. S. Erickson[1], *[1]University of New Hampshire, Durham, [2]Western College of Veterinary Medicine, University of Saskatchewan, Saskatoon, SK, Canada.*

Eighty Holstein and Holstein cross dairy calves were blocked by birth date and randomly assigned to 1 of 8 treatments within each block. The objective of this experiment was to examine the effect of colostrum replacer (CR) feeding regimen, supplementation of CR with sodium bicarbonate ($NaHCO_3$), and provision of a milk replacer (MR) feeding on IgG absorption. Calves were offered CR containing 184.5 g/L of IgG in either 1 feeding at 0 h (within 30 minutes of birth), with or without 30 g of $NaHCO_3$, with or without a feeding of MR at 6 h, or 2 feedings of CR (123 g/L of IgG at 0 h with or without 20 g of $NaHCO_3$ and 61.5 g/L at 6 h with or without 10 g of $NaHCO_3$), with or without a MR feeding at 12 h. Blood samples were obtained at 0, 6, 12, 18, and 24 h after birth and were analyzed for IgG via radial immunoassay. Results indicated that CR feeding regimen, MR treatments, and the interactions CR*Na, CR*MR, and CR*Na*MR were not significant for 24 h serum IgG, apparent efficiency of absorption (AEA), or area under the curve (AUC). Serum IgG at 24 h ($P < 0.0001$), AUC ($P < 0.0001$) and AEA (P = 0.0002) were decreased with addition of $NaHCO_3$ compared to calves not receiving $NaHCO_3$ (12.6 g/L vs. 16.08 g/L; 236.67 g/L·h vs. 314.50 g/l·h; and 24.8% vs. 31.07% respectively). There was a trend ($P = 0.09$) for a Na*MR interaction in reference to AUC indicating that feeding MR without $NaHCO_3$ supplementation (295.2 g/L·h) or not feeding MR with $NaHCO_3$ (229.2 g/L·h) is not beneficial compared to feeding neither MR nor $NaHCO_3$ (333.8 g/L·h), or feeding MR with $NaHCO_3$ (244.1 g/L·h). These data indicate that supplementation of CR with $NaHCO_3$ is not beneficial to IgG absorption and feeding MR within 6 h of CR feeding does not impact IgG absorption.

Key Words: colostrum replacer, sodium bicarbonate, milk replacer

T134 Serotonin (5-HT) increases gene expression of fatty acid enzymes and activates pAMPK in the mammary gland of transition rats. J. Laporta*, S. Weaver, C. Cronick, K. E. Merriman, T. L. Peters, and L. L. Hernandez, *University of Wisconsin-Madison, Madison.*

Fatty acids are fundamental to energy production and storage, cellular structure and are critical to the synthesis of milk fat. The role of serotonin (5-HT) in regulating milk protein gene expression in the mammary gland is established, however little is known regarding 5-HT's role in fatty acid metabolism in the mammary gland. Serotonin is synthesized in a two-step reaction from the amino acid L-tryptophan (L-TRP). The rate-limiting step is catalyzed by tryptophan hydroxylase (TPH1) to form 5-hydroxytryptophan (5-HTP), and 5-HTP is then converted directly into 5-HT. To explore the role of 5-HT in mammary gland fatty acid synthesis and energy expenditure during the transition period (9 d pre to 9 d postpartum) we fed 30 rats (n=15 per diet) 2 diets: (I) control (CON) and (II) 5-HTP (0.2% total diet). Blood was collected on d 9 of lactation to measure circulating 5-HT. Total RNA was isolated from mammary gland tissues collected on d 9 of lactation to measure the expression of peroxisome proliferator-activated receptor gamma (PPARG), leptin (LEP) and fatty acid synthase (FASN) by real time RT-PCR. Additionally, total protein was extracted from mammary glands to measure phosphorylated 5′ AMP-activated protein kinase (pAMPK, which regulates metabolic energy balance and metabolism of glucose and fatty acids) by western blot, and 5-HT by ELISA. Feeding 5-HTP effectively increased serum 5-HT concentrations over time ($P < 0.0003$). Mammary gland gene expression of PPARG, LEP and FASN was markedly up-regulated in the 5-HTP fed dams on d 9 of lactation ($P < 0.034$). Additionally, 5-HT concentrations were increased in the mammary gland of 5-HTP fed rats compared to CON ($P = 0.0083$). Finally, 5-HTP fed dams had significantly increased pAMPK compared to CON animals ($P = 0.006$). These results suggest the possibility that 5-HT is involved in regulating fatty acid and energy metabolism during the transition from pregnancy to lactation in the mammary gland of rats. However, the physiological significance and the mechanism of action regulating these findings needs to be further investigated.

Key Words: fatty acid, serotonin, lactation

T135 Effect of induced subclinical hypocalcemia (SCH) on physiological parameters and function of immune cells in dairy cows. N. Martinez*, L. D. P. Sinedino, R. S. Bisinotto, E. S. Ribeiro, G. C. Gomes, F. S. Lima, L. F. Greco, J. P. Driver, C. A. Risco, and J. E. P. Santos, *University of Florida, Gainesville.*

Objectives were to create a model to induce SCH [blood ionized calcium (Ca^{2+}) NC, 0.9% NaCl i.v. plus 43 g of oral Ca at 0 and 12 h) or an induced SCH (SCHI, 5% EGTA at pH 7.4, i.v.) in a crossover design. The infusion lasted 24 h. The sequence of treatments was either NC-SCHI or SCHI-NC. A 6-d period between treatment administrations was used to minimize carryover effects. Heart and respiratory rates, rectal temperature, and rumen contractions were measured during and after infusion at 6 to 12-h intervals. Ionized Ca, K, Mg, and blood pH were evaluated

at 0 h, hourly during the infusion period, and at 24, 48 and 72 h after the infusion to monitor Ca^{2+}. In addition, DMI, neutrophil function, and white blood cell differential count (WBC) were evaluated at 0, 24, 48 and 72 h after treatments. Data were analyzed using PROC GLIMMIX of SAS. Infusion of a 5% EGTA solution successfully induced SCH in SCHI cows (0.78±0.01 vs. 1.27±0.01 mM Ca^{2+}) during 23 h. There were no differences in heart and respiratory rates, rectal temperature, and WBC between SCHI and NC cows. On the infusion day, SCHI cows had lower ($P < 0.01$) K (2.92 ± 0.07 vs. 3.47 ± 0.07 m*M*) and higher ($P < 0.01$) Mg (0.94 ± 0.03 vs. 0.68 ± 0.03 m*M*) in blood. The decrease in blood Mg was likely caused by supplemental oral Ca in NC. SCHI cows had reduced ($P < 0.01$) DMI on the day of infusion (5.1 vs. 10.0 kg/d) and decreased ($P = 0.01$) rumen contractions every 2 min (1.7 vs. 2.7) in the second half of the infusion period. Cows in SCHI had a reduced ($P < 0.01$) percent of neutrophils with phagocytosis (79.9 ± 8.8 vs. 119.2 ± 13.0, % baseline) and oxidative burst (80.2 ± 17.9 vs. 140.3 ± 17.9, % baseline), evident at 24 h after the end of the infusion. A 5% EGTA solution successfully induced SCH in dairy cows. Subclinical hypocalcemia reduces DMI, rumen contractions and neutrophil function and it is suggested to be linked with peripartum immunosuppression.

Key Words: dairy cow, neutrophil, subclinical hypocalcemia

T136 Modification of AOAC method to measure total starch in animal feeds. S. D. Ranathunga*, J. L. Anderson, K. J. Herrick, and K. F. Kalscheur, *South Dakota State University, Brookings.*

Various methods are currently available to measure total starch in animal feeds. The ease of use, time spent on analysis, and cost per assay may vary between methods. The AOAC method 996.11 (1996) has been recognized as an accurate, repeatable, and efficient method to measure total starch. The objective of this study was to determine if an alternative starch method would be more economical and alleviate technical difficulties associated with the AOAC method. Modification of the AOAC method was done by combining the AOAC method with the acetate buffer method by M. B. Hall (2009) and using alpha-amylase (1200 liquefon units/assay) and amyloglucosidase (400 units/assay) concentrations from different sources (Ankom Technology Inc. and Sigma-Aldrich Inc.). The modified method was performed in sealable vessels. Nine samples including pure corn starch, TMR, concentrate mixture, alfalfa, corn silage, dried distillers grains with solubles, ground corn, dried fecal, and dried rumen samples were analyzed using the two methods. Two technicians performed two runs of each method. All samples were analyzed in duplicate within each run. The effect of method, technician, and run was analyzed using Tukey's test. Starch concentrations of the analyzed samples were not different between the two methods (pure corn starch = 101, TMR = 27.9, concentrate mixture = 33.3, alfalfa = 2.62, corn silage = 22.7, dried distillers grains with solubles = 4.51, ground corn = 72.7, fecal sample = 2.2 and rumen sample = 1.67% with SE of 0.15%). The average starch concentration for all samples (29.8% with ± 0.07% SE) was not affected by method ($P = 0.24$), technician ($P = 0.49$), nor run ($P = 0.59$). The average time spent to analyze 18 samples was around 3 h for both methods. Average cost per sample assayed with the modified method was $0.76 compared with $3.30 for the AOAC method. Therefore, the modified starch assay could be considered a more cost effective and less technically difficult method compared with the AOAC starch method.

Key Words: AOAC method 996.11, starch, feed analysis

T137 Concentrations of luteinizing hormone and ovulatory responses in dairy cows before timed AI. S. L. Pulley*[1], D. H. Keisler[2], and J. S. Stevenson[1], *[1]Kansas State University, Manhattan, [2]University of Missouri, Columbia.*

Our objective was to determine the incidence of spontaneous and GnRH-induced LH surges and ovulatory responses in lactating dairy cows enrolled in a timed AI (TAI) program. Cows were assigned randomly at calving to 2 treatments: 1) Pre10 (n = 37): two 25-mg injections of $PGF_{2\alpha}$ (PG-1 and PG-2) 14 d apart (Presynch); or 2) PG3G (n = 33): one 25-mg injection of PG 3 d before 100 µg GnRH (G-1), with a PG injection administered at the same time as PG-2. Cows were enrolled in a TAI protocol 10 d after PG-2 (Ovsynch; injection of GnRH 7 d before [G-2] and 56 or 72 h after [G-3] PG-3 with TAI at 72 h after PG-3). Blood was collected to determine LH at: (1) G-1: 0 to 80 h after PG-2 and hourly from 72 to 78 h (G-1 at 72 h); (2) G-2: 0 to 6 h after G-2; and (3) G-3: 0 to 80 h after PG-3 and hourly from 56 to 62 or 72 to 78 h for cows injected with GnRH (G-3) at 56 or 72 h after PG-3. Ovaries were scanned before injections and pregnancy per TAI (P/TAI) was diagnosed 31 d post-TAI by ultrasonography. The PG3G cows had increased ($P < 0.01$) incidence of induced LH surges in response to G-1 than Pre10 cows (75.8 vs. 0%). Proportion of cows with spontaneous (43.2 vs. 24.2%) or no LH surge (56.8 vs. 0%) was greater ($P < 0.01$) in Pre-10 than PG3G cows, respectively. An induced LH surge occurred in all cows at G-2 regardless of treatment. More ($P < 0.05$) cows had induced LH surges after G-3 at 56 (100%) than after 72 h (88.6%). Ovulation rate at G-1 was greater ($P = 0.003$) in PG3G (90.9%) than Pre10 (59.5%) cows, but did not differ at G-2 (PG3G = 51.5%; Pre10 = 61.2%). At G-3, ovulation was more ($P < 0.05$) likely in Pre10 than PG3G cows (94.6 vs. 84.9%) and after G-3 at 56 than 72 h (94.3 vs. 85.7%). The P/TAI for PG3G vs. Pre10 (56.7 vs. 37.8%) and for 56- vs. 72-h G-3 injections (54.5 vs. 38.2%) did not differ. We conclude that more PG3G cows had LH surges at G-1 compared with Pre10. Consistent with our earlier report, PG3G cows had increased ovulation rates at G-1 and greater ($P = 0.069$) progesterone at G-2 (4.1 vs. 2.7 ± 0.5 ng/mL) than Pre10 cows.

Key Words: Presynch, LH surge, pregnancy

T138 Discovery of genomic markers for gut health in dairy calves. G. Liang*[1], N. Malmuthuge[1], H. Bao[1], X. Sun[1], P. Stothard[1], T. B. McFadden[2], P. J. Griebel[3], and L. L. Guan[1], *[1]Department of Agricultural, Food and Nutritional Science, Edmonton, AB, Canada, [2]Divison of Animal Sciences, University of Missouri, Columbia, [3]Vaccine and Infectious Disease Organization, University of Saskatchewan, Saskatoon, SK, Canada.*

Enteric diseases significantly impair the health and productivity of both beef and dairy cattle. Moreover, it is well known that calf gut health is a critical determinant of a cow's lifelong performance and efficiency. MicroRNAs (miRNAs) are a large family of small, non-coding RNAs that have emerged as key regulators of gene expression involved in numerous biological processes including innate and adaptive immunity. We hypothesized that miRNAs regulate development of gut immune function and innate immune responses to enteric pathogens in pre-weaned dairy calves. In this research, expression profiles of miRNA and their potential target genes in the gut were characterized using next-generation sequencing analysis of small intestine tissues (ileum, mid-jejunum and distal-jejunum) collected from healthy calves at 1 week (n = 6), 3 week (n = 6), or 6 week (n = 6) postpartum. In total, 103,452,564 high-quality small RNA tags were obtained, of which 75,903,402 tags were mapped to a known bovine miRNA database (miRBase 19). The results showed that 495 known miRNAs were identified in distal-jejunum, 472 in mid-jejunum and 455 in ileum. Moreover, 141 candidate novel miRNAs were also detected from these tissues. Further analysis revealed that the expression pattern of some miRNAs known to be involved in regulation of immune

functions differed between calves of different ages and among different regions of the small intestine. For example, miRNAs of the bta-miR-29 and bta-miR-146 families, which may regulate immune responses and TLR signaling, respectively, were differentially expressed across the three ages. In addition, members of the bta-miR-10 and bta-miR-196 families, which may play crucial roles in the development of the intestinal mucosal immune system of dairy calves by regulating intercellular junctions, were differentially expressed. In conclusion, we have identified several miRNAs that were differentially expressed during the early life of dairy calves. These miRNAs may play a role in development of the gut immune system and therefore may be useful as molecular diagnostic markers to predict host response and susceptibility to enteric infections and diseases.

Key Words: dairy calf, gut health, microRNA

T139 Effects of an adjustable fan and mister cooling system with different motor size and water output on core body temperature (CBT) of lactating dairy cows. S. D. Anderson*[1], J. D. Allen[2], R. J. Collier[1], and J. F. Smith[1], *[1]The University of Arizona, Tucson, [2]Northwest Missouri State University, Maryville.*

Evaporative cooling in arid environments is effective in reducing heat stress on dairy cows during periods of high temperature. The FlipFan Dairy Cooling System (FLFN) is an adjustable fan and mister cooling system which is available in either 0.50 HP (372.85 W) or 0.75 HP (559.27 W) versions. In this study, water output of 0.50 HP FLFN ranged from 0.42 to 1.26 L/min per fan under 1,379 to 1,551 kPa of pressure, and 0.75 HP FLFN had water output of 0.40 to 3.14 L/min per fan under 689 to 6895 kPa of pressure. Misters in both systems automatically turned off when relative humidity (RH) exceeded 65%. Our objective was to determine if FLFN operated at 0.75 HP was more effective than 0.50 HP FLFN at lowering CBT of multiparous, lactating Holstein cows (46.7 ± 0.75 kg/milk per d, 143 ± 6 DIM) on a commercial dairy in Arizona. Twenty four cows were measured continuously in a switchback design for 8 d. Cows were housed in 1 of 2 pens with 12 study cows/pen. Pen served as the experimental unit. The study consisted of 4 2-d periods in which the first day served as an acclimation period, whereas data collected on the second day was used for statistical analysis. All cows were subjected to each cooling treatment twice. Mean daily dry-bulb temperature was 30.0 ± 0.80°C and ranged from 24.0°C to 36.3°C. Mean daily RH was 55.5 ± 2.16% and ranged from 39.9% to 73.2%. Mean daily temperature-humidity index (THI) was 78.8 ± 0.78 and ranged from 72.7 to 84.3. Mean 24-h CBT was lower ($P < 0.001$) for cows cooled by 0.75 HP FLFN compared to 0.50 HP FLFN (38.69°C vs. 38.84°C). Furthermore, mean hourly CBT was lower ($P < 0.001$) at all times of day for cows cooled by 0.75 HP FLFN. No treatment × time interaction was detected ($P = 0.3219$). Results suggest that 0.75 HP FLFN has greater cooling capacity as measured by lower CBT. However, additional work will be required to determine what situations warrant the additional electrical and water cost to operate the 0.75 HP FLFN. There may be different conclusions for different climates, stage of lactation, and parity.

Key Words: heat stress, adjustable fan, water output

T140 The effect of induced ascites syndrome on blood gas parameters and internal organ weights in broilers. M. Naghous[1], A. Pakdel[2], R. V. Torshizi[3], and H. Bazdidi*[1], *[1]Dept. of Animal Science, Faculty of Agriculture, Birjand University, Birjand, Iran, [2]Dept. of Animal Science, University College of Agriculture & Natural Resources, University of Tehran, Karaj, Iran, [3]Dept. of Animal Science, Faculty of Agriculture, Tarbiat Modares University, Tehran, Iran.*

In order to evaluate the effects of induced ascites syndrome on blood gas parameters and internal organ weights, 149 male birds and 200 females birds were randomly selected from a commercial broiler strain and rearing under two normal and induced ascites condition. Several traits including body weight gain, feed intake (FI), food conversion ratio (FCR) between 23 and 54 d of age were evaluated. Moreover the blood gas parameters and hematocrit value were evaluated at 21, 35 and 54 d of age. At the end of experiment all the birds were slaughtered and the internal organs like liver, heart and spleen were inspected. There was no significant difference between two groups based on FCR and Body weight gain, while in the broiler males, FI was significantly different ($P < 0.05$). The result showed that liver and spleen weights were not significant different between two treatment in both sex. Right ventricle to total ventricle ratio (RATIO) of the male birds in the induced ascites treatment (T2), was higher than that of male birds in the control treatment (T1) ($P < 0.01$). However RATIO of females was not significantly different. The blood gas parameters including PH, $pvCO_2$, total CO_2, and pvO_2, were not significantly different between both groups of T1 and T2 in both sex However the O_2 saturation at 35 and 54 d of age in T1 group was higher than that of T2 group ($P < 0.05$). The results of current study indicated that O_2 saturation could be a useful measure for predicting ascites syndrome.

Key Words: ascites syndrome, blood gas parameter, broiler

T141 The relationship between growth curve and ascites syndrome in broilers. M. Naghous[1], A. Pakdel[2], R. V. Torshizi[3], and H. Bazdidi*[1], *[1]Dept. of Animal Science, Faculty of Agriculture, Birjand University, Birjand, Iran, [2]Dept. of Animal Science, University college of Agriculture & Natural Resources, University of Tehran, Karaj, Iran, [3]Dept. of Animal Science, Faculty of Agriculture, Tarbiat Modares University, Tehran, Iran.*

Ascites syndrome is a metabolic disorder in broilers. Birds that selected for higher body weight (BW) and lower feed conversion ratio (FCR) are more susceptible to this syndrome. The aim of present study was to investigate the relationship between growth curve and ascites syndrome in broilers. The BW at 1, 4, 7, 10, 14, 17, 21, 28, 35, 42, 49 and 54 d of age were measured on 299 male birds kept under normal (T1) and more susceptible condition to ascites syndrome (T2). The birds were chosen randomly from two sire lines A & B of a commercial broiler strain. These lines (A & B) were primarily selected for lower FCR and higher BW, respectively. Mortality in the induced ascites condition (T2) was higher than normal condition (T1) in both lines (mean 5.2% vs. 21.8%). Moreover right ventricle to total ventricle ratio of the induced T2 was higher than that of T1 ($P < 0.01$). The results of growth curve parameters in the sire line A showed that mature index and age at the inflection point between two treatments were significantly different ($P < 0.05$), but hatch weight, mature weight and weight at the inflection point weren't significantly different. The birds in T2 reached to the age at inflection point 1.55 d earlier than birds in T1, but weight at inflection point was similar in both treatments. The growth rate in T2 was higher than that of T1 until 35 d of age, but later on the growth rate was lower in T2 in compared to T1 ($P < 0.05$). Growth curve parameters in the sire line B showed that hatch weight, mature index, mature weight, weight and age at the inflection point between two treatments weren't significantly different. The growth rate in T2 was higher than that of T1 until 35 d of age, but later on the growth rate was lower in T2 in compared to T1. The results of current study indicated that induced ascites condition changed linear phase of growth in the male broiler chickens with lower FCR.

Key Words: ascites, low FCR, high body weight

T142 Performance, gut morphology and meat quality characteristics of broilers fed diets with probiotics supplementation. M. D. Olumide*, O. A. Adebiyi, and D. E. Bamisaye, *University of Ibadan, Ibadan, Oyo State, Nigeria.*

Large amounts of antibiotics have been used to control diseases and improve performance in livestock. However, due to growing concerns about antibiotics resistance and drug residues on carcass meat, bans had been placed on antibiotic growth promoters in many countries in the world. There is an increasing interest in finding alternatives to these antibiotics in poultry production. One alternative is beneficial bacterial-derived probiotics feed supplements. A total of 150 day-old Arbor Acre broiler chicks were distributed randomly into 5 treatments with 3 replicates (10 birds/replicate) in a completely randomized design. Treatments include: Control (0.00 g/kg), T1 (0.02 g/kg), T2 (0.04 g/kg), T3 (0.06/kg), and T4 (0.08 g/kg) of probiotics feed supplement. Data on performance, carcass quality and gut morphology were obtained. Data taken were subjected to statistical ANOVA procedure of SAS, 2010. No significant ($P > 0.05$) difference was observed in the final weight gain for all the birds on the respective treatment. Meat quality characteristics revealed significant ($P < 0.05$) differences in cooking loss, thermal shortening, cold shortening and water holding capacity of meat cuts from breast, drumstick and thigh areas. Birds fed the T4 diet had the lowest mean values for cooking losses (16.23%), thermal shortening (20.17%), cold shortening (0.20%) and water holding capacity (47.00%) for the thigh muscle when compared with birds on other treatments. Birds fed diet supplemented with 0.08 g/kg probiotics (T4) had a significant villus height and crypt depth compared to the others. Therefore, it can be concluded from this study that supplementing diets of broiler birds with 0.08 g/kg probiotics improves significantly the performance, meat quality and improve nutrient absorption of broilers.

Key Words: probiotic, broiler performance, gut morphology

T143 Evaluating the effectiveness of *Bacillus subtilis* (DMF) and yeast cell wall (YCW) in the performance of broiler chickens. M. Aronovich*[2], L. A. M. Keller[1], J. R. Sartori[3], J. E. Butolo[5], and A. N. Andrade[4], *[1]University Federal Rural of Rio de Janeiro (UFRRJ), Seropédica, RJ, Brazil, [2]Agricultural Development Company of the Rio de Janeiro State (PESAGRO), Niteroi, RJ, Brazil, [3]Universidade Estadual de São Paulo (UNESP), Botucatu, SP, Brazil, [4]Lesaffre Feed Additives (SAF), Rio de Janeiro, RJ, Brazil, [5]JEB Instituto de Biociências, São Paulo, SP, Brazil.*

Probiotics are live microorganisms that may confer a health benefit leading to increased performance. Lactic acid bacteria, bifidobacteria and certain yeasts are the most common types of microorganisms used. The functional capacity of the digestive tract of broilers during the first weeks of life can be considered a factor possible limiting to health and productivity. The focus of this study was determine if the use of *B. subtilis* and yeast cell

wall (Safmannan) offer benefits in production compared to antibiotic-based growth promoters (Virginiamycin). For this study 3,600 day-old male birds (Cobb) were acquired and randomly distributed in 5 treatments of 70 experimental units: Basal Ration (negative control); Basal Ration (positive control with growth promoter Virginiamycin-10g/ton); Basal Ration with *B. subtilis*-2g/ton; Basal Ration with *B. subtilis*-4g/ton; Basal Ration with Safmannan-500g/ton. Birds were observe daily and evaluated at d 0 (start), 21, 35 and 42 of treatment. The intestines of euthanized birds were collected and sectioned (duodenum, jejunum and ileum) for histopathological evaluation. All results were subjected to ANOVA with further tests of differences using Tukey analysis. Mean values for weight, weight gain, feed consumption, feed efficiency and mortality for treatment were not different from control values though tendencies towards reduced mortality were present for bacterial probiotics (Table 1). The data suggest that live culture *B. subtilis* probiotic treatment may be more beneficial towards reduced mortality than other tested options though more study is needed.

Table 1. Mean weight (MW), weight gain (WG), mean of feed consumption, feed conversion and mortality during the experimental period of 0 to 21 days

Treatment	MW and WG/ bird (kg)		Average consumption of feed (kg)	Feed conversion	Mortality (%)
T1- Negative Control	0.768	0.720	1.141	1.582	0.29
T2- Positive Control	0.773	0.725	1.144	1.574	0.57
T3- B. subtilis (2g/ton)	0.765	0.717	1.143	1.593	0.29
T4- B. subtilis (4g/ton)	0.760	0.713	1.142	1.602	0.14
T5- Safmannan (500g/ton)	0.780	0.732	1.142	1.556	0.49

T144 In vitro anthelmintic activity of crude aqueous extracts of *Pithecellobium dulce* and *Lysiloma acapulcensis* againts gastrointestinal nematodes in small ruminants. A. Olmedo[1], R. Rojo*[1], J. Arece[3], A. Salem[2], E. Morales[2], F. Aviles[1], J. Hernández[1], B. Albarrán[1], and F. Vázquez[1], *[1]Centro Universitario UAEM Temascaltepec, Temascaltepec, Estado de México, México, [2]Facultad de Medicina Veterinaria y Zootecnia, UAEM, Toluca, Estado de México, México, [3]Estación experimental Indio Hatuey, Central España Republicana, Matanzas, Cuba.*

An experiment was conducted to evaluate the effect two lyophilized aqueous extract of tree leaves of *Lysiloma acapulcensis* and *Phitecellobium dulce* on an in vitro assessment of hatching eggs, larval development and migration of gastrointestinal nematodes of small ruminants. Treatments were extracts from both species at different concentrations (0, 12.5, 25.0 and 50.0 mg/mL) and albendazole and levamisole were used as positive control (1%). A general lineal model test was used to determine the dose effect of each plant extract in the assays. The extracts of *L. acapulcensis*, compared with extracts of *P. dulce* showed better inhibition effect ($P < 0.05$) on the hatching of eggs (Table 1). Larval development in both extracts showed larvicidal effect ($P < 0.05$) on all larvae exposed to different doses of the extract. In the larval migration assay, we found a similar effect with levamisole doses of 25 and 50 mg/mL of the extract of *L. acapulcensis*. The extract of *P. dulce* presented a lower larvicidal effect ($P < 0.05$) of levamisole and the extract of *L. acapulcensis*. Aqueous extracts of both species have antiparasitic effect in small ruminants, and could be used as biological alternative to control gastrointestinal nematodes in sheep and goats under subtropical conditions.

Table 1. Mean inhibition (%) of egg hatch, larval development and migration of gastrointestinal nematodes by *L. acapulcensis* (LA) and *P. dulce* (PD) aqueous extracts

Treatment[1]	Eggs hatching	Larval development	Larval migration
PBS	96.68^{a}	86.38^{b}	79.31^{a}
LEV1.25			4.64^{gf}
LEV2.50			6.67^{ef}
LEV5.0			2.94^{g}
ALBZ	30.50^{e}	1.28^{c}	
DMSO	68.12^{b}	100.00^{a}	
LA 1.25	38.01^{de}	0.00^{c}	12.04^{cd}

T145 Anthelmintic and immunomodulating effects of *Moringa olifera* extracts in goats. M. Worku*, K. Gyenai, H. Ismael, and J. Reddy, *North Carolina Agricultural and Technical State University, Greensboro.*

Gastrointestinal parasites pose a serious threat to the US goat industry due to inefficacy of existing anthelmintic drugs. Alternative anthelmintics are being sought from plants such as *Moringa oleifera* (moringa). The objective of this study was to evaluate the effect of aqueous extracts of dried moringa leaves on adult Boer goats infected with gastrointestinal parasites. Following initial screening for infection goats were assigned to three groups of five each (n = 15). Powdered moringa leaves were soaked in hot or cold water with stirring. Sterile filtered extracts were prepared. Goats were drenched daily with 10 ML of the hot (Treatment I) or cold extract (Treatment II) daily for a 4 week period, a control group of five age matched goats received sterile water (Treatment III). Body weight, FAMACHA score, packed cell volume (PCV), white blood differential count (WBC), total white blood cell count (TWBC) and *Haemonchus* and coccidia fecal egg counts were determined once a week, for a 4 week period. Serum was evaluated for 8 pro-inflammatory cytokines using a commercial ELISA(Sygnosis). There was no treatment effect on coccidia egg counts, FAMACHA score, and PCV or body weight. Moringa treatment increased mononuclear cells and decreased *Haemonchus* eggs per gram feces. The hot extract had a greater anthelmintic effect than the cold extract and higher TWBC ($P < 0.05$). The hot extract increased and the cold extract decreased cytokine concentrations compared to controls. Aqueous extracts from moringa affect cell-mediated immunity in goats and may aid in the reduction of parasite burden in a species specific manner.

Key Words: goat, moringa, anthelmintic

T146 Sericea lespedeza diets modulate gene expression and rumen microbial diversity in goats. A. Abdalla, M. Worku*, H. Mukhtar, and N. Whitley, *North Carolina Agricultural and Technical State University, Greensboro.*

Sericea lespedeza (SL) is considered high-quality, low input forage that suppresses gastro-intestinal parasites in goats. The objective of this study was to evaluate the impact of a diet containing SL on goat rumen micro flora, and on transcription of markers of innate immunity in goats. Samples were collected from 16 Female goats fed a diet of 75% SL (n = 9) and a control group (n = 7), 0% SL. Rumen contents were collected at slaughter and stored at −20°C. Microbial DNA was isolated from frozen rumen samples using the QIAamp DNA kit (Qiagen) to test for the presence of bifidobacteria. General microbial 16S rDNA and targeted genus specific PCR primers for *Bifidobacteria* were used to amplify specific DNA. Amplified samples and DNA markers were separated by electrophoresis on a 2% agarose gel, stained with ethidium bromide and visualized. Denaturing gradient gel electrophoresis of PCR-amplified 16S rRNA gene segments was used to profile microbial populations in rumen fluid. Pooled serum samples collected from goats on SL or non-treated animals were used to determine total protein using the BCA assay. Blood collected in PAX gene tubes was used to isolate RNA. The concentration and purity of RNA were determined using a Nanodrop spectrophotometer. Quantitative real time PCR was used to evaluate expression of cytokine (TNF, IL8, INF and IL-10) and receptor (CD14, TLR 2, TLR4) genes. Data was analyzed by GLM of SAS 9.2. Variations were observed in microbial DGGE profiles indicating an impact of diet. Six animals out of the seven in the control group 0% SL showed *Bifidobacteria* genus specific band of 523 bp. Rumen samples from treated animals did not show any specific bands. SL decreased transcription of all cytokine genes (18% TNF, 24%IL8, 37%INF and 53%IL-10) and increased transcription of receptor genes (12%CD14, 21%TLR2, 6%TLR4). These differential effects of SL on goat innate immunity and rumen microbial diversity need further evaluation to maximize the benefits of feeding SL to goats.

Key Words: diet, sericea lespedeza, immunity

T147 Influence of probiotics on innate immune response in goats. K. Gyenai*[1], M. Worku[1], M. Tajkarimi[2], and S. Ibrahim[1], [1]*North Carolina Agricultural and Technical State University, Greensboro,* [2]*University of North Carolina at Greensboro, Greensboro.*

Immunostimulants can induce nonspecific resistance against parasites. The use of probiotics to control development of animal gastrointestinal parasites could help reduce the risks of infestation or complement anti-parasite treatments. In this study, we investigated the effects of probiotic administration on gastrointestinal parasites coccidia, *Haemonchus contortus* epg and markers of infection. Three month-old male Spanish Boer kid-goats (n=6) were used. A cocktail of probiotic mix including *Bifidobacterium longum* and *Bifidobacterium breve, Lactobacillus acidophilus, Lactobacillus reuteri* and *Lactobacillus rhamnosus* were used. Treatment animals were drenched daily with 10 CUF/ml of probiotic once a day, a control group age matched received sterile water for a 4 week period. Body weight, fecal egg count, FAMACHA scores, packed cell volume (PCV), and white blood cell differential count (WBCDC) was determined once a week, for a 4-wk period. Denaturing gradient gel electrophoresis (DGGE) was used to monitor fecal bacteria using bacteria 16S rDNA primers. Pro-inflammatory cytokines, prostaglandin (PGE) and immunoglobulin E levels in serum were evaluated using commercial ELISAs. Analysis of variance and GLM was used to evaluate differences between probiotic drenched and control. Results showed no significant difference in PCV, body weight, WBCDC, FAMACHA score, PGE and IgE levels between probiotic drenched and control. However, epg were increased significantly ($P < 0.05$) for probiotic drenched 100, 90 and 120% at wk 2, 3 and 4 for *Haemonchus* and 70% for coccidia at week 3 respectively. An increase of 50 to 300% in proinflamatory cytokines was observed for probiotic drenched over control at weeks 2, 3 and 4 with GM-CSF been highest. Results from PCR-DGGE analysis showed increased fecal microbial DNA for probiotic drenched, with no difference in band pattern and staining intensity. Although increase in fecal egg count levels initiated an increase in cytokine levels probiotics had no immunostimulatory effect against coccidia or *Haemonchus*. This study supports the idea that use of probiotics in ruminants may be impacted by lack of microbial retention in the rumen. Further studies on establishment and retention are needed.

Key Words: cytokine, goat, probiotic

T148 Evaluation of the protective effect of pelleted beet pulp as a substitution for ground corn fed to dairy cows during a subacute ruminal acidosis challenge. Y. Guo*, Y. Zou, S. Li, Z. Cao, X. Xu, and Z. Yang, *State Key Laboratory of Animal Nutrition, College of Animal Science and Technology, China Agricultural University, Beijing, China.*

Eight multiparous Holstein dairy cows (568.5±34.7 kg of BW; 164±15 DIM), 4 of them fitted with rumen cannulas, were assigned to the following experimental treatments during 4 successive periods designed: (1) control (W0); (2) TMR containing 10% finely ground wheat (FGW) (W10); (3) TMR containing 20% FGW (W20); and (4) the W20 diet was amended with 10% BP as a replacement for 10% ground corn (BP10). Each period consisted of a 12-d period of adaptation to the diets, followed by 5 d (d 13-17) for sample collection. Average ruminal pH was lower ($P <0.01$) during SARA (W20 treatment) than during the weeks of adaptation (5.94 versus 6.37). The substitution of BP for corn increased the daily mean ruminal pH by 0.11 pH units and the minimum ruminal pH by 0.22 pH units compared with the W20 treatment, and no ruminal pH values <5.6 were found during the BP10 treatment. Ruminal concentrations of total volatile fatty acid, propionate, butyrate, valerate, and isovalerate increased ($P < 0.01$) with the W20 treatment compared with the W0 and W10 treatments. The cows fed the BP10 diet had a higher ($P < 0.01$) molar percentage of acetate and a lower ($P < 0.01$) molar percentage of butyrate compared with the W20 treatment. The diets had no effect on the DMI and the milk yield, but the milk fat percentage, yield, and 3.5% FCM were reduced ($P < 0.01$) in the W20 and BP10 treatments. The cows fed the W20 diet had greater ($P < 0.05$) milk concentrations (g/100 g of FA) of C11:0, C13:0, C15:0, C14:1, C16:1, C17:1, C18:2n6c, C20:3n6, and lower ($P < 0.05$) concentrations of C18:0 compared with cows receiving the W0 diet. These results indicate that an increase in the concentration of odd-chain FA in milk could be a good candidate for the diagnosis of SARA and that the substitution of pelleted BP for ground corn could regulate rumen fermentation patterns and lower the risk of SARA.

Key Words: beet pulp, dairy cow, subacute ruminal acidosis

T149 Milk components predicted by mid-infrared spectrometry as indicators of the udder health status of the dairy cow. C. Bastin*, A. Lainé, and N. Gengler, *University of Liège, Gembloux Agro-Bio Tech, Animal Science Unit, Gembloux, Belgium.*

Mastitis affects milk composition. Hence, early detection of mastitis could be based on indicators present in milk. The objective of

this research was therefore to investigate components predicted by mid-infrared (MIR) analysis of milk as early indicators of the udder health status of the dairy cow. First, mastitis data collected in 26 herds from the Walloon Region of Belgium were merged with test-day data including milk composition data collected as a part of milk recording. Out of 762 mastitis events, 243 were associated with records from a test-day occurring before the infection (from 30 to 50 days before the event) and with records from a test-day occurring during the infection (from 10 days before to 10 days after the event). Milk components investigated were somatic cell score (SCS), somatic cell count (SCC), titratable acidity recorded as Dornic degree and the content in milk of fat, protein, urea, lactose, lactoferrin, minerals (Na, Ca, P, Mg, K), and 17 individual and groups of fatty acids. Paired t tests were performed on the dataset and showed significant differences before and during mastitis for SCC, SCS, titratable acidity and contents in milk of protein, lactoferrin, K, and lactose. While SCC, SCS, lactoferrin and protein increased during the infection, titratable acidity, K, and lactose decreased. These changes could be related to disease-combating response of the cow, reduced secretory activity and alteration of blood-milk barrier. This preliminary research substantiated the opportunity of using MIR-predicted milk components as mastitis indicators. Future research needs to be conducted on larger dataset and will further investigate the changes in milk composition before, during, and after mastitis. Also, differences in milk composition between cows that have experienced mastitis at least once during the lactation and healthy cows will be examined.

Key Words: mid infrared, mastitis, milk

T150 Gliotoxin occurrence in pre- and postfermented corn, sorghum and wet brewer's grains silage in Sao Paulo, Brazil. L. A. M. Keller*[1,2], M. Aronovich[3], L. R. Cavaglieri[4], and C. A. R. Rosa[1,2], *[1]University Federal Rural of Rio de Janeiro (UFRRJ), Seropédica, RJ, Brazil, [2]Conselho Nacional de Pesquisas Científicas (CNPq), Belo Horizonte, MG, Brazil, [3]Agricultural Development Company of the Rio de Janeiro State (PESAGRO), Niteroi, RJ, Brazil, [4]Universidad Nacional de Río Cuarto (UNRC), Rio Cuarto, Cordoba, Argentina.*

Silage is an important feed source for beef cattle in Brazil is a widespread practice to preserve forages. Poor storage conditions can lead to mold contamination and mycotoxin production. The aim of this study was to determine total fungal counts and the relative density of *A. fumigatus* in silage samples intended for bovines before and after fermentation in farms located in São Paulo State, Brazil, to monitor the natural occurrence of gliotoxin in silage samples (pre- and post-fermentation) and to evaluated the ability of strains of *A. fumigatus* to produce gliotoxin. A total of 300 samples were taken, immediately after opening of the silos (3-5 months) and during the ensiling period of years 2009 to 2012. Fungal counts were done by surface-spread method and the toxigenic ability of isolates strains was evaluated *in vitro* condition. Gliotoxin natural contamination was determined both by TLC and HPLC. All post fermented samples had total number of moulds that exceeded 1×10^4 cfu g^{-1} and *Aspergillus* sp. was the most prevalent genus in all materials evaluated (Table 1). Toxigenic *A. fumigatus* strains isolated produced more than one mycotoxin as shown by TLC. More than 50% of the samples showed contamination with gliotoxin with concentrations that exceeded the levels that are known to induce immunosuppressive and apoptotic effects in cells (level range 0.1 to 32 µg g^{-1}). The present data suggest that care should be taken because gliotoxin and the fungal levels contamination of in feedstuffs. Can could affecting productivity and present a health risk for the herd.

Table 1. Isolation frequency of *Aspergillus* spp. (%) and relative density of *Aspergillus fumigatus* (%)

		Aspergillus spp.		*A. fumigatus*	
Sample	Silage	No. of strains/total	Isolation (%)	No. of strains/total	Relative density (%)
Corn	Prefermented	52/136	38	18/55	32
	Postfermented	203/354	57	69/209	33
Sorghum	Prefermented	18/44	41	12/47	26
	Postfermented	42/84	50	19/44	43
Wet brewer grains	Prefermented	6/22	27	2/7	29
	Postfermented	12/40	30	5/19	26

Key Words: *Aspergillus fumigatus*, mycotoxin production, fungi

T151 Evaluation of β-hydroxybutyrate blood concentration in early lactation in a grazing Jersey herd and its effect on milk yield and reproduction. A. Saborio-Montero* and J. M. Sanchez, *University of Costa Rica, Animal Nutrition Research Center, San Jose, Costa Rica.*

The aim of this study was to analyze blood BHBA concentration in a commercial grazing Jersey herd in Costa Rica (9°55' N, 83°51' W, 2350 m of altitude), measured in 117 cows (24% primiparous, 76% multiparous) at 8±3 and 30±3 days in milk (DIM), to determine its relationship with actual milk yield, milk yield at 305d, open period length, services (AI) per conception and calving interval. The study was carried out from September, 2010 to August, 2012. The close-up period diet was based on grazing 30d regrowth kikuyu grass (*Kikuyuocloa clandestina*) and 4 kg of grain mixture (14% CP, 1.7 Mcal of NEL/kg, 35% starch, 0.2% Ca) per cow daily. The fresh period diet consisted of the same pasture and 4 to 6 kg of a concentrate mixture (20% CP, 1.9 Mcal NEL/kg, 48% starch, 1% Ca). Blood samples were taken from the coccygeal vessels of 117 and 114 cows at 8 ± 3 and 30 ± 3 DIM, respectively. Each sample was analyzed in situ for BHBA concentration using an electrochemical cowside test (Abbott Diabetes Care). Milk yield and reproductive data was registered weekly. Statistical significance was declared at $p<0.05$. BHBA concentration in multiparous cows at 8 ± 3 DIM (0.71 mmol/L) differed ($P < 0.01$) from those at 30 ± 3 DIM (1.03 mmol/L). BHBA concentration at 8 ± 3 DIM in primiparous cows was correlated to open period length (0.554, $P < 0.01$) and services per conception (0.486, $P < 0.05$). A lineal regression ($R^2 = 0.31$, $P < 0.05$) indicated that the open period length with a blood BHBA concentration of zero would be 57 days, and for each 0.1 units of increment in blood BHBA , the open period increases 10.2 days. Another lineal regression ($R^2 = 0.24$, $P < 0.05$) showed that the number of services per conception with a blood BHBA concentration of zero would be on average 1.24 and for each unit of increment in blood BHBA , 2.28 services per conception would be necessary in primiparous cows. No other traits were associated with blood BHBA concentration. Data suggest that elevated blood BHBA concentration at 8 ± 3 DIM may be an early indicator of future reproductive problems in primiparous grazing dairy cows.

Key Words: β-hydroxybutyrate, grazing cows, ketosis

T152 Evaluation of the accuracy of an electronic beta-hydroxybutyrate meter using fresh and stored whole blood and serum from dairy cows. J. L. Gordon*, S. J. LeBlanc, and T. F. Duffield, *University of Guelph, Guelph, Ontario, Canada.*

The purpose of this study was to determine the accuracy of an electronic handheld BHBA meter (Precision Xtra (PX); Abbott) under various

conditions. This meter was previously validated for measurement of BHBA in whole blood in cattle at time of collection, but it is unclear how this device will perform using stored whole blood or serum. Blood was collected into tubes without additive (NA, red top), with EDTA (purple top), or sodium heparin (NaHep, green top) from the same cows at the same time. All BHBA measurements were performed using one meter, test strips from one lot, and by one individual. Blood from all tubes was tested immediately for BHBA at the time of collection. EDTA and NaHep tubes were placed in a refrigerator (4°C) and tested 1 and 7 days after collection. Serum harvested from NA tubes was tested using the PX and submitted to a diagnostic lab to measure BHBA via colorimetric enzymatic reaction (gold standard). Subclinical ketosis (SCK) was defined as BHBA ≥1.2 mmol/L. In 98 samples collected from 80 cows, there was near perfect agreement among measurements taken from all 3 tube types at the time of collection ($R^2 = 0.99$, $P < 0.0001$). The correlation was high between the lab serum BHBA and fresh whole blood meter BHBA at time of collection ($R^2 = 0.98$, $P < 0.0001$) and within tubes tested over time compared to the time of collection of the same tube (EDTA: day+1 $R^2 = 0.97$, $P < 0.0001$, day+7 $R^2 = 0.82$, $P = 0.0003$; NaHep: day+1 $R^2 = 0.97$, $P < 0.0001$, day+7 $R^2 = 0.84$, $P = 0.0002$). The correlation between serum tested on the PX and in the lab was high ($R^2 = 0.98$, $P < 0.0001$). Using a threshold of 1.2 mmol/L, the sensitivity of SCK diagnosis using the PX to measure whole blood at the time of collection, whole blood on day+1 and serum was 93%, 100%, and 100% and the specificity was 96%, 86%, and 74% respectively. This suggests that the PX can be used to accurately measure BHBA in whole blood with various additives, even after storage. The PX is also an accurate tool for diagnosis of SCK in whole blood, but lacks specificity for SCK diagnosis in serum.

Key Words: Precision Xtra, β-hydroxybutyrate, ketosis

T153 Application of sodium chlorate to reduce coliform bacteria in rumen and feces of sheep: 1. Effects on ruminal and fecal coliforms. C. Arzola*[1], R. Copado[1], F. Rodriguez[1], C. Rodriguez-Muela[1], J. Salinas[2], A. Corral[1], O. Ruiz[1], and H. Gaytan[1], *[1]Universidad Autonoma de Chihuahua, Chihuahua, Chih., Mexico, [2]Universidad Autonoma de Tamaulipas, Cd. Victoria, Tamaulipas, Mexico.*

The use of chlorate is being investigated as a non-antibiotic alternative to control certain pathogenic bacteria capable of reducing chlorate to the autocytotoxic compound chlorite, but the lowest effective dose has not yet been clearly established. The objective of this study was to evaluate the efficacy of sodium chlorate administered orally as a regulator of total coliform populations in ewes. A 30% sodium chlorate product or a sodium chloride placebo was administered to twelve lactating Dorper × Blackbelly or Pelibuey crossbred ewes averaging 65 kg body weight. The ewes were acclimated to a balanced diet formulated to meet NRC requirements for production. Ewes were randomly assigned (4/treatment) to each of three treatments administered twice daily by oral gavage for 5 consecutive days: a control (Group 1) consisting of 3 g NaCl/animal/d, a 1× treatment (Group 2) consisting of 0.9 g of $NaClO_3$/animal/d, and a 3× treatment (Group 3) consisting of 2.7 g $NaClO_3$/animal/d; the latter was intended to approximate a lowest known effective dose. Ruminal samples collected by stomach tube and freshly voided fecal samples were collected daily beginning 3 days before treatment initiation and for 6 days thereafter. Contents were cultured quantitatively to enumerate total coliforms. There were no significant differences in colony forming units per gram (cfu) in the feces between treatment groups ($P = 0.832$). There were differences ($P < 0.02$) in ruminal cfu per gram between groups (4.1, 4.3 and 5.0 log10/g contents in Groups 1, 2 and 3, respectively) which tended to increase in cfu from the beginning until the 5th day of treatment ($P < 0.05$). Overall, we did not obtain the expected results with oral administration of $NaClO_3$ with the applied doses. By comparing the trends in coliform populations in the rumen contents in all treatments, there was an increase over the days. The opposite trend occurred in the feces, due mainly to differences among rumen contents and feces in Group 3 treated ewes ($P = 0.06$), suggesting that low chlorate doses used here were suboptimal for the control of coliforms in the posterior gastrointestinal tract.

Key Words: *E. coli*, coliforms, chlorate

T154 Sodium chlorate to reduce the carriage of coliforms in rumen and feces of sheep: 2. Effects on ruminal and fecal bacterial diversity. R. Copado*[1], C. Arzola[1], S. V. R. Epps[2], F. Rodriguez[1], C. Rodriguez-Muela[1], J. Salinas[3], A. Corral[1], O. Ruiz[1], and H. Gaytan[1], *[1]Universidad Autonoma de Chihuahua, Chihuahua, Chih., Mexico, [2]Department of Veterinary Integrative Bioscience, Texas A&M University, College Station, TX, USA., [3]Universidad Autonoma de Tamaulipas, Cd. Victoria, Tamaulipas, Mexico.*

Sodium chlorate is being investigated as a potential intervention to reduce the carriage of certain pathogenic bacteria in food-producing animals, but the minimal effective dose has not yet been clearly established. In this study, the effect of low potentially suboptimal oral chlorate administration to ewes was assessed by comparing the diversity of prominent bacterial populations in their gastrointestinal tract. Twelve lactating Dorper × Blackbelly × Pelibuey crossbred ewes averaging 65 kg body weight were acclimated to a balanced diet formulated to meet NRC production requirements. Ewes were randomly assigned (4/treatment) to receive a control (Group 1) treatment consisting of 3 g NaCl/animal/d, or either of two chlorate treatments (Group 2) or (Group 3) consisting of 0.9 g or 2.7 g $NaClO_3$/animal/d, respectively. Treatments were administered twice daily in equal amounts via oral gavage for 5 consecutive days. Ruminal and fecal samples were collected daily beginning 3 days before and ending 6 days after initiation of treatments and were subjected to denaturing gradient gel electrophoresis of the 16s rRNA gene sequence amplified from total population DNA. For populations of ruminal microbes, between group similarity coefficients varied from 23.0 to 67.5% and from 39.4 to 43.3% during pre-treatment and treatment periods, respectively. During the treatment period, within group similarity varied across days, ranging from 39.4 to 90.3%, 43.3 to 86.7% and 67.5 to 92.4% for Groups 1, 2 and 3, respectively. For fecal microbes, between group similarity coefficients varied from 38.0 to 85.2% and 38.0 to 94.2% during pre-treatment and treatment periods, respectively. Within group similarity coefficients for fecal populations during treatment were most varied for Group 1 (38.0 to 67.9%), intermediate for Group 3 (75.6 to 92.0%) and least varied for Group 2 (80.6 to 90.6%). We concluded, however, that the observed heterogeneity within and between groups before and after treatment provided little if any evidence of an effect of chlorate treatment on prominent ruminal or fecal microbial populations.

Key Words: coliform bacteria, DGGE, chlorate

T155 Effects of spray-dried whole colostrum and spray-dried plasma on veal calf health and performance. D. Wood*, R. Blome, and J. Sowinski, *Animix, Juneau, WI.*

Study objective was to evaluate effect on veal calf health and performance from supplementing whole spray-dried colostrum (SDC) and spray-dried plasma (SDP). Auction-sourced Holstein bull calves (n=120; app.1 wk of age) were randomly placed in individual, raised,

slatted stalls. Treatment pairs were equally placed within each row, i.e. calves in stalls 1 and 2 were fed supplemental SDP/dry fat blend, calves in stalls 3 and 4 were supplemented SDC, and calves in stalls 5 and 6 were supplemented WPC/dry fat blend (control). Each respective supplement contained 50% CP 20% fat. SDC contained min. 18% and SDP est. 11% IgG. Serum total protein averaged 4.68 g/dL (83% <5.5 g/dL) and there was no difference between groups. Calves were fed liquid milk replacer (all-milk, 17% CP 19% fat) and supplemented 50 gram (g)/feeding (2X/day) of respective supplement for weeks 1 to 6, then 40 g/feeding week 7, 20 g weeks 8 to 9, 10 g week 10 and 5 g weeks 11 to 12. Calves were harvested 19.9 weeks. Accounting for total solids intake, calves started on 26:20 (CP:Fat), increased to 1,330 g/day (d) of 20:19 by 28d and 1,871 g/d 18:19 by 56d. Milk replacer was medicated to 56d. Calves received no dry feed. Incidence of morbidity during the combined room-filling period (4 d) and the first week the barn was full, was lower in SDC (17%, $P < 0.028$) and SDP (19.5%, $P < 0.054$) vs. control (42%). During week 7 when feeding rate was reduced, incidence of morbidity was greater for SDC vs. control ($P < 0.048$). Average individual calf treatment costs were $4.26, $8.91 and $9.78/calf for SDP, SDC and control respectively. SDP tended ($P < 0.10$) to reduce medical treatment costs verses control. Data was analyzed using F-test for variances and student t-test comparing two means. Mortality/culls were 4.8% each for both SDP and SDC and 13.2% for control. In conclusion, SDC and SDP reduced morbidity during typical stressful first weeks of life in low-colostrum status, co-mingled auction-sourced calves treated prophylactically with antibiotics. Some difficulty was noted in weaning calves off SDC. No differences in ADG were noted.

Key Words: calf, colostrum, plasma

T156 Growth and health costs used to evaluate OmniGen-AF feeding strategies in Jersey heifer calves reared on a commercial dairy. A. E. Holland*[1], J. D. Chapman[1], L. O. Ely[2], and Y. Q. Wang[3], *[1]Prince Agri Products Inc., Quincy, IL, [2]University of Georgia, Athens, [3]OmniGen Research LLC, Corvallis, OR.*

The objectives were to determine growth, treatment costs and immune parameters in Jersey heifer calves fed diets supplemented with OmniGen-AF (OG) from birth to weaning or to 160 d of age. Newborn calves were randomly assigned to three groups: G1 controls (n = 50) no OG fed d 1 to 160 either in the milk replacer or pasteurized milk (MR) or starter feed (SF) or heifer TMR, G2 (n = 53) OG fed d 1 to 90 via MR (10 g/h/d) and SF (2 g/lb. of feed) only, G3 (n = 53) OG fed d 1 to 160 via MR, SF, and TMR (3 g/lb. DM). Each calf was housed in a hutch and body weights (BW), hip heights (HH), body condition scores (BCS), and blood were taken on d 1, 50, 90, and 160. Blood samples were analyzed for neutrophil L-selectin (NLS) and interleukin 8 receptor (IL8) mRNA using quantitative RT-PCR. Medications used and costs/treatment were recorded on each calf. Differences were tested using PROC GLM (SAS). Birth weights and HH of G1 (26.1 kg, 71.6 cm), G2 (26.3 kg, 71.1 cm) and G3 (25.6 kg, 70.9 cm) at start were not different. Average daily gain (ADG) for G1 (0.2 kg) from d 5 to 50 differed ($P < 0.05$) from G2 (0.30 kg) and G3 (0.30 kg). ADG were not different between groups at d 90 or 160. BW between groups at d 60 was not different. HH gains in G2 (25.7cm) and G3 (26.0cm) calves were greater ($P < 0.05$) than G1 (24.1 cm) at d 160. BCS at d 50 and 90 were not different between groups; however at d 160, G1 (3.04) and G2 (3.07) were different ($P < 0.05$) from G3 (2.92). Treatments differed between groups ($P < 0.05$), with G1 calves treated 2.3× more often than G2 and 4.7× more often than G3. Total medication costs/treated calf for G1 ($9.80) differed ($P < 0.05$) from G2 ($8.53) and G3 ($7.25). NLS levels were similar for all groups to d 50; however G2 and G3 at d 90 had NLS levels 2.5 times greater than G1. G3 NLS levels were 2 to 4 times greater than G1 and G2 at d 160. IL8 levels differed ($P < 0.05$) between groups at d 1, 90, and 160. Results from this study demonstrated that supplementing OG to pre- and postweaned calves improved growth and health resulting in reduced medication costs.

Key Words: calves, health, OmniGen-AF

T157 Ex vivo and in vitro effects of *Lactobacillus rhamnosus* in the control of gastrointestinal infections in calves. F. Fàbregas*[1], S. Genís[1], A. Bach[1,2], and A. Arís[1], *[1]Department of Ruminant Production-IRTA, Caldes de Montbui, Spain, [2]ICREA, Barcelona, Spain.*

The objective of this study was to assess the potential of *L. rhamnosus* to modulate the inflammatory response against gastrointestinal infections and its protective effect on intestinal cells. Jejunal bovine Peyer patches explants of 1 cm^2 were obtained from a 2-mo calf immediately after sacrifice. Tissue fragments were ex vivo cultured in 6-well plates with Krebs media. Explants were treated with 2×10^9 cfu/well of *L. rhamnosus* or control media (n = 6) for 1 h and infected for additional 8 h with 10^7 cfu/well of *Escherichia coli* EPEC at 37ºC at 5% CO_2. Supernatant and tissue samples were taken to analyze cytokines involved in inflammatory response by qRT-PCR and ELISA. To assess the effect of *L. rhamnosus* on the integrity of intestinal cells, a primary culture of jejunal epithelial cells was established and seeded at 5×10^4 epithelial cells/well. Primary cells were treated with 1, 2, 5, 10, 25, 50 and 100 MOI of *L. rhamnosus* or control media (n = 6), and incubated during 24h at 37°C at 5% CO_2 to further analyze the cell viability by lactate dehydrogenase assay (LDH). Data were analyzed using ANOVA. The EPEC infection caused an inflammatory response by increasing ($P < 0.05$) the levels of pro-inflammatory cytokines IFN-γ, IL-6, IL-1β, and TNF-α, and decreasing ($P < 0.05$) the levels of anti-inflammatory cytokines TGF-β and IL-10. *Lactobacillus rhamnosus* down-regulated the basal tissue inflammation level and the inflammatory response against EPEC by decreasing ($P < 0.05$) the levels of pro-inflammatory cytokines IFN-γ, IL-6, IL-1β, TNF-α, whereas the anti-inflammatory cytokines were unaffected. The LDH levels were less ($P < 0.05$) in *L. rhamnosus*-treated cultures at MOI = 25 (0.55 ± 0.10 mU/mL), MOI = 50 (0.75 ± 0.12 mU/mL), and MOI = 100 (0.58 ± 0.06 mU/mL) than in control cultures (24.72 ± 3.21 mU/mL). In conclusion, *L. rhamnosus* has a positive effect on ex vivo and in vitro bovine intestinal cultures, regulating not only the inflammatory response triggered by an infection, but also modulating the basal inflammatory response and enhancing cell viability.

Key Words: *Lactobacillus rhamnosus*, immunity, intestinal infection

T158 Application of intravaginal lactic acid bacteria improved reproductive performance of Holstein dairy cows. Q. Deng[1], J. F. Odhiambo[2], U. Farooq[1], T. Lam[1], S. Sharma[1], S. M. Dunn[1], Y. Wang[1], M. Gänzle[1], and B. N. Ametaj*[1], *[1]Department of Agricultural, Food and Nutritional Science, University of Alberta, Edmonton, Alberta, Canada, [2]Department of Animal Science, University of Wyoming, Laramie.*

The objective of this investigation was to test whether intravaginal infusion of lactic acid bacteria (LAB) around calving can improve reproductive performance in periparturient dairy cows. One hundred pregnant Holstein dairy cows were assigned (based on parity, body condition score, and milk yield) to 3 treatment groups at 2 wk before the expected day of parturition as follows: (1) 1 mL of LAB infused intravaginally on wk -2 and -1, and 1 mL of carrier (i.e., sterile skim milk) on wk +1 relative to the expected day of parturition (TRT1);(2) 1 mL of LAB

infused intravaginally on wk −2, −1, and +1 (TRT2); and (3) 1 mL carrier infused intravaginally on wk −2, −1, and +1 (CTR). Lactic acid bacteria were a mixture of *Lactobacillus sakei* FUA3089, *Pediococcus acidilactici* FUA3138, and *Pediococcus acidilactici* FUA3140 frozen in sterile skim milk with a cell count of 10^8 to 10^9 cfu. Insemination and pregnancy diagnosis records were analyzed retrospectively for all the cows enrolled in this experiment for 12 consecutive months. Data were analyzed with GLIMMIX procedure of SAS. Results showed that cows in the TRT1 had higher (46.9 ± 8.8% vs. 38.2 ± 8.3%, $P = 0.48$), while cows in the TRT2 had lower (28.0 ± 9.0% vs. 38.2 ± 8.3%, $P = 0.42$) first service conception rate than those in the CTR. Cumulative pregnancy rates up to five services were 84.4 ± 6.4%, 72.0 ± 9.0% and 76.5 ± 7.3% in TRT1, TRT2 and CTR, respectively ($P = 0.61$). Cows in TRT1 and CTR required less than 2, while those in the TRT2 required more than 2 services per conception. Consequently, cows in the TRT1 had shorter days open than those in the CTR (82.7 ± 8.0 vs. 109.7 ± 8.1 d, $P < 0.01$), but cows in the TRT2 had longer days open than those in the CTR (137.4 ± 8.4 vs. 109.7 ± 8.1 d, $P < 0.01$). In conclusion, the LAB treatment had distinct effects on reproductive performance. Cows benefited from 2 prepartum doses of LAB (TRT1) for shorter days open. However, the additional postpartum dose (TRT2) did not confer any benefit. The reason for this discrepancy is not clear at present and deserves further inquiry.

Key Words: dairy cow, lactic acid bacteria, reproductive performance

T159 Application of intravaginal lactic acid bacteria modified prostaglandin production of periparturient Holstein dairy cows. Q. Deng[1], J. F. Odhiambo[2], U. Farooq[1], T. Lam[1], S. Sharma[1], S. M. Dunn[1], Y. Wang[1], M. Gänzle[1], and B. N. Ametaj*[1], *[1]Department of Agricultural, Food and Nutritional Science, University of Alberta, Edmonton, Alberta, Canada, [2]Department of Animal Science, University of Wyoming, Laramie.*

The objective of this study was to test whether intravaginal infusion of lactic acid bacteria (LAB) around calving could modify prostaglandin production in periparturient dairy cows. One hundred pregnant Holstein dairy cows were assigned randomly (based on parity, body condition score, and milk yield) to 3 groups at 2 wk before the expected day of parturition as follows: (1) 1 mL of LAB infused intravaginally on wk -2 and -1, and 1 mL of carrier (i.e., sterile skim milk) on wk +1 relative to the expected day of parturition (TRT1); (2) 1 mL of LAB infused intravaginally on wk −2, −1, and +1 (TRT2); and (3) 1 mL carrier infused intravaginally on wk −2, −1, and +1 (CTR). Lactic acid bacteria were a mixture of *Lactobacillus sakei* FUA3089, *Pediococcus acidilactici* FUA3138 and FUA3140 with a cell count of 10^8 to 10^9 cfu. Blood samples from 10 cows in each group were used to quantify the concentrations of 15-keto-13,14-dihydro-$PGF_{2\alpha}$ (PGFM) and PGE_2 with enzyme immunoassay kits. Data were analyzed with MIXED procedure of SAS. Results showed that LAB treatment elevated serum PGFM relative to CTR, which were 1346.08 ± 172.21, 1600.02 ± 192.68, and 980.86 ± 220.37 pg/mL in TRT1, TRT2 and CTR, respectively ($P = 0.08$). Overall PGFM increased sharply from wk −1, peaked at parturition and dropped to the prepartum level by wk +2 ($P < 0.01$). Concentrations of serum PGE_2 were 384.97 ± 56.80 pg/mL in TRT1, 687.69 ± 65.21 pg/mL in TRT2 and 471.29 ± 58.52 pg/mL in CTR ($P < 0.01$). Serum PGE_2 dropped at parturition and wk +1, and then increased at wk +2 and +3 ($P < 0.01$). No significant difference was detected among groups regarding the ratio PGFM/PGE_2, but it increased sharply at parturition, and then decreased to a basal level by wk +2 ($P < 0.01$). In conclusion, cows in TRT2 had highest concentrations of both PGFM and PGE_2, while TRT1 had intermediate PGFM and lowest PGE_2, translating into higher PGFM/PGE_2 ratio in TRT1 and intermediate ratio in TRT2 relative to CTR. These findings suggest that postpartum infusion of LAB exerted a distinct effect on prostaglandin production from the prepartum infusion.

Key Words: dairy cow, lactic acid bacteria, prostaglandin

T160 The effect of late pregnancy supplementation of ewes with trace mineral on ewe hematology and lamb vigor. M. Mallaki*, M. A. Norouzian, A. A. Khadem, and M. M. Bardzardi, *The University of Tehran, Tehran, Iran.*

The present study was conducted to evaluate the effect of parenteral supplementation of cobalt, copper and iron in late pregnancy on ewe hematology parameters and lamb vigor. Twenty ewes were allocated to one of two groups (n = 10). In the test group, on d 120 of pregnancy, cobalt, copper and iron were injected at a dose of 0.1 mL/kg BW (Fercobsang, France, cobalt gluconate 5 mg/100 mL, copper gluconate 0.5 mg/100 mL and ferrous citrate 1000 mg/100 mL). Ewes in control group received equal amounts of normal saline as placebo. Blood samples were taken from the jugular vein at the beginning of the study (day 0, 40 ± 5 pre-partum, before injection of trace elements, and saline) and at 24 and 72h postpartum. Group had no significant effect on ewe hematological parameters ($P > 0.05$). There were no significant effects of parenteral mineral supplementation on lamb birth weight, rectal temperature and weaning weight after birth. Lamb viabilities are reported as scores as these gave a true representation of the effects of treatment on underlying measurements. However, there were no differences between groups in lamb vigor and sucking assistance score. It seems that using of additional trace elements in late pregnancy could be effective in deficiency situations.

Key Words: ewe hematology parameter, lamb viability, trace element

T161 From animal breeding to bio-medical research: Day-blind sheep as an animal model for restoration of visual function using gene therapy. E. Gootwine*[1], R. Ofri[2], E. Averbukh[3], H. Honig[1], A. Rosov[1], R. Ezra-Elia[2], A. Obolensky[3], E. Yamin[3], W. W. Hauswirth[4], and E. Banin[3], *[1]Institute of Animal Science, the Volcani Center, Bet Dagan, Israel, [2]Koret School of Veterinary Medicine, Hebrew University of Jerusalem, Jerusalem, Israel, [3]Hadassah Hebrew University of Jerusalem Medical Center, Jerusalem, Israel, [4]University of Florida, Gainesville.*

We reported on novel hereditary recessive day-blindness in sheep caused by a mutation in the *CNGA3* gene (Genomics 95:101–104, 2010). Mutations in this gene can also cause achromatopsia in humans. Culling carrier rams eliminated the birth of affected lambs in a commercial sheep flock. Following establishment of a day-blind sheep population, different types of adeno-associated viral (AAV) vectors carrying the intact human or mouse *CNGA3* gene under the control of a red-green Opsin promoter were delivered unilaterally into the subretinal or vitreal space of affected sheep. Animals were electrophysiologically and behaviorally assessed preoperatively and up to 12 months after treatment. Cone function was measured by electroretinography (ERG) following light adaptation (10 min, 30 cd/m^2). Responses to flash and flicker (10 to 80 Hz) stimuli were recorded at 4 intensities (1 to 10 cd × s/m^2). Behavioral assessment included scotopic (night time) and photopic (day time) maze testing, where passage times and number of fence collisions were recorded. Age-matched normal and non-treated day-blind sheep were similarly assessed as controls. Cone function was significantly depressed in affected sheep prior to surgery. Following surgery, there was significant improvement in eyes treated by either the human or the mouse *CNGA3* gene. Behaviorally, there were no differences between day-blind and normal controls in scotopic testing. While untreated affected animals failed to navigate the maze under photopic conditions, the ability of the day-blind treated sheep to navigate the

photopic maze improved dramatically, approaching that of normal controls. The electrophysiological and behavioral improvement in operated sheep persisted for at least 1 year post-op without affecting animals' health. The long-term electrophysiological and behavioral improvement in this naturally-occurring large animal model following gene therapy may pave the way to application of a similar treatment in human achromatopsia patients.

Key Words: sheep, achromatopsia, gene therapy

T162 OmniGen-AF supplementation improves leukocyte responses and hematology of multiparous peripartum cows. C. R. Nightingale*[1], M. D. Sellers[1], A. R. Pepper-Yowell[1], J. D. Chapman[2], D. L. O'Connor[2], and M. A. Ballou[1], *[1]Texas Tech University, Lubbock, [2]Prince Agri Products Inc., Quincy, IL.*

Objectives of the current study were to determine if supplementing OmniGen-AF (Prince Agri Products Inc.) during the peripartum period improved leukocyte responses and hematology of multiparous dairy cows. Forty-seven multiparous Holstein cows were randomly assigned to two treatments (Control; n = 24, Treatment; n = 23). Treatment cows were supplemented with 2 oz/cow/day of OmniGen-AF from dry-off through 28 d in milk of the subsequent lactation. On d −60 (dry-off), −30, 0, 14, and 28 relative to calving, peripheral blood samples were collected for measurement of hematology and leukocyte responses, which included: neutrophil surface L-selectin (CD62L) protein expression, neutrophil oxidative burst capacity in response to an *Escherichia coli*, plasma haptoglobin concentrations, and whole blood secretion of tumor necrosis factor-α and interferon-γ when co-cultured with lipopolysaccharide and phytohemagglutinin-P, respectively. A linear mixed model was fitted with the effects of treatment, time, and treatment × time, using baseline (−60 d) measurements as a covariate. Baseline measurements were not different between treatments for all variables ($P > 0.22$). Hemoglobin concentrations and hematocrit percentages decreased ($P < 0.01$) on d 14 and were lower among Control cows from d −30 to 28 (10.5 vs. 10.9 ± 0.12 g/dL and 33.5 vs. 34.3 ± 0.31%, for hemoglobin and hematocrit, respectively; $P < 0.01$). Neutrophil L-selectin protein concentrations were greater in Treatment cows on d 0 (769 vs. 431 ± 84.6 GMFI; $P < 0.01$). In contrast, neutrophil oxidative burst intensity was elevated among Control cows on d 0 (373 vs. 259 ± 28.1 GMFI; $P < 0.01$). Plasma haptoglobin concentrations were also elevated among Control cows on d 14 (1.6 vs. 1.2 ± 0.09 optical density; $P < 0.01$). These data indicate that supplementing OmniGen-AF attenuates the peripartum suppression of neutrophil L-selectin, hemoglobin concentrations, and hematocrit percentage. Moreover, treatment cows did not have an elevated neutrophil oxidative burst at parturition or haptoglobin concentrations on d 14, suggesting OmniGen-AF improved health status during this period.

Key Words: immune, OmniGen-AF, peripartum

T163 Water treatment by magnetic field on production and blood gas level in dairy cow. G. B. Neto*[1], N. J. Ramos[1], P. M. Graça[1], J. R. E. Filho[2], M. C. M. Coelho[2], and S. S. Luz[3], *[1]Agencia Paulista de Tecnologia dos Agronegocios, Ribeirão Preto, São Paulo, Brazil, [2]Faculdade de Ciencias Agrarias e Veterinarias da Universidade Estadual Paulista, Jaboticabal, São Paulo, Brazil, [3]Faculdade de Zootecnia e Engenharia de Alimentos da Universidade de São Paulo, Pirassununga, São Paulo, Brazil.*

Data suggest that the properties of magnetically treated water are different from the ones of untreated water. This fact is usually attributed to the weaknesses in or breaking of intermolecular interactions (hydrogen bonds) and nucleation processes (effect of impurity, frequency and growth of nuclei). Water treatment by magnetic field is an attractive but still controversial issue as might apply to animal production. The purpose of the present study was to investigate the effects of water treatment by magnetic field on milk production and blood gas and ionic character. The treatment of water was performed using a commercial magnetic conditioner (Sylocimol) designed to generate a strong magnetic monopole field. These devices were inserted into the water troughs (500 L); the strength of the static magnetic field was 32,400 Gauss. A completely randomized design was used. Twenty-six Jersey cows were allotted into two groups: control (C; n=13) and group consuming magnetic water (MW; n = 13) for 75 days to compare the milk production and blood gas level and Na ion concentration ([Na]). Blood samples were collected by caudal auricular artery using a blood sampling kit for blood gas analysis (3 ml ventilated syringes with 23 G 1 in needle, containing freeze-dried lithium heparin). All the samples were immediately analyzed in a calibrated blood gas analyzer set at the body temperature of cows. No significant difference was found on daily milk yield. However, higher pH and lower pCO2 levels were found in arterial blood of MW compared to C. Lower [Na] and [Cl] were associated with lower osmolality in MW compared to C. The test results suggested that animals consuming water conditioned by magnetic field technology have blood characteristics different from those consuming unconditioned water.

Table 1. Magnetic treatment of water on milk production and blood gas and ion content

	Control	Test	CV	MSE	Pr > F
Daily milk yield (kg/cow)	10.30	11,.40	21.14	2.309	0.357
Osmolality (mOsm/kg)	280.1[a]	273.3[b]	1.45	4.03	0.0007

T164 Evaluation of chlorine stability in a novel teat dip disinfectant system. L. L. Timms*[1], M. Pawlak[2], and C. Durham[2], *[1]Iowa State University, Ames, [2]Zurex Pharmagra, Middleton, WI.*

Objective was to evaluate chlorine stability of a novel germicidal product as well as dilutions developed for pre and post milking teat dipping with different additives. Initial base germicidal compound (ECAlogix System) was designed to have 8000 ppm chlorine. A teat dip cup filled with initial solution was placed in milking parlor and served as base control over time (all trials - never used for dipping). Pre (500 to 1000 ppm) and post (1000 to 2000 ppm) milking teat dips were made, used, and tested (trial 1: 14 days). 1000 ppm and 2000 ppm pre and post dips, respectively from trial 1, were chosen to evaluate different emollient levels (trial 2 – 21 days) and subsequent trial against commercial dip products (trial 3 – 49 days). Additives for prototype pre and post dips for trials 1-3 were PREP and POST, PREP/PRE-POST and POST+ / PRE-POST (different emollient levels), and PREP and POST/POST-Blue, respectively. Pre and post milking teat dips were made in 1 gallon quantities (last ~ 1 week). A single dip cup was used for each dip in each trial. Chlorine concentrations in all products were tested every 2-3 days by drawing directly from teat dippers used in the milking parlor. Samples

were tested in duplicate using a chloride titration kit (10 drops of 50% Potassium iodide; 3 drops of 50% sulfuric acid; 5 drops of 1% starch solution; drops of thiosulfate solution until sample turned colorless). Chlorine levels of pre dips (500 and 1000ppm + PREP), post dips (1000 and 2000 ppm + POST) and stock solution (8000 ppm) were stable and not significantly different within any product across Trial 1. In trial 2, pre (1000 ppm) and post (2000 ppm) dips with additives PREP and POST+, respectively, were stable and not significantly changed (21 d) while dips with PRE-POST additive resulted in significant reductions to 200 ppm chlorine within 24 h post mixing. In trial 3, pre (1000 ppm) and post (2000 ppm) dips with additives PREP and POST (same as trial 1), respectively, were stable and not significantly changed (49 d) while post dips with POSTBlue showed significant reductions to 200 ppm chlorine within 24 h post mixing. This novel technology shows excellent chlorine stability over time and importance of measuring potential effects of different solution additives.

Key Words: chlorine, teat dip, disinfection

T165 Development and evaluation of experimental chlorine technology pre and postmilking teat dips on teat end and teat skin condition and health. L. L. Timms*[1], M. Pawlak[2], and C. Durham[2], *[1]Iowa State University, Ames, [2]Zurex Pharmagra, Middleton, WI.*

Objectives were to evaluate pre and post teat dip formulations using a novel chlorine disinfectant technology (ECAlogix System) and their effect on teat health and integrity. There were 2 trials with 3 pens (10, 11, and 12) in both trials. Trial 1 (2 wk) was designed to evaluate maximal chlorine concentrations; trial 2 (3 wk) assessed emollient levels. Pen 12 (48 cows) had all teats dipped with current herd commercial pre and post dips (hydrogen peroxide pre and lactic acid barrier post- herd sentry pen). Pen 11 (48 cows) was pre-dipped in a half udder design and all teats post dipped with herd commercial product. Trial 1 compared 500 and 1000 ppm chlorine pre-dips. Trial 2 compared 1000 ppm predips with different emollient levels. In trials 1 and 2, Pen 10 (24 cows) was pre-dipped with commercial herd product and post dipped in a half udder design. Trial one compared 1000 and 2000 ppm. Trial 2 compared 2000 ppm postdips with different emollient levels. Teat skin (1 = normal, 2 = slightly dry; 3 = chapped) and teat end (1 to 1.5 = normal; 2 to 3 = smooth ring; 3.5 to 4 = rough ring; 4.5 to 5 very rough ring) scoring was performed twice per week. Mixed procedure of SAS with repeated measured (mixed model with quarter within cow as a repeated measure) were used to analyze average teat skin score (TSS), average teat end scores (TES), and % rough teats, with $P < 0.05$ considered significant. Prior to trial initiation, all pens had similar TSS (1.08; 3 to 16% scoring 2), with pen 10 having slightly lower TES and % rough teats (2; 50%) compared to pens 11 and 12 (2.5; 60%). Trial 1 showed no overall change in TSS, TES, and % rough teat ends for pen 12 (sentry) and 11 (prototype pre dips) with no differences between 500 and 1000 ppm chlorine pre-dips in Pen 11. Pen 10 (prototype post dips) showed significant improvements in TSS (1.01, < 1% score 2), TES (1.7), and % rough teat ends (30%), with no differences between 1000 and 2000 ppm chlorine post dips. Trial 2 showed similar results to trial 1 (improved teat integrity with prototype chlorine post dips) with no additional benefits seen to extra emollient addition to either pre or post chlorine dips. No adverse effects were seen at any chlorine concentration.

Key Words: chlorine, teat dipping

T166 Evaluation of experimental chlorine technology pre and post milking teat dips vs. a commercial hydrogen peroxide pre dip and iodine barrier post milking teat dip on teat end and teat skin condition and health. E. Smith[1], L. L. Timms*[1], M. Pawlak[2], and C. Durham[2], *[1]Iowa State University, Ames, [2]Zurex Pharmagra, Middleton, WI.*

Objectives were to evaluate (using half udder design model) a novel chlorine predip and postdip combination (ECAlogix System) versus a control commercial hydrogen peroxide premilking teat dip and iodine barrier postmilking teat dip on overall teat end and teat skin condition and health. There were 3 pens (10, 11, and 12) in the trial (7 weeks). Pen 12 (48 cows) had all teats dipped with current herd pre and post dips (herd sentry pen). Pen 11 (48 cows) and Pen 10 (24 cows) had left side teats dipped with commercial herd pre and post dips while right teats were dipped with 1000 ppm chlorine predip and 2000 ppm chlorine post dips (experimental prototypes). Teat skin (1 = normal, 2 = slightly dry; 3 = chapped) and teat end (1 to 1.5 = normal; 2 to 3 = smooth ring; 3.5 to 4 = rough ring; 4.5 to 5 = very rough ring) scoring was performed two times per week. Mixed procedure of SAS with repeated measured (mixed model with quarter within cow as a repeated measure) were used to analyze average teat skin score (TSS), average teat end scores (TES), and % rough teats, with $P < 0.01$) TSS, TES, and % rough teats than control dipped teats within 10 days of trial initiation (1.01, 2.0, 30 to 40% vs. 1.03, 2.6, and 60%, respectively) and maintained this improved teat integrity through the trial. Prototype chlorine teat dips were stable and provided significantly better teat skin and teat end health and integrity compared to commercial products.

Key Words: chlorine, postmilking teat dipping, premilking teat dipping

T167 Supplementation of organic selenium and its effect on productive and reproductive performance in grazing dairy cows in Costa Rica. J. Sanchez-Salas*[1], J. A. Elizondo-Salazar[1], C. Orozco-Vidaorreta[2], and E. Viquez-Matei[3], *[1]Estacion Experimental Alfredo Volio Mata. Facultad de Ciencias Agroalimentarias, Universidad de Costa Rica, [2]Alltech, Inc, Costa Rica, [3]Alimentos Balanceados, Cooperativa de Productores de Leche Dos Pinos, Costa Rica*

The objective was to evaluate the effect of supplementation of selenized yeast derived from a specific strain of *Saccharomyces cerevisiae* (CNCM I-3060) on productive and reproductive performance and on selenium concentrations in milk of grazing dairy cows. Multiparous Holstein cows (n=40) with an average body weight of 607 ± 62 kg and a body condition score of 3.1 ± 0.2 before parturition were randomly assigned to one of two treatments. Treatment 1 consisted of a basal diet supplying 0.7 mg of Se/kg dry matter. Treatment 2 consisted of the same basal diet supplemented with 3.0 mg of Se from d 5 to 56 of lactation. Milk production, milk composition, SCC, and Se content of milk from individual cows were determined at d 5, 14, 28, 42, and 56 of lactation. Blood samples from each cow were also taken during the same days to measure glutathione peroxidase (GSH-Px) and Se concentration. To evaluate reproductive performance the ovaries were examined by transrectal ultrasonography at d 22 and 57 postpartum. Days open, days to conception and services per conception were also recorded. Milk production (41.7 vs. 40.2 on d 56), milk composition, and SCC did not differ between treatments ($P > 0.05$) during the trial. Selenium supplementation increased ($P < 0.01$) Se apparent efficiency of transfer into milk (9.9 vs. 7.9%) and Se content of milk (20.5 vs. 12.7 µg/L). Selenium supplementation did not alter ($P > 0.05$) GSH-Px (220.3 vs. 199.0 U/g Hb) or Se concentration in blood (184.2 vs. 166.4 µg/L). There were no treatment effects on animal reproductive performance. Considering that 35% of Costa Rican population is Se deficient and taking into account the increase in Se content in milk, milk derived from cows supplemented with selenized yeast could contribute to a person's daily intake of Se.

Key Words: selenium, trace mineral, grazing cattle

T169 Inhibition of nuclear factor kappa B in duodenal mucosa of piglets by a grape seed and grape marc meal extract. D. K. Geßner[1], A. Fiesel[1], M. Lohölter*[2], B. Eckel[2], and K. Eder[1], *[1]Institute of Animal Nutrition and Nutrition Physiology, Universität Gieesen, Germany, [2]Dr. Eckel GmbH, Niederzissen, Germany.*

Enteric infections and the development of gut disorders commonly observed in piglets after weaning have negative effects on digestive capacity of the intestine, feed consumption, and growth of animals. The underlying molecular mechanism of this is an activation of nuclear factor kappa B (NF-κB), which leads to an increased expression of pro-inflammatory target genes. Studies in rodent models have shown that polyphenols have the ability to suppress inflammatory processes in the intestine by inhibiting NF-κB. The present study investigated the hypothesis that feeding a grape seed and grape marc meal extract (GSGME) as a dietary supplement has the potential to suppress the inflammatory process in the duodenum of piglets by modulating the activity of NF-kB polyphenols. Twenty-four crossbred (Danzucht × Pietrain) piglets, 6 weeks of age, were randomly assigned to a control group and a treatment group and fed a nutritionally adequate basal diet, based mainly on wheat, barley and soy bean meal for a period of 4 weeks. The control group received the basal diet; the treatment group received the basal diet supplemented with 1% of GSGME (AntaOx, Dr. Eckel GmbH, Niederzissen, Germany). There were no differences in average daily gains and daily feed intake between the two groups. However, the gain:feed ratio was increased in the treatment group ($P < 0.05$). Additionally, the treatment group had a lower activity of NF-κB and lower expression levels of NF-κB target genes such as TNFa, IL-8 and MCP-1 in the duodenal mucosa ($P < 0.05$). Moreover, the villus height:crypt depth ratio in the duodenum was increased in the pigs fed the GSGME, suggesting an increased absorptive capacity. In conclusion, the present study shows that a polyphenol rich GSGME has an anti-inflammatory effect in the small intestine of piglets. It is suggested that feeding of polyphenol rich plant extracts might provide a useful dietary strategy to inhibit inflammation in the intestine frequently occurring in piglets.

Key Words: grape seed and grape meal extract, anti-inflammatory, piglets

T170 Degradation of ergopeptines by *Rhodococcus erythropolis* MTHt3. M. Thamhesl*[1], E. Apfelthaler[2], E. Kunz-Vekiru[2], I. Schöner[3],H. Schwartz[3], F. Berthiller[3], R. Krska[2], G. Schatzmayr[1],and W.-D. Moll[1], *[1]Biomin Research Center, Tulln, Austria, [2]Christian Doppler Laboratory for Mycotoxin Research, Department for Agrobiotechnology (IFA-Tulln), University of Natural Resources and Life Sciences, Vienna, Tulln, Austria, [3]Christian Doppler Laboratory for Mycotoxin Metabolism, Department for Agrobiotechnology (IFA-Tulln), University of Natural Resources and Life Sciences, Vienna, Tulln, Austria.*

Ergot alkaloids are secondary metabolites produced by ergot fungi (*Claviceps* species) in cereals and endophytes (*Epichloë*, *Neotyphodium*, and *Balsania* species) in grasses. Ergot poisoning occurs predominantly in livestock after consumption of endophyte infected grasses and leads to reduced animal performance. Diverse strategies on pasture and animal management or feed treatments have been investigated. Ergot degrading microorganisms, which can be applied as feed additives and are active in the gastrointestinal tract, may be a technological solution to ameliorate the problem. The objective of this research was to isolate ergot alkaloid-degrading microorganisms from natural habitat. Strain MTHt3 was isolated from soil and identified by phylogenetic analysis based on 16S rRNA as member of the species *Rhodococcus erythropolis*. In comparison to a number of tested *R. erythropolis* strains the ability to metabolize ergopeptines was unique for strain MTHt3. In a degradation experiment with an extract from ground sclerotia (acetonitrile/water; 1:1; v/v; 2 hours at room temperature) strain MTHt3 was capable of converting all detected ergopeptines (ergotamine, ergovaline, ergocryptine, ergocristine, ergocornine, and ergosine) to ergine and cyclic dipeptides (diketopiperazines). Ergine was further de-amidated to lysergic acid. Cyclic dipeptides were completely catabolized by strain MTHt3, but not utilized by *R. erythropolis* type strain DSM 43066. Characterization of strain MTHt3 showed that conversion of ergopeptines to ergine occurred in a broad pH and temperature range whereas deamination of ergine to lysergic acid was strongly influenced by pH and temperature. Lysergic acid has lower vasoconstrictive activity compared to ergopeptines and simple lysergic acid amides. Hence, metabolization of ergot alkaloids to lysergic acid by *R. erythropolis* MTHt3 may reduce toxicity. Application as feed additive of strain MTHt3, however, seems to be difficult due to characteristics of the strain. Isolation of responsible enzymes combined with enzyme engineering and application as feed enzymes can be an alternative approach to reduce effects of ergot alkaloid-contaminated fodder on animals.

Key Words: ergot alkaloid, degradation

T171 The impact of grazing toxic tall fescue on bull growth, fat deposition and blood flow. S. K. Duckett*[1], G. E. Aiken[2], H. M. Stowe[1], M. C. Miller[1], S. M. Calcatera[1], M. D. Owens[1], J. G. Andrae[1], and S. L. Pratt[1], *[1]Clemson University, Clemson, SC, [2]ARS-Forage-Animal Production Research Unit, Lexington, KY.*

Tall fescue is utilized extensively in the Southeastern United States; however, most tall fescue contains an ergot alkaloid producing fungal endophyte. Consumption of ergot alkaloids (EA) results in the syndrome known as tall fescue toxicosis. The objective of this study was to evaluate growth, fat deposition, and blood circulation for bulls grazing an EA containing toxic tall fescue (Toxic) compared to a novel non-toxic (NT) endopyhte, which lacks EA. Angus bulls (n = 21) were stratified by BW and BCS and allotted to graze either KY31 or NT for 155 days. Body weights were taken on d 0 and d 140. Body condition scores were taken on d 0, 35, 84, 112, and 140. Doppler ultrasound was conducted on the caudal and testicular arteries to evaluate blood flow and real-time ultrasound conducted on the loin and rump to determine subcutaneous fat deposition, intramuscular fat (IMF) and muscle depth (MD) on d 8, 57, 106 and 155. GLIMMIX procedures were used to perform an ANOVA to test for the main effects of treatment (TRT), day, and TRT × day interaction for all parameters. TRT × day combination means were generated and compared using Fisher's LSD test. No difference in BW ($P = 0.43$) was observed on d 0; however, by d 140 BW was decreased ($P = 0.04$) in the Toxic bulls (546.2 ± 16.6 kg) compared to the NT bulls (595.9 ± 16.6 kg). The gain in BW was increased in NT bulls compared to bulls grazing Toxic ($P = 0.0001$; 105.8 ± 8.9 versus 33.8 ± 8.1 kg, respectively). No difference was observed for TRT ($P = 0.3$) or TRT × day interactions ($P = 0.08$) for BCS. No differences were observed for IMF ($P = 0.8$) or fat thickness ($P \geq 0.06$) due to TRT; however, the rump MD was decreased in bulls grazing Toxic compared to NT ($P < 0.001$). Luminal area was reduced from 9.7 ± 0.9 to 4.8 ± 0.8 mm^2 for the caudal artery ($P = 0.001$) and 10.3 ± 0.8 to 5.0 ± 0.8 mm^2 for the testicular artery ($P = 0.01$) for NT compared to Toxic bulls, respectively. These data support previous research demonstrating the negative effects of ergot alkaloids on BW and blood flow.

Key Words: fescue toxicosis, bull, ultrasound

T172 Finishing residual feed intake is positively correlated with backgrounding growth of metabolically imprinted Angus-sired steers. J. K. Smith*, S. P. Greiner, and M. A. McCann, *Virginia Polytechnic Institute and State University, Department of Animal and Poultry Sciences, Blacksburg.*

Backgrounding is commonly utilized within the beef industry to achieve economical weight gains while providing feeders with a continuous cattle supply. Previous research has indicated implications of early growth dynamics on finishing (FIN) performance and carcass traits. The objective of this study was to identify relationships between FIN residual feed intake (RFI) and early growth performance or carcass traits of conventionally weaned (CW; n = 22; weaned at 204 ± 18 DOA; d 204) or metabolically imprinted (MI; n = 21; weaned at 104 ± 18 DOA; d 104) Angus-sired steers that were MI via concentrate supplementation (100 d) immediately following weaning. Upon completion of the MI feeding period, MI and CW calves were commingled and backgrounded for a minimum of 153 d prior to being finished on a concentrate- and corn silage-based ration for 92 ± 6 d after a 21 day adaptation period. Average daily metabolic BW gain (ADMG) was calculated throughout the early (EG; d 104 to 204), backgrounding (BG) and FIN growth phases. ADFI was measured and used to calculate FIN RFI. Cattle were harvested in groups upon reaching a common subcutaneous fat thickness (BFT) of 1 cm. Pairwise correlations between RFI and growth or carcass measurements were determined using the Multivariate and Pairwise Correlations procedure of JMP. When evaluated irrespective of weaning regimen, RFI was correlated ($P < 0.05$) with ADMG during the EG and BG phases, ribeye area and yield grade, and tended ($P < 0.10$) to be correlated with BFT with respective r values of -0.37, 0.51, -0.30, 0.46 and 0.27. Within weaning regimen, RFI was correlated ($P < 0.05$) with ADMG during the BG phase, ribeye area, yield grade and BFT for MI steers with respective r values of 0.54, -0.42, 0.60 and 0.51, but was not correlated ($P > 0.10$) with growth or carcass traits for CW steers. These results suggest relationships between FIN RFI and pre-finishing growth that were unique to MI cattle in this experiment. Targeting MI cattle for low ADMG during the BG phase may improve FIN feed efficiency through decreasing RFI.

Key Words: metabolic imprinting, residual feed intake, beef

T173 Early metabolic imprinting for improved feed efficiency of backgrounded Angus-sired steers. J. K. Smith*, S. P. Greiner, and M. A. McCann, *Virginia Polytechnic Institute and State University, Department of Animal and Poultry Sciences, Blacksburg.*

Previous research has indicated the ability of energy supplementation early in life to metabolically imprint cattle for improved growth and carcass traits. The objective of this study was to evaluate the effect of metabolic imprinting (IMP) on finishing (FIN) average daily residual feed intake (RFI) of Angus-sired steers. Calves born in the fall of 2009 (FB) and spring of 2010 (SB) were stratified by sire and age before being randomly assigned to a metabolically imprinted (MI; weaned at 104 ± 18 d of age; n = 21) or conventionally weaned (CW; weaned at 204 ± 18 d of age; n = 22) treatment group. Following weaning, MI calves were adapted to and received a concentrate-based ration in a feedlot setting for 100 d. Upon completion of the MI feeding period, previously unsupplemented CW calves were commingled with MI calves and backgrounded for a minimum of 153 d prior to being finished on a concentrate- and corn silage-based ration for 92 ± 26 d following a 21 d adaptation period. ADFI was collected using a Calan Broadbent feeding system and used to calculate average daily TDN intake (TDNI). Cattle were harvested in groups upon reaching a common 12th rib subcutaneous fat thickness (BFT; 1 cm). Predicted average daily metabolic BW (MBW) gain was regressed against predicted mid-finishing MBW and TDNI using the Fit Y by X procedure of JMP to express RFI in kg of TDN. While analysis of a compiled FB and SB dataset using the Fit Model procedure of JMP revealed no effect ($P > 0.10$) of IMP on finished MBW, HCW, BFT, ribeye area (REA), KPH and yield grade (YG), IMP resulted in lower RFI ($P < 0.05$; −0.299 vs. 0.246 kg TDN) and greater marbling score ($P < 0.05$; 542 vs. 595) when compared to conventional weaning. Although not associated ($P > 0.10$) with carcass measurements of CW steers, RFI was associated ($P < 0.05$) with BFT ($R^2 = 0.26$) and YG ($R^2 = 0.36$) of MI steers, with a tendency ($P < 0.10$) toward an association with REA ($R^2 = 0.17$). These results indicate the ability of IMP to decrease the amount of TDN required by FIN cattle to reach a common carcass endpoint. Economic savings in FIN TDN may be capable of offsetting a portion of IMP feed costs.

Key Words: metabolic imprinting, residual feed intake, beef

T174 Comparison of serial and parallel beef fabrication methods in a traceable supply chain. T. Foster*[1], D. Buskirk[1], and J. Schweihofer[2], *[1]Michigan State University, East Lansing, [2]Michigan State University Extension, East Lansing.*

Traceability of meat attributes from small and mid-sized farms through supply chains is recognized as a market barrier. Automatic identification and data capture technologies, such as radio frequency identification (RFID) and two-dimensional (2-D) barcodes, offer the feasibility of maintaining animal and product data through carcass fabrication. The objective of this study was to determine the influence of fabrication method on beef traceability system requirements. Individual animal identity of seventy-two (72) beef carcasses were maintained during either serial or parallel processing of carcass quarters. Each carcass quarter was labeled with a 2-D barcode containing the animal's unique RFID ear tag number at harvest. Nine carcasses were processed on alternating days of processing by one of two methods for eight days of processing. Carcasses were serially fabricated (SER) resulting in creation of all wholesale cuts of a single carcass before moving on to the next, or parallel fabricated (PAR) by processing 10 hindquarters, followed by 10 forequarters, 8 hindquarters, and 8 forequarters. The major difference between processing method was that beef from only one animal was on a cutting table for SER, whereas beef from multiple carcasses was on a cutting table for PAR. In-process, 5.1 × 2.5 cm "child" labels were generated by scanning the 2-D barcode on the parent carcass label with a handheld mobile computer and wirelessly printed with a mobile printer. Tracking of SER and PAR carcass quarters were accomplished by creating in-process labels for lugs and individual wholesale cuts, respectively. The amount of time required to fabricate each carcass was similar ($P > 0.05$) for SER (2 hours 35 minutes) and PAR (2 hours 49 minutes). The mean number of in-process labels generated per carcass for SER was 3.7 and for PAR was 30.9 ($P < 0.01$). The amount of time required for generating labels for SER (2 minutes 16 seconds) was less than that for PAR (8 minutes 45 seconds) ($P < 0.01$). Logistics of traceability was less complex for SER than PAR and did not significantly add to the time of processing beef carcasses.

Key Words: radio frequency identification, two-dimensional, beef traceability

T175 Effect of supplement and resynchronization protocol on body weight, body condition score, and estrus appearance of Charolais cows grazing Buffelgrass in Northeastern Mexico. E. Garza Brenner*[1], H. Bernal Barragán[1,3], E. Gutiérrez Ornelas[1,3], F. Sánchez Dávila[1], A. S. Juárez Reyes[2,3], and E. Olivares Sáenz[1], *[1]Universidad Autónoma de Nuevo León, San Nicolás de los Garza, Nuevo León, México, [2]Universidad Juárez del Estado de Durango, Durango, México, [3]Red Internacional de Nutrición y Alimentación Animal, México.*

The effects of type of supplement and resynchronization protocol on condition and reproductive performance were evaluated using 32 Charolais cows grazing Buffelgrass (*Cenchrus ciliaris* L.), supplemented daily with 1 kg of either dried distillers grains with solubles (DDGS) or 50% DDGS:50% dried citrus pulp (DDGS:DCP) during 30 d. Estrus was synchronized by inserting on d 0 a controlled internal drug-releasing (CIDR) device, containing 1.38 g of progesterone, with retrieval on d 9; artificial insemination (AI) was conducted 12 h after estrus onset. Resynchronization started 5 d after AI, reinserting to each female its own CIDR device, for either 8 d (R8D) or 14 d (R14D). Body weight (BW) and body condition score (BCS) were registered at d 0, 9, 15, 23, and 30. Intervals from CIDR retrieval to estrus were registered by visual observation. Cows were blocked (age, parity, weight) and randomly assigned in a 2 × 2 factorial arrangement of treatments (two supplements: DDGS and DDGS:DCP, and two resynchronization protocols: R8D and R14D). Data were analyzed using two-way ANOVA (BW, BCS, intervals to estrus), and nonparametric test (Mann-Whitney for estrus appearance). Initial and final BW were similar (mean = 485 kg); however, on d 15 (487 vs. 464 kg) and d 23 (500 vs. 485 kg), cows receiving DDGS:DCP were heavier ($P < 0.05$) than those receiving DDGS. BCS changed ($P < 0.05$) from 4.7 (d 0) to 5.1 (d 30), but there was no effect ($P > 0.05$) of supplements. Fourteen out of 16 cows receiving DDGS:DCP, and 8 out of 16 cows receiving DDGS ($P < 0.05$), showed estrus. There was no effect ($P > 0.05$) of supplement on interval of CIDR retrieval to estrus onset (mean = 34.2 h). After resynchronization, 5 and 6 out of 16 cows for each protocol ($P > 0.05$) showed estrus, but it started later ($P < 0.01$) by R8D than R14D (141.9 vs. 27.8 h). In conclusion, Charolais cows grazing Buffelgrass and supplemented with DDGS:DCP had greater estrus appearance rate than those receiving DDGS. Length of resynchronization affected time, but not rate, of estrus appearance.

Key Words: dried citrus pulp, DDGS, resynchronization

T176 Influence of previous experience on performance and grazing behavior in beef heifers. G. A. Perry*, E. L. Larimore, and J. A. Walker, *Department of Animal Science, South Dakota State University, Brookings.*

Previous research has reported that grazing experience can impact performance when heifers are moved from a drylot to forage. The objective of this study was to determine the impact of prior grazing experience on weight change and activity when heifers were moved to spring forage. Angus-cross beef heifers were developed in a single pen following weaning. At the start of treatment (d 0) heifers were blocked by weight and allot to either remain in the drylot (n = 34) or were move to spring forage (n = 35). Body weights were collected on d 0, 9, 20, 41, 53, and 74. Pedometers were placed on 5 heifers per treatment on d 25 and measured numbers of steps taken, and amount of time standing and lying down. On d 44 all heifers were moved to spring forage, but were maintained in their respective group (12.1 ha/group). The statistical model included treatment, time, and their interaction. There was a treatment ($P < 0.01$), time ($P < 0.01$), and a treatment by time ($P < 0.01$) effect on ADG. Heifers moved to spring forage on d 0 had decreased ($P < 0.01$) ADG from d 0 to 9 compared to heifers that remained in the drylot. There was no difference between treatments in ADG from d 9 to 20 and from d 20 to 41. Following being moved to spring forage on d 44 the drylot group had decreased ($P < 0.01$) ADG from d 41 to 53 and from d 53 to 74 compared to the group that had previous grazing experience. From d 25 to 38, there was an effect of treatment ($P < 0.01$), time ($P < 0.01$), and a treatment by time ($P = 0.03$) on the number of steps taken each day, with heifers on forage taking more ($P < 0.05$) steps per d than heifers in the drylot. However, there was no effect of treatment on the amount of time a heifer spent standing or lying down per d. Following being moved to spring forage, heifers that remained in the drylot took more ($P < 0.05$) steps per d on d 44, 45, 46, and 47 compared to heifers that had previous grazing experience. However, there was no treatment effect on the amount of time a heifer spent standing and lying down per day. In summary, prior grazing experience can impact grazing behavior and heifer performance when heifers are moved to spring forage.

Key Words: heifer development, grazing behavior, ADG

T177 Immunocastration effect on performance in feedlot cattle. G. Z. Miguel*[1,3], R. O.Roça[2], C. T. Santos[3], M. H. de Faria[4], F. D. de Resende[4], G. R. Siqueira[4], J. M. Homem[3], A. D. Moreira[5], and B. R. C.

C. Lima[6], *[1]Fundação de Amparo à Pesquisa do Estado de São Paulo, São Paulo, SP, Brazil, [2]FCA / Universidade Estadual Paulista, Botucatu, SP, Brazil, [3]FMVZ / Universidade Estadual Paulista, Botucatu, SP, Brazil, [4]Agência Paulista de Tecnologia dos Agronegócios, Colina, SP, Brazil, [5]FCAV / Universidade Estadual Paulista, Jaboticabal, SP, Brazil, [6]Dep Tecnologia de Alimentos / Universidade Federal Fluminense, Niteroi, RJ, Brazil.*

Our objective was to determine the effect of immunocastration on performance of finishing cattle of 2 genetic groups (GG) and 3 sex conditions (SC). Thirty Nellore (NE) and 30 Nellore × Angus (NA) with average of 450 kg BW and 20 mo of age were evaluated during two periods: pre-feedlot and feedlot. The first period was defined from 130 to 90 d prior to harvest, while the second period was the last 90 d prior harvest. In the pre-feedlot period 10 NE and 10 NA were immunocastrated (IM) by vaccinating twice with Bopriva (anti-GnRH vaccine; Pfizer Animal Health) at 28 d and 1 d prior to transfer to feedlot. Surgical castration (CA) treatment was imposed on 10 animals from each GG, which occurred at 28 d before transferring to feedlot. Ten animals from each GG were kept intact (NC). During the pre-feedlot period the animals were raised on pasture and supplemented at 0.25% of BW, while during the feedlot period, the animals were fed ad libitum a high-grain diet formulated to contain 85% concentrate. In the feedlot the animals were finished in individual pens. Statistical analyses were performed according to a 2 × 3 factorial scheme (2 GG × 3 SC) in a completely randomized design. Data were analyzed using the MIXED procedure of SAS with initial weight as a covariate, and the means were compared by Student's t-test at 5% probability. As expected, NA animals had greater BW and ADG than NE ($P < 0.05$), but similar DMI and G:F ($P > 0.05$). Although IM and CA animals showed similar results for ADG, DMI and G:F ($P > 0.05$), IM had greater BW ($P < 0.05$). NC bulls had greater BW, ADG and G:F than the other SC ($P < 0.05$), but equivalent DMI ($P > 0.05$). Among IM treatments NA had greater BW, ADG and G:F than NE ($P < 0.05$). In this study NA animals and NC bulls were more efficient on high-grain diets due to greater BW and ADG. Additionally IM-NA animals had better performance than IM-NE with greater BW, ADG and G:F.

Key Words: sexual conditions, *Bos indicus*, beef cattle

T178 Correlations of visual scores and ultrasound carcass traits with economically relevant traits in Nellore cattle. R. C. Gomes*[1], P. H. Cancian[2], F. Manicardi[2], A. C. Ianni[2], M. N. Bonin[2], P. R. Leme[2], and S. L. Silva[2], *[1]Embrapa Beef Cattle, Campo Grande, MS, Brazil, [2]Faculdade de Zootecnia e Engenharia de Alimentos, Universidade de Sao Paulo, Pirassununga, SP, Brazil.*

Visual scores (VS) and carcass ultrasound have been used for genetic selection purposes in the Brazilian Nellore herd. However, the impacts on economically relevant traits, such as feed efficiency and the yield of commercial meat cuts, still lack investigation. The aim was to evaluate the correlations of VS and carcass traits evaluated by ultrasound (US), with feed efficiency (FE), hot carcass weight (HCW), dressing percentage (DP) and retail product yield (RPY). Fourty-two bulls and 44 steers were evaluated for both VS and US, in the postweaning phase (15 mo of age) and in the beginning of the finishing phase (21 mo of age). Cattle were ultrasound scanned for measuring backfat thickness (UBFT), rump fat thickness (URFT) and ribeye area (UREA). Visual scores of conformation (C), precocity (P) and muscling (M) were attributed individually. Gain-to-feed ratio (G:F) and residual feed intake (RFI) were measured in feedlot. HCW, DP and RPY were determined at harvest. Pearson correlation analyses were carried out. Bulls had greater HCW (321 vs. 292 kg; $P < 0.0001$) and RPY (74.5 vs. 71.8%; $P < 0.0001$) and lower finishing UBFT (0.58 vs. 1.60 mm, $P < 0.0001$) and URFT (1.96 vs. 3.64 mm; $P < 0.0001$) than steers. C and P did not differ across sex types ($P > 0.05$) in both phases, but bulls had greater M scores in the finishing phase (4.49 vs. 3.42, $P < 0.01$). Feedlot RFI and G:F were poorly correlated with postweaning VS and US in both sex types ($P > 0.05$). G:F was negatively correlated with finishing C ($r = -0.39$; $P < 0.05$), P ($r = -0.50$; $P < 0.01$) and M ($r = -0.50$; $P < 0.01$) in steers. DP was negatively correlated with postweaning P ($r = -0.31$; $P < 0.05$), M ($r = -0.32$; $P < 0.05$) and UREA ($r = -0.51$; $P < 0.01$) in steers. Finishing URFT was negatively correlated with RPY in bulls ($r = -0.41$; $P < 0.01$). Greater subcutaneous fat thickness in the beginning of the finishing phase may indicate cattle with lower retail product yield. The associations of visual scores and ultrasound carcass traits with feed efficiency and retail product yield are affected by age at evaluation and by castration, but are generally small.

Key Words: body composition, edible portion, feed conversion

Breeding and Genetics: Applications and Methods in Animal Breeding—Beef

T179 Genetic analysis of female weights via random regression and multiple trait models in a multibreed beef cattle population. B. Y. Coy[1,2], C. A. Martinez[1], C. Manrique[2], and M. A. Elzo*[1], *[1]University of Florida, Gainesville, [2]Universidad Nacional de Colombia, Bogota, Colombia.*

The objective was to obtain REML estimates of covariance functions and variance ratios for weights taken during the productive life of beef cows from a multibreed Angus-Brahman population using random regression models. The dataset contained 40,009 weights from 1,792 cows. Genetic analyses were performed using random regression models (RRM) with Legendre polynomials (LP). Reference heritabilities at birth, weaning, and 1, 2, 3, 4 and 5 years of age were estimated using 2-trait mixed models (MTM). Fixed effects for RRM were contemporary group (year-period of measurement), and cubic LP covariates for age of female, interactions between age of female and expected Brahman fractions of female and her dam, and direct and maternal heterozygosity. Random effects were cubic LP age covariates for direct and maternal additive genetic and direct permanent environment, and residual. Two-trait models for weights up to one year had contemporary group (year-period of measurement), age of female, expected Brahman fractions of female and her dam, and direct and maternal heterozygosity as fixed effects. Random effects were direct and maternal additive genetic, maternal permanent environment and residual. Two-trait models for weights taken after one year of age ignored maternal effects. Legendre polynomials behaved badly at extreme ages. The MTM direct heritability estimates were similar to RRM values, except for birth weight (0.3 ± 0.06 for MTM and 0.02 ± 0.02 for RRM). The RRM direct heritability increased from near zero at birth to 0.59 ± 0.05 at 764 d and then decreased to 0.39 ± 0.09 at 2,500 d of age. Maternal heritability reached its maximum value at 222 d (0.09 ± 0.02) and decreased towards 2,500 d (0.02 ± 0.05). Direct permanent environment variance ratios increased from 0.04 ± 0.02 at birth to 0.57 ± 0.08 at 2,500 d of age. Results suggested that this dataset should be reanalyzed using functions less sensitive at extreme age values such as splines to obtain reasonable estimates of variance ratios over the entire range of ages.

Key Words: cattle, multibreed, random regression

T180 Ranking of Nellore cattle at agricultural shows: Genetic and phenotypic parameters with production traits. M. E. Z. Mercadante*[1], E. A. Simielli Filho[1], J. A. V. Silva[2], T. R. Pinheiro[3], A. L. Grion[1], and L. A. Josahkian[4], *[1]Centro APTA Bovinos de Corte, Instituto de Zootecnia, Sertaozinho, Sao Paulo, Brazil, [2]Faculdade de Medicina Veterinária e Zootecnia, UNESP, Botucatu, Sao Paulo, Brazil, [3]AVAL, Goiania, Goias, Brazil, [4]ABCZ, Uberaba, Minas Gerais, Brazil.*

Although livestock judging does not use techniques of genetic evaluation and the population samples are not comprehensive in terms of the number of animals evaluated, agricultural shows exert an effect on breed improvement since the champion animals are rapidly disseminated in the population through semen or oocytes. Records (28,279) of 17,141 Nellore cattle participating in 26 agricultural shows, born from 1994 to 2009, from 764 sires, were used to estimate genetic and phenotypic parameters between animal rank in cattle judging and growth traits (yearling weight-YW, hip height-HH, body length-BL, heart girth-HG), scrotal circumference (SC) and ultrasound carcass traits (longissimus muscle area-LMA, backfat-BF, rump fat thickness-RF). Two traits were defined for animal rank in cattle judging: value 1 was attributed to animals ranked 1st to 3rd place within the age category and value 0 to the remaining animals (TOP3); and, value 1 was attributed to animals ranked 1st to 5th place within the age category and value 0 to the remaining animals (TOP5). TOP3 and TOP5 were evaluated from weaning to 36 months of age as repeated traits and YW, HH, BL, HG, SC, LMA, BF and RF were evaluated as single traits at 365 days of age. The (co) variance components were estimated by Bayesian inference under a two-trait threshold-linear animal model. The heritabilities posterior means estimated for TOP3 and TOP5 were 0.182 ± 0.010 and 0.260 ± 0.012, and the repeatabilities were 0.341 ± 0.007 and 0.400 ± 0.007. Genetic correlation between TOP3, TOP5 and YW were higher (0.941 ± 0.016 and 0.943 ± 0.014) than the estimates between TOP3, TOP5 and HH, BL, HG (from 0.535 ± 0.098 to 0.757 ± 0.038). Low genetic correlations were estimated between animal rank traits and SC (0.439 ± 0.072 and 0.382 ± 0.067) and carcass traits (from 0.341 ± 0.114 to 0.231 ± 0.145). The highest phenotypic correlations were estimated between TOP3, TOP5 and YW (0.485 ± 0.010 and 0.535 ± 0.009), followed by the phenotypic correlations with HG (0.379 ± 0.019 and 0.390 ± 0.018), suggesting that judges are most influenced by these two traits at the time of awarding prizes.

Key Words: *Bos indicus*, categorical trait, Zebu

T181 Genetic parameters and genetic trends for preweaning growth in an Angus-Brahman cattle population in the Colombian tropics. O. D. Vergara[1], M. A. Elzo*[2], R. M. Patino[3], A. Calderon[1], and R. Almanza[4], *[1]University of Cordoba, Monteria, Colombia, [2]University of Florida, Gainesville, [3]University of Sucre, Sincelejo, Colombia, [4]Gencaribe Hacienda Abastecedora de Carnes SA, Planeta Rica, Colombia.*

The objective of this research was to estimate genetic parameters and trends for birth weight (BW) and weaning weight adjusted to 270 d of age (WW270) in a beef cattle population composed of Angus and Brahman straightbred and crossbred animals located in a Colombian premontane humid forest. Data were from 561 calves born from 1999 to 2010. The 2-trait model included the fixed effects of contemporary group (year-season-sex), age of dam, breed direct genetic effects, breed maternal genetic effects, individual heterosis, and maternal heterosis. Random effects were calf direct genetic, dam maternal genetic, permanent environmental maternal, and residual. Variance components and genetic parameters were estimated by restricted maximum likelihood. Program AIREML was used to perform computations. Heritabilities estimates for additive direct genetic effects were 0.08 ± 0.005 for BW and 0.10 ± 0.006 for WW270. Maternal heritability was 0.04 ± 0.002 for BW and 0.08 ± 0.005 for WW270. Low direct and maternal preweaning heritabilities suggest that nutrition should be improved to allow fuller expressions of calf direct growth and cow maternal ability. The correlation between additive direct genetic effects for BW and WW270 (0.18 ± 0.03) indicated that genes affecting BW also affected WW270. The genetic correlations between direct and maternal additive effects were negative for BW (−0.51 ± 0.02) and for WW270 (−0.21 ± 0.03) suggesting that genes increasing weight would lower maternal ability. Calf weighted yearly means showed near zero trends during these years for direct and maternal effects for BW and WW270. This indicated that the intensity of selection applied to this multibreed population

was insufficient to influence direct and maternal genetic yearly EBV means during this 12-yr period. To make genetic progress for direct and maternal growth traits, a selection program that utilizes direct and maternal animal EBV to select replacement sires and dams will need to be implemented in this population.

Key Words: beef cattle, genetic parameters, genetic trends

T182 Population structure and relation among inbreeding coefficient and breeding values in Guzera beef cattle. D. G. F. Guidolin*[1,3], N. V. Grupioni[2,3], N. C. Tramonte[2,3], I. Urbinati[3,5], T. C. S. Chud[2,3], R. B. Lobo[4], and D. P. Munari[3,5], *[1]Coordenacao de Aperfeicoamento de Pessoal de Nivel Superior, CAPES, Brasilia, DF, Brazil, [2]Fundacao de Amparo a Pesquisa do Estado de Sao Paulo, FAPESP, Sao Paulo, SP, Brazil, [3]Universidade Estadual Paulista Julio de Mesquita Filho, UNESP, Jaboticabal, SP, Brazil, [4]Associacao Nacional de Criadores e Pesquisadores, ANCP, Ribeirao Preto, SP, Brazil, [5]Conselho Nacional de Desenvolvimento Cientifico e Tecnologico, CNPq, Brasilia, DF, Brazil.*

The aim of this study was to estimate population parameters and inbreeding coefficients and its relation with breeding values and with the index indicated for the Guzera breed (MGT). The reason to do that was to provide information for the breeding program hold by ANCP. For this we used pedigree data from 26,160 animals, born between 1943 and 2009, bred in 43 herds participant in the Guzerá Breeding Program (PAGRG). The population parameters estimated were average inbreeding coefficient (F), inbreeding per generation (DF), effective population size (Ne), generation interval, effective number of founders (Nf) and number of ancestors (Na). The traits studied were age at first calving (AFC), scrotal circumference at 365 and 450 days of age (SC365) and (SC450), body weight at 365 and 450 days of age (BW365) and (BW450). Ne presented equal to 78.59, indicated low genetic diversity in the herds studied. The generation intervals observed in the population is considered to be high, 9.1 years. The F observed was 0.93% and DF was 0.64%, this indicates that the inbreeding coefficient is increasing through the period studied. Although it was observed that the inbreeding coefficient does not influence animal performance. Despite the fact that inbreeding depression was not observed in this study, mating related animal is not recommended.

Key Words: parameter, selection, zebu

T183 Genetic parameters and trends for productive, reproductive and carcass traits in Guzera beef cattle. D. G. F. Guidolin*[1,3], N. V. Grupioni[2,3], N. C. Tramonte[2,3], P. A. Bernardes[3,5], G. B. Nascimento[1,3], G. Vargas[1,3], R. B. Lobo[4], and D. P. Munari[3,5], *[1]Coordenacao de Aperfeicoamento de Pessoal de Nivel Superior, CAPES, Brasilia, DF, Brazil, [2]Fundacao de Amparo a Pesquisa do Estado de Sao Paulo, FAPESP, Sao Paulo, SP, Brazil, [3]Universidade Estadual Paulista Julio de Mesquita Filho, UNESP, Jaboticabal, SP, Brazil, [4]Associacao Nacional de Criadores e Pesquisadores, ANCP, Ribeirao Preto, SP, Brazil, [5]Conselho Nacional de Desenvolvimento Cientifico e Tecnologico, CNPq, Brasilia, DF, Brazil.*

The objectives of this study were to estimate genetic parameters and genetic trends for traits evaluated by the Guzera Breeding Program (PAGRG), in order to provide support for the genetic improvement of the breed. Records on 18,491 animals from 43 farms were used. Traits studied were rib eye area (REA), fat thickness between the 12th and 13th rib (FT), rump fat thickness (RF), age at first calving (AFC), scrotal circumference at 365 (SC365) and 450 (SC450) days of age, gestation length (GL), mature weight of the cow (MWC), body weight at birth (BWB), 120 (BW120), 210 (BW210), 365 (BW365), 450 (BW450 days old) and cumulative productivity in females (CP). Genetic parameters and breeding values were estimated by restricted maximum likelihood, by one and two-trait analysis whose general model included additive genetic random effect and fixed effect of contemporary groups (CG), for CP, AFC, SC365 and SC450. For GL, BWB, BW120, BW210, BW365 and BW450, a maternal additive random genetic effect and the fixed effect (linear and quadratic) of the cow's age at calving were added to the base model. For carcass traits, the fixed effect (linear) of weight at ultrasound was included. Genetic trends were obtained by linear regression of average annual breeding values (obtained by one-trait analysis) on year of birth (1987 to 2009) The t statistic was used and the null hypothesis considered the regression coefficient as zero. Most traits showed sufficient additive genetic variation, except CP, FT and RF, which expressed low genetic correlations with other traits. The trend graphs indicate that genetic change is occurring in the average breeding value of animals over time, with the exception of CP, GL and the maternal genetic effect for BWB. The inclusion of RF in a selection index proposed by ANCP is recommended.

Key Words: zebu, heritability, breeding

T184 Genetic trend on growth traits in Hanwoo. Y.-S. Choi*[1], S.-W. Kim[1], K.-S. Kim[1], S.-K. Lee[1], D.-J. Yu[1], A.-A Yun[1], M.-J. Ku[1], D.-H. Park[1], J.-W. Lee[2], and W.-H. Kim[1], *[1]Livestock Research Institute Jeollanamdo Agricultural Research & Extension Service (JARES), Gangin-gun, Jeollanamdo, Republic of Korea, [2]Chonnam National University, Gwangju, Republic of Korea.*

The objectives of this study were to figure out factors affecting growth performance of Korean native cattle called Hanwoo and to analyze phenotypic correlations among carcass traits. Birth and weaning weights and carcass traits were considered for prediction of potential ability on growth. Linear model was used to analyze sex of calves, dam parity and age, birth year, birth season, slaughter season were used as fixed factors in this study. Birth and weaning weights by sex of calves were 27.32 ± 2.26kg and 83.84 ± 14.23kg in bull and 26.24 ± 3.08kg and 82.44 ± 14.34kg in heifer, respectively. Birth weight in bull was significantly heavier than those in heifer ($P < 0.05$). Carcass weight by the sex of calves was 399.07 ± 56.25 kg in steer and 302.16 ± 56.25 kg in cow. Eye muscle area was 87.37 ± 11.36 cm^2 in steer and 73.37 ± 13.02 cm^2 in cow. Birth weight by parity of dam was significantly different ($P < 0.05$). Birth and weaning weights at 4th parity was 28.86 ± 2.86 kg and 88.00 ± 14.29kg, respectively. Birth and weaning weights by birth season were not different. But carcass weight born in summer season was 386.85 ± 67.28 kg which was heavier than those of them born in spring season ($P < 0.05$). Backfat thickness by slaughter season was significantly different ($P < 0.05$). Carcass weight and eye muscle area slaughtered at winter were 379.38 ± 68.53 kg and 84.27 ± 14.20cm^2. Phenotypic correlation coefficient between carcass weight and eye muscle area was 0.84 in cow and 0.66 in steer. Other correlation coefficients of carcass traits were positive. Phenotypic correlation coefficient by birth season winter was negative between eye muscle area and backfat thickness and the other traits of correlation coefficient were positive 0.84 in cow and 0.66 in steer. Other correlation coefficients of carcass traits were positive. Especially phenotypic correlation coefficients between carcass weight and eye muscle area were 0.86 in spring, 0.81 in summer, 0.79 in fall, and 0.73 in winter, respectively. These results indicated that age of dam should be an important factor for better growth performance and eye muscle area could be used as a selection indicator to increase carcass weight.

Key Words: Korean native cattle, genetics, growth trait

T185 Genetic and phenotypic (co)variance component estimation of reproductive traits in a multibreed beef cattle population. Y. Mu*, T. Caldwell, G. Vander Voort, J. Jamrozik, R. Ventura, and S. Miller, *Centre for Genetic Improvement of Livestock, Department of Animal and Poultry Science, University of Guelph, Guelph, ON, Canada.*

Accurate (co)variance estimates are necessary to optimize selection response in reproductive traits of economic importance for commercial beef cow/calf operations. The objective of this research was to determine the heritability of and relationship among 5 reproductive traits in a multi-breed beef cattle population. Records on 1369 cows from 505 sires and 1360 dams were collected between the years 2002 and 2011. Binary traits of first-service conception rate (FSCR) and pregnancy rate (PR), a categorical trait (number of service per conception, NS) were analyzed by a threshold model, while interval traits of gestation length (GL) and days to calving (DC) were analyzed using a linear model.Models included fixed effects of contemporary group (herd, year, breeding season and breeding method), age of cow, age of dam and linear regressions on breed proportions of Angus, Limousin, Charolais, Simmental, Gelbvieh and Piedmontese. Additive genetic and permanent environment due to repeated records on cows were included as random effects with service sire fitted in the threshold model as random univariate and bivariate animal models were fitted using ASReml (Gilmour et al, 2008). Estimates of heritabilities (repeatabilities) for FSCR, PR, NS, GL and DC were 0.121 (0.149), 0.143 (0.143), 0.016 (0.045), 0.211 (0.211) and 0.068 (0.096), respectively, which were relatively high compared to previous research. Genetic correlations between FSCR and PR, DC and GL were positive and high (r_G = 0.985 and 0.744). Furthermore, in addition to the negative correlation between the FSCR and GL (r_G = -0.562), the other traits appeared to be genetically independent. Phenotypically, reproductive traits were correlated with low to mediate correlation coefficients from -0.249 to 0.537. These parameters indicate genetic progress in reproductive traits of a multibreed beef cattle population would be possible.

Key Words: beef cattle, reproduction, genetic correlation

T186 Genetic analysis of a temperament trait in a Nellore cattle population in Brazil. F. L. Silva*[1], L. C. A. Regitano[3], F. Penagaricano[2], A. L. Paco[5], T. Sonstegard[4], L. L. Coutinho[1], M. A. Mudadu[3], M. M. Alencar[3], G. J. M. Rosa[2], and G. B. Mourao[1], *[1]ESALQ, USP, Piracicaba, SP, Brazil, [2]Department of Animal Sciences, University of Wisconsin, Madison, [3]Embrapa Pecuaria Sudeste, Sao Carlos, SP, Brazil, [4]USDA-ARS-ANRI-BFGL, Beltsville, MD, [5]UNESP, Jaboticabal, SP, Brazil.*

Temperament in cattle is generally assessed as the reaction of an animal to a stressful event, such as human handling. Flight speed (FS) is a temperament trait measured the time the animal takes to exit a squeeze chute over a given distance. A lower FS is indicative of a calmer animal, which is then easier to handle and manage. In addition, FS has been found to influence the productive performance of herds, due to its correlation with other traits such as carcass quality, daily gains, pregnancy rate and feed efficiency. However, almost nothing is known regarding the genetic landscape controlling FS variation in cattle. Thus, the objectives of this study were to identify genomic regions and biologically relevant pathways associated with FS in a Nellore cattle population in Brazil. The analysis included 599 Nellore males belonging to 34 paternal half-sib families born between 2007 and 2009 at the experimental farms Embrapa Cattle-Southeast and Embrapa Beef Cattle, and three additional farms in the State of Mato Grosso do Sul, Brazil. The genomic information consisted of 563,672 single nucleotide polymorphisms (SNPs). Associations between SNPs and FS were assessed using a series of linear mixed models, one for each SNP, including a random polygenic effect and a permanent environmental effect. These analyses were performed using the pedigreemm package in R. Gene set enrichment analysis also was conducted in order to find potential Gene Ontology (GO) terms related to this trait. Estimated SNP effects indicated some genomic regions that might be associated with FS, such as in chromosomes 5, 13 and 15. Additionally, we found a total of 28 GO terms significantly enriched with genes associated with FS. Interestingly, several of these functional categories are related to stress, such as cellular adhesion (GO: 0007155) and process of cellular response to toxins, physical stresses and inflammatory cytokines which occur by signaling via the stress-activated protein kinase (IPR017441). Results of this study shed some light regarding the genetic architecture underlying this trait in beef cattle. Financial support: FAPESP, EMBRAPA.

Key Words: beef cattle, gene ontology, GWAS

T187 The effects of winter hair coat shedding of Angus dams on adjusted weaning weight of calves. K. Fleetwood*[1], G. Hansen[1], T. Smith[2], J. Parish[2], and J. P. Cassady[1], *[1]North Carolina State University, Raleigh, [2]Mississippi State University, Mississippi State.*

Heat stress is a major concern for some beef cattle producers. Methods to select cattle that are resistant to the negative effects of heat stress are economically important for these producers. Decreases in feed intake, conception rates and milk production lead to reduced gains for cows and calves. A visual scoring method of how winter hair coat is shed may help identify cattle more resistant to heat stress. The objectives of the study were to collect hair coat shedding scores (HCS) on registered Angus dams throughout the Southeast, Missouri and Texas and to explore the relationship between HCS of the dam and adjusted weaning weight (WW) of her calf. Hair coat shedding scores were collected from 18 farms in 2011-2012 in North Carolina, South Carolina, Virginia, Tennessee, Kentucky, Missouri, Alabama, and Texas. Hair coat shedding scores were on a 1-5 scale with 5 being a cow with a full winter hair coat and a 1 being a slick summer coat. Two technicians independently scored each cow. Using the average of the two scores, cows were assigned to one of three categories for analysis. If a cow had an average HCS of less than 3, she was assigned to HCS1. If a cow had an average HCS between 3 or 4, she was assigned to HCS3. If a cow had an average HCS of 4 or greater, she was assigned to HCS5. Data were separated into two groups by calving season and analyzed separately. Regions were considered as Southeast, Missouri, and Texas. Data were analyzed in SAS using PROC GLM. There were no differences in HCS for cattle in Texas. However, for the lactating cows in Missouri and Southeast, calves from dams that were a HCS1 weighed, on average, 4.84 ± 1.62 kg ($P < 0.01$) heavier than calves from dams that were a HCS5. Calves from dams that were a HCS3 weighed, on average, 3.71 ± 1.72 kg ($P < 0.05$) heavier compared to calves from dams that were a HCS5. Calf WW did not differ between HCS1 and HCS3 dams. Regional differences observed in this project maybe due to forage differences such as the presence or absence of endophyte infected fescue. In conclusion, HCS can be a visual method to help producers determine if their cattle are suffering from heat stress.

Key Words: heat stress, beef

T188 Characterization and genetic selection for beef tenderness in polled Nellore cattle. C. U. Magnabosco*[1], E. C. Eifert[1], C. S. Prado[2], E. S. Miyagi[2], L. C. Moreira[2,1], L. M. Castro[2,1], A. F. Nakagawa[3], and R. D. Sainz[1,4], *[1]Embrapa, Brasília, DF, Brazil, [2]Universidade*

Federal de Goiás, Goiânia, GO, Brazil, [3]Guaporé Pecuária, Pontes e Lacerda, MT, Brazil, [4]University of California, Davis.

Brazil is the world's largest beef exporter, but receives low prices due to quality issues. The predominant Zebu breeds (80% Nellore) are well adapted to the tropics but generally lack tenderness. This project aims to establish the foundations for selection of Nellore animals of high genetic merit for tenderness. A base population was established by Guaporé Pecuária, using data from progeny tests of 25 sires representative of the Nellore breed and *inter se* matings of the animals with greatest potential for producing beef with high and low shear force (WBSF). A total of 82 bull calves from the third generation resulting from those matings were used in this study. Calves were born at the Guaporé Pecuária ranch in Mato Grosso, then transported to Embrapa for growing on pasture with supplementation and finally finished in a feedlot (40% corn silage + 60% concentrate, 14% CP). Calves were harvested at a minimum backfat of 4 mm in five lots after 54, 96, 104, 137 and 166 days on feed. Steaks were taken from the Longissimus muscle at the 12th rib, aged for 7 days and frozen pending measurement of shear force. Data were subjected to analysis of covariance, with Group as the main effect and age and weight at the beginning of finishing as covariates, using the GLM procedure (Minitab v. 16, State College, PA). Average initial weight of the animals was 215.3 ± 39.5 kg. There were no differences ($P > 0.10$) between Tender and Tough groups in ADG (1.443 ± 0.272 kg/d), final weight (529 ± 37.6 kg), dressing % (56.0 ± 1.38%), marbling score (Slight-) or pH (6.08 ± 0.30). There was a trend ($P = 0.072$) for greater fat thickness in the Tender group (7.3 mm) compared to the Tough group (6.5 mm). Animals in the Tender group produced beef with lower WBSF in comparison to animals in the Tough group (4.10 and 4.92 kg, respectively; $P = 0.05$). These data confirm that there is genetic variability in beef tenderness within the Nellore breed, and indicate that this trait will respond to genetic selection. Future studies will attempt to identify molecular markers to assist in genetic improvement programs for Zebu cattle.

Key Words: beef, tenderness, breeding

T189 Genetic association between heifers rebreeding and reproductive traits in Nellore heifers. R. B. Costa[1,2], A. P. N. Terakado*[1,3], and L. G. Albuquerque[1,3], *[1]Universidade Estadual Paulista (UNESP) - FCAV, Jaboticabal, SP, Brazil, [2]Fundacao de Amparo a Pesquisa do Estado de Sao Paulo (FAPESP), Sao Paulo, SP, Brazil, [3]Conselho Nacional de Desenvolvimento Cientifico e Tecnologico (CNPq), Brasilia, DF, Brazil.*

The aim of this study was to estimate genetic correlations between heifer rebreeding and other reproductive traits in Nellore heifers, and verify the possibility to include these traits as selection criteria in beef cattle breeding programs. Data from 231,473 Nellore females belonging to Agropecuaria Jacarezinho LTDA were used. Primiparous heifer rebreeding (PHR) was defined by assigning value 1 (failure) or value 2 (success) for heifers that did not calve or calved, respectively, given that they had previously calved. Early pregnancy occurrence (P16) was defined based on the conception and calving of the heifer, given that heifers entered the breeding season around 16 months of age. For heifers that calved before 31 months of age it was assigned the value 2 (success) and those who failed, the value 1 (failure). Age at first calving (AFC) and Days to first calving (DFC) were also analyzed. Genetic parameters were estimated by Bayesian inference in two-trait analyses, assuming a linear animal model for AFC and DFC and a threshold model for PHR and P16. For all traits, the additive direct effect was considered as random and the effect of contemporary group, as fixed. For PHR, the linear effect of the number of days between the first calving date and the second conception date was used as covariable. For P16, the linear effect of the covariable age of the heifer at the beginning of the breading season was used. Heritability estimates were 0.18 ± 0.02; 0.05 ± 0.01, 0.20 ± 0.03, and 0.56 ± 0.03 for PHR, DFC, AFC, and P16, respectively. Genetic correlation estimates between PHR and DFC (−0.59 ± 0.04), AFC (−0.68 ± 0.05), and P16 (0.72 ± 03) suggest that selection to improve any of these traits will result in an increase in re-conception rate.

Key Words: age at first calving, beef cattle, early pregnancy

T190 Evaluation of sire breed type on growth and carcass characteristics utilizing multigenerational Angus sired calves versus Charolais-sired calves. J. Bailey*, M. J. Canal, T. R. Howard, G. T. Gentry, and M. D. Garcia, *Louisiana State University, Baton Rouge.*

The objective of this study was to evaluate the effect of sire breed type on growth, performance, and carcass characteristics. This study compared the effects of sire breed type between calves sired by either multigenerational Angus sires or Charolais sires. A total of 132 calves were evaluated for growth performance traits were collected at the Central Research Stations in Baton Rouge, LA, and included birth weight, weaning weight, hip height, and average daily gain. Carcass quality and composition traits were also collected and included hot carcass weight (HCW), rib eye area (REA), back fat (BF), and marbling score (MARB). Analyses were conducted by breed using a means separation analysis with simple t-test procedures in SAS. Mean birth weights were significantly higher ($P < 0.05$) for Charolais-sired steers and heifers as compared to Angus-sired heifers. Charolais-sired steers had a significantly higher ($P < 0.05$) birth weight than Angus steers. Mean weaning weights however were significantly higher ($P < 0.05$) for Angus-sired steers and heifers as compared to Charolais-sired heifers. No significant differences were reported between the two groups for hip height, average daily gain, or hot carcass weight. Charolais-sired calves had a significantly larger ($P < 0.05$) rib eye area when compared to the Angus-sired calves. A significant difference ($P < 0.05$) was reported for back fat with the Angus-sired calves having a larger recorded measurement than the Charolais-sired calves. A significant difference ($P < 0.05$) was reported for marbling with the Angus-sired calves having a greater measurement than the Charolais-sired calves. The results of a larger rib eye area and lesser amount of marbling and back fat in the Charolais-sired calves as compared to the multigenerational Angus sired calves is in agreement with previous reports describing the differences in growth and carcass traits associated with each of these breeds.

Key Words: growth trait, carcass quality, carcass composition

T191 Genetic association between carcass, growth and visual scores traits in Hereford × Nellore cattle. A. P. N. Terakado*, R. B. Costa, D. R. Ayres, R. Carvalheiro, and L. G. Albuquerque, *Universidade Estadual Paulista (UNESP) - Faculdade de Ciencias Agrarias e Veterinarias, Jaboticabal, Sao Paulo, Brazil.*

The use of genetic evaluation is an important tool to increase farming profitability, allowing the identification and selection of superior genetically animals. The aim of this study was to estimate genetic associations among post-weaning daily gain (PWG), loin eye area (LEA) and backfat thickness (BT) measured by ultrasound, and visual scores of body structure (S), finishing precocity (F) and muscling (M) in Hereford × Nellore animals, to verify the possibility to include these traits as selection criteria in beef cattle breeding programs. Data from 231,354 animals from Conexao Delta G breeding program were used. The animals were scanned for LEA between the 12th and 13th ribs and for BT over the

longissimus muscle at a point 3/4 the length ventrally of LEA. Scores ranging from 1 to 5 were attributed to the traits S, F and M, with 5 corresponding to the highest expression of the trait and 1 corresponding to the lowest expression. For all traits, the individual and maternal breed compositions were considered as a fixed effects and the yearling age (linear and quadratic effects) as a covariate. For LEA and BT, it was considered the yearling weight (linear and quadratic effects) as a covariate. The genetic parameters were estimated by Bayesian inference in multi-trait analysis, under a linear animal model. Heritability estimates for PWG, LEA, BT, S, F and M were 0.13 ± 0.008; 0.20 ± 0.047; 0.09 ± 0.029; 0.16 ± 0.011; 0.16 ± 0.012 and 0.25 ± 0.012, respectively. Genetic correlations between PWG and visual scores ranged from 0.31 to 0.46, thus selecting to increase PWG will lead to genetic changes in the same direction in S, F and M. Otherwise, correlations between PWG and carcass traits were −0.22 (LEA) and −0.33 (BT), suggesting that selection for higher PWG will decrease LEA and BT. The genetic correlation estimates between S, F, M and carcass traits were practically null, −0.01 (S × LEA); 0.07 (S × BT); 0.08 (F × LEA); 0.05 (M × LEA) and 0.13 (M × BT), thus visual scores are not good indicators of those traits. However, a moderate genetic correlation was found between F × BT (0.44), this indicates that selection for F will increase BT.

Key Words: beef cattle, crossbred, genetic correlation

T192 Evaluation of growth and performance characteristics of crossbred calves sired by Charolais, Simmental, or Braunvieh sires. M. S. Mizell*, T. Page, K. Harborth, M. Canal, A. Canal, and M. D. Garcia, *Louisiana State University, Baton Rouge.*

The objective of the current study was to evaluate the growth and performance characteristics for a crossbred calf crop sired by three different paternal breeds of sires. The sire breeds consisted of Braunvieh, Charolais, and Simmental cattle that all originated from herds in the southeastern United States. The three sire types were mated to a population of crossbred cattle that are classified by the breed types comprising the MARC germplasm cycle 8 dams. A total of 44 Simmental calves, 34 Charolais calves, and 32 Braunvieh calves were calved at the LSU AgCenter Central Research Station and all had birth weights, weaning weights, and hip height measurements collected. Birth weight measurements were recorded within 48 hours of birth. Weaning weight and hip height measurements were recorded at weaning on approximately day 210 days of age. The average birth weight, weaning weight, and hip height for the Simmental heifers were 37.57 kg, 282.79 kg, and 113.77 cm. The average birth weight, weaning weight, and hip height for the Simmental steers were 40.01 kg, 307.24 kg, and 115.87 cm. The average birth weight, weaning weight, and hip height for the Charolais heifers were 34.98 kg, 266.67 kg, and 111.48 cm. The average birth weight, weaning weight, and hip height for the Charolais steers were 39.01 kg, 300.93 kg, and 115.14 cm. The average birth weight, weaning weight, and hip height for the Braunvieh heifers were 36.88 kg, 255.08 kg, and 111.53 cm. The average birth weight, weaning weight, and hip height for the Braunvieh steers were 35.28kg, 270.91kg, and 112.67 cm. Utilizing the mixed model procedure and the LSMEANS function of SAS it was observed that Simmental sired calves had a significantly higher birth weight ($P < 0.05$) than both the Braunvieh- and Charolais-sired calves. Simmental-sired calves also had a significantly ($P < 0.05$) higher hip height measurement than Braunvieh-sired calves but were not taller than Charolais-sired calves. No significant differences were reported between sire breeds for weaning weight.

Key Words: growth, birth weight, weaning weight

T193 An evaluation of 55 years of performance trends from the Dean Lee Research Station performance bull test. T. R. Howard, S. DeRouen, K. Harborth, K. Bondioli, and M. D. Garcia*, *Louisiana State University, Baton Rouge.*

The objective of this study was to evaluate genetic trends for bulls that have comprised the LSU AgCenter Dean Lee performance bull test that has been conducted for the past 55 years. The LSU AgCenter Performance bull test at the Dean Lee Research Station has collected data on yearling bulls on 112d of test for the last 55 years. To date 7,488 yearling bulls from 34 breeds have been evaluated for such traits, including birth weight (BW), initial weight, 112-day weight, average daily gain (ADG), adjusted yearling weight, and scrotal circumference (SC). The top 4 represented bull breeds with greater than 500 animals being tested were included in a Angus, Charolais, Hereford, and Simmental. In 1958, initial weights averaged 249.38 kg and 112-day weights averaged 362.19 kg. Initial weights and 112-d weights in 2011 averaged 332.52 kg and 510.49 kg, respectively. Analyses revealed that all growth traits for all animals regardless of breed demonstrated a linear increase across the years with BW and SC being the lone exceptions. Initial weight increased 1.61 kg/year, 112-d weight increased 2.63 kg/yr, ADG increased .0091 kg/day/year and adjusted yearling weight increased 3.67 kg/year while BW and SC decreased −0.44 kg/year and −0.23 cm/year respectively. The mixed model procedure of SAS and interval regression analyses were utilized to evaluate the positive slope increase observed for all traits over the past 55 years for the four highest represented breeds. Analysis of each individual breed's performance across all years indicated that the Simmental breed had the greatest increase ($P < 0.05$) in initial weight with 3.92 kg/year over Angus (1.92 kg/year), Charolais (0.12 kg/year), and Hereford (1.21 kg/year) ($P < 0.05$). Results for 112-day weight indicated that the Simmental breed made a greatest increase ($P < 0.05$) of 3.79 kg/year when compared to Angus (3.23 kg/year), Charolais (1.99 kg/year), and Hereford (2.24 kg/year). Charolais displayed the largest increase ($P < 0.05$) in ADG across all years with 0.02 kg/day/year while Angus, Hereford, and Simmental increased 0.01, 0.009, and 0.001 respectively.

Key Words: bull test, performance testing, genetic trend

T194 Multivariate heavy-tailed distribution modeling of residuals in estimation of genetic parameters of carcass traits in beef cattle. S. O. Peters[1,2], K. Kizilkaya[3,4], D. J. Garrick[3], R. L. Fernando[3], E. J. Pollak[5], M. De Donato[1,6], T. Hussain[1,7], and I. G. Imumorin*[1], *[1]Cornell University, Ithaca, NY, [2]Berry College, Mt Berry, GA, [3]Iowa State University, Ames, [4]Adnan Menderes University, Aydin, Turkey, [5]US Meat Animal Research Center, Clay Center, NE, [6]Universidad de Oriente, Cumana, Sucre, Venezuela, [7]University of Veterinary and Animal Sciences, Lahore, Pakistan.*

Evaluation of carcass quality and estimation of genetic parameters for carcass traits are of considerable importance in the genetic improvement for beef cattle. Assumption of normality of residuals in linear mixed models for carcass evaluation may make inferences vulnerable to the presence of outliers. Heavy-tail densities are viable alternatives to normal distributions. We compared estimates of genetic parameters by fitting Multivariate Normal (MN), Multivariate Student's-*t* (MS*t*) or Multivariate Slash (MS) and treating degrees of freedom (ν) as unknown for residuals in data of hot carcass weight (HCW), longissimus muscle area (REA) and 12th to 13th rib fat (FAT) traits in beef cattle. A total of 2,476 HCW, REA and FAT records were obtained from a large commercial operation in Nebraska between 2007 and 2008. The data set included pedigree information, contemporary groups, feed lot and breed types. Models included fixed effects of contemporary group of year and pasture and also feed lot type and sire breed. Deviance information criteria for

model comparisons favored MS*t* over MS and MN models respectively. The posterior means (PM) (and 95% posterior probability intervals, PPI) of *v* for the MS*t* and MS models were 5.90 ± 0.86 (4.37, 7.70) and 2.02 ± 0.17 (1.70, 2.38) respectively. Smaller values of posterior densities of *v* for MS*t* and MS models confirm that the assumption of normally distributed residuals is not adequate for the analysis of HCW, REA and FAT datasets. Posterior inference on additive heritabilities for HCW, REA and FAT using MN, MS*t*, and MS models indicated that they are similarly and moderately heritable and were comparable to those reported in literature. PM of genetic correlations for the HCW, REA and FAT were variable but positive except for the correlation between REA and FAT, which shows an antagonistic relationship. The 95% PPI estimates from MN and MS*t* models for HCW did not overlap indicating significant difference between PM estimates from MN or MS*t* models.

Key Words: cattle, genetic parameter, residual

T195 Heritability and correlations of immune response parameters in cattle treated for bovine respiratory disease. R. R. Cockrum*[1], S. E. Speidel[1], J. L. Salak-Johnson[2], C. C. L. Chase[3], R. K. Peel[1], R. L. Weaber[4], H. Van Campen[1], G. H. Loneragan[5], J. J. Wagner[1], P. Boddhireddy[6], M. G. Thomas[1], K. Prayaga[6], and R. M. Enns[1], *[1]Colorado State University, Fort Collins, [2]University of Illinois, Urbana, [3]South Dakota State University, Brookings, [4]Kansas State University, Manhattan, [5]Texas Tech University, Lubbock, [6]Zoetis, Kalamazoo, MI.*

We hypothesized that cattle vary in their innate immune response, which may serve as indicators of developing bovine respiratory disease (BRD). The objectives of this study were to determine the heritability and associative relationships among immune response parameters. Two contemporary groups of crossbred steer calves (n = 2869) were received approximately 83 d post-weaning (221.7 ± 24.34 kg) at a commercial feedlot in Southeastern Colorado. Upon receiving, jugular blood was collected via silicone-coated vacutainer tubes for immune response analyses. Immune response measures were collected at 227 d and 238 d for contemporary groups one and two, respectively. Heritability estimates for immunoglobulin G (IgG), immunoglobulin G1 (IgG1), immunoglobulin G2, (IgG2), IgG1 to IgG2 ratio (IgG1:IgG2), cortisol, and interleukin 8 (IL8) were estimated from a sire model using ASREML. Estimated heritability was low to moderate for the following immune response parameters: IgG (0.13), IgG1 (0.02), IgG2 (0.27), IgG1:IgG2 (0.13), cortisol (0.15), and IL8 (0.30). Furthermore, incidence of BRD as measured from observed clinical signs was heritable (0.21). Correlations among phenotypes and genotypes for traits of interest were calculated. There were low to high positive phenotypic correlations (0.12–0.87 ± 0.02; $P < 0.001$) between IgG, IgG1, IgG2, and IgG1:IgG2. Low negative phenotypic correlations ($P < 0.001$) were estimated between cortisol and IgG (−0.15 ± 0.02), IgG1 (−0.08 ± 0.02), and IgG1:IgG2 (−0.07 ± 0.02). Interleukin 8 had a low positive phenotypic correlation (0.04 ± 0.02; $P = 0.033$) with IgG. Moderate to high positive genetic correlations were observed between IgG1 and IgG2 (0.34) and cortisol (0.57), and a moderate negative genetic correlation was observed with IL8 (−0.36). Results from this study suggest that immune response parameters are heritable suggesting that immune response may be improved through genetic selection.

Key Words: bovine respiratory disease, cattle, immunity

T196 Genome-wide association study of cholesterol and poly- and monounsaturated fatty acids of beef from crossbred cattle. L. N. Schiermiester*, C. M. Ahlberg, J. T. Howard, C. Calkins, and M. L. Spangler, *University of Nebraska, Lincoln.*

Crossbred cattle of varying percentages of Angus, Simmental, and Piedmontese were used to investigate the proportion of phenotypic variation explained by the BovineSNP50 assay for the traits of cholesterol (CH), polyunsaturated fatty acids (PUFA), and monounsaturated fatty acids (MUFA). Steers and heifers (n = 239) were split into 4 groups and placed in a feedlot over a 2-year period between 2010 and 2012. After harvest, half-inch thick steaks were sampled from the eye of round (eye) and the longissimus dorsi (strip) and trimmed to a 1/8 inch of subcutaneous fat for nutrient analysis. All animals were genotyped with the BovineSNP50 assay and had a call rate above 97.5%. Illumina data analysis software was used to assign quality scores (GenCall) for each genotype. If genotypes were missing or a GenCall score was below 0.20, genotypes were replaced with the mean allele frequency across all animals. No SNP were culled based on minor allele frequency. A Bayes C algorithm was employed fitting group as a fixed effect using the GenSel software incuding a chain length of 150,000 samples with the first 50,000 being discarded as burn-in. In general, there was strong agreement between the posterior heritability estimates between the 2 cuts for all traits. The resulting posterior heritability (SE) estimates were 0.46(0.11), 0.52(0.06), 0.67(0.06), 0.71(0.08), 0.61(0.07), and 0.43(0.10) for eye CH, strip CH, eye PUFA, strip PUFA, eye MUFA, and strip MUFA, respectively. SNP were blocked into 1 Mb windows and the top 0.5% windows (n = 13) were compared across cuts within a trait. Of the windows in common between the 2 cuts for MUFA, 5 were on BTA2 and one on BTA19 (7–8 Mb). For PUFA, all 8 windows in common were on BTA2 and the one window in common for CH was also on BTA2. The influence of regions on BTA2 suggest that the Myostatin mutation (C313Y) segregating in some of these animals influences CH, MUFA and PUFA content of beef.

Key Words: beef cattle, genome-wide association study, fatty acids

T197 Genome-wide association study of protein and mineral content of beef from crossbred cattle. C. M. Ahlberg*, L. N. Schiermiester, J. T. Howard, C. Calkins, and M. L. Spangler, *University of Nebraska, Lincoln.*

Crossbred cattle of varying percentages of Angus, Simmental, and Piedmontese were used to investigate the proportion of phenotypic variation explained by the BovineSNP50 assay for the traits of protein, iron, potassium and sodium. Steers and heifers (n = 239) were split into 4 groups and placed in a feedlot over a 2-year period between 2010 and 2012. After harvest, half-inch thick steaks were sampled from the eye of round (eye) and the longissimus dorsi (strip) and trimmed to a 1/8 inch of subcutaneous fat for nutrent analysis. All animals were genotyped with the BovineSNP50 assay and had a call rate above 97.5%. Illumina data analysis software was used to assign quality scores (GenCall) for each genotype. If genotypes were missing or a GenCall score was below 0.20, genotypes were replaced with the mean allele frequency across all animals. No SNP were culled based on minor allele frequency. A Bayes C algorithm was employed fitting group as a fixed effect using the GenSel software incuding a chain length of 150,000 samples with the first 50,000 being discarded as burn-in. In general, there was strong agreement between the posterior heritability estimates between the 2 cuts for all traits. Posterior heritability estimates (SE) were 0.67(0.08), 0.75(0.06), 0.38(0.13), 0.33(0.09), 0.73(0.08), 0.64(0.08), 0.13(0.08), and 0.05(0.08) for strip protein, eye protein, strip iron, eye iron, strip potassium, eye potassium, strip sodium, and eye sodium, respectively. SNP were blocked into 1 Mb windows and the top 0.5% windows (n = 13) were compared across cuts within a trait. Windows in common between the 2 cuts for protein included 6 regions on BTA2. There was only one window in common between the 2 cuts for potassium and iron, both on BTA2. There were no windows in common between the 2 cuts for sodium. The influence of regions on BTA2 suggest that the Myostatin mutation (C313Y) segregating in some of these animals influences protein and the content of some minerals in beef.

Key Words: beef cattle, genome-wide association study, nutrient profile

T198 Association between single nucleotide polimorphisms and sexual precocity in Nellore heifers. I. C. Regatieri[1,3], R. Espigolan[1,3], R. B. Costa[1,3], F. Baldi[1], and L. G. Albuquerque*[1,2], *[1]Universidade Estadual Paulista (UNESP) - FCAV, Jaboticabal, SP, Brazil, [2]Conselho Nacional de Desenvolvimento Cientifico e Tecnologico(CNPq), Brasilia, DF, Brazil, [3]Fundacao de Amparo a Pesquisa do Estado de Sao Paulo (FAPESP), Sao Paulo, SP, Brazil.*

Reproductive traits, such as age at first calving (AFC) and occurrence of early pregnancy (OP), are used as selection criteria in beef cattle breeding programs since these traits affect production system profitability. The measure (r^2) of linkage disequilibrium (LD) is used in genome-wide association studies to detect genetic markers and major genes (QTL) that influence economically important traits. The aim of this study was to determine the extent of LD in the genome of Nellore cattle, and examine associations between single nucleotide polymorphisms (SNP) and AFC and OP, using a panel of high-density SNPs. Data from 1,182 Nellore born in 2007 and 2008, belonging to Agropecuaria Jacarezinho were used. A total of 13 contemporary groups (CG) consisting of farm, season and year of birth, with an average of 90 animals per CG were formed. For genomic-wide association, only autosomes were used and SNPs with minor allele frequency (MAF) below 0.05, and animals with Call Rate below 0.90 were excluded, totaling 431,885 SNPs. The model of analysis for both traits, AFC and OP, included the CG and SNPs (0, 1 and 2) as fixed effects. The Bonferroni correction was applied to adjust the limit of significance (1.16×10^{-7}). The average r^2 for all autosomes was 0.18 at a distance of 4.8 kb and the average MAF was 0.25 ± 0.13. The LD decreased as the distance between markers increased: 0.35 (1 kb) to 0.12 (100 kb). Eleven SNP showed significant effects on the traits and were distributed in 7 different chromosomes (BTA1, BTA4, BTA6, BTA11, BTA17, BTA21, and BTA22). Among these, 7 SNPs were associated with AFC and 4 with OP. Three SNPs were significant for both traits (BTA1, BTA21, and BTA22). Chromosome BTA21 showed 2 SNPs associated with OP. A total of 19 chromosomes showed potential QTL regions for AFC and OP. The most evident peaks of significant SNPs, that may suggest potential QTL regions, were located on chromosomes BTA4, BTA6, BTA8, BTA17, and BTA19.

Key Words: genome-wide association, linkage disequilibrium, quantitative trait loci

T199 Genome-wide associations study for Nelore and Angus Heifers with low and high ovarian follicle count. M. G. Favoreto*[1], B. Loureiro[1], R. L. Ereno[1], A. G. Pupulim[1], A. S. Carmo[2], J. Buratini[1],

and C. M. Barros[1], *[1]UNESP - Universidade Estadual Paulista, Botucatu, SP, Brazil, [2]DEOXI biotecnologia, Araçatuba, SP, Brazil.*

High variation of follicle numbers in cows during the estrus cycle can influence their reproductive performance. Animals with high follicle count (HFC) have a better reproductive performance when compare with low follicle count (LFC) animals (Mossa et al. 2012). Moreover animals with HFC can be more responsive to reproductive biotechniques such as superovulation, ovum pick-up and in vitro fertilization. Identifying these animals with superior genetic potential for fertility would be desirable to increase farm profitability. The SNP profile of 72 Nelore (32 HFC and 40 LFC) and 48 Angus heifers (21 HFC and 27 LFC) was determined using high-density SNP chip (BovineHD Illumina). Initial data cleanup was performed to remove poorly performing and nonautosomal probes from the analysis, considering as criteria for SNP or samples exclusion minor allele frequencies >0.02, call rates >0.98, significant deviations from Hardy-Weinberg equilibrium with $P < 10^{-5}$ and samples with call rate <0.90. Fast score test (qtscore) method, equivalent to the Armitage test, was used for case–control comparisons (GenABEL package). A total of 181 SNPs from the Nelore heifers and 201 from the Angus heifers met genome wide significance ($P < 10^{-4}$). The 181 SNPs from the Nelore heifers were associated on 23 different BTA chromosomes (UMD v3.1 assembly) and the 10 most significant SNPs ($P < 9.8 \times 10^{-5}$) were detected on BTA 1, 3, 7, 9, 14, 16 and 22. In the Angus population the 201 SNPs were associated on 29 different chromosomes and the highest significant SNP ($P = 1.2 \times 10^{-5}$) were located on BTA 3. This is the first time a high density SNP chip is used to identify polymorphisms in high and low follicle counts Nellore and Angus heifers. Results show biomarkers that can contribute to identification of animals with HFC. More analysis must be performed to determine which genes associated with reproduction are linked with those SNPs. This research was financed by FAPESP grant number 2011/5964-0. Scholarships for Loureiro, Ereno, Favoreto, and Pupulim were from FAPESP.

Key Words: GWAS, follicle, SNP

T200 An SNP association study evaluating modern Charolais sired calves versus multigenerational Angus sired calves for growth and carcass traits. J. Bailey*, M. S. Mizell, A. Canal, T. R. Howard, R. Hill, T. Page, and M. D. Garcia, *Louisiana State University, Baton Rouge.*

The objective of this study is to evaluate the association of single nucleotide polymorphisms with growth, performance, and carcass quality and composition characteristics in a population of cattle consisting of multigenerational Angus sired calves and modern characteristic Charolais sired calves. Previous studies have consistently indicated considerable differences in the growth and carcass quality and composition traits between the Angus and Charolais breeds. The data collected in the current study included growth and performance traits as well as raw carcass measurements. Specifically, birth weight (BW), weaning weight (WW), hip height (HH), and average daily gain (ADG) were the growth traits collected. Carcass quality and composition traits that were collected included hot carcass weight (HCW), rib eye area (REA), back fat (BF), and marbling score (MARB). Two candidate genes were selected based on their previous associations with carcass and growth traits. These genes were the calpastatin (CAST) gene located on BTA7 and the calpain 3 (CAPN3) gene located on BTA10. A total of 40 SNP were utilized for genotyping and subsequent association analyses. Calves were genotyped for 20 single nucleotide polymorphisms located equidistant across the CAST gene and for 20 single nucleotide polymorphisms located equidistant across the CAPN3 gene. Analyses to evaluate potential SNP association were conducted via the mixed model procedure of SAS and the LSMEANS function was utilized to determine significant difference in performance for specific traits between genotypes. Multiple SNP for production and carcass quality and composition traits were identified as significant ($P < 0.05$) or exhibited a trend ($P < 0.1$) for both candidate genes. Thus, identification of SNP associated with production and carcass traits in the current study require validation in association with the use of more SNP in other cattle populations.

Key Words: cattle, growth trait, carcass

T201 SNP associated with growth and performance of yearling bulls on a forage performance bull test. T. R. Howard, M. S. Mizell, K. Harborth, M. Canal, A. Canal, K. Bondioli, T. Page, and M. D. Garcia*, *Louisiana State University, Baton Rouge.*

The objective of the current study was to evaluate the association of single nucleotide polymorphisms (SNP) on 3 candidate genes for growth and performance traits in bulls participating in forage based performance bull test. Single nucleotide polymorphisms on 3 candidate genes including calpastatin (CAST), growth hormone (GH1), and insulin-like growth factor 1 (IGF-1) were utilized for association analysis. Single nucleotide polymorphisms were selected that were evenly distributed and represented the total length of the candidate gene. Of the 49 SNP genotyped, 20 were chosen for CAST, 9 for GH1, and 20 for IGF-1. These SNP were genotyped on 47 purebred Angus, Braford, and Brahman bulls on a forage based performance bull test. The measured traits included average daily gain, birth weight, final weight, hip height, intramuscular fat (IMF), ribeye area (REA), and scrotal circumference (SC). The mixed model procedure of SAS was utilized to evaluate associations of the 49 SNPs and measured traits. Associations were reported as significant if $P < 0.05$ and as a trend if $P < 0.1$. Seven SNP exhibited a trend for ADG (rs109022910, rs109199979, rs110266103, rs132665612, rs132951819, rs109327701 and rs110959643). No SNP for BW were significantly associated; however, 3 SNP (rs109327701, rs136939207, and rs137140434) displayed a trend. For finwt, 2 SNP (rs109275907 and rs132951819) were of significant and 7 SNP (rs109022910, rs109199979, rs109327701, rs110266103, rs110959643, rs132665612, and rs133980322) displayed a trend. Hip height and SC were both significantly associated with 1 SNP (rs133980322). Intramuscular fat exhibited a trend with 3 SNP (rs132951819, rs133980322, and rs137651874). No significant associations for REA were identified while 6 SNP (rs109022910, rs109199979, rs110266103, rs110959643, rs132665612, and rs137651874) displayed a trend. In total, one SNP within the GH1 gene was significantly associated with finwt, and 2 SNP within the IGF-1 gene were significantly associated with finwt, HH, and SC. Eleven different SNPs displayed trends associated with ADG, BW, finwt, HH, IMF, REA, and SC.

Key Words: forage performance bull test, SNP

T202 Genomic-polygenic evaluation of multibreed Angus-Brahman cattle for feed efficiency and postweaning growth using actual and imputed Illumina 50k SNP genotypes. M. A. Elzo*[1], M. G. Thomas[2], C. A. Martinez[1], G. C. Lamb[1], D. D. Johnson[1], I. Misztal[3], D. O. Rae[1], J. G. Wasdin[1], and J. D. Driver[1], *[1]University of Florida, Gainesville, [2]Colorado State University, Fort Collins, [3]University of Georgia, Athens.*

The objectives were to estimate the fractions of additive genetic variances for 4 postweaning feed efficiency and growth traits explained by 40,276 actual and imputed SNP genotypes, to compare EBV rankings from genomic-polygenic (GP), genomic (G), and polygenic (P) models, and to

determine EBV trends from Angus to Brahman in a multibreed population. Traits were residual feed intake (RFI), daily feed intake (DFI), feed conversion ratio (FCR), and weight gain (PWG). Phenotypes were from 807 bull, heifer, and steer calves measured at the Feed Efficiency Facility of the University of Florida from 2006 to 2010. Imputation from 2,899 SNP (Illumina 3k) to 46,909 SNP (Illumina 50k) was done with program findhap2 using a reference population of 828 Brangus heifers. Fixed effects for all models were contemporary group (year-pen), age of dam, sex of calf, age of calf, Brahman fraction of calf, and heterozygosity of calf. Random effects were additive SNP (GP and G models), additive polygenic (GP and P models), and residual. Software GS3 was used to compute variance components and heritabilities (option VCE; Markov Chain Monte Carlo), and EBV (option BLUP). Heritabilities were 0.31 for RFI, 0.38 for DFI, 0.25 for FCR, and 0.34 for PWG. The fractions of additive genetic variances explained by the 46,909 actual and imputed SNP were 0.46 for RFI, 0.36 for DFI, 0.47 for FCR, and 0.28 for PWG. These fractions were 3.0, 3.2, 1.9, and 1.8 times larger than those obtained for these 4 traits using 2,899 SNP from the Illumina3k chip. Rank correlations between EBV from GP and P and from GP and G models were high (0.89 to 0.98; $P < 0.0001$). Lower rank correlations existed between EBV from G and P models (0.69 to 0.81; $P < 0.0001$). Regressions of EBV on Brahman fraction were negative with the G model for DFI ($P < 0.0344$) and with all models for PWG ($P < 0.0171$ to $P < 0.0001$). This suggested that calves of similar EBV for RFI, DFI and FCR existed in all breed compositions, but EBV for PWG tended to decrease as Brahman fraction increased.

Key Words: cattle, imputation, multibreed

T203 Genetic parameters and single nucleotide polymorphism of feed utilization in beef cattle. D. Gonzalez-Pena*, N. V. L. Serão, J. E. Beever, D. B. Faulkner, and S. L. Rodriguez-Zas, *University of Illinois at Urbana-Champaign, Urbana.*

Three widely used indicators of feed utilization, residual feed intake (RFI), residual average daily gain (RADG), and residual intake gain (RIG) place different weights on the 2 main components of the system, input and output. Variation in intake and growth are at the center of RFI and RADG, respectively meanwhile RIG is an index of both indicators. The previous differences are expected to affect the total genetic variation and specific single nucleotide polymorphisms (SNPs) corresponding to each indicator. The aim was to estimate the genetic variation and co-variation of the 3 feed efficiency indicators and to uncover SNPs associated with these indicators that could explain the genetic variation. Phenotypic and genotypic measurements were available on approximately 1,300 Angus, Simmental and crossbred steers, assigned to 5 feeding treatments. The pedigree matrix included 3331 individuals across 3 generations. A model including a random animal effect and the fixed effects of breed composition, treatment, contemporary group, and age was implemented in Wombat to estimate the genetic parameters. The fixed effect of genotype was added to the model and fitted on a per-SNP basis using QxPak. The heritability estimates (standard errors) for RFI, RADG and RIG were 0.40 (0.10), 0.17 (0.07), and 0.40 (0.10), respectively and the genetic correlation were −0.43 (0.09), −0.99 (0.002) and 0.55 (0.08) for RFI with RADG, RFI and RIG, and RADG and RIG, respectively. Seven, 9, and 8 SNP were associated ($P < 0.0001$) to RFI, RADG and RIG, respectively. The RFI SNPs were annotated to genes including Ciliary neurotrophic factor receptor (CNTFR) and Transmembrane protein 40 (TMEM40). The RADG SNPs were associated to genes including KDEL Lys-Asp-Glu-Leu containing 1-like (KDELC2), ELMO/CED-12 domain containing 1 (ELMOD1), and PAK1 interacting protein 1 (PAK1IP1). The RIG SNPs were also annotated to KDELC2. In total, 24 SNP on 5 genes were associated with the 3 indicators. The genetic parameter and SNP estimates can support genome-enabled selection programs to improve feed utilization in the beef cattle industry.

Key Words: feed efficiency, genetic parameter, SNP

T204 Genomic variants and genetic parameters of feed efficiency from univariate and multivariate analyses. C. Zavala*, N. V. L. Serão, D. González-Peña, and S. Rodriguez-Zas, *University of Illinois at Urbana-Champaign, Urbana.*

Average daily gain (ADG) and dry matter intake (DMI) are 2 main components of feed efficiency in beef cattle. Univariate analysis of these components hinders the ability to evaluate the genetic correlation between them, the identification of genomic variants with pleiotrophic effects on both components, and could result in lower statistical power. The goals of this study were to assess the genetic variation and co-variation of ADG and DMI and to identify single nucleotide polymorphisms (SNPs) associated with these traits using multivariate analyses, and to compare the results to univariate analyses. Records from 1,321 feedlot steers across 5 farms and 4 years were analyzed. The steers pertained to one of 5 crosses between Angus and Simmental and received one of 5 diets. Univariate and bivariate animal models including the fixed effects of crossbreeding, diet, contemporary group, age and the random effect of animal were used to estimate the genetic parameters using Wombat. Similar univariate and multivariate models including a fixed SNP effect were evaluated using QxPak and a univariate linear model including all fixed effects was evaluated in PLINK. The heritability estimates (and standard errors) for ADG and DMI were 0.14 (0.06) and 0.24 (0.08), respectively and the genetic correlation was 0.30 (0.11). Seven SNPs were associated with ADG (P-value <0.0001) in the linear fixed effects model. Genes containing or in the proximity of the SNPs detected have functions associated with growth including calmodulin regulated spectrin-associated protein 1-like 1 (CAMSP1L1), Kruppel-like factor 6 (KLF6), Fanconi anemia, complementation group F (FANCF) and pseudo gene fucosidase α-L-1 tissue-like (FUCA1, LOC100140646). The bivariate mixed-effects analysis identified the highest number of variants (11 SNPs) and the DMI and ADG mixed effects analyses identified 9 and 8 associations, respectively. The total number of SNP detected was 28, mapping to 19 unique SNPs and 9 unique genes. These results can help in the identification of variants with favorable effect on both components of feed efficiency in beef cattle.

Key Words: SNP, heritability, multi-trait analysis

T205 Accuracy of genomic predictions in Nelore cattle with different marker densities. P. Boddhireddy*[1], R. B. Lobo[2], K. Prayaga[1], P. Barros[1], and S. DeNise[1], *[1]Zoetis Inc., Kalamazoo, MI, [2]Technical Centre of Genetic Evaluation (CTAG), Ribeirão Preto, Brazil.*

The objective of this study was to investigate the improvement in accuracies of genomic predictions associated with increasing the number of markers from 50,000 (50K) to 770,000 (770K) in the Brazilian Nelore breed. Expected progeny differences (EPD) for growth, reproductive, carcass, and conformation traits were available in the study. All animals genotyped with the BovineSNP50 BeadChip were imputed to 770K using FImpute software based on a reference data set with 763 records genotyped with the BovineHD BeadChip (770K). Genomic calibrations were performed using: 50K; 770K; and trait specific (770K_trait) SNPs. Trait specific SNPs were included if they were significantly associated ($P < 0.05$) in single point association analysis. The total number of informative markers from 50K and 770K platforms were 26,458 and 492,887, respectively. The number of informative markers in the 770K_trait sets ranged from 100K to 200K depending on the trait.

Sixty percent of the animals with the highest accuracy EPDs for each individual trait comprised training data sets, and the remaining animals were used for validation. Marker effects were estimated using BayesC as implemented in Gensel software. The training data set was clustered into 5 groups based on genotype similarity using an identical-by-descent strategy. Estimated marker effects were used to calculate direct genomic values (DGVs). A 5-fold cross validation was performed on the training data set. The average correlations across all traits, between DGVs and EPDs obtained with 50K, 770K and 770K_trait were 0.50, 0.50 and 0.59, respectively for the cross-validation, and 0.63, 0.63 and 0.62, respectively, for the external validation. Cross-validation correlations were higher when markers were pre-selected. However, the correlations observed for individual traits in the external validation were similar for 50K, 770K and 770K_trait data sets. The results demonstrate that increasing marker density from 50K to 770K did not improve genomic prediction accuracies as measured by correlations between DGVs and EPDs, supporting published results in dairy populations.

Key Words: Nelore, HD genotype, prediction accuracy

T206 Genomic evaluation and identification of a haplotype affecting fertility for Ayrshire dairy cattle. T. A. Cooper*, G. R. Wiggans, D. J. Null, and J. L. Hutchison, *Animal Improvement Programs Laboratory, Agricultural Research Service, USDA, Beltsville, MD.*

Genomic evaluation of dairy cattle in the United States has been available for Holstein, Jersey and Brown Swiss since 2009. As of February 2013, there were 1,100 genotyped Ayrshires in the North American database including 646 bulls with traditional evaluations allowing for the evaluation of this breed. Gains in reliability due to genomics were determined by comparing parent averages and genomic evaluations from August 2008 to January 2013 daughter performance for bulls born on or after January 1, 2000 who received a traditional evaluation by January 2013. The number of bulls tested ranged between 147 and 180 bulls by trait. The average gain in reliability over parent average for all traits was 8.2. The highest gains were found in milk yield (16.6), protein yield (16.9) and stature (16.2). These evaluations were calculated based on the North American population and may not be suitable to all red dairy cattle because linkage disequilibrium probably differs by population. There are 12 SNP in Ayrshire that can be used for breed determination because they are nearly monomorphic (>90%) in Ayrshire and have fewer than 30% of animals homozygous for that allele in Holstein, Jersey and Brown Swiss. There are fewer breed determining SNP in Ayrshire than in Holstein, Jersey and Brown Swiss, mostly due to the similarity of Ayrshire and Holstein. A haplotype affecting fertility was located on chromosome 17. This haplotype first originated in the genotyped population with Selwood Betty's Commander (b. 1953). The carrier frequency for genotyped Ayrshires is 23.2%. Sire conception rate was 3.0% lower for carriers of the haplotype as determined by 483 carrier by maternal grandsire carrier matings. Genomic evaluations of Ayrshire provide improved prediction over parent average, raising reliability by 8.2 over all traits.

Key Words: dairy cattle, genomic evaluation, fertility haplotype

T207 Regression metamodels of an optimal genomic testing strategy in dairy cattle when selection intensity is low. A. De Vries*[1], J. B. Cole[2], and D. T. Galligan[3], *[1]University of Florida, Gainesville, [2]Animal Improvement Programs Laboratory, ARS, USDA, Beltsville, MD, [3]University of Pennsylvania, Kennett Square.*

Genomic testing of dairy cattle increases reliability and can be used to select animals with superior genetic merit. Genomic testing is not free and not all candidates for selection should necessarily be tested. One algorithm used to compare alternative genomic testing decisions is time-consuming and not easily applicable in practice. Therefore, the objective of this study was to develop regression metamodels that predict increases in estimated breeding value (EBV) of net merit ($NM) in selected animals based on the reliability of pre-ranking of animals, reliability of the genomic test, proportion of animals that are genomically tested, and selection intensity. First, the increase in EBV $NM in selected animals (>50% of the population) was calculated using Monte Carlo methods when all animals were pre-ranked for EBV $NM with reliabilities varying from 0 to 100% in increments of 10 percentage points (PP). After pre-ranking all animals, the genomic test was applied to all ranges of pre-ranked animals in 10 PP increments (n = 36,300 scenarios). Selection was applied after the second ranking and the gain in EBV $NM was recorded. For example, gain in EBV $NM with 20% pre-rank reliability, testing the 60 to 90 percentiles of the pre-ranked animals, 60% genomic test reliability, and 90% selection intensity was $80. Second, the SAS procedure glmselect was used to develop regression metamodels that predict gain in EBV $NM given 30 variables constructed from reliabilities, ranges of genomically tested animals, selection intensity and their logs, squares and reciprocals. Models constrained to 5, 10, 20, or 40 variables including 2-way interactions had RMSE of $14.90, $10.98, $6.47 and $5.11, respectively. The R-squared ranged from 94.4% to 99.4%. The same 4 models including 4-way interactions had RMSE of $12.20, $6.61, $3.62, and $2.45. The R-squared ranged from 96.3% to 99.9%. In conclusion, the larger metamodels accurately predicted gain in EBV $NM and can easily be implemented in decision support aids. The cost of genomic testing may be added to find the optimal range of pre-ranked animals that should be genomically tested.

Key Words: genomics, reliability, regression

T208 Prioritizing sequence polymorphisms for potential association with phenotype. W. M. Snelling*[1], G. L. Bennett[1], R. M. Thallman[1], A. K. Lindholm-Perry[1], L. A. Kuehn[1], T. G. McDaneld[1], S. D. Kachman[2], M. L. Spangler[2], H. Koshinsky[3], and T. S. Kalbfleisch[4,5], *[1]USDA, ARS, U.S. Meat Animal Research Center, Clay Center, NE, [2]University of Nebraska, Lincoln, [3]Eureka Genomics Inc., Hercules, CA, [4]Intrepid Bioinformatics, Louisville, KY, [5]University of Louisville, Louisville, KY.*

The millions of SNP, insertions and deletions revealed by next generation sequencing (NGS), are certain to include polymorphisms responsible for phenotypic variation. Distinguishing causal from benign variants may allow genomic predictions that are robust across populations. While variants underlying phenotypic variation may never be known with certainty, classifying NGS variants according to expected effects on gene function may reveal likely candidates. Associations between phenotypes and available genotypes of markers flanking each variant may further indicate those likely to affect phenotype through altered gene function. Low-coverage NGS of 96 sires used in a 7-breed population of crossbred beef cattle revealed 10,028,578 variants. 1,309 were classified as having a high impact on protein coding genes, and 1,503 occurred in non-coding RNA, which may regulate protein coding genes. Potential impact of these variants on birth weight was assessed using 2,940 birth weight records from the 7-breed population, 3,812 records from a somewhat related 16-breed population, and imputed high-density SNP genotypes for both populations. Genomic heritability estimates (SE) in the 7-breed population were 0.38 (0.03) with 3,810 SNP flanking the high-impact and non-coding RNA variants, 0.25 (0.02) with 291 SNP surrounding 217 variants with the largest flanking SNP effects, 0.64 (0.03) with the full set of high-density SNP, and 0.38 (0.05) for the 300 high-density

SNP with the largest effects. Genetic correlations between 16-breed birth weights and genomic EBV predicted from 7-breed SNP effects were 0.42 (0.05) for the 3,810 SNP and 0.58 (0.05) for the 291 SNP around selected variants. Estimated birth weight-genomic EBV genetic correlations were 0.51 (0.04) for all high-density SNP and 0.48 (0.05) for the top 300. Genomic predictions with SNP flanking variants affecting gene function may be more robust than predictions based only on associations with phenotype. Further assessment of direct genotypes for the functional variants is needed. USDA is an equal opportunity provider and employer.

Key Words: cattle, DNA sequence variant, genomic prediction

T209 Accuracy of mixed model methods for genomic prediction and variance component estimation of additive and dominance effects using SNP markers. S. Wang, G. Hu*, C. Wang, and Y. Da, *Department of Animal Science, University of Minnesota, St. Paul.*

The accuracy of GREML and GBLUP methods for additive and dominance effects were evaluated using simulation data for various heritability levels of additive and dominance effects. SNP marker sets included 1K causal variants, 1K, 3K and 7K inter-QTL SNP markers, and 41K SNP marker with minor allele frequency > 0.05 including the 1K causal variants. Genomic additive and dominance relationship matrices using SNP markers were consistent with theoretical expectations. GREML and GBLUP using genome-wide SNP markers were able to capture small additive and dominance effects each accounted for 5 (10^{-5}) ~3 (10^{-4}) of the phenotypic variance. Accuracy of GREML and GBLUP increased as the heritability increased for both additive and dominance effects. GBLUP of total genetic values as summation of breeding values and dominance deviations had higher accuracy breeding values or dominance deviations. GREML was more sensitive than GBLUP to the true additive and dominance heritability levels and to the density of SNP markers. Low density of non-causal SNP markers (3K or less) had a tendency to underestimate additive and dominance variance components by GREML. The 41K that included the 1K causal variants overestimated the variance components for the phenotype with 1006 underlying QTL and performed better for the phenotype with 100 underlying QTL than lower density inter-QTL SNPs. Causal variants had the highest accuracy of GREML and GBLUP and adding whole genome SNP markers to the causal variants did not improve accuracy.

Key Words: genomic prediction, variance component, dominance

T210 Bias in genomic evaluations attributable to unknown parent group estimates. S. Tsuruta*, D. A. L. Lourenco, and I. Misztal, *University of Georgia, Athens.*

The objective of this study was to investigate bias in genomic evaluations due to unknown parent group estimates. Genomic (G)BLUP was predicted for final score in US Holsteins, 305-d milk yields in 3 parities in Israeli Holsteins, and multiple traits in pigs, using genomic and phenotypic combined data. The US Holstein data consisted of 10,167,604 records for 6,586,605 cows and 9,602,031 animals in pedigree including 34,506 genotyped bulls with 42,503 SNP; the Israeli Holstein data consisted of 1,205,801 records for 713,686 cows and 829,437 animals in pedigree including 1305 genotyped bulls with 30,359 SNP; the pig data consisted of 2,923,141 records for 884,250 pigs and 906,660 animals in pedigree including 4853 genotyped animals with 63,219 SNP. Original unknown parent groups (UPG) were defined based on year of birth by sex, year of birth by sex by breed, and year of birth for US Holstein, Israeli Holstein, and pig data, respectively. Genomic (G)EBV and UPG estimates were compared using original and refined UPG and separating additive genetic effects into those with UPG from pedigree and those without UPG from genotypes. The BLUP90IOD program using a single-step approach was used to estimate UPG effects and GEBV. The last UPG effect for US Holstein was significantly overestimated. The last UPG effects for Israeli Holstein bulls were overestimated. The UPG estimates in pigs were similar in original and refined UPG. For US Holstein, Israeli Holstein, and pig data sets, correlations between GEBV from original and refined UPG models were 0.99, 0.95–9.97, and 0.97–0.99, respectively. Those correlations between GEBV from original and 2 additive models were 0.91, 0.91–0.93, and 0.96–0.98, respectively. Refinement of UPG improved convergence in GBLUP by 4%, 55%, and 35% for US Holstein, Israeli Holstein, and pig data sets, respectively. Refinement of UPG is recommended to reduce bias in GEBV and improve computing speed in GBLUP.

Key Words: genomic evaluation, unknown parent group

T211 Accounting for heterogeneous pleiotropy in whole genome selection models. N. M. Bello*[1], J. P. Steibel[2], and R. J. Tempelman[2], *[1]Kansas State University, Manhattan, [2]Michigan State University, East Lansing.*

The additive genetic correlation between economically relevant traits is generally considered a critical factor determining the relative advantage of multi-trait models over single-trait models for whole genome prediction of genetic merit. Yet, the additive genetic correlation between traits may be considered an aggregate summary of between-trait correlations at the individual QTL level, thereby defining pleiotropic mechanisms by which individual genes have simultaneous effects on multiple phenotypic traits. Pleiotropic effects, in turn, may be gene specific and heterogeneous across the genome. In this study, we present a hierarchical Bayesian extension to bivariate genomic prediction models that accounts for heterogeneous pleiotropic effects across SNP markers. More specifically, we elicit a function of the SNP marker-specific correlation between traits as heterogeneous across markers following a square-root Cholesky reparameterization of the marker-specific covariance matrix that ensures necessary positive semidefinite constraints. We use simulation studies to demonstrate the properties of the proposed methods. We assess the relative performance of the proposed method by comparing prediction accuracy for genomic breeding values and for SNP marker effects for each of 2 traits across putative scenarios of homogeneous and heterogeneous pleiotropic genetic mechanisms. We also consider extensive model comparisons for cases of null and non-null additive genetic correlations under conditions of high and low heritability of the traits of interest. Overall, the relative advantage of genomic prediction bivariate models that account for heterogeneous pleiotropy relative to their univariate counterparts depended upon trait heritability and genetic architecture of the pleiotropic mechanisms and was of small magnitude (~1% net gain in predictive accuracy) when at all present. The trade-off between methodological and computational modeling complexity and net gain in prediction accuracy is also discussed.

Key Words: genomic selection, bivariate model, heterogeneous correlation

T212 Comparison of milk fatty acids composition from buffalo, camel, cow, goat, and yak. J. H. Yang, D. P. Bu*, J. Q. Wang, L. Ma, J. X. Zhang, and J. T. Chen, *Institute of Animal Science, Chinese Academy of Agricultural Sciences, Beijing, China.*

Milk originated from different mammals has its own characteristic. The objective of this study was to investigate variation of FAs profile in milk from different dairy mammals. Milk samples collected from buffalo (n = 22), camel (n = 19), cow (n = 108), goat (n = 23) and yak (n = 22) were analyzed in this study. The FA methyl esters were determined via Agilent 6890 GC (Agilent Technologies, Hewlett Packard Co., Avondale, PA) fitted with a flame-ionization detector and expressed as grams per hundred grams. Data was processed through multi-comparison and principle component analysis (PCA), completed by SAS 9.0 (SAS Institute Inc., Cary, NC) and the Unscrambler 9.8 (Camo Software AS, Oslo, Norway), respectively. Results showed that composition (%) of camel milk contained the lowest C4-C12 (all below 0.90) and the highest C16:1 (3.51), C18 (21.30), C18:1 (35.58), c9c12C18:2 (2.66), c9t11C18:2 (1.85), C18:3 (1.81), C20:1 (0.22), C20:2 (1.52) and C20:3 (0.53). Goat milk had the highest C8 (2.92), C10 (10.24)and C12 (5.30). C4 (6.43) in buffalo milk and C14:1 (0.94) in cow milk were higher than in others, while yak milk highlighted FAs above 14 carbons without unsaturated bond like C15 (1.94), C17 (1.56), C20 (0.48) and C22 (0.35). Moreover, there was no difference in saturated FA (71.67–73.47%) and monounsaturated FA (MUFA, 24.10–25.39%) among bovine milk samples, whereas camel had maximum MUFA and polyunsaturated FAs. Short and median chain FA (sum of C4-C16:1) in buffalo (63.96), goat (62.67), cow (60.51), and yak (59.03) milk were higher than in camel milk (32.95). Scores and loading plots of PCA showed that high t11C18:1, c9C18:1, C18:0 in camel milk and high C8, C10, C12 in goat milk separated their samples from others, while buffalo, cow and yak milk clustered together for similar FA composition. It was suggested that camel milk highlight characteristic on long chain and unsaturated FA, and goat milk had special effects on short chain FA, while bovine milks exhibited much similarity.

Key Words: milk, fatty acid, different mammals

T213 Characterizing the relationship between peroxidase activity and enzymatic bleaching in fluid whey. R. E. Campbell*[1], P. D. Gerard[2], and M. A. Drake[1], *[1]North Carolina State University, Raleigh, [2]Clemson University, Clemson, SC.*

The carotenoid norbixin (annatto) is added to Cheddar cheese milk to impart desired color to cheese. Norbixin is also present in whey and is bleached using benzoyl or hydrogen peroxide. Due to increased regulations and off-flavors produced by these bleaching agents, alternative bleaching agents have been explored. Lactoperoxidase (LP), naturally in milk, or an external peroxidase (EP) may be used to bleach fluid whey or retentate with the addition of low concentrations (<50 ppm) of hydrogen peroxide. A working knowledge of enzyme activity and how activity relates to bleaching efficacy is required. The objective of this study was to characterize the relationship between enzyme activity and bleaching efficacy in fluid whey and whey protein retentate. A range of pH (5.5–6.5) and temperature (4–60°C) was evaluated. Colored Cheddar cheese whey was manufactured in triplicate from pasteurized whole milk and fat-separated pasteurized whey and whey protein retentate (10% solids, 80% protein) were manufactured. Subsequently, the effects of selected temperatures and pH in both fluid whey and whey protein retentate were evaluated for their effects on LP and EP activity and bleaching efficacy using a response surface model – central composite design (RSM-CCD) matrix. Peroxidase activity was determined using an established colorimetric method and bleaching efficacy was measured by quantifying norbixin destruction via high performance liquid chromatography. Across the pH and temperature ranges evaluated (5.5–6.5, 4–60°C), peroxidase activity associated with LP and bleaching efficacy increased with increasing temperature. The effects of pH were not as pronounced as temperature effects ($P < 0.05$). Increased peroxidase activity with the addition of EP was not evident while increased bleaching was observed, suggesting that peroxidase activity and bleaching are not necessarily linear. These results suggest that peroxidase activity is not always an accurate prediction of bleaching efficacy and that addition of exogenous EP may be beneficial to manufacturers to improve bleaching consistency across processing variables.

Key Words: whey protein, enzymatic bleaching, lactoperoxidase

T214 Factors that influence the required membrane area of a multi-stage microfiltration process to separate serum protein and lactose from micellar casein in skim milk. E. E. Hurt* and D. M. Barbano, *Northeast Dairy Foods Research Center, Department of Food Science, Cornell University, Ithaca, NY.*

Our objective was to determine how to minimize the microfiltration (MF) membrane area required to produce a micellar casein concentrate (MCC) from skim milk (SM). Several factors were studied. The 1st factor was feeding a MF system with ultrafiltered (UF) SM versus SM. Other factors (when UF SM was the MF feed) were the concentration of the UF SM, the number of MF stages and MF flux. To determine the effect of these factors on MF membrane area, a theoretical model based on a mass balance was developed. The model was based on previously measured performance of a 0.1µm ceramic uniform transmembrane pressure MF system producing a final MCC of 9% protein with ≥ 95% of the serum protein (SP) removed and <0.2% lactose from SM. The model was used to minimize the total mass of MF permeate removed by changing the concentration factor (CF) of the UF SM feeding the MF (if UF SM was the feed) and the CF and diafiltration factor for each MF stage. The MF permeate removed was converted to membrane area by specifying flux (54 kg/m^2 per h), processing time (18h) and mass of SM before UF (150,000 kg). It was assumed that 76% of the lactose had been removed from SM by UF. A 95% removal of lactose (equal to the SP removal) from this UF SM by MF would produce a MCC with <0.2% lactose. If the feed was UF SM, the MF membrane area required for a 5-stage process was 182 m^2 compared with 315 m^2 when SM was the feed. For 5-stages, increasing the UF SM CF from 1.0 to 1.7 decreased MF membrane area from 202 m^2 to 182 m^2. The UF SM CF that minimized MF membrane area for 2, 3, 4 and 5-stages was 0.8, 1.2, 1.5 and 1.7 respectively. Increasing the number of stages also decreased the required MF membrane area. When UF SM was used, increasing the number of stages from 2 to 5 decreased MF membrane from 297 m^2 to 182 m^2. Finally, for 5-stages, increasing the flux from 54 to 60 kg/m^2 per h decreased the MF membrane area from 182 m^2 to 164 m^2. Using UF SM, the UF SM CF, the number of MF stages and flux were all important factors for minimizing the membrane area of a MF system.

Key Words: microfiltration, micellar casein concentrate, optimization

T215 The impact of bleaching on functionality of whey protein isolate. T. J. Smith*, E. A. Foegeding, and M. A. Drake, *North Carolina State University, Raleigh.*

Whey protein is a highly functional food ingredient used in a wide variety of applications. A large portion of whey produced in the United States is derived from Cheddar cheese manufacture and contains annatto, and therefore must be bleached. We have demonstrated bleaching effects on whey protein flavor but bleaching effects on protein functionality have not been fully elucidated. The objective of this study was to compare functional properties of bleached and unbleached whey protein isolate (WPI). Cheddar whey was manufactured followed by addition of no bleach (control), hydrogen peroxide (HP, 250 mg/kg) or benzoyl peroxide (BP, 50 mg/kg) at 50°C for 1 h. WPI were then produced and spray dried. WPI were manufactured in triplicate. Functional properties were evaluated by measurement of foam stability, protein solubility, native PAGE, and the effect of sodium chloride (NaCl) concentration on gelation. In addition to functional properties, descriptive analysis and gas chromatography-mass spectrometry were performed to characterize flavor differences among treatments. Overrun and yield stress were not different between bleached and control WPI ($P < 0.05$). Foam stability of WPI was increased in both bleached treatments relative to the control ($P < 0.05$). Soluble protein loss at pH 4.6 was decreased by bleaching with either HP or BP ($P < 0.05$). The effect of NaCl concentration on gelation was also distinct with bleaching agent ($P < 0.05$). Lastly, native PAGE results suggested that both HP and BP contributed to protein degradation, which was likely a factor in the functional differences observed between unbleached and bleached WPI. These results suggest that chemical bleaching does have a significant effect on many of the functional characteristics of whey proteins.

Key Words: functionality, WPI, flavor

T216 Optimizing methods for improved raw milk analysis by NIR spectroscopy. T. J. Reuter*[1], X. Xiong[2], G. Rolland[2], and T. C. Schoenfuss[1], *[1]University of Minnesota, St. Paul, [2]BHI Labortechnik AG, Flawil, St. Gallen, Switzerland.*

Raw milk is hard to analyze by NIR because of excessive light scattering effects caused by large size variations in the fat component. How the sample is prepared and presented for NIR analysis could improve predictions of component quantities. In this study, sample presentation (static and dynamic) and fat particle size reduction by various homogenization processes were investigated for 160 diverse samples to predict 5 component quantities in raw milk (fat, moisture, ash, protein, casein) by FT-NIR. Spectra were acquired with a polarization inferometer in transflection in the wavelength range 1000 to 2500 nm, and preprocessed using standard normal variation scatter correction and Savitzky-Golay smoothing. The calibration models were created using PLS method. Excellent results were obtained for the standard errors of prediction following no homogenization (0.02, 0.02, 0.01, 0.01, and 0.01) for fat, moisture, ash, protein, and casein, respectively. Results from homogenization with sonicator and tube dispersion methods were not significantly improved from non-homogenized samples, but were still better compared with 2-stage valve homogenization for moisture and casein components (0.12 and 0.07, respectively) possibly because of whey protein denaturation that occurred during 2-stage processing. Relatively high sample temperatures during analysis could have led to more positive results for all component calibrations compared with reference values. For sample presentation, both the static and dynamic flow cell methods were shown to be very accurate based on the lowest standard errors of prediction (0.02, 0.02, 0.01, 0.01, and 0.01) for fat, moisture, ash, protein, and casein, respectively. The Petri dish presentation method was similarly accurate but may have been limited by the poor structural design of the transflectance cover, which allowed for sample dehydration and loss of reflected light.

Key Words: near-infrared spectroscopy, milk analysis, sample preparation

T217 The mechanism of resistance to plasmin activity through protein succinylation: A model study using β-casein. H. Bhatt*[2,1], A. Cucheval[1], C. Coker[1], H. Patel[3], A. Carr[2], and R. Bennett[2], *[1]Fonterra Research & Development Centre, Palmerston North, Manawatu, New Zealand, [2]Institute of Food, Nutrition and Human Health, Massey University, Palmerston North, Manawatu, New Zealand, [3]Dairy Science Department, South Dakota State University, Brookings.*

Plasmin-induced proteolysis is a major concern in the dairy industry, leading to defects in the texture and taste e.g., gelation and bitterness, of various milk systems. It is therefore important to control the activity of plasmin in milk systems. Several techniques have been investigated; the present work explores inhibition of the plasmin-catalyzed hydrolysis of β-casein, which is the primary target of plasmin action. As plasmin hydrolyses proteins on the carboxyl site of lysine-X and arginine-X bonds with a preference for the lysine-X bond, lysine residues on the β-casein backbone were targeted by succinylation. The target lysine sites were identified by liquid chromatography-tandem mass spectrometry to be Lys-28, 29, 99, 105 and 107. To get greater insight into the effect of different levels of succinylation on the hydrolysis of β-casein by plasmin, the reaction was monitored by quantifying the formation of the hydrolyzed product using sodium dodecyl sulfate PAGE and reverse-phase high performance liquid chromatography. This allowed the primary stage of the hydrolysis of β-casein, i.e., the formation of γ-caseins and proteose peptones, and the secondary stage, i.e., further hydrolysis of the γ-caseins and proteose peptones, to be distinguished. The results clearly indicated that succinylation affected both stages of hydrolysis negatively. Succinylated β-casein and proteose peptones became resistant to hydrolysis by plasmin. The following mechanism is proposed. The formation of succinyl-lysine renders the casein unrecognizable to the substrate-binding pocket of plasmin. Thus, the modified substrate cannot be positioned into the pocket and is not hydrolyzed by the catalytic triad of plasmin. These results indicate that succinylation may be useful for controlling the plasmin-induced hydrolysis of milk proteins and that the proposed mechanism may be useful as a base hypothesis for developing plasmin-resistant proteins by other means of modification.

Key Words: plasmin, succinylation, β-casein

T218 Effect of processing and storage temperatures on the physical stability of sodium-caseinate-stabilized emulsions. Y. C. Liang*[1,2], H. Patel[3], L. Matia-Merino[2], A. Q. Ye[4], G. Gillies[1], and M. Golding[2,4], *[1]Fonterra Research and Development Centre, Palmerston North, New Zealand, [2]Institute of Food, Nutrition and Human Health, Massey University, Palmerston North, New Zealand, [3]Dairy Science Department, South Dakota State University, Brookings, [4]Riddet Institute, Massey University, Palmerston North, New Zealand.*

Oil-in-water emulsions are an important basis of many food and nutraceutical products. Liquid beverages are processed at high temperature (e.g., retort or UHT processing) and maybe stored at different temperatures (e.g., at 40°C). There is little information on the effect of high heat treatment and high storage temperatures on the caseinate and droplet sizes, depletion potential, and creaming stability of caseinate-stabilized emulsions. This study investigated the influence of processing and

storage conditions on the structure and stability of caseinate-stabilized emulsions. Sodium caseinate was reconstituted to a 3% (wt/wt) solution. Corn oil (60% w/w) was mixed with the protein solution. The mixture was homogenized to yield a stock emulsion, which was then mixed with stock caseinate (20% wt/wt) to produce 30% oil-in-water emulsions containing 2 to 10% caseinate. The pH was adjusted to 6.8 ± 0.04 for all model emulsions. Each model emulsion was prepared at least in duplicates. The experimental data was analyzed by Student's *t*-tests, significant differences among the means were determined at a 95.0% confidence level. Heat-treated (120°C, 10 min) caseinate emulsions phase separated much more rapidly than unheated emulsions ($P < 0.05$). The droplet size was found to be unchanged after heating. The change in phase separation behavior can be attributed to the change in caseinate size because of the heat-induced polymerization of casein molecules. A small change in caseinate size resulted in a moderate change in the depletion interaction potential. In addition, unheated caseinate emulsions stored at 40°C phase separated much more rapidly than unheated emulsions stored at 20°C ($P < 0.05$). This change appeared to be influenced by the continuous phase viscosity. The formation of the droplet network and its rearrangement as a function of the caseinate concentration at 40°C were well reflected by small deformation rheology and Turbiscan curves. We show the interrelations between the formation of the droplet network and the processing conditions.

Key Words: caseinate, physical stability, depletion interaction potential

T219 Effect of reconstitution temperatures on the solubility of different protein fractions present in milk protein concentrates (MPC 80). H. Patel*[1,2], [1]*Dairy Science Department, South Dakota State University, Brookings,* [2]*Animal Sciences and Industry, Kansas State University, Manhattan.*

The solubility of high protein ingredients such as milk protein concentrates (MPC) influences important functional properties such as emulsification, foaming and gelling. The rate of solubility of MPC and different protein fractions present in MPC may vary depending on the reconstitution conditions. However, there is lack of reliable information on the solubility behavior of individual protein fractions during reconstitution process. Better understanding of such factors would help the manufacturers to identify optimum conditions for reconstitution. Considering this, the objective of present study was to study the order in which individual protein fractions are solubilize during reconstitution process. Five representative samples of MPC80 with similar protein (81–82%), lactose contents were obtained. Solutions (5% w/w) of these MPC were prepared by reconstituting MPC at 20, 40, 50 and 60°C. During reconstitution, the aliquots from each of this were withdrawn at different time interval (2, 10, 20, 30, 45 and 60 min). Percent solubility of these samples was analyzed using standard methods. The rate of solubility of different protein fractions was determined using PAGE under different reconstitution condition. The data were analyzed using SAS. Percent solubility of all MPC samples increased significantly ($P < 0.05$) with increase in the temperature and time of reconstitution up to 50°C and up to 30 min. The results of PAGE showed that the whey proteins were solubilized within initial 2 min of reconstitution process. The order of solubility of different proteins was found to be β-lactoglobulin = α-lactalbumin > α_{s1}-casein > β-casein > α_{s2}-casein > κ-casein. It required almost double time to reconstitute MPC at 20°C compared with 50°C. It was found that the disulfide interaction of casein and whey proteins were responsible for the poor solubility of some MPC samples. The manufacturers can use such insights for identifying processing conditions and, for achieving desired functionality of MPC in the final products.

Key Words: milk protein concentrate (MPC), solubility, polyacrylamide gel electrophoresis (PAGE)

T220 Comparison of the in vitro digestion of raw pasture milk and commercial HTST and UHT pasteurized milk. D. X. Ren[1,2], D. L. Van Hekken*[1], M. H. Tunick[1], and P. M. Tomasula[1], [1]*USDA, ARS, ERRC, Dairy and Functional Foods Research Unit, Wyndmoor, PA,* [2]*Zhejiang University, Institute of Dairy Science, College of Animal Science, Hangzhou, China.*

Consumption of raw milk from pasture-fed cows, typically purchased at local farms, is steadily increasing in the US because many consumers believe that high-temperature short-time (HTST) or ultrahigh temperature (UHT) pasteurization affects the digestibility of milk proteins and thus the bioavailability of their nutrients. The objective of this study was to compare the evolution of curd or clot size distribution with time during in vitro digestion of protein under simulated fasting gastro-intestinal conditions for commercial whole and skim milk treated by HTST or UHT pasteurization and raw whole and skim milk from pasture-fed cows. Milk digestion procedures followed the 2012 US Pharmacopeia with simulated gastric fluid (SGF) using pepsin and simulated intestinal fluid (SIF) using pancreatin. The in vitro protein digestibility of whole milk samples was greater than that of skim milk samples ($P < 0.05$), with milk fat acting as a barrier to the protein aggregation observed in skim milk samples. In a second series of experiments, the degradation kinetics of clots that formed upon initiation of SGF digestion were followed for 3 h using a light-scattering particle-size analyzer. The average clot sizes of the proteins upon initiation of digestion decreased in the order raw pasture > HTST > UHT milk with the clot sizes for skim milk (130.5, 128.3 and 52.9 μm, respectively) being larger than those for whole milk (98.5, 86.3 and 32.7 μm; $P < 0.05$). After 3 h of digestion, a single particle-size peak was observed for all samples. With the exception of the UHT milk samples, the clot sizes in skim milk samples averaged 38.5 μm and were larger than those in whole milk which averaged 29.3 μm ($P < 0.05$). Clot sizes of skim and whole milk UHT samples averaged 8.0 μm ($P < 0.05$), indicating that UHT milk was the most digestible since the smaller clot sizes offered increased surface area for enzyme contact. The results showed an inverse relationship between clot size and extent of in vitro digestibility. Moreover, the results indicated that raw pasture milk is as digestible as commercial HTST milk and not as digestible as commercial UHT milk.

Key Words: in vitro digestion, raw milk, pasteurized milk

T221 Computer simulation to predict energy use, greenhouse gas emissions and costs for production of extended shelf-life milk using microfiltration. P. M. Tomasula, W. C. F. Yee, A. J. McAloon, and L. M. Bonnaillie*, *USDA, ARS, ERRC, Dairy and Functional Foods Research Unit, Wyndmoor, PA.*

Extended shelf-life (ESL) milk has a shelf life between that of high-temperature short-time (HTST) and ultrahigh temperature (UHT) pasteurized milk. ESL milk is usually pasteurized at temperatures exceeding 125°C which may give the milk a cooked taste. ESL milk produced using crossflow microfiltration (MF) before HTST pasteurization at 72°C produces milk with the fresh taste of HTST milk and depending on raw milk quality, packaging and cold-chain handling, may have a shelf-life of up to 30 d. Little information is available on the additional energy use, greenhouse gas (GHG) emissions and operating costs of installing MF in an existing HTST processing plant. The objective of this study was to develop a model for milk MF and incorporate it into a computer simulation model of the fluid milk process that was recently

developed for processors to benchmark their current energy use, GHG emissions, and capital and operating costs. MF was modeled as 2 MF skids in series, each containing the housings for 1.4 µm membranes. In the simulator, skim milk leaves the separator at 55°C as the feed to the first skid. The retentate from the first skid fed the second MF skid. Permeates from both skids were blended with cream and pasteurized to produce 3.25% whole milk. Retentate (3% of the total feed stream) was added to the remaining cream stream and heated to 130°C before storage. Simulations conducted for medium–sized milk plants processing 27,300 L/h of milk showed GHG emissions, electricity and natural gas use were 88.6 gCO_2eq/kg milk, 0.38 MJ/L and 0.12 MJ/L using HTST pasteurization alone and 93.6 gCO_2eq/kg milk, 0.38 MJ/L and 0.14 MJ/L for the HTST/MF plant, showing the additional electricity and natural gas used by the MF process and for heating of the cream/retentate stream. The difference in operating costs between HTST and HTST/MF was estimated as 0.10 cents/L in agreement with literature estimates. This study demonstrates that computer simulation allows rapid assessment of process changes and evaluation of new technologies in an existing processing line without costly pilot testing.

Key Words: greenhouse gas, microfiltration, energy

T222 Effect of preheating temperature and time on the properties of evaporated milk. B. Chen*, A. Grandison, and M. Lewis, *University of Reading, Reading, Berkshire, UK.*

The objective of this study was to investigate the effect of different preheating temperature/time combinations on the properties of evaporated milk. Pasteurized whole milk was preheated at 85°C, 90°C and 95°C for 10, 20 and 30 min at each temperature. After evaporation to 28% total solids, different concentrations of disodium hydrogen phosphate and trisodium citrate were added (8 to 24 m*M*) and the density and heat stability of evaporated milk were measured after in-container sterilization. Heat stability was assessed by measuring the amount of sediment in the evaporated milk. Concurrently, pH, $Ca^{2+}$and viscosity were monitored at every processing stage. Overall, the pH and $Ca^{2+}$of raw milk was around 6.72 and 1.54 m*M*. Preheating caused only a small pH reduction and a fall in Ca^2 of about 0.30 m*M*, whereas sterilization caused a dramatic reduction in pH but an increase of Ca^{2+}. Also, viscosity of evaporated milk increased after preheating and also after evaporation but the most dramatic increase was brought about by sterilization. Higher preheating temperatures and longer preheating times resulted in evaporated milk with significantly lower pH and Ca^{2+}. The viscosity of evaporated milk without pre-heating was significantly higher than those which had been preheated. Addition of stabilizing salts significantly reduced the viscosity of evaporated milk. However, higher additions of up to 24 m*M* stabilizing salts sometimes resulted in a viscosity which was higher and above the range found for commercial samples. Adding increasing amounts of these stabilizing salts to evaporated milk increased pH, decreased Ca^{2+} and slightly increased the dry sediment. In addition, dialysis was used for measuring pH and Ca^{2+}at preheating temperatures. The pH of dialysates decreased as pre-heating temperature increased but Ca^{2+} did not change significantly. It was concluded that 85°C or 90°C for 10 min pre-heating were the best conditions for the evaporated milk manufacture to obtain a satisfactory viscosity.

Key Words: evaporated milk, preheating temperature and time, viscosity

T223 Predicting color change of skim milk during high pressure thermal processing. A. F. Devi[1,2], R. Buckow*[2], Y. Hemar[3], and S. Kasapis[1], *[1]School of Applied Sciences, RMIT University, Melbourne, VIC, Australia, [2]CSIRO Animal, Food and Health Sciences, Werribee, VIC, Australia, [3]School of Chemical Sciences, The University of Auckland, Auckland, New Zealand.*

The demand of extended shelf-life with fresh-like quality and retained nutrients has driven studies on high pressure treatment of milk. Inactivation of bacterial spores for milk sterilization purpose requires the incorporation of heat in the high pressure process. Currently, little is known about the influence of high pressure thermal (HPT) processing on physicochemical properties of milk. Therefore, the objective of this study was to develop a predictive model describing kinetics of color change (from white to caramel brown) of skim milk during HPT processing. Reconstituted skim milk (10% wt/wt) was treated under isothermal/isobaric conditions at 100 to 140°C and 0.1 to 600 MPa for up to 60 min. Its color was measured within 4 h after treatment using a chromameter and reported in CIE-Lab system. The total color change was calculated referring to the initial color of skim milk and represented as total color difference (ΔE_{ab}*). ΔE_{ab}* increased with time (t) and was described with an empirical equation: $\Delta E_{ab}^* = 38\ t/(k+t)$. Coefficient k varied with temperature and pressure, following a third order polynomial equation and reached the minimum value at 400 MPa. Consequently, ΔE_{ab}* was largely enhanced during HPT at 400 MPa. Meanwhile, ΔE_{ab}* increased progressively with temperature regardless of the applied pressure. Compared with atmospheric pressure, 60 min HPT treatment at 110°C and 200, 400, and 600 MPa increased ΔE_{ab}* by approximately 50, 200, and 100%, respectively. Selected images of processed skim milk, mathematical models, and pressure-temperature diagrams of color conversion as a function of pressure, temperature, and treatment time will be presented. The resultant knowledge can possibly help to identify suitable HPT process conditions for improved sensory quality of sterilized milk.

Key Words: high pressure processing, skim milk, color

T224 Feed substrates influence biofilm formation on reverse osmosis (RO) membranes and their cleaning efficacy. S. Marka* and S. Anand, *Dairy Science Department, Midwest Dairy Foods Research Center, South Dakota State University, Brookings.*

In recent times, there is a greater use of RO membranes for concentration of various feed materials such as whey and ultrafiltration (UF) permeate in the dairy industry. This study compares the influence of skim milk UF permeate and cheese whey on membrane biofilm formation. A resistant *Bacillus* sp., previously isolated from a membrane biofilm, was used to develop 48-h-old static biofilms on the RO membrane pieces using UF permeate and whey as feed substrates. Biofilms were analyzed for viable counts by swab technique and for microstructure using scanning electron microscopy (SEM). The membrane cleaning process included 6 sequential steps; alkali, surfactant, acid, enzyme, a second surfactant, and sanitizer application. The data were statistically analyzed. The SEM images showed a significant difference in the microstructure of biofilms for the 2 feed substrates. In the case of UF permeate biofilms, the bacilli were found to be adherent in small groups of random arrangement that were covered with a thin film of exopolysaccharide material having protrusions. On the other hand, the bacilli in whey biofilms were found to be in bigger groups with cells arranged in long chains covered with smoother and thinner films of exopolysaccharide material without any protrusions. Differences were also noticed in the resistance pattern of these 2 types of biofilms. The mean pre-treatment counts of the 48-h UF permeate biofilms were log 5.39, which were much higher than the whey biofilms pre-treatment counts of log 3.44. After 6 steps cleaning cycle, there were 2.6 log survivors of the *Bacillus* isolate on UF permeate biofilms, whereas only 1.82 log survivors were found in whey biofilms. In conclusion, the UF permeate substrate biofilms resulted in a higher

resistance to cleaning process as compared with the biofilms developed by whey substrate. The biofilm microstructure variations for the 2 feed substrates might have caused differences in their resistance to the CIP protocol. Further studies are in progress.

Key Words: whey and UF permeate, biofilm, reverse osmosis membrane

T225 Characterization of some changes in composition and physicochemical properties of casein micelles from cream to buttermilk. M. Looney*[1], Y. Pouliot[2], M. Britten[3], and R. Jiménez-Flores[1], *[1]Dairy Products Technology Center, California Polytechnic State University, San Luis Obispo, [2]STELA Dairy Research Center, Institute of Nutrition and Functional Foods (INAF), Laval University, Quebec City, QC, Canada, [3]Food Research and Development Center (FRDC), Agriculture and Agri-Food Canada, St-Hyacinthe, QC, Canada.*

It is well-documented that the poor coagulation properties of buttermilk are attributed to the changes that occur to the casein micelles during the butter-making process. It was hypothesized that churning is a critical step for the changes that occur in composition of the casein micelles. Raw cream was processed using a rotary churn at 18°C for approximately 30 min, and buttermilk was collected for analysis. Raw milk was skimmed at 10°C by centrifuging at 3,000 × *g* for 20 min. Cream, skim milk and buttermilk were centrifuged at 60,000 × *g* for 40 min twice using imidazole buffer at pH 6.8 to isolate the micellar content in the pellet. Variation in physical properties of the casein micelles was determined using a Malvern Zetasizer. Protein profiles of UP cream, skim milk, and buttermilk were analyzed using 1- and 2-dimensional gel electrophoresis technique. Experiments were performed using 3 different batches of UP cream, skim milk and buttermilk. Statistical analyses showed that processing the buttermilk significantly increased the surface charge ($P < 0.05$) of the micelle but had no significant effect on their size ($P > 0.05$). Our results also indicate that churning of cream promoted interactions between casein micelles and MFGM proteins as shown by the more complex 2D-gel electrophoresis pattern obtained for casein micelles sedimented from buttermilk.

Key Words: buttermilk, casein micelle, churning

T226 Investigation of the mechanism of membrane fouling in cold microfiltration of skim milk: A proteomics study. T. J. Tan* and C. I. Moraru, *Department of Food Science, Cornell University, Ithaca, NY.*

The main challenge in milk microfiltration (MF) is membrane fouling, which leads to a significant decline in permeate flux over time. This work aims to elucidate the mechanism of membrane fouling in cold MF of skim milk, by identifying and quantifying the milk proteins and minerals involved in the external and internal fouling of the membrane. Skim milk was subjected to MF using a 1.4 µm ceramic membrane, at a temperature of 6 ± 1°C, cross-flow velocity of 6 m/s and transmembrane pressure of 159 kPa, for 90 min. First, RO water rinses (20°C, 5 min) were conducted to collect the loosely attached external foulants (S1) and then loosely attached internal foulants (S2) from the membrane. After that, pressurized hot water extractions (70°C, 10 min) were performed to collect the strongly attached external foulants (S3) and the strongly attached internal foulants (S4). The collected foulants were analyzed for protein content using the Bradford method. The foulants were further analyzed by liquid chromatography coupled with tandem mass spectrometry for protein identification and relative quantitation of individual proteins. The mineral composition of the foulants was analyzed using Inductively Coupled Plasma Spectrophotometry and potentiometric titration. All experiments and analyses were carried out in triplicate. Significant differences among samples were determined by Tukey's HSD test at $P \leq 0.05$. The protein concentrations for S1, S2, S3, and S4 were 62.2 ± 10.1 µg/mL, 10.7 ± 1.0 µg/mL, 6.6 ± 0.7 µg/mL, and 1.0 ± 0.1 µg/mL, respectively. All major milk proteins were identified in the 4 foulants. α-Lactalbumin and BSA were found in higher levels in S4 than in the other foulants. This suggests that these proteins strongly attached to the internal pores of the membrane, which likely results in pore constriction and subsequent flux reduction. In general, the concentration for all mineral was very small (below 7.7 ppm) in all foulants, and likely they do not have a major contribution to membrane fouling. The knowledge generated in this study can be used to identify solutions to minimize membrane fouling and thus increase the efficiency of skim milk MF.

T227 Evaluation of thermization and CO_2 addition as methods of raw milk preservation. P. R. Rocha, V. P. Voltarelli, V. O. Gaino, C. M. V. B. de Rensis, and P. C. B. Vianna*, *Universidade Norte do Paraná (UNOPAR), Londrina/PR/Brazil.*

The aim of this study was to evaluate the use of thermization or dioxide carbon (CO_2) addition as methods of raw milk preservation before processing. Raw milk was divided into 3 treatments: (1) Control milk (without treatments), (2) thermized milk (65°C/20 s) and (3) CO_2 added raw milk (until pH 6.2). The samples were stored in plastic bottles hermetically sealed at 4 ± 1°C. Raw milk was evaluated upon receipt (d 0) for physicochemical composition, standard plate count and psychrotrophic bacteria count. Samples were randomly selected and evaluated after 3, 6, 10, 13 and 16 d for proteolysis and the same microbial counts evaluated at the reception. Decreased in casein as a percentage of true protein (CN/TP) was used as an index of proteolysis. Split-plot design was used with 3 replications and the results were evaluated by ANOVA and Tukey's test, at 5% significance level. The lag phase of psychrotrophic bacteria count was analyzed by Gompertz model. Raw milk presented typical whole milk composition and the standard plate count and psychrotrophic count were 3.1×10^4 cfu/mL and 3.1×10^2 cfu/mL, respectively. Standard plate count and psychrotrophic bacteria count increased during refrigerated storage for all the samples, however, this increase was significantly higher for control milk. Based on the initial standard plate count, the time required for control milk reaches the critical count regulated by Brazilian legislation (6.0×10^5 cfu/mL) was 10 d. For thermized and CO_2 added milk, microbiological counts remained below critical limits during the 16 storage days. The CO_2 addition and thermization extended the lag phase of psychrotrophic bacteria in ~2.2 and ~10.3 times, respectively, when compared with raw milk control. Proteolysis significantly increased during refrigerated storage for all samples. However, in this study, the increased proteolysis could not be related to greater psychrotrophic count of raw milk control. The results showed that both CO_2 addition and thermization are effective and can be used to preserve the quality of raw milk before processing and to prevent quality problems in dairy products.

Key Words: raw milk, carbon dioxide, thermization

T228 Utilizing clean label starches in yogurts processed with challenging temperature and homogenization pressures. B. Roa*, A. Perez, E. Yildiz, I. Potrebko, T. Shah, and L. Carr, *Ingredion Incorporated, Bridgewater, NJ.*

Formulating yogurts with thermally inhibited, clean label starches has often been challenging because of the harsh processing conditions

manufacturers utilize. This is the case when manufactures use high temperature and homogenization pressures, which degrade the integrity of many existing clean label starches. The loss of starch integrity affects the functionality and ultimately the texture of finished yogurt product. This presentation will focus primarily on the next generation clean label starch that extends the functionality of clean label starches in yogurts processed with demanding temperature/pressure parameters. The next generation clean label starch performance was compared with existing clean label starches and chemically modified counterparts, over a range of different parameters including upstream/downstream homogenization configurations. The downstream yogurts were processed over a pasteurization range of 185 to 195°F and 0 to 2610 psi total homogenization pressure. The upstream yogurts were processed over a preheat range of 140 to 170°F and 725 to 3625 psi total homogenization pressure. Based on instrumental characterization results from the Brookfield DV-II+ Viscometer and SMS TA-XT2 Texture Analyzer, the next-generation clean label starches were able to be processed with up to 1450 psi more total homogenization pressure at certain temperatures than with previously available clean label starches, while still providing the desired texture effect. Using a downstream homogenization configuration with 2610 psi total pressure, the next generation clean label sample had a viscosity of 5100 cps compared with the previously available clean label starch sample's viscosity of 1674 cps. The instrumental characterizations also demonstrated that the enhanced functionality of the next generation clean label starches yielded process tolerance comparable to highly inhibited chemically modified starches. Based on the results of this work, the next generation clean label starch was able to be processed with very demanding parameters, while still providing functionality in terms of viscosity and overall texture.

Key Words: yogurt, starch, processing

T229 Proteomic evaluation of milk fat globule membrane proteins and bovine health status. M. Vaiente*, L. Tomanek, M. Yeung, and R. Jimenez-Flores, *California Polytechnic State University, San Luis Obispo.*

Proteins associated with the milk fat globule membrane (MFGM) have been associated with many biological functions in the dairy cow. These proteins are also purported to confer nutritional and health benefits to human. However, there is little information about the effect of the health of the cow on the composition and expression of these membrane proteins. Since the overabundance of casein and whey in milk interfere with typical MFGM protein analysis, a contemporary proteomic approach offers an ideal solution. To this end, this study was aimed to observe and measure changes in the MFGM proteins collected from cow with different health status. MFGM fractions and somatic cell pellets were extracted from raw bovine milk collected from 3 healthy cows at the dairy farm on campus. These were separately pooled to form a MFGM sample and a somatic cell sample. Similarly, the samples were pooled from 3 cows exhibiting suboptimal health, indicated by elevated levels of somatic cell count. To generate the MFGM and somatic cell proteome maps, 2D gel electrophoresis was conducted and the gel images were analyzed using Delta2D program. Spot intensities were compared between samples derived from healthy and suboptimally healthy cow by using permutation ANOVA ($\alpha = 0.02$) available within Delta2D. The proteomes were also visualized using principal components analysis to explore differences between the proteomes and bovine health status. The proteome maps for somatic cells and MFGM proteins show differentially protein expression and distinct characteristics, including numerous putative novel proteins. Unique proteins were selected for MALDI-TOF mass spectrometry analysis and identification. Our results suggest that cow lactation physiology is markedly different under varying health status and lead to changes in the MFGM proteome. The outcome of this study further helped generate specific hypotheses to test the interaction between bovine health and individual protein species, and the role of these proteins in human health.

Key Words: milk fat globule membrane, proteomics, somatic cell

T230 Production of sodium chloride nanoparticles by nanospray drying method. M. Moncada*[1], K. Aryana[1,2], C. E. Astete[3], and C. Sabliov[3], *[1]School of Animal Sciences, Louisiana State University Agricultural Center, Baton Rouge, [2]Department of Food Science, Louisiana State University Agricultural Center, Baton Rouge, [3]Biological and Agricultural Engineering, Louisiana State University Agricultural Center, Baton Rouge.*

Reduction in sodium intake decreases blood pressure and could prevent hypertension; hypertension is a major risk factor in the development of cardiovascular diseases. One alternative to reduce sodium content without replacing sodium chloride (NaCl) in foods by other food additives is to reduce the particle size of salt without modifying its chemical composition to produce nanosalt. Reducing the particle size of sodium chloride crystal would increase dissolution rate in saliva leading to a more efficient transfer of the ions to the taste buds and hence a saltier perception of foods. The goal of this study was to develop nanosalt by using a nanospray drying method. The processing parameters were optimized to ensure formation of the smallest size nanosalt, as measured by scanning electron microscopy (SEM) and dynamic light scattering. A sodium chloride solution (3% wt/wt) prepared in deionized water was processed by nanospray drying (Nanospray dryer B-90, Büchi Corporation). The sodium chloride solution was sprayed through 2 different nozzle sizes (4 and 7 μm) at 20, 10, 5 and 3% (wt/wt). The gas flow (125 L/min), pressure (38 mbar), head temperature (95°C) and spray percentage (90%) were kept constant in all treatments. The resulting nanoparticles were analyzed by SEM to visually analyze shape and size. Of the 3 concentrations studied, the lower concentration (3% wt/wt) provided the smallest size nanosalt. Three replicates were conducted at this concentration, and particle size distribution from each nozzle size was analyzed using ANOVA of SAS. There was a significant ($P < 0.05$) difference in NaCl particle sizes using 4 and 7 μm nozzles. The NaCl solution subjected through the 4-μm nozzle had the smallest sodium chloride nanoparticle size (500–700 nm). The outcomes from these trials showed that smaller sodium chloride nanoparticles were produced when utilizing a 4-μm nozzle in the Nanospray dryer B-90 with a 3% (wt/wt) NaCl solution. Studies are on the way to test the nanosalt on the physicochemical, microbiological and sensory characteristics of surface-salted cheese crackers.

Key Words: nanosalt

T231 Physiochemical property, microstructure and probiotic survivability of nonfat goat milk yogurt using heat-treated whey protein concentrate as fat replacer. T. H. Zhang[1], J. McCarthy[2], G. R. Wang[2], Y. Liu[2], and M. R. Guo*[2], *[1]Jilin University, Changchun, Jilin, China, [2]University of Vermont, Burlington.*

Low-fat and probiotic dairy foods are getting popular in the United States. A nonfat goat milk yogurt containing probiotics (*Lactobacillus acidophilus* and *Bifidobacterium* spp.) was developed using heat-treated whey protein concentrate (HWPC) as a fat replacer and pectin as thickening agent. The yogurt was analyzed for chemical composition, water-holding capacity (syneresis), microstructure, changes in pH and viscosity, mold, yeast and coliform counts, and probiotic survivability during storage at 4°C for 10 wk. The results showed that the nonfat goat milk yogurt made with 1.3% of HWPC (12% WPC solution heated at 85°C for 30 min at pH 8.5), and 0.35% pectin had high viscosity 1650 ± 40.2 mPa·s and low syneresis (4%). The pH value of the yogurt was decreased significantly during the first week ($P < 0.05$), but there was no significant decrease after wk 2 ($P > 0.05$). Counts for mold, yeast, and coliform were negative the 10-wk study. *Bifidobacterium* spp. remained stable and was $>10^6$ cfu/g during the 10-wk storage. However, the population of *Lactobacillus acidophilus* dropped to $<10^6$ cfu/g after 4 wk of storage. Microstructure analysis of the non-fat goats' milk yogurt by scanning electron microscopy revealed that HWPC interacted with casein micelles to form a more comprehensive network in the yogurt gel. The results indicated that HWPC could be used as a fat replacer for improving the consistency of nonfat goat milk yogurt and other products alike.

Key Words: goat milk, nonfat yogurt, heated whey protein

T232 Do dairy cattle classified as high immune responders yield nutritionally better milk compared with average and low immune response cows? K. Fleming*, M. Corredig, D. Hodgins, F. Miglior, and B. Mallard, *University of Guelph, Guelph, Ontario, Canada.*

It is known that some dairy cattle have an enhanced immune response that is capable of defending against a wide array of infectious pathogens. These High immune response (HIR) cows have more robust and balanced antibody-mediated and cell-mediated immune responses compared with Average (A) or Low (L) immune responders. In this study, it is hypothesized that HIR cows produce higher quality milk with elevated contents of nutritionally valuable components. The presence of Lactoferrin (LF) is the focus of this work. Milk (n = 5) and colostrum (n = 9) samples from Holstein cattle classified as High, A or L immune responders were analyzed. Cows had previously been classified using a patented HIR test system. Milk and colostrum samples were collected at d 5 and d 0 relative to calving, respectively. Concentrations of LF were measured using a bovine LF enzyme-linked immunosorbent assay kit (Bethyl Laboratories, Inc.). Preliminary results indicate that there is substantial biological variation of LF concentrations in milk and colostrum among cows. Values range from 0.023 to 0.24 mg/mL in milk and 0.066–1.7 mg/mL in colostrum with net differences of approximately 0.22 mg/mL and 1.6 mg/mL, respectively. These values and the moderate heritability of LF provide the potential to naturally improve the nutrition of foods by implementing selective breeding programs. Quantification of LF concentrations as well as other nutritionally valuable components (i.e., glycosphingolipids) in additional samples is currently underway. Data will be analyzed with statistical analysis software using a generalized linear model upon completion of component measurement and subsequent matching of cows to immune response categorization. Overall, consumption of functional foods such as higher quality milk with elevated contents of nutritionally important components would provide one potential solution to improve the health of individuals.

Key Words: lactoferrin (LF), high immune response (HIR), milk quality

T233 Physicochemical and sensory properties of milk supplemented with dispersible nanopowdered oyster shell during storage (II). Y. K. Lee*, M. A. Mijan, and H. S. Kwak, *Sejong University, Seoul, South Korea.*

The present study was carried out to investigate the dispersibility of nanopowdered oyster shell (NPOS), Zn-activated nanopowdered oyster shell (Zn-NPOS) or powdered oyster shell (POS) and to determine the effect on the physicochemical and sensory properties of the oyster shell-added milks during storage at 4°C for 16 d. For dispersing, 20% (w/v) oyster shell samples were added in distilled water and mixed at 800 rpm for 2 h, and then 0.5% polyglycerol monostearate (PGMS) was added and mixed again at 800 rpm for 24 h. The sizes of NPOS, Zn-NPOS and POS were measured as 257 nm, 389 nm, and 180 μm, respectively. The pH values of all the milk samples ranged from 6.62 to 6.89 during the storage. The thiobarbituric acid (TBA) of NPOS- and Zn-NPOS-added milks increased to 0.36 and 0.37, respectively, but POS-added milk was higher TBA than that of samples (0.44) at d 16. In color, L* and a* values in the milks were not significantly influenced from all treated milks ($P > 0.05$). However, b* value was significantly increased during storage ($P < 0.05$). The sensory attribute revealed that NPOS- and Zn-NPOS (0.5, 1.0 and 1.5%)-added samples were significantly increased in yellowness, calcite and astringency scores, but fishy smell, bitterness and sandy were not changed during 16 d ($P < 0.05$). However, POS-added sample was significantly increased in yellowness, calcite, astringency, bitterness and sandy scores during the storage ($P < 0.05$). Base on the data obtained from this study, it is concluded that the dispersible nanosized oyster shell could be added to milk without significant adverse effects on the physicochemical and sensory properties.

Key Words: milk, nanopowdered oyster shell, sensory properties

T234 Comparison of physicochemical properties in nanopowdered red ginseng and powdered red ginseng (I). K. H. Choi*, M. A. Mijan, and H. S. Kwak, *Sejong University, Seoul, South Korea.*

Red ginseng is known to have several health benefits, such as antiinflammtory, anticancer, and antioxidative activities, In addition, red ginseng contains some distinct functional ingredients, such as Rg_3, Rg_5 and Rk_1 ginsenoside, which are not found in white ginseng. However, low bioavailability was attributed previously to their poor oral absorption. Nanotechnology may be capable of enhancement of the bioavailability for red ginseng. Therefore, this study was carried out to compare the physicochemical properties of nanopowdered red ginseng (NRG) with powdered red ginseng (PRG) and to determine the quantitation measurement of ginsenosides in NRG. To study the physicochemical properties of the NRG, the size of particles, proximate composition, pH, tapdensity, color, and water or oil holding capacities were measured. In the result, sizes of NRG and PRG were 200.6 ± 13.7 nm and 120.810 ± 1.171 μm, respectively under the particle size analyzer, and similarities were observed between NRG and PRG in proximate composition. But, the pH value was decreased from 5.6 to 5.4 when the concentrations were increased from 2 to 8%, and tap densities were 0.3030 and 0.6667 g/cm^3 in NRG and PRG, respectively. Color of NRG was significantly different from PRG, and water- and oil-holding capacities were 2 to 3 times higher in NRG than in PRG ($P < 0.05$). In quantitative analysis, total ginsenosides of NRG

(4,609.30 mg/kg) was 30% higher than that of PRG (3,335.71mg/kg). In conclusion, NRG was significantly different from PRG in most properties and nanosizing markedly increased the total ginsenosides of red ginseng. Considering these results, NRG is worth to make functional cheese.

Key Words: nanopowdered red ginseng, physicochemical property, ginsenoside

T235 Isolation of lactic acid bacteria from Xin Jiang fresh cheese and the studies of property. L. Zhang, Y. Zhang*, and X. Xu, *College of Food Science and Engineering, Harbin Institute of Technology, Harbin, China.*

Sixteen lactobacillus and 6 lactococcus were screened from traditional fermented fresh domestic acid-coagulated cheese. Then, the acid production ability, sticky production ability, fragrance production ability, textural property, the content of diacetyl, proteolysis and lipolysis capacity of these screened strains was analyzed. The strains that had the fastest production of acid were C63M and C34M. The higher production of sticky was C63M, C34M, and C61–2M. The higher content of diacetyl was C34M and C103M, which were 7.47 ± 0.01 and 6.62 ± 0.01 μg/mL separately. The higher proteolysis capacity were found in strains C104 and C61–2M, the free amino acid of these 2 strains were 469.42 mg/L and 390.68 mg/L separately. These selected 5 strains showed almost no lipolysis capacity but had good textural properties. Combined these 5 strains each other and fermented milk to make fresh acid-coagulated cheese. One group was selected for have good characteristics. Then the inoculate rate were studied. The results showed that cheese have the fastest yield with 5% inoculate, the amount was 56.79%. And the cheese moisture, texture property and its sensory evaluation are also good.

Key Words: acid-coagulated cheese, lactic acid bacteria, quality

T236 Effects of mineral content of bovine drinking water: Does iron affect milk quality? G. R. Mann, S. E. Duncan*, S. F. O'Keefe, K. A. Knowlton, A. D. Dietrich, R. E. James, C. Martel, and X. Feng, *Virginia Polytechnic Institute and State University, Blacksburg.*

Water is an important nutrient for dairy cattle; however, influences of water chemistry on milk synthesis are not well described. High mineral concentrations (>0.3 mg/kg Fe and other metals) may be from natural sources in ground water, run-off from contaminating sources, drought, or water storage systems. This study evaluated the effects of added iron in bovine drinking water on milk composition and oxidative stability. Ferrous lactate treatments corresponding to 0, 2, 5, and 12.5 mg/kg drinking water concentrations were delivered through the abomasum at 1 L/d to 4 lactating dairy cows over 4 periods (1 wk infusion/period), in a Latin square design. On d 6 of infusion milk was collected, processed (homogenized, pasteurized), and analyzed. Mineral content (Fe, Cu, P, Ca) was measured by inductively coupled plasma mass spectrometry. Oxidative stability of whole processed milk was measured by thiobarbituric acid reactive substances (TBARS) assay for malondialdehyde (MDA) and sensory analysis (triangle test) within 48 h of processing and after 7 d of refrigerated storage. Significant sensory differences ($P < 0.05$) between processed milks from cows receiving iron treatment and the control infusion were observed. No differences in TBARS (1.46 ± 0.04 mg/kg MDA) or mineral content (0.22 ± 0.01 mg/kg Fe) were noted. A case study of raw milk from cows receiving water with naturally high (1.4 mg/kg) and low (0.02 mg/kg) iron content revealed no significant differences ($P > 0.05$) in mineral composition (0.23 ± 0.06 mg/kg Fe) or analytical measures of oxidation (0.77 ± 0.03 mg/kg MDA). While iron added directly to milk causes changes in oxidation of milk, high levels of iron given to cattle in drinking water did not have such an effect.

Key Words: milk, oxidation, iron

T238 Tetracycline residues in pasteurized goat milk. R. Attaie* and A. Mora-Gutierrez, *Prairie View A&M University, Prairie View, TX.*

Twelve milking does, 5 La Monchs, 5 Alpines, and 2 Nubians were randomly selected from the milking herd of the International Goat Research Center at Prairie View A&M University. The objective was to determine the residual amount of tetracycline in the milk of treated goats after pasteurization. The tolerance limit of this antibiotic in milk for human consumption is 300 ppb. The selected goats were treated with recommended doses of tetracycline and then the milks of treated animals collected and analyzed. The residual amount of tetracycline was quantified for each milking time until the level went below the tolerance limit. High-performance liquid chromatography was used to quantify the residual amount of tetracycline in milk. Milk samples containing antibiotic residues were deproteinized by 1 *N* hydrochloric acid and addition of 15 mL acetonitrile. The sample was filtered and concentrated by using sample concentrator to approximately less than 1 mL. The samples were adjusted to exactly 1 mL using deionized water. The samples were filtered (0.45 μm) before injection into reversed-phase HPLC using isocratic procedure. For analysis, a Wakosil II C_{18} column was used with mobile phase of 0.02 *M* H_3PO_4 and 0.01 Na decanesulfonate:acetonitrile (35%:65%) at the rate of 1 mL/min using UV detector at 380 nm. The HPLC procedure was able to detect the tetracycline residues at levels less than the tolerance level in goat milk. Furthermore, it was determined that pasteurization significantly reduced the level of tetracycline residues in goat milk compared with fresh or 72 h aged goat milk.

Key Words: tetracycline residues, goat milk, high-performance liquid chromatography

T384 Assessment of consumer perceptions, preferences, and behaviors with fluid milk from different packaging. M. Paterson*[1], S. Clark[1], and M. Bozic[2], *[1]Iowa State University, Ames, [2]University of Minnesota, St. Paul.*

The objective of this study is to understand consumers' "intellectual" (beliefs or expectations) and actual sensory perceptions about fluid milk. Seven sessions, composed of approximately 10 consumers in each, were carried out. All sessions began with explanation of a consent form and process for the experiment; panelists filled out a survey about demographics and milk purchasing/consumption behaviors. Consumers were blindly served 2 pairs of milk samples (2% and skim; from 1/2 gallon translucent plastic and paperboard containers) and asked to indicate preference and acceptability for each sample using a 7 point scale. A panel of 9 judges was trained to evaluate milk quality attributes on a 15cm line scale; all samples tasted by consumers were simultaneously evaluated by the trained panel. All milk was from the same source, processed on the same day, and evaluated within 5 to 7 d of packaging; milk had only been stored in the dairy warehouse; none of the milk was exposed to a lighted dairy case. Only 2 participants (3%) indicated preference for glass in the surveys; 7% indicated preference for paperboard, and 90% indicated preference for plastic packaging. However, upon tasting, consumers did not have a preference for 2% milk from translucent plastic over paperboard, or for skim from translucent plastic over paperboard ($P > 0.05$). These findings were in agreement with their acceptability scores, which were 4.6 for skim in plastic, 4.7 for skim in paperboard, 5.0 for 2% in plastic and 5.0 for 2% in paperboard ($P > 0.05$). Trained panelists did not detect oxidized off flavor in skim milk from translucent packaging (4.7) or paperboard (3.5), or 2% milk from translucent plastic (3.6) or paperboard (1.6) ($P > 0.05$). These results confirm that trained panelists and consumers cannot distinguish fresh milk from different packaging before exposure to lighted dairy cases. Additionally, purchasing behavior is not necessarily linked to actual sensory experience. A future paper will discuss the relationship of these findings with consumer perceptions about milk after exposure to UV light.

Key Words: milk, packaging, consumer perceptions

T239 Evaluation of sensory properties of goat milk ice creams formulated with three different levels of caprine milk fat. C. McGhee, B. P. Gupta*, J. Jones, and Y. W. Park, *Fort Valley State University, Fort Valley, GA*.

Ice cream is a very popular frozen dairy food around the world. Although many studies have been reported on bovine milk ice cream, the scientific literature on caprine milk ice cream has been almost nonexistent. A study was conducted to evaluate sensory characteristics of goat milk ice creams manufactured with 3 fat levels of goat milk and a commercial powdered mix containing 0.25% fat. Three batches of 3 different low fat ice creams were produced as skim (0.46%; SIC), 2.0% (2IC) and whole (3.65%; WIC) goat milk ice creams formulated with the commercial ice cream mix. The Sani Serv ice cream machine (A5223P, Mooresville, IN) was used to make soft-serve ice creams. Upon manufacture, all experimental fresh ice creams were stored in a freezer at −18°C for 0, 2, 4 and 8 weeks. Sensory characteristics of all ice creams were evaluated by an 8-member sensory panel, using ADSA collegiate ice cream scorecards. Flavor traits were determined by normal range of flavor score 1–10, where excellent 10 (no criticism), good 8–9, fair 6–7, and poor 5 or less, respectively. Body and texture, and color properties were assessed by normal range of 1–5 scores, where 5 indicated no criticism. The results showed that there were no significant differences in all sensory characteristics of flavor, body and texture, and color traits between 0 to 8 weeks storage periods for the 3 goat ice creams, except a few cases of flavor and body and texture. No detectable color changes were found in all 3 types of ice creams. For flavor properties, the sweet and whey flavors between 0 and 2–8 weeks for 2IC and WIC were appeared to be different, while no differences in flavors were observed in SIC. For body and texture traits, increases in weak body in WIC, and increases in sandiness and sogginess were occurred in 2IC from 0 to 8 weeks. The 2IC showed a slight improvement in weak body as the storage time advanced. It was concluded that very few changes occurred in sensory properties of all 3 types of goat milk ice creams up to 8 weeks frozen-storage.

Key Words: goat milk, ice cream, sensory property

T241 Influences and mechanisms of heat-related processes during manufacture of milk powder on coagulation quality of milk. X. Han*, L. Zhang, and W. Wang, *Harbin Institute of Technology, College of Food Science and Engineering, Harbin Institute of Technology, Harbin, China.*

Thermal processing during milk powder production changed not only the nutritional characteristics of milk but also its technological characteristics. The purpose of this study is to analyze the effects of the conventional heat sterilization during the manufacture of milk powder on the milk coagulation properties (rennet-induced coagulation and acid-induced coagulation). The texture of rennet-induced gel and acid-induced gel during different heat treatment of milk were analyzed. And the protein distribution of milk serum heat-induced changes in casein micelle size, surface hydrophobic and calcium ion activity were also detected. The results showed the heating parameters have the good regression relationship with the variables of coagulations. The coefficients of determination R^2 were greater than 0.88. The hardness of gel were decreased when heat the raw milk at 70°C for 15 s, while 90°C for 8 min decreased by 37.27% compared with the raw milk. The changes in serum protein aggregates (SPA) were also affected by different heat treatments. The protein aggregates caused by the thermal denaturizing of milk protein can be performed as part of the casein micelles in the solidification process, or as a "bridge" between the micelles, thus contributing to the process of acid curd. However, the protein aggregates did not act such a role in the rennet-induced gel according to the data in the experiment. And the size of SPA increased with the increase of heating temperature and time, ranging from ~30 nm at low-intensity heat treatment increased to ~100 nm at high-intensity treatment. By the test of rennet coagulation with SPA addition the inhibition effect was not found, suggesting the inhibition of heating on rennet coagulation was not derived from SPA. The rennet coagulation of milk was influenced by the properties of casein micelles and calcium ion. Thus, the combined (positive and negative) effects of heat induced changes of SPA and the properties of casein and calcium ion activity led to the reduced ability of rennet coagulation.

Key Words: milk powder, protein aggregate, rennet gel

T242 Light-protective packaging effectiveness to enhance sensory and nutrient stability of extended shelf life milk and n-3 enriched milk. D. Johnson, S. E. Duncan*, W. N. Eigel, and S. F. O'Keefe, *Virginia Tech, Blacksburg.*

Modification of milk composition with n-3 (omega-3) fatty acids increases risk of product oxidation, which can be accelerated by light. Effectiveness of light protection additives (LPA) incorporated into high density polyethylene (HDPE) packaging in limiting light-induced oxidation of extended shelf-life milk (2% total fat) and n-3 fatty acid enriched milk (2% total fat) was studied. Packaging effectiveness was determined by assessing changes to packaged milk flavor, oxidation, and riboflavin concentration throughout a 35-d shelf life study. Extended shelf-life fluid milk, with and without n-3 fatty acids, was stored in a lighted dairy case (average light intensity: 2200 lx; 4°C). HDPE packaging included no LPA (control; translucent appearance); light-protected (foil overwrap over no LPA control); and 3 LPA levels (low, medium, high) for the experimental treatments. Over the study period, riboflavin concentration in the 2% milk decreased 11% and 29% in the light-protected control and the high LPA packages respectively. Thiobarbituric acid reactive substances assay (TBARS) of more than 1.3 μmol of malondialdehyde (MDA) indicated significant change in flavor; the high LPA package provided effective protection for the 2% milk. In n-3 milk, the high LPA package provided greater protection of sensory quality and riboflavin than the other packages; however, riboflavin decreased by 28% through the 35-d study even in the light-protected control representing a higher loss rate than observed in milk without n-3 lipids. The n-3 milk packaged in the no LPA-HDPE package exceeded MDA of 3.0 μmol by d 7, suggesting the milk would not be of sufficient sensory quality for consumer acceptance. Conversely, the high LPA package protected riboflavin and controlled MDA development most effectively of the LPA packages studied in the n-3 enriched milk beverage. Packaging innovation and design, including light protection material incorporation, can provide improved protection of milk flavor and nutrient content. Product composition influences packaging light protection effectiveness.

Key Words: n-3, packaging, oxidation

T243 Properties of whey protein isolate-maltodextrin conjugates as affected by powder acidity during the Maillard reaction. W. Wang* and Q. Zhong, *The University of Tennessee, Knoxville.*

A challenge of producing shelf-stable high protein (>4.2% wt/vol) beverages using whey proteins is the protein denaturation and aggregation during heating that result in turbidity and possibly gelation. Our previous studies showed that transparent dispersions of whey protein isolate (WPI) glycated

with maltodextrin (MD) were heat stable at pH 3.0–7.0. Glycation was achieved by heating powders spray-dried from a neutral pH solution with equal mass of WPI and MD – the Maillard reaction. However, the undesired brown color and health-concerning advanced Maillard reaction products are to be reduced. In this study, WPI and MD were dissolved at equal mass in water, adjusted to pH 4–7, hereafter referred as "mixture pH – m-pH," and spray-dried. The obtained powder was incubated at 80°C, 65% relative humidity for 1, 2, and 4 h to prepare conjugates. The resultant conjugates were prepared at 5% (wt/vol) protein in deionized water, adjusted to pH 4–7, hereafter referred as "solution pH – s-pH," 0–100 mM NaCl and 5% (wt/wt) sucrose. After heating at 138°C for 1 min, the absorbance at 600 (Abs_{600}) and 420 nm (Abs_{420}) was measured as indicators of turbidity and color formation, respectively. A darker brown color, higher Abs_{420} and lower Abs_{600} were observed for conjugates glycated for a longer time, with all conjugates prepared by 4-h glycation being transparent at all s-pH. For samples glycated for 2 h, a lower m-pH corresponded to a lighter color but was generally less heat stable; the m-pH 6.0 treatment was the most heat stable, with only the pH 5.0 and 0 m*M* NaCl sample showing turbidity. The m-pH 6.0 treatment corresponded to the highest degree of glycation assessed based on free amino group concentration and the highest denaturation temperature according to differential scanning calorimetry. The transparent samples after heating had mean particle diameters as small as ~13 nm. The combination of m-pH 6 and 2-h glycation was concluded as the most desirable treatment in terms of both heat stability improvement and color reduction. This study suggests that the quality of glycated WPI can be improved by controlling m-pH.

Key Words: whey protein, heat stable, conjugate

T244 Caseinomacropeptide index for cheese whey detection in pasteurized milk, Brazil. P. R. Lobato[1], M. E. R. Fortini[1], R. S. Conrrado[1], M. M. O. P. Cerqueira[1,2], L. M. Fonseca*[1,2], M. O. Leite[1,2], R. Rodrigues[1], M. R. Souza[1], and C. F. A. M. Penna[1], *[1]Department of Food Technology and Inspection, School of Veterinary Medicine, Universidade Federal de Minas Gerais (UFMG), Belo Horizonte, MG, Brazil, [2]CNPq, Brasilia, DF, Brazil.*

Cheese whey is a high nutritive by-product of the cheese industry. However, due to its low commercial value, its use to adulterate milk is a well known and hard to detect in practice. Caseinomacropeptide (CMP) index determination by high performance liquid chromatography with gel filtration (HPLC-GF) is officially used in Brazil to investigate whey addition to milk, and it should be no more than 30 mg/L. If CMP index is 30 to 75 mg/L, milk can be used only for specific dairy products, and above 75 mg/L, only for animal feeding. The objective of this study was to evaluate the CMP index method by HPLC-GF to detect fraudulent addition of whey to retailed pasteurized milk in Minas Gerais, a state responsible for about 30% of Brazilian milk production. Fifty-six samples of several brands of pasteurized milk were collected from randomly chosen retail stores, and kept under refrigerated conditions until analysis in the Laboratory of Chromatography, School of Veterinary Medicine, Universidade Federal de Minas Gerais, Brazil. CMP index ranged from 30 to 75 mg/L for 1.8%, and above 75mg/L for 30.4% of the samples. Based on CMP index, only 67.9% of the samples were compliant to the standards, with CMP index below 30 mg/L. Fraudulent addition of cheese whey to pasteurized milk was aggravated in some regions with up to 90% of occurrence, and it was brand related. The levels of cheese whey found in pasteurized milk in the current study indicate lower nutrient levels in the final product. It is concluded that quality monitoring in the milk collection must be emphasized and stricter plant inspection is necessary to keep milk integrity in Brazil. Routine CMP index determination by HPLC-GF might play an important role to monitor cheese whey fraudulent addition to pasteurized milk.

Key Words: food adulteration, CMP index, cheese whey

T245 Milk mineral harvest from dairy streams using filtration technology. L. Mealy*, C. Marella, A. Biswas, and L. Metzger, *Midwest Dairy Foods Research Center, South Dakota State University, Brookings.*

Milk minerals harvested from dairy processing streams have applications in several areas including use as a supplement in a wide variety of foodstuffs. Dairy stream demineralization methods are employed in commercial lactose isolation and can also be used as a pretreatment for other filtration processes to minimize membrane fouling. The objective of this research was to investigate the potential of wide pore ultrafiltration membranes for removal of minerals from skim milk ultrafiltration permeate. Filtration experiments were conducted using a lab scale plate and frame filtration unit. Pre-production water flux rates were obtained at 27°C (80°F). Subsequently, 2000 mL of feed was added to the balance tank and processed at 49°C (120°F) until a 5× volume reduction was achieved. After a rinse of 2000 mL water at 49°C, post-product water flux values were obtained at 27°C. Membrane performance evaluation was based on the flux obtained during the filtration process, percent flux recovery after production and rinsing as well as by mineral retention. In this study, 3 feeds that varied in mineral content (0.91, 0.97 and 1.04%) were standardized to 11.03% total solids and concentrated using [polyethersulfone (PES) membrane with a molecular weight cut off (MWCO) of 20 kDa, and 2 polyvinyledefluoride (PVDF) membranes with a MWCO of 30 and 40 kDa, respectively]. Significant differences in both product flux values and ash recovery were seen between feed - membrane pairs analyzed. The PVDF membrane with MWCO 40 kDa exhibited the highest product flux rate of 117 LMH and ash retention of 41%. Future work will focus on using these membranes for industrial scale applications.

Key Words: milk mineral, ultrafiltration

T246 Characterization of whey protein films incorporated with oregano essential oil (*Origanum vulgare*). S. P. L. F. de Oliveira[1], I. M. B. Dianin[1], A. P. Bilck[1], C. M. V. B. de Rensis[1], L. C. Bertan[2], and P. C. B. Vianna*[1], *[1]Universidade Norte do Paraná (UNOPAR), Londrina/PR/Brazil, [2]Universidade Federal da Fronteira Sul (UFFS), Laranjeiras do Sul/PR/Brazil.*

The aim of this study was to evaluate the characteristics properties (visual appearance, thickness, water vapor permeability and water solubility) of the whey protein films incorporated with oregano essential oil. The films were produced by casting technique from whey protein isolate and added of oregano oil at 4 concentrations: 0% (control film), 0.5%, 1.0% and 1.5% (vol/vol). The whey protein isolate was dispersed in distilled water, added with glycerol (3%) and heated at 90°C/30 min in water bath. The oregano oil was added to the solutions before heating. The film solution was spread on Petri dishes (90 cm of diameter) and dried for 24 h at room temperature. The films were removed from the plates with a spatula and stored at controlled humidity (52%) at 25°C/48 h before analysis. The results were evaluated by ANOVA and Tukey's test at 5% significance level. Generally, films presented transparent and homogeneous, with a slight yellow color. The films were more flexible with increasing oregano oil concentration. The films thickness ranged from 0.013 mm to 0.015 mm, and the control film showed significantly thinner than the films added with 0.5 and 1.0% of oregano oil. The water vapor permeability decreased significantly in added oregano oil films when compared with control film. However, increasing the concentration of oregano oil caused no significant changes in water vapor

permeability. The solubility ranged from 14.0% to 20.2%, with the control film significantly more soluble than 1.5% added oregano oil. Probably the hydrophobic characteristic of oregano oil influenced the decrease in water vapor permeability and solubility of the films suffered its addition. The results indicate that whey protein isolate is a good matrix for production of biodegradable films and addition of oregano essential oil, even in small quantities positively affected the characteristics of the films. The oregano essential oil can also confer antimicrobial properties for these films.

Key Words: whey protein, film, oregano oil

T247 Effect of Sicilian pasture feeding management on content of α-tocopherol and β-carotene in cow milk. V. M. Marino*[1], I. Schadt[1], S. Carpino[1], M. Caccamo[1], S. La Terra[1], C. Guardiano[1], and G. Licitra[1,2], *[1]CoRFiLaC, Ragusa, Italy, [2]DISPA, Catania, Italy.*

This study was performed to evaluate α-tocopherol and β-carotene content of pasture milk under ordinary Sicilian farming conditions. Fourteen dairy farms were allocated into 2 balanced groups on the basis of cultivated (CULT) and spontaneous (SPO) pasture type feeding. Bulk milk per farm was collected 4 times from February through April with 3-wk intervals. Pasture botanical and diet composition, diet nutritional quality, milk yield and composition were estimated each time. Pasture intake levels were calculated based on feed analyses and hay and concentrate amounts fed and, on milk yield and chemical composition using CPM Dairy. In accordance to pasture intake the farms were split into a low pasture (LPI; < 29.5% DMI) and a high pasture intake group (HPI; > 29.5% DMI). Milk samples per farm were analyzed for α-tocopherol and β-carotene contents. Spontaneous milk had higher levels ($P < 0.05$) of α-tocopherol and β-carotene in milk (0.7 and 0.3 mg/L, respectively) and in milk fat (19.0 and 7.5 mg/kg fat, respectively) compared with CULT (0.5 and 0.2 mg/L milk; 14.6 and 4.9 mg/kg fat, respectively). High pasture intake compared with LPI increased α-tocopherol in milk fat (18.0 and 16.0 mg/kg fat, respectively; $P < 0.05$). However, only in SPO but not in CULT milk, HPI increased α-tocopherol ($P < 0.05$) and β-carotene ($P < 0.01$) in milk and β-carotene in milk fat ($P < 0.05$) (0.8, 0.3 mg/L milk and 8.4 mg/kg milk fat, respectively) compared with LPI (0.6, 0.2 mg/L milk and, 6.6 mg/kg milk fat, respectively). All results may be explained by the different botanical composition of both pasture types. Spontaneous pasture compared with CULT contained more Asteraceae, Fabaceae, Cruciferae, Euphorbiaceae and Malvaceae. Milk and milk fat α-tocopherol levels were higher at the test-d 1, 2 and 4 compared with 3 ($P < 0.01$). At HPI milk fat β-carotene content was higher at the first 2 test-days compared with the others ($P < 0.05$). These differences are probably related to plants' biological stage. On Sicilian dairy farms highest milk α-tocopherol and β-carotene content may be obtained feeding SPO pasture at high levels.

Key Words: milk, fat-soluble vitamin, pasture

T249 Whey permeate used as salt substitute in processed foods. S. Chizonda*, E. M. Dixon, Y. Jiang, and J. C. Allen, *North Carolina State University, Raleigh.*

Whey permeate (WP) from ultra-filtration of whey and milk is considered a low-priced by-product in cheese and whey protein production. WP contains lactose (80–89%) fat, moisture, soluble non-protein nitrogen and minerals. WP minerals help provide salty taste even if Na content is low. The objectives of this study were to utilize WP as a salt substitute to decrease Na and Cl content and increase K, Ca, and Mg content in several food products. People who consume significant quantities of such products might decrease hypertension risk. Furthermore, with increasing demand for cheese and whey protein, there will be more WP available and a need to find new ways to utilize it. Powdered WP was analyzed with ICP for 7 minerals (Na, K, Ca, Mg, Fe, Zn, Cl). The saltiness intensity of WP and NaCl in aqueous solution were determined by a trained descriptive panel (n = 12) to calculate the equivalent concentrations of salt and permeate for salty taste. WP was used as a salt substitute based on the salty taste equivalencies in reformulating canned cream soup base, fresh cream soup base, smoked sausage, and bread. Consumer panels evaluated the products. Fresh WP soup was ranked in salty taste slightly lower and canned soup slightly higher than soup with 50% of salt omitted. However, the fresh and retorted soup formulations made from permeate actually contained only 11% and 19% as much Na as the full-salt recipe, respectively. Sausages made with 25% WP salt substitution were not different than the 100% salt sausage in overall liking, flavor, saltiness, texture, firmness, juiciness or deformability ($P < 0.05$). WP sausages had lower water activity and pH than the 100% salt sausage, and lower ingredient cost. The foods made with WP were lower in Na and Cl and had higher K, Ca, and Mg levels. The WP foods had higher saltiness than the actual sodium content's contribution to the taste, but not as high as predicted from the salty taste of the permeate in aqueous solution, suggesting mineral interaction with other food ingredients. This research showed the feasibility of using WP as a salt substitute in several processed food products.

Key Words: whey permeate, sodium reduction, processed food

T250 Application of a rising plate meter to estimate forage yield on dairy farms in Pennsylvania. A. N. Hafla*, K. J. Soder, M. Rubano, and R. Stout, *USDA-Agricultural Research Service-Pasture Systems and Watershed Management Research Unit, University Park, PA.*

Accurately assessing pasture forage yield is necessary to budget feed expenses. The rising plate meter (RPM) is a rapid method of estimating dry matter (DM) forage yield but calibrations and equations provided by manufactures may be unreliable. The objective of this study was to evaluate the ability of a RPM to accurately estimate pasture forage yield on dairy farms with multiple plant species and determine the best calibration equation. The 3 PA farms in this study used rotational grazing with lactating dairy cows. Forage mass was estimated in each pasture, a day before grazing, using 45 measurements from a FILIPS RPM (n = 180–225 per farm). To measure forage DM yield, 15 clippings (n = 60–75 per farm) of 1 m × 10 cm were taken alongside RPM measurements. Visual estimates of botanical composition were made to assess species diversity. Equations for estimating pasture forage mass were determined by regressing measured DM yield on the corresponding RPM value. Four calibration equations based on measurements were evaluated: (1) pooled from all farms (2) by farm (3) by season (summer or fall) and (4) by farm and season. Two equations provided by the RPM manufacturer were also evaluated: a default and seasonal equation. Equations were evaluated by regression procedures (PROC REG, SAS) and estimated standard error of prediction (SEP). Measured DM forage yield was 1209, 896, and 2,246 kg/ha for farms 1, 2 and 3, respectively. Grasses made up 23, 44, and 63% of pasture composition; legumes composed 48, 25, and 20%, for the 3 farms. Manufacturer equations had the greatest SEP (32 and 38% of measured forage yield, respectively) and low r^2 (0.58 and 0.51, respectively). Error levels for calibration equations 1, 2 and 4 were greater than the 10% level considered acceptable by previous studies (12 to 21%). The equation considering season had the lowest SEP (9%) and a high r^2 (0.76). Our results indicate that manufacturer equations are unreliable for estimating forage yield on farms in PA in pastures with multiple species. Calibration equations should be developed and adjusted for each season to ensure the greatest accuracy.

Key Words: forage yield, grazing, rising plate meter

T251 Case study: Dairies utilizing ultra-high stock density grazing in the Northeast. K. J. Soder*[1], M. Hautau[2], A. N. Hafla[1], M. D. Rubano[1], B. Moyer[2], and R. Stout[1], *[1]USDA-ARS, University Park, PA, [2]The Pennsylvania State University, University Park.*

Ultra-high stock density (UHSD) grazing has recently gained interest in the dairy industry. However, little research exists to support anecdotal claims that forage and soil improvement occur through trampling high proportions (75+%) of mature forage into the soil by grazing dense groups of cattle on small paddocks (550,000+ kg per 0.4 ha) with long (60–90+ days) rest periods. Furthermore, UHSD may not be appropriate for northeastern dairies. A case study was conducted to evaluate grazing management of dairies that are early adopters of self-defined UHSD grazing. Data, collected on 4 dairy farms in PA and NY during the 2012 grazing season, included: forage and soil nutrient analyses, stock density, botanical composition and pasture stratification. Data were analyzed using the MIXED procedure of SAS. Least squares means are presented. Pasture area ranged from 80 to 250 ha with 60 to 270 lactating cows. Milk yield ranged from 9 to 18 kg/cow. Stock density ranged from 37,800 to 180,444 kg/ha with an average 39 (±7) day rest cycle. Forage consumed ranged from 50 to 70% of total forage available. Cows averaged 75% (±18) consumption above 20 cm of growth with lower layers averaging 53% (±11) consumption. Soil mineral content and pH were within recommended levels. Forage crude protein averaged 20% (±3.5; DM basis) in June and 29% (±3.7) in Oct. Neutral detergent fiber decreased from 52% to 34% (DM basis) from June until Oct. Forage net energy for lactation increased from 1.34 to 1.61 Mcal/kg DM between the 2 grazings, resulting from grazing at a less mature state in the autumn. Dairies in the Northeast took a modified approach to current UHSD definitions by grazing forages slightly more mature than that recommended in rotational grazing systems, and slowing the rotation to allow plants to mature (but not nearly as mature as what has been anecdotally reported in other UHSD situations) to increase forage DM available as well as improve nutrient balance (e.g., protein and fiber) in forage to better meet nutritional needs. Data from this case study will help identify needed areas to compare this grazing strategy with more traditional methods.

Key Words: dairy, grazing, ultra-high stock density

T252 Feed efficiency by dairy cows in China: A farm survey result. C. Wang*[1,2], J. X. Liu[2], N. B. Wei[1], Q. M. Xu[1], and H. P. S. Makkar[3], *[1]Zhejiang Agriculture and Forestry University, Hangzhou-Lin'an, China, [2]Institute of Dairy Science, Zhejiang University, Hangzhou, China, [3]Animal Production and Health Division, FAO of the United Nations, Rome, Italy.*

This work was conducted to evaluate feed efficiency and economic profits under different dairy systems in China. Twenty-three farms across China were selected for survey on the basis of differences in management systems and animal numbers. Three dairy systems were defined: (i) Smallholder subsistence farms (SH): < 10 cows per farm and farm is owned by one person or one family; (ii) Peri-urban farms (PR): > 100 cows herd per farm, with good management practices; and (iii) Cooperative farms (CO): usually >100 cows per farms but the cows in the farm are owned by several different person and kept collectively in a farm. Data were statistically analyzed by using GLM procedure of SAS. Though statistical significance was not observed, numerically more concentrates were used in PR than other 2 systems (Table 1). Human edible grain was the most used feedstuff in all the systems with higher percentage in SH than in the other 2 systems where farmers used more cottonseed, extruded soybeans, and by-products. Milk production per cow ranked across groups as PR > CO > SH ($P < 0.01$). Average feed efficiency for lactating cows was significantly higher in PR than that in CO or SH system ($P < 0.01$), with highest value (1.51 kg milk/kg DMI) in PR and lowest value (0.93 kg milk/kg DMI) in SH system recorded for single farm. Nitrogen utilization efficiency was higher in PR than in CO or SH system, with little difference between CO and SH systems. Overall, although the milk produced per USD ($) worth of feed was similar in different systems, the economic profitability and ecological benefit were higher in PR system because of the higher sales price, high nitrogen conversion, and less use of human edible grains.

Table 1. Production and economic profits for different systems of dairy farms

Item	PR	CO	SH	SEM	*P*-value
Concentrate, % DM	53.9	49.4	44.4	3.04	0.28
Grains, % DM	27.1	29.2	35.1	2.32	0.10
Milk yield, kg/d/cow	27.0[a]	22.3[b]	17.2[c]	1.00	<0.01
Feed efficiency, kg milk/kg DMI	1.36[a]	1.17[b]	1.06[b]	0.028	<0.01

T253 Silage management on high-producing dairy farms in Brazil. R. C. Amaral*[1], T. Gama[1], I. De Oliveira[2], and T. F. Bernardes[2], *[1]DeLaval, Campinas, São Paulo, Brazil, [2]University of Lavras, Lavras, Minas Gerais, Brazil,*

Silage management on dairy farms is important to reduce the dry matter losses and maintain the quality of silage during the year. Most of the research on silages in Brazil has been performed in laboratory-scale silos, but limited research has been conducted on farm-produced silages. The objective was to assess the silage management practices in high producing dairy farms. A survey was carried out on 13 high producing dairy farms in 5 Brazilian States. All farms had Holstein cows, which average of 1,818 milking cows/farm. A questionnaire was applied to identify the silage management, regarding the harvest, silo type and feed-out management. The data were collected during a spring (August until November) in 2012. Silages samples were taken at 2 locations across the feed-out face (3 samples on the top and 3 samples on the center) to determine pH of the silages. The silage from top was measured to determine the spoilage silage and silage color. All data were tabulated in an Excel spreadsheet. The number of responses, mean, minimum value, maximum value, and standard deviation were calculated. The average milk production was 24,211.9 kg/d/farm and 31.4 kg/d/cow. For a silage harvest, 76.5% of the farms used contracted harvest and 23.5% used their own machines. One-hundred percent used self-propelled harvesters. Seventy one percent of the farms used a Penn State Particle Size Method to determine the distribution and the particle size of the forage, 6.0% used a ruler and 24.0% did not use any method. In these farms, 70.6% used inoculants in the ensiling process (75.0% homolactic and 25.0% heterolactic inoculant). The trench silo represented the major silo type (82.3%), followed by 11.3% of pile silo and 5.9% pressed bag. In the feed-out phase 58.8% of the farms used milling cutter and 41.2% wheel loader. Silage pH <4.0 was found in 64.7% of center silage samples and 47.1% on the top. Higher pH on top can explain the presence of spoiled silage of 4.4 cm average depth on top for 47.1% of the farms.

Key Words: corn silage, dairy nutrition, silage quality

T254 Modelling the effect of white clover protein degradability on milksolids production and nitrogen excretion. E. N. Khaembah*[1], P. Gregorini[1], P. C. Beukes[1], and G. P. Cosgrove[2], *[1]DairyNZ, Hamilton, Waikato, New Zealand, [2]AgResearch, Palmerston North, Manawatu, New Zealand.*

There is a positive correlation between dietary white clover (WC) content and milk production; however, utilization of WC-rich diets may be limited by increased urinary nitrogen (UN) excretion resulting from rapid ruminal degradation of WC proteins. Increasing the dietary fraction of rumen undegradable protein (RUP) has the potential to increase protein passage to the small intestine, thus improving protein utilization. Model simulation provides a tool to evaluate the effect of the RUP fraction in dietary WC on milk production and UN excretion. This study used the DairyNZ Whole Farm Model (with Molly cow model) to evaluate a Waikato dairy system with 2–7 year old Friesian cows (stocking rate = 3.0 cows/ha) for whole-farm productivity and N partitioning, over the 2004/2005 milking season. The control diet (standard perennial ryegrass (PR)/WC containing 15% WC) was compared with mixed PR (60%) and WC (40%) diets containing 0.3, 0.4 and 0.5 RUP fraction of WC (treatments 1, 2 and 3, respectively). Model adjustments were made to allow 22% extra dry matter intake (DMI) on WC of the treatment diets. Pasture silage was fed during feed deficits. Model outputs were DMI, milksolids (fat + protein) production, N intake and N in milk, urine and feces. There was greater DMI from treatment diets compared with the control (4.6 vs. 4.4 t DM/cow/lactation). Milksolids (kg/ha) production was 1179, 1260, 1264, 1269 for the control and treatments 1, 2 and 3, respectively. Dietary N intake was 14 kg/cow/lactation greater on treatment diets relative to the control. Nitrogen excretion (kg/cow/lactation) for the control and treatments 1, 2 and 3 were 26.9, 28.8, 28.9, and 29.1 in milk, 76.8, 87.5, 86.8, 86.2 in urine, and 33.6, 35.4, 35.9 and 36.3 in feces, respectively. Under this study's assumptions, increasing dietary WC content increased MS production, but also increased UN excretion. Increasing RUP of WC protein only slightly reduced UN excretion. This model-derived outcome indicates that breeding for decreased protein degradability would offer only limited prospects for reducing UN excretion from WC-rich diets.

Key Words: white clover, protein degradability, nitrogen partitioning

T255 Effect of cow genotype and level of supplementation at pasture on milk performance of animals under a simplified rotational grazing system. A. I. Roca-Fernandez*[1,2], L. Delaby[2], S. Leurent[3], Y. Gallard[3], and M. E. Lopez-Mosquera[4], *[1]Agrarian Research Centre of Mabegondo, La Coruña, Galicia, Spain, [2]INRA Agro-Campus Ouest UMRPL, Saint Gilles-Rennes, Bretagne, France, [3]INRA Experimental Farm Le Pin au Haras, Borculo-Exmes, Normandy, France, [4]University of Santiago de Compostela, Lugo, Galicia, Spain.*

Milk performance of 2 cow genotypes, Holstein-Friesian (F, n = 178) vs. Normande (N, n = 174), managed at 2 levels of concentrate supplementation at pasture, low (0 kg DM/cow/day, n = 174) vs. high (4 kg DM/cow/day, n = 178), was studied in 4 groups (F0, F4, N0 and N4) applying a 2 × 2 factorial design. A simplified rotational grazing system, with a mean residence time per cycle of 10 d, was examined at Pin au Haras farm (France) during 2001–2005. The objective of this work was to determinate the maximum milk yield (MY max.) and the milk yield drop (Dm) in each grazing cycle for both cow genotypes in both grazing feeding regimens. Data were analyzed using PROC MIXED in SAS. MY and peak of MY per lactation were higher ($P < 0.001$) in Holstein-Friesian (7,591 and 36.2 kg/cow, respectively) than in Normande cows (6,214 and 29.2 kg/cow, respectively), with lower ($P < 0.001$) body weight (BW) and body condition score (BCS) in Holstein-Friesian (659 kg and 2.18, respectively) than in Normande cows (695 kg and 2.83, respectively). Supplemented cows showed higher ($P < 0.001$) MY and peak of MY (7,567 and 35.0 kg/cow, respectively) than cows without supplementation (6,238 and 30.4 kg/cow, respectively), with higher ($P < 0.001$) BW and BCS in supplemented cows (702 kg and 2.85, respectively) than in cows without it (652 kg and 2.15, respectively). Supplemented cows had higher ($P < 0.001$) MY max. but lower ($P <$

0.001) Dm (24.9 and –5.3 kg/cow, respectively) than those cows without it (21.2 and –6.1 kg/cow, respectively). MY max. and Dm were higher ($P < 0.001$) in Holstein-Friesian (25.1 and –6.4 kg/cow, respectively) than in Normande cows (21.0 and –4.9 kg/cow, respectively). Milk protein and fat content were higher ($P < 0.001$) in Normande (34.5 and 40.6 g/kg DM, respectively) than in Holstein-Friesian cows (31.5 and 36.4 g/kg DM, respectively). To choose an appropriate cow genotype for an efficient milk performance at grazing is an important goal for adjusting food supply to animal demand by considering cow lactation stage and level of supplementation at pasture.

Key Words: cow genotype, simplified rotational grazing system, supplementation

T256 Effect of forage proportion on milk fatty acids profile of Holstein-Friesian cows under Galician conditions (NW Spain). A. I. Roca-Fernández*[1], A. González-Rodríguez[1], O. P. Vázquez-Yáñez[1], and J. A. Fernández-Casado[2], *[1]Agrarian Research Centre of Mabegondo, La Coruña, Galicia, Spain, [2]Agrarian and Fitopathologic Laboratory of Galicia, La Coruña, Galicia, Spain.*

The aim was to investigate the effect of forage proportions: S, 100% silage (50% grass + 50% maize); G/S, 50% grazing + 50% silage; and G, 100% grazing (80% perennial ryegrass + 20% white clover) on profiles of milk fatty acids (FA) from autumn calving Holstein-Friesian cows (n = 60) in NW Spain. From March to August, weekly milk samples were collected from individual cows for FA determination, measured by gas chromatography-mass spectrometry. There were differences in saturated FA, with higher levels in S ($P < 0.001$, 65.85 g/100 g) and G/S ($P < 0.001$, 65.34 g/100 g) than in G (61.95 g/100 g). Those differences were mainly due to C14:0, C16:0, C18:0 and to a minor extent to C6:0-C12:0. Lower content of short chain FA (C6:0-C10:0) was found in G ($P < 0.05$, 10.15 g/ 100 g) than in G/S (11.31 g/100 g). The lowest content of medium chain FA (C12:0-C16:0) was found in G (40.75 g/100 g) compared with S ($P < 0.001$, 44.68 g/100 g) or G/S ($P < 0.001$, 43.99 g/100 g). The highest content of long chain FA was found in G (38.50 g/100 g) compared with S ($P < 0.01$, 35.41 g/100 g) or G/S ($P < 0.001$, 34.78 g/100 g) due to C18:0, C18:1, C18:2 and C18:3. The highest level of unsaturated FA was found in G (27.45 g/100 g) compared with S ($P < 0.01$, 25.06 g/100 g) or G/S ($P < 0.001$, 24.75 g/100 g). The levels of oleic and linoleic acid were higher in G (23.70 and 3.13 g/100 g) than in S ($P < 0.001$, 21.81 g/100 g for oleic acid; $P < 0.001$, 2.86 g/100 g for linoleic acid) and in G/S ($P < 0.01$, 21.49 g/100 g of FA for oleic acid; $P < 0.001$, 2.76 g/100 g of FA for linoleic acid). Highest levels of mono- and polyunsaturated FA were found in G (23.70 and 0.75 g/100 g) compared with S ($P < 0.001$, 21.81 g/100 g for MUFA; $P < 0.001$, 0.26 g/100 g for PUFA) or to G/S ($P < 0.001$, 21.49 g/100 g for MUFA; $P < 0.001$, 0.25 g/100 g for PUFA) due to C18:1, C18:2 and C18:3. Linolenic and conjugated linoleic acid (g/100 g) differed ($P < 0.001$) between groups, with higher contents in G (0.62 and 1.14 g/100 g) than in S (0.40 and 0.49 g/100 g) or in G/S (0.50 and 0.82 g/100 g).

Key Words: dairy cow, forage proportion, milk fatty acids profile

T257 Effect of forage proportion on sward characteristics and milk performance of Holstein-Friesian cows under Galician conditions (NW Spain). A. I. Roca-Fernández*, A. González-Rodríguez, and O. P. Vázquez-Yáñez, *Agrarian Research Centre of Mabegondo, La Coruña, Galicia, Spain.*

A trial was carried out to investigate the effect of forage proportions (S, 100% silage; G/S, 50% grazing + 50% silage; G, 100% grazing) on sward characteristics and milk performance of autumn calving Holstein-Friesian cows (n = 60). On average, the G/S and G groups completed 4–5 rotations with 139 grazing days. The G group had less grazing days per rotation ($P < 0.001$, 27.9 d) than the G/S group (34.8 d). The G/S group was allocated to greater herbage mass (kg DM/ha) ($P < 0.05$, 3,347) than the G group (3,069). The G/S group had higher herbage allowance (kg DM/cow/day) ($P < 0.05$, 23.94) than the G group (19.34). Lower herbage utilization (%) was found in the G/S (40.1) than in the G group (89.2). The G group showed higher ($P < 0.01$) crude protein (G, 144 vs. G/S, 118 g/kg DM), carbohydrates (G, 182 vs. G/S, 148 g/kg DM) and digestibility (G, 785 vs. G/S, 756 g/kg DM) than the G/S group but lower acid (G, 271 vs. G/S, 289 g/kg DM) and neutral (G, 525 vs. G/S, 573 g/kg DM) detergent fiber. Pre- and post-grazing heights were lower in the G (16.4 and 4.7 cm) than in the G/S group (17.3 and 7.2 cm). Total intake (kg DM/cow/day) was lower in the S (21.2) than in the G/S ($P < 0.05$, 22.8) and G ($P < 0.01$, 23.6) groups. Pasture intake (kg DM/cow/day) was higher in the G (17.3) than in the G/S group ($P < 0.001$, 9.6). Silage intake (kg DM/cow/day) was higher in the S (14.9) than in the G/S group ($P < 0.001$, 6.9). Cows in the S group showed the highest ($P < 0.01$) body weight (631 kg) and body condition score (3.2) than those in the G/S (600 kg and 2.9) and G (580 kg and 2.7) groups. Milk yield was higher in the S (23.3 kg/cow/day) than in the G/S ($P < 0.001$, 21.5 kg/cow/day) and G ($P < 0.01$, 22.6 kg/cow/day) groups. The highest milk protein was found in the G (3.16 g/kg) compared with the S ($P < 0.001$, 3.03 g/kg) and G/S ($P < 0.01$, 3.06 g/kg) groups. Milk fat was higher ($P < 0.05$, 4.18 g/kg) in the S than in the G group (3.96 g/kg). Higher milk protein content was achieved in cows fed with higher proportion of forage in its diet due to higher crude protein levels in the swards.

Key Words: forage proportion, sward characteristics, milk performance

T258 Stocking strategies and stocking rate to enhance forage utilization, gain per animal, and gain per unit land area from rye-ryegrass pastures. F. Rouquette Jr.*, J. Kerby, G. Nimr, and K. Norman, *Texas A&M AgriLife Research, Overton.*

Small grain pastures (PAS) in the Southeastern United States have a bimodal DM production trait with a minor peak in the fall, and a major DM peak during mid-February to mid-May. Climatic conditions create erratic monthly DM that challenges management of stocking strategies (STRG) for stocker cattle. During a 3-year season (2008–2009, 2009–2010, 2011–2012), bermudagrass [*Cynodon dactylon* (L.) Pers] was overseeded with 112 kg/ha 'Maton' rye (*Secale cereale* L.) plus 34 kg/ha 'TAM 90' annual ryegrass (*Lolium multiflorum* Lam.). Two replicate PAS of all STRG included stocking initiation at a normal or early (RLY) date of late December and a delayed (DLA) date of late January. The RLY PAS consisted of 2 fixed (FIX) stocking rates (STK) of low (LO) and medium (ME) and 2 variable (VAR) STK. For the RLY FIX PAS, the STK were 3.7 hd/ha for LO and 6.2 hd/ha for ME. Forage allowance (kg forage DM/kg BW) was 1.6 to 2.1 on LO and 1.2 to 0.7 on ME. The 2 RLY VAR STRG included an initial LO STK until mid-late March, then increased to ME and high (HI). The DLA PAS had FIX STK of ME and HI. Six 1/2 Simmental stockers (3 steers and 3 heifers) at 250 kg were used on each replicate PAS each year (total = 202 hd). The ADG and gain/ha were assessed via PROC MIXED with STRG and Year as Fixed, and rep as random effects. Year affected STRG for ADG. The RLY FIX LO with respective gains of 1.53, 1.60, and 1.22 kg/hd for the 3 years had highest ($P < 0.01$) ADG. In contrast, the DLA FIX HI STK had the lowest ($P < 0.01$) ADG for the 3 years at 0.69, 1.15, and 0.94 kg/hd. The greatest ($P < 0.01$) gains/ha were from RLY FIX ME with 1162, 1504, and 1329 kg/ha, respectively, for years 1–3

using STK of 5.9, 8.2, and 8.4 hd/ha. Lowest gain/ha ($P < 0.01$) resulted from DLA FIX HI with gains of 663, 975, and 627 kg/ha for years 1–3. The STRG of increasing STK to maximize forage utilization on PAS during the last 60 d of stocking lowered ADG which also reduced gain/ha. The actual, season-long STK was not as important a STRG as was the timing of stocking intensity.

Key Words: small grain, stocking rate, stocking strategy

T259 Effects of supplement or fertilizer on forage quality, and performance of stocker cattle grazing warm-season pastures in South Mississippi. J. D. Rivera*[1] and R. W. Lemus[2], *[1]South MS Branch Experiment Station, Mississippi Agriculture and Forestry Experiment Station, Poplarville, [2]Department of Plant and Soil Sciences, Mississippi State University, Starkville.*

Crossbred (*Bos taurus* × *Bos indicus*) beef steers (BW = 224 kg; n = 54) were used over 2-yr to examine the efficacy of nitrogen fertilizer compared with feed supplementation on forage quality, animal production, and nitrogen cycling. Steers were weighed, and assigned to graze six 4-ha paddocks of mixed warm-season perennials (bermuda and bahiagrass) for an average of 126 d. Paddocks were randomly assigned to 1 of 3 treatments: no fertilizer and no supplement; 1.1 kg of dried distillers grains per steer/d and no fertilizer; or fertilizer (68 kg N per ha) and no supplement. Cattle were individually weighed every 28 d, and an individual fecal sample was collected. Pasture clippings were taken weekly and pooled for nutrient analysis for each 28 d period. Data were analyzed as a randomized complete block with year and block as random effects and pasture as the experimental unit. Supplement increased BW ($P < 0.04$) at d 56, 84, 112 and for the overall grazing period. No differences ($P > 0.10$) were noted regarding BW in steers that grazed fertilized pastures or non-fertilized pastures at any point in the study. Supplement also increased ($P < 0.05$) ADG d 56, 84, 112, and for the overall study compared with grazing alone (regardless of fertilizer). Moreover, ADF in forage samples was reduced ($P < 0.07$) in pastures that were fed a supplement or fertilized at d 56, 84 and for the overall study. In addition, forage CP was increased ($P < 0.06$) by supplementing or fertilizing at d 56, 112 and for the overall study, and pasture TDN at d 56, 84 and overall was increased ($P < 0.07$) by supplementing or fertilizing. In year 1, fecal N increased at d 28 ($P < 0.05$) for supplemented cattle compared with their counterparts, increased at d 56 ($P < 0.09$) for both supplement and fertilizer groups, and increased at d 84 for the fertilizer group. Overall fecal N was increased ($P < 0.08$) using either supplement or fertilizer application. Results suggest that supplementing cattle grazing warm-season pastures will improve performance compared with fertilization with no negative consequence to pasture quality.

Key Words: beef cattle, warm-season pasture, supplement

T260 Nutritional assessment and productive response in tropical sheep fed with conserved agricultural byproducts in Ecuador. A. Sánchez-Laiño*[1,2], J. Avellaneda-Cevallos[1,2], D. Zambrano-Gracia[1], E. Torres-Navarrete[1,2], L. Montenegro-Vivas[1], and I. Espinoza-Guerra[1], *[1]Facultad de Ciencias Pecuarias, Quevedo, Los Ríos, Ecuador, [2]Dirección de Investigación Científica y Tecnológica, Quevedo, Los Ríos, Ecuador.*

The nutritional value of corn, rice, and soybean stover (CS, RS and SS) stored dry (12–14% moisture), after ammonification (3% urea), or stored as silage (10.12% molasses+1.0% urea) was determined using 18 tropical sheep. A factorial arrangement 3 (agricultural byproducts) × 3 (conservation methods) within a completely randomized design was applied. The ensiled CS, when compared with RS and SS stored dry and after ammonification, registered the highest ($P < 0.01$) in vivo digestibility coefficient (IVDC) for dry matter (DM: 59.8%); organic matter (OM: 64.9%); ether extract (EE: 60.2%); crude protein (CP: 43.3%); crude fiber (CF: 71.9%); nitrogen free extract (NFE: 50.8%); neutral detergent fiber (NDF: 69.7%); acid detergent fiber (ADF: 62.0%); total digestible nutrients (TDN: 49.8%) and metabolizable energy (ME: 1768 kcal/kg DM). Forty tropical sheep (3 months of age) were used for fattening. A factorial arrangement (3 × 3) + 1 control diet based on *Panicum maximum* Jacq was used within a completely randomized block design. Feed consumption (FC), weight gain (WG), feed conversion ratio (FCR) and carcass yield (CY) were assessed. Profitability was determined by the cost-benefit ratio. With ensiled CS, higher WG (184.3 g/animal/d), FCR (6.08), and CY (49.3%) were obtained. The highest profitability was obtained when ensiled CS (60.8%) and ammoniated SS (60.04%) was provided. The conserved agricultural byproducts enhanced performance compared to the grazing control ($P < 0.01$). According to these results, it is concluded that preservation methods increase the digestibility of the agricultural byproducts and the productive response in tropical sheep documents their value as a staple food for ruminants during the dry season.

Key Words: ruminant, digestibility, byproduct

T261 Effect of Next Enhance with or without Rumensin on performance of growing steers grazing cool-season annual pasture. P. Beck*[1], H. Gray[1], B. Stewart[1], and T. Wistuba[2], *[1]University of Arkansas Division of Agriculture, Hope, [2]Novus International Inc., St. Charles, MO.*

Ionophores have been proven to increase daily gains of growing steers on pasture. Essential oils (such as garlic oils and cinnamon extracts) have recently been found to have ruminal effects with potential to improve performance of growing beef steers. This research was conducted to determine the effects of Next Enhance (NE, 250 mg/d, Novus International Inc.) and Rumensin (R, 200 mg/d, Elanco Animal Health) supplementation on performance of growing steers grazing cool-season annual pasture. In the spring of 2012 (Exp. 1), 24 – 0.8 ha bermudagrass pastures that had been interseeded to either a mixture of cereal rye and annual ryegrass or oats and annual ryegrass the previous fall were stocked with 4 mixed breed beef steers per pasture (average BW 215 ± 4.8 kg) in early March for an 84 d grazing period. In the fall of 2012 (Exp. 2), 20 – 1.6 ha bermudagrass pastures that had been interseeded to cereal rye and annual ryegrass with 4 mixed breed beef steers per pasture (average BW 217 ± 6.7) in mid-November for an 84-d grazing period. Mineral premixes including the treatment materials were blended with soybean hulls and offered to steers in respective pastures 5-d/wk at a rate of 0.9 kg/steer each feeding. Steer BW were collected following a 16-h fast on 28-d intervals. Animal performance data for each year were analyzed as RCBD with a 2 × 2 factorial arrangement of treatments using the mixed procedure of SAS. There were no interactions between R and NE for steer BW or performance in either Experiment ($P \geq 0.17$). Over the 84-d spring grazing period in Exp. 1, NE increased ($P = 0.03$) steer BW by 10 kg, and steer ADG was increased ($P = 0.05$) by 0.06 kg/d, whereas there was no effect of R on steer BW or ADG ($P \geq 0.93$). In Exp. 2, NE had no effect on steer BW ($P = 0.83$) or ADG ($P = 0.77$), whereas R additions increased ($P = 0.05$) ADG by 0.09 kg/d. These results indicate that NE and R have potential to improve performance of steers grazing high quality pastures but additional research is needed to elucidate these effects.

Key Words: beef steer, cool-season annual pasture, Next Enhance

T262 Calf response to summer legumes as a creep grazing option in bermudagrass pastures. R. M. Martin*[1], R. S. Walker[2], G. Scaglia[3], B. Buckley[4], M. W. Alison[5], K. J. Han[6], G. Gentry[7], and W. D. Pitman[2], *[1]LSU Agcenter School of Animal Sciences, Baton Rouge, [2]LSU AgCenter Hill Farm Research Station, Homer, [3]LSU AgCenter Iberia Research Station, Jeanerette, [4]LSU AgCenter Red River Research Station, Bossier City, [5]LSU AgCenter Macon Ridge Research Station, Winnsboro, [6]LSU AgCenter Southeast Research Station, Franklinton, [7]LSU AgCenter Dean Lee Research Station, Alexandria.*

Nutritive value of bermudagrass (*Cynodon dactylon*) pastures can limit growth of nursing calves. Summer legumes with high nutritive value have been evaluated for use by creep grazing in Florida and Georgia with contrasting results. Thus, calf responses to creep grazing and legume species were evaluated at 4 Louisiana locations from mid-summer to weaning. Each location included pastures with a creep-grazed summer annual legume treatment (CREEP) and a control with similar cattle, grass, and stocking rate but no legume. Legume creeps were planted on 10% of the pasture areas available. Legume species and grazing duration differed among locations with only alyceclover (*Alysicarpus vaginalis*) at the Iberia Research Station, aeschynomene (*Aeschynomene americana*) and cowpea (*Vigna unguiculata*) at the Dean Lee Research Station, cowpea and soybean (*Glycine max*) at the Red River Research Station, and all 4 of the legumes at the Hill Farm Research Station with 83, 96, 60, and 82 grazing d, respectively. Pasture size of 2.5 to 8 ha differed among locations with 2 replications per location except at Hill Farm, which had 3 replications. Initially, grazing was limited by novelty of the legumes and, at Dean Lee, accumulated legume growth (>1 m height and 15,000 kg/ha) despite 17% crude protein concentration of leaves of cowpea and aeschynomene, which was grazed very little. All legumes were heavily grazed at the Hill Farm and Red River with legume availability of approximately 3,000 kg/ha in mid season declining through August and likely limiting legume intake through September. At Iberia, alyceclover provided about 40% of creep swards dominated by bermudagrass, and grass dominance of the novel alyceclover may have limited intake and calf gains. CREEP calves gained more (76 vs. 71 kg per head, $P = 0.062$) at all locations except Iberia where legume accessibility was limited. Earlier grazing of legumes and increased legume availability in September should further increase calf weaning weights with creep grazing; however, creep grazing required substantially more intensive management than did the control treatment.

Key Words: cattle, creep grazing, summer legume

T263 Responses to creep feeding protein to calves for cow-calf pairs grazing limpograss pastures during summer in Florida. A. D. Aguiar*[1], J. M. B. Vendramini[1], J. D. Arthington[1], L. E. Sollenberger[2], M. Hersom[2], J. D. Sanchez[1], and W. L. Ladeira[1], *[1]Range Cattle Research Education Center, Ona, FL, [2]University of Florida, Gainesville.*

Limpograss (*Hermatria altissima* [Poir] Stapf and C.E. Hubb) is a warm-season grass routinely used by cow-calf (*Bos* sp.) producers in South Florida; however, limpograss has low CP concentration, which may limit animal performance. The objective of this study was to test the effects of creep feeding protein supplements to calves on performance of cow-calf pairs grazing limpograss pastures during the summer. The experiment was conducted in Ona, FL from June to August 2012. Treatments were calves receiving 0, 200, or 400 g/d of soybean meal on creep feeding in randomized incomplete block design with 3 replicates for 0, and 200 g/d and 2 replicates for 400 g/d. Twenty-four cow-calf pairs (434 ± 49 and 182 ± 27 kg, respectively) were randomly distributed in 8 limpograss pastures (experimental units; 1.0 ha/pasture; 3 cow-calf pairs/pasture). Cows and calves weights were recorded every 28 d. Herbage mass (HM) and nutritive value was measured every 14 d. The data were analyzed using PROC MIXED with treatment and months as fixed effects, and replicates and its interactions as random effects. There was no difference in HM (mean = 6,645 kg/ha, $P = 0.41$, SE = 686), herbage allowance (HA; mean = 3.4 kg DM/kg LW, $P = 0.67$, SE = 0.4), CP concentration (mean = 10.9%, $P = 0.29$; SE = 0.9), and IVDOM (mean = 50.3%, $P = 0.56$; SE = 3.4) between treatments. Herbage mass and HA decreased from June to July from 8,300 to 5,500 kg/ha and 4.5 to 2.9 kg DM/kg LW, respectively. Conversely, there was an increase in HM from July to August from 5,500 to 6,300 kg/ha. There was a linear ($P = 0.03$) effect of treatments in calf ADG (mean = 0.29, 0.48, and 0.60 kg/d for C, 200 and 400, respectively, SE = 0.07); however, there was no effect of the treatments ($P = 0.47$) on cows ADG (0.07, 0.38, 0.19 kg/d for C, 200, and 400, respectively, SE = 0.15). Both levels of soybean meal supplemented to calves in this study increased ADG of calves grazing limpograss pastures.

Key Words: cow-calf, creep-feeding, performance

T264 Heifer growth and reproductive performance following two levels of fall pasture allocation. B. L. Bailey[1], T. C. Griggs[2], and K. M. Krause*[1], *[1]Division of Animal and Nutritional Sciences, West Virginia University, Morgantown, [2]Division of Plant and Soil Science, West Virginia University, Morgantown.*

The objective of this study was to compare heifer growth and reproductive performance following 2 patterns of gain during the fall grazing season. Three 5-ha fields were selected as blocks in a randomized complete block design for application of grazing treatments. All fields contained cool-season grass-legume mixtures. Spring-born heifers (yr 1, n = 72; yr 2 n = 64; yr 3 n = 67) of primarily Angus background and 246 kg mean BW were allocated to 2 grazing treatments during the fall period each replicated 3 times per year. The fall grazing treatment consisted of daily herbage dry matter (DM) allocation of 3.5 (LOW) or 7.0 (HIGH) % of BW. During the winter feeding period haylage (5.9 kg DM/hd/d, yr 1; 5.4 kg DM/hd/d, yr 2; 5.6 kg DM/hd/d, yr 3) and soybean hulls (1.7 kg DM/hd/d, yr 1; 1.5 kg DM/hd/d, yr 2; 1.8 kg DM/hd/d, yr3) was fed. Heifers were grazed continuously (as one group) throughout the spring and summer during all years. Heifers were synchronized and artificially inseminated (A.I) utilizing a single sire each year. A cleanup bull was used for 35 d. Mean ADG was greater for HIGH heifers (0.40 kg/d) than LOW heifers (0.12 kg/d) during the fall grazing period ($P < 0.0001$). During the winter feeding period, ADG were 0.30 kg/d and 0.39 kg/d ($P < 0.05$) for LOW vs. HIGH heifers. During the spring grazing period, ADG were 1.38 kg/d and 1.30 kg/d ($P = 0.17$) for LOW vs. HIGH heifers. Mean ADG was greater for LOW heifers (0.74 kg/d) than HIGH heifers (0.67 kg/d) during the summer grazing period ($P < 0.05$). Proportion of heifers that reached puberty at the onset of the breeding season did not differ (33% and 34%, $P = 0.82$ for LOW vs. HIGH), although LOW heifers had lower BW at the time of breeding (335 kg vs. 355 kg, $P < 0.05$ for LOW vs. HIGH). No treatment differences occurred for overall pregnancy rates by A.I., (34% vs. 44%, $P = 0.18$) bull (39% vs. 33%, $P = 0.43$), or overall (73% vs. 77%, $P = 0.55$) for LOW vs. HIGH heifers. We interpret these results to indicate that delaying the majority of weight gain until late in heifer development may decrease costs of winter feeding without detrimental effects on reproductive performance.

Key Words: heifer, grazing, reproductive performance

T265 Stocker steer performance on tall fescue or meadow fescue alone or in binary mixture with white clover. M. R. Schaefer*, K. A. Albrecht, and D. M. Schaefer, *University of Wisconsin-Madison, Madison.*

An evaluation of meadow fescue (*Festuca pratensis* L.) in pastures has not been reported in the USA since the early 1900s. This research was conducted to determine effects of either meadow fescue (MF) or tall fescue (TF, *Festuca arundinacea* L.) in binary mixture with white clover (*Trifolium repens* L.) or these species as N-fertilized monocultures on forage and animal performance in Upper Midwest pastures. Treatments were replicated 3 times, and data were collected over 3 grazing seasons. There was no attempt to reseed legume-containing swards. One hundred 80 crossbred beef steers (*Bos taurus*, 257 kg) were rotationally grazed across all pastures using a variable stocking rate to detect treatment differences. White clover persisted similarly ($P < 0.05$) in either grass pasture, and fraction of white clover in the sward decreased as the trial progressed (45, 24, and 14% for years 1, 2, and 3, respectively). The poor persistence of white clover may be attributed to below average rainfall and accentuates the need for a legume adapted to a variety of climatic conditions. Swards containing TF had greater available forage (3200 and 2800 kg/ ha) and lower in vitro true digestibility (82.2 and 84.6%), neutral detergent fiber digestibility (66.5 and 70.6%), and steer ADG (0.84 and 0.98 kg/d) than meadow fescue ($P < 0.05$). Adding white clover to MF and TF swards increased all forage quality variables, steer ADG (0.98 and 0.84 kg/d), animal gain per hectare (780 and 680 kg/ha) ($P < 0.05$) and tended to lower available forage ($P < 0.10$) compared with monoculture pastures. Even though MF containing swards had greater steer ADG, TF had an increased stocking rate ($P < 0.05$) which resulted in similar gain per hectare (720 and 750 kg/ha for TF and MF respectively). Data collected suggests that both grass species are suitable for inclusion in Upper Midwest pastures. The addition of a legume to either grass species increased ADG and gain per hectare, both of which have positive economic implications.

Key Words: fescue, grazing, beef

T266 Bovine lateral saphenous veins exposed to ergopeptine alkaloids do not relax. J. L. Klotz[1], A. Pesqueira*[2], A. F. Branco[3], and D. L. Harmon[2], *[1]USDA-ARS, Forage-Animal Production Research Unit, Lexington, KY, [2]Department of Animal and Food Sciences, University of Kentucky, Lexington, [3]Universidade Estadual de Maringa, Brazil.*

The ergot alkaloid, ergovaline has demonstrated a persistent binding and sustained contractile response in several vascular models. It was hypothesized that different alkaloids isolated from endophyte- (*Neotyphodium coenophialum*) infected tall fescue (*Lolium arundinaceum*) will contribute to this response differently. The objective was to compare contractile-response patterns of single additions of $1 \times 10^{-4} M$ lysergic acid (LSA), lysergol (LYS), ergonovine (ERN), ergotamine (ERT), ergocristine (ERS), ergocryptine (ERP), ergocornine (ERO) and $1 \times 10^{-6} M$ ergovaline (from a tall fescue seed extract; EXT). Lateral saphenous veins were collected from 6 Holstein steers (397 ± 28 kg) immediately after slaughter, sliced into cross-sections, and suspended in myograph chambers containing oxygenated Krebs-Henseleit buffer (95% O_2/5% CO_2; pH = 7.4; 37°C). Treatments were added at 0 min and buffer was replaced in 15-min intervals for a 120-min incubation. The maximum tension (g) and time interval to reach maximum tension were determined for each compound. Percent relaxation and rate of relaxation were determined following maximum tension for each treatment. Contractile response data were normalized to a reference addition of 1×10^{-4} *M* norepinephrine and analyzed as a CRD with repeated measures using mixed models of SAS. All compounds tested produced significant contractile responses ($P < 0.05$). Ergoline alkaloids, LSA, LYS, and ERN reached maximum tension in less time the remaining compounds ($P < 0.05$) and began to relax immediately with LSA having the greatest percent relaxation ($P < 0.05$). The EXT and ergopeptine alkaloids, ERT, ERS, ERP, and ERO all had slower developing contractile responses with a longer interval until maximum tension was achieved. Maximal responses to these alkaloids, however, all persisted for the remainder of the 120-min experiment with negligible relaxation occurring. Persistence of contractile response caused by ergopeptine alkaloids is thought to be the primary contributing factor to vasoconstriction in animals demonstrating signs of fescue toxicosis.

Key Words: bovine, ergot alkaloid, vasoconstriction

T267 Effect of fescue toxicosis on ruminal kinetics, nitrogen and energy balance in Holstein steers. A. F. Koontz*[1], D. H. Kim[1], A. P. Foote[1], J. L. Klotz[2], K. R. McLeod[1], and D. L. Harmon[1], *[1]Department of Animal and Food Sciences, University of Kentucky, Lexington, [2]USDA-ARS, Forage-Animal Production Research Unit, Lexington, KY.*

This study was designed to examine alteration of ruminal kinetics, as well as N and energy balance during fescue toxicosis. Six ruminally cannulated Holstein steers (BW = 217 ± 7 kg) were weight-matched into pairs and pair-fed throughout a crossover design experiment with a 2 × 2 factorial treatment structure. Factors were endophyte (infected, E+ vs. uninfected, E-) and feeding level ($1.8 \times NE_m$, H vs. $1.1 \times NE_m$, L). During each period after 8 d of diet adaptation one steer per pair was ruminally dosed with ground endophyte-infected fescue seed (E+), the other with ground endophyte-free fescue seed for the remainder of the period. In situ degradation of ground alfalfa was determined on d 13–16. Total fecal and urinary collections were performed on d 17–21, with animals placed into indirect calorimetry head-boxes during d 20 and 21for determination of heat production (HP) using the Brower equation. Liquid and particulate passage rates were evaluated using Cr:EDTA and iADF respectively on d 22 and 23. There was no difference ($P > 0.9$) in DMI/$kg^{0.75}$ between endophyte treatments, and DMI/$kg^{0.75}$ was different ($P < 0.01$) between H and L intake by design. Animals on H feeding had higher ($P < 0.01$) water, N, and energy intakes. Energy and N excretion, as well as retained N, DE, ME, RE, and HP were higher ($P < 0.03$) for H v L. There were no differences in retained N, DE, ME, or HP ($P > 0.15$) between endophyte treatments. Neither rate nor extent of in situ degradation was altered by intake level or endophyte treatment ($P > 0.3$). Dry matter percentage and DM weight of rumen contents were increased ($P < 0.01$) by E+ dosing. Particulate passage was decreased by both L feeding ($P < 0.01$) and endophyte ($P = 0.02$). Ruminal liquid passage rate increased ($P = 0.03$) with H feeding. Total VFA concentration increased with both H feeding ($P < 0.01$) and E+ dosing ($P < 0.01$). Despite these differences, the N and energy balance data indicate that reduced weight gain during fescue toxicosis is primarily a function of reduced intake which may be driven by a reduction in ruminal particulate passage rate.

Key Words: bovine, energy, fescue

T268 The fatty acid profile and retention time in the rumen in cattle grazing tropical grasses. D. F. A. Costa*[1], P. Isherwood[1], S. Quigley[1], S. R. McLennan[2], J. De Souza[3], J. Gibbs[4], X. Q. Sun[5], and D. P. Poppi[1], *[1]The University of Queensland, Gatton, Queensland, Australia, [2]The University of Queensland, Brisbane, Queensland, Australia, [3]University of Sao Paulo, Piracicaba, Sao Paulo, Brazil,*

[4]Lincoln University, Lincoln, Canterbury, New Zealand, [5]Northwest A&F University, Yangling, Shaanxi, China.

The objectives of this study were to examine the fatty acid (FA) profile in the rumen fluid (RF) and relate the extent of biohydrogenation (BH) to the retention time (RT) of fluid in the rumen. Four rumen cannulated steers (790 ± 17 kg BW) grazing pastures of C3 ryegrass *Lolium multiflorum* and C4 species, signal grass *Brachiaria decumbens*, stargrass *Cynodon dactylon* and speargrass *Heteropogon contortus*. Each pasture was grazed for 21d followed by 3d collection. On d 22 CrEDTA was used to estimate RT (182 mg Cr/100 kg BW injected via cannula) and RF samples collected at 0, 4, 8, 12, 16, 24, 28, 32 and 48 h after dosing for Cr analysis and at 0, 8 and 16h for FA profile by gas chromatography. One way model analysis was used for RT and repeated measures procedure for FA profile, both carried out using GLM procedure. Speargrass had a longer RT than ryegrass (8 vs. 11 h) while signal and stargrass grasses had intermediate values (10h) with the differences not expected to results in differences in extent of BH due to RT. Palmitic and stearic acids in RF were much higher than in forage plucked samples (PS) but all grasses had similar total saturated fatty acid (TSFA) with a greater degree of saturation for ryegrass. A higher CLAc9,t11 content in RF of steers grazing ryegrass resulted from the higher linolenic concentration in PS but linoleic concentration in RF was lower for those steers. Total unsaturated FA (TUFA) content of RF was reduced markedly compared with the TUFA of the forage with some small differences between forages.

Table 1. Fatty acid profile in PS and in RF samples

T269 Effects of forage type and season on rumen parameters of grazing cattle. D. F. A. Costa*[1], P. Isherwood[1], S. Quigley[1], S. R. McLennan[2], and J. De Souza[3], *[1]The University of Queensland, Gatton, Queensland, Australia, [2]The University of Queensland, Brisbane, Queensland, Australia, [3]University of Sao Paulo, Piracicaba, Sao Paulo, Brazil.*

The objective of this study was to evaluate the effects of forage type and season on retention time (RT) and rumen function of grazing cattle. Four rumen cannulated steers (790 ± 17kg BW) grazing pastures (herbage mass 2600–6200 kg DM/ha) of C3 ryegrass *Lolium multiflorum* and C4 grasses kikuyu *Pennisetum clandestinum*, speargrass *Heteropogon contortus* in the wet season and the latter grass and a legume leucaena *Leucaena leucocephala* in consortium with *Panicum maximum* in the dry season. Each grazing run consisted of 21d followed by 3d collection period. On d 22 CrEDTA was used to estimate RT (182 mg Cr/100 kg BW via cannula) and rumen fluid (RF) samples collected at 0, 4, 8, 12, 16, 24, 28, 32 and 48h after dosing for Cr analysis. Diet crude protein (CP) and dry matter digestibility (DMD) were estimated by fecal NIRS. NH_3N concentration in RF was determined at 0, 8 and 16h. Volatile fatty acids (VFA) concentration was from bulked RF from 0, 8 and 16h and determined by gas liquid chromatography. Speargrass treatment in dry season had the lowest CP and DMD, which was associated with less NH_3N and VFA concentration and a much longer RT. Despite the season of the year speargrass diet had the highest Acetic:Propionic (A:P). Total VFA was intermediate for grasses on wet season and highest for leucaena grass mix. Ryegrass had higher CP and DMD but a similar NH_3N to kikuyu and leucaena/grass mix. The RT of all wet season grasses, including the C3 ryegrass, was similar (even though some small quantitative significant differences) and similar to a leucaena/grass mix in the dry season. Only dry season speargrass had very long RT.

Table 1. Crude protein and DMD estimated by fecal NIR, rumen NH_3N and VFA concentration, A:P and RT of liquid phase in the rumen

Parameter	Ryegrass	Kikuyu	Speargrass (wet)	Speargrass (dry)	Leucaena	SEM
CP (g/kg)	200^{e}	176^{d}	99^{b}	39^{a}	135^{c}	0.56
DMD (g/kg)	68^{d}	62^{c}	59^{b}	49^{a}	58^{b}	0.84
NH_3N (mg/L)	113^{bc}	130^{c}	29^{a}	9^{a}	147^{c}	20.1

T270 Interactions between grazing management and a low level of energy supplementation on ingestive behavior of beef cattle. L. R. D. Agostinho Neto*, J. R. R. Dorea, V. N. Gouvea, D. F. A. Costa, A. V. Pires, M. G. M. F. Santos, and F. A. P. Santos, *University of Sao Paulo, Piracicaba, Sao Paulo, Brazil.*

The objective of this trial was to evaluate the effect of 2 pregrazing canopy heights and 2 levels of energy supplementation on ingestive behavior of Nellore steers grazing intensively managed tropical grass during the rainy season. Treatments were a control (mineral supplementation) and a low level of energy supplementation (0.3% BW of fine ground corn) combined with 2 pregrazing canopy heights (25 and 35 cm). Eight 48-mo-old rumen-cannulated steers (343 kg BW ± 5.97) were assigned to 2 4x4 Latin squares and allocated in 2 ha of *Brachiaria brizantha* pasture. Ingestive behavior was evaluated through a 24-h observation period in which grazing, rumination and resting activities were monitored every 5 min. Bite and ingestion rates were also evaluated Grazing time decreased when 25 cm of canopy height and energy supplementation were used (78.3 and 39.7 min, respectively). The rumination time was not affected by energy supplementation and pre-grazing canopy height. However, resting time increased when the grazing management was 25 cm. Energy expenditure for maintenance could be reduced by this fact, resulting in an increased animal performance. The pregrazing canopy height of 25 cm increased ingestion rate what possibly is related to a higher harvest efficiency, but no further effects were observed for energy supplementation. A higher bite rate was also observed for the 25 cm grazing management also indicating a higher harvest efficiency and consequently more dry matter intake. The pregrazing canopy height of 25 cm was determinant to improve harvest efficiency, but there was little influence of low level of energy supplementation on ingestion behavior.

T271 Interactions between grazing management and a low level of energy supplementation in beef cattle. L. R. D. Agostinho Neto[1], J. R. R. Dorea*[1], V. N. Gouvea[1], D. F. A. Costa[1], A. V. Pires[1], L. G. R. Pereira[2], and F. A. P. Santos[1], *[1]University of Sao Paulo, Piracicaba, Sao Paulo, Brazil, [2]Empresa Brasileira de Pesquisa Agropecuaria, Juiz de Fora, Minas Gerais, Brazil.*

The objective of this trial was to evaluate the effect of 2 pregrazing canopy heights and 2 levels of energy supplementation on voluntary intake and ruminal parameters of Nellore steers grazing intensively managed tropical grass. Treatments corresponded to control (mineral supplementation) and a low level of energy supplementation (0.3% of BW of fine ground corn) combined with 2 pregrazing canopy heights (25 and 35 cm), with a common stubble height of 15 cm for all treatments. Eight 48-mo-old rumen-cannulated steers (300 kg BW ± 5.97) were assigned to two 4 × 4 Latin squares and allocated in 2 ha of *Brachiaria brizantha* pasture. Chromium oxide was used as an indigestible marker. Concentration of purine derivatives in the urine was used to estimate microbial synthesis. Forage intake decreased for 35 cm of canopy height and for use of energy supplementation (1.03 of substitution rate). The total and energy intake were not affected by energy supplementation. However, grazing management of 35 cm decreased both total and energy intake. Ruminal pH was affected only by grazing management, but remained above 6.0. Concentration of NH_3N decreased with grazing management and energy supplementation whereas microbial synthesis was not affected by either. The N retention decreased when the pre-grazing canopy height was 35 cm. Interactions between management and supplementation were not significant. Pre-grazing canopy of 35 cm affects intake and may result in lower animal performance; these effects were more significant on voluntary intake than responses to a low level of energy supplementation.

T272 Effects of resistant starch in milk replacer on fecal volatile fatty acids and pH and performance in neonatal Holstein calves. C. C. Williams*, B. F. Jenny, B. L. Fisher, A. H. Dolejsiova, E. L. Chartier, and E. Eckelkamp, *LSU AgCenter, Baton Rouge, LA.*

Resistant starch (RS) may help in preventing intestinal disturbances in calves. Thirty female Holstein calves were assigned to 1 of 3 treatments at 2 d of age to study effects of adding commercial resistant wheat starch to milk replacer (MR) on growth and health. Treatments were 0, 4, or 8g RS mixed into reconstituted MR. Calves were housed in hutches and fed MR until 56 d of age. MR was fed once daily according to body weight (BW), 10% of BW containing 15% solids. Initial amount of MR fed was based on birth weight and was increased at 7, 14, 21, and 28 d according to BW change and then held constant until weaning at 56 d. An 18% crude protein calf starter was offered ad libitum beginning on d 29 throughout the duration of the trial. Water was offered ad libitum beginning on d 3. Calves remained in hutches until d 70 to determine post weaning performance. BW was determined at birth and weekly throughout the trial. Wither height (WH), hip height (HH) and hip width (HW) were measured on d 7, 14, 28, 42, 56, and 70 of age. Feed intake and fecal scores were recorded daily. Fecal samples were collected weekly beginning at d 7 for analysis of pH and volatile fatty acids (VFA). Blood was collected on d 14, 28, 42, 56, and 70 for analysis of hematocrit (HCT), plasma urea nitrogen (PUN) and total protein (TP). Effects of treatment, week, and their interactions were analyzed using the MIXED procedure of SAS. HCT, PUN and TP did not differ ($P > 0.05$) and were within normal ranges suggesting no major metabolic problems. There was no effect ($P > 0.05$) of treatment on BW, HH, HW, WH, or fecal scores. There was a week effect ($P < 0.01$) for grain intake, with all calves increasing intake throughout the duration of the study. There was a week effect ($P < 0.01$) for fecal scores, with calves having lower fecal scores at the end of the study compared with the beginning. There was no effect ($P > 0.05$) of treatment on fecal pH or concentrations of VFA. Overall, incorporation of RS in the milk replacer of neonatal dairy calves did not show any significant effects on growth or gut health of Holstein dairy calves.

Key Words: dairy calf, resistant starch, milk replacer

T273 Effects of a simplified feeding program on growth and rumen development of dairy calves C. Julien*[1,2], B. Gestes[1,2], C. Lacroux[3], C. Bayourthe[1,2], and F. Enjalbert[1,2], *[1]INRA, UMR1289 TANDEM, Tissus Animaux Nutrition Digestion Ecosystème et Métabolisme, Castanet-Tolosan, France, [2]Université de Toulouse, INPT ENSAT, INP-ENVT, UMR1289 TANDEM, Castanet-Tolosan, France, [3]UMR INRA ENVT 1225, Interactions Hôte Agent Pathogène, Ecole Nationale Vétérinaire de Toulouse, 23 Chemin des Capelles, Toulouse, France.*

The experiment aimed at testing the effect of a simplified feeding program on growth and rumen development of dairy calves ("Technique Once a Day," Bonilait-Protéines, France). It was carried out on 16 male Holstein calves from birth (d1) to weaning (d63) moved to individual pens at birth. Two feeding programs were tested. Each one was based on a milk replacer (MR), with the same proportions of dairy proteins (from skim milk powder and/or whey protein concentrate) and the same chemical composition: 20% CP and 18% fat, on DM basis. Calves were divided into 2 groups at 4 d of age: (1) OAD (n = 8): calves received MR once a day (200 g/L of MR), (2) TAD (n = 8): calves received MR (125 g/L) twice a day; volume distributed per calf and per meal varied with age but did not differ between groups leading to a total of 34.1 and 40.9 kg/calf of MR over 63d for OAD and TAD, respectively. The week before weaning, all calves received MR once a day. All calves received water, wheat straw and a starter concentrate (16.6% CP) ad libitum. Four calves per group were harvested at weaning. Reticulo-rumen, omasum and abomasum were emptied, cleaned and weighted separately and carcass weight (CW) was recorded. Rumen epithelium was sampled at a fixed location (ventral sac) and fixed in a neutral 10% formaldehyde solution. Rumen papillae (RP) were counted and averaged on 3 1cm^2 areas by image analysis (Visilogue 6.5 Noesis, France). The mucosa was observed for histopathologic investigation. Body weight of calves averaged 45.9 ± 5.7 kg and 96.3 ± 11.4 kg at birth and weaning, respectively, without significant difference between treatments. Total stomachs weight (5.2% of CW, on average) and relative weights of reticulo-rumen (62.9%), omasum (16.8%) and abomasum (20.3%) did not differ with treatment. The RP count were higher ($P = 0.03$) for OAD calves (84.8 RP/cm^2) than TAD (64.7 RP/cm^2) and no pathologic abnormality was detected. Simplifying dairy farmer practices by giving MR once a day to dairy calves is possible without compromising calves' growth and reticulo-rumen development but effects on welfare remain not evaluated.

Key Words: calf, rumen, papillae

T274 Comparison of planes of nutrition on growth performance and rumen papillae development of dairy calves. J. A. Davidson*[1], B. L. Miller[1], H. C. Puch[1], T. J. Earleywine[2], K. M. O'Diam[3], and K. M. Daniels[3], *[1]Purina Animal Nutrition Center, Gray Summit, MO, [2]Land O'Lakes Animal Milk Products, Shoreview, MN, [3]Ohio Agricultural Research and Development Center, The Ohio State University, Wooster.*

The objective was to determine if the plane of nutrition combinations of specific protein:fat milk replacer and starter affect the growth performance of dairy calves from 0 to 84 d of age and subsequently altered the rumen papillae surface area. Holstein bull calves (n = 16) were assigned to 1 of 2 nutritional programs: conventional (C) or full potential (FP). Conventional program consisted of feeding 454 g DM/d of a 20:20 milk replacer and 18% CP starter. Full potential program consisted of 818 g DM/d of a 28:20 milk replacer followed by increased feeding rate to 1136 g DM/d at d 10 of age and 22% CP starter. Milk replacer was offered twice daily from 0 to 44 d of age, and calves were weaned (d 45) with 50% reduction in milk replacer DM for 6 d. Starter was offered ad libitum from 0 to 84 d of age. Body weight (BW, kg) and hip height (HH, cm) measurements were completed every 2 weeks. Calves were euthanized at 28, 56, or 84 d of age (2 per program at each age) to examine ruminal papillae characteristics. Four regions of the rumen were analyzed for muscle and sub-mucosal thickness, and length and area of the papillae. On d 42, 49, 56, and 84, calves fed FP had greater BW gains of 11.0, 8.9, 7.5, and 4.7 kg (SE = 2.77, $P = 0.05$) over gains of C fed calves. Average gains of frame were also greater for FP of (SE = 1.08, $P = 0.02$) relative to C fed calves. Sub-mucosal thickness and papillae area were different ($P < 0.05$) for age and region of rumen. Greatest increases of sub-mucosal thickness were observed in the caudal ventral region from d 28 to 84 of age, regardless of nutritional program. At d 28 of age, papillae area and length could not be measured digitally. At d 56, the ruminal papillae area were 4.8 and 6.5 mm^2 for FP and C fed calves, whereas at d 84 ruminal papillae area were 11.6 and 9.5 mm^2, regardless of region (SE = 1.55, ns). Growth performance was greater for calves fed a FP program, whereas rumen papillae area and sub-mucosal thickness increased similarly with age, regardless of the nutritional program.

Key Words: calf, papillae, growth

T275 Whole oats effects on digestive system development in neonatal dairy calves. F. X. Suarez-Mena*[1], A. J. Heinrichs[1], T. M. Hill[2], and C. M. Jones[1], [1]*The Pennsylvania State University, University Park,* [2]*Nurture Research Center, Provimi North America, Lewisburg, OH.*

The objective of this experiment was to study effects of whole oats in starter grain on digestive system development of pre-weaned calves. Male Holstein calves (n = 8, 42.5 ± 2.0 kg BW at birth) were fitted with a rumen cannula in wk 2 of life. Calves were housed in individual pens in a heated facility; bedding was covered with landscape fabric to avoid any consumption of bedding. Water was offered free choice, and milk replacer was fed to 12% of birth BW. A fixed amount of starter (containing 25% oats either ground and in the pellet or whole) was offered daily based on average intakes of calves on similar milk replacer diets; orts were fed through the cannula. Calves were randomly assigned to all pelleted starter (P, n = 4) or pellets plus whole oats (O, n = 4). Rumen contents were sampled at −8, −4, 0, 2, 4, 8, and 12 h after grain feeding for pH determination at wk 3, 4, and 5 of age. At 35 ± 1 d of age calves were euthanized, and organs were harvested, emptied, rinsed, and weighed to gauge digestive organ development. Total starter intake (3 wk; 4,596 P vs. 4,449 O ± 111 g) was not different ($P > 0.05$). Digestive organ mass was analyzed as a percentage of BW at harvest. Reticulorumen (0.81 P vs. 0.81 O ± 0.05%) and liver (2.21 P vs. 2.25 O ± 0.08%) were not different ($P > 0.05$). Omasum (0.16 P vs. 0.19 O ± 0.01%) was greater ($P < 0.05$), and abomasum (0.40 P vs. 0.46 ± 0.02%) had a tendency to be greater ($P < 0.10$) for O. Rumen papillae length (0.67 P vs. 0.59 ± 0.05 mm), width (0.48 P, 0.45 O ± 0.02 mm), and rumen wall thickness (0.96 O vs. 0.90 O ± 0.09 mm) were not different ($P > 0.05$). Average rumen digesta pH at 3 wk of age (6.32 P vs. 6.22 O ± 0.16) was higher ($P < 0.01$) than at 4 (5.93 P vs. 5.85 O ± 0.16) and 5 (5.86 P vs. 5.74 O ± 0.16) wk; pH was not different ($P > 0.05$) between treatments. Whole oats had no effect on reticulorumen weight or rumen papillae size but increased omasum and abomasum weight. Lack of treatment effect on papillae may be related to calves eating grain for only 3 wk. Rumen digesta pH decreased with age likely as a consequence of greater intake of starch and digestible nutrients.

Key Words: calf, rumen development, oats

T276 Puberty attainment is affected by growth performance before 4 mo of age in dairy heifers. V. Lollivier[1,2], F. Dessauge[1], M. Boutinaud*[1], and Y. Le Cozler[1,2], [1]*INRA UMR1348PEGASE, Saint Gilles, France,* [2]*Agrocampus Ouest, UMR1348 Pegase, Rennes, France.*

In seasonal calving systems where heifers first calved at a young age, age at 1st insemination may be delayed for those born at the end of the calving period. A possible alternative is to increase growth intensity during the 1st year of rearing, and then, to reduce age at 1st calving (21 mo of age or less). Puberty should then occur at an early age for optimal fertility. A long-term experiment aiming at studying the effect of controlled growth intensity throughout feeding procedure is being conducted since 2009 including 60 to 70 Holstein heifers / year. In 2012, the effect of rearing intensity on puberty attainment was closely studied on 65 heifers born between August 26 and December 27, 2011. Animals born before December 1 were either fed a standard (SD) or an intensive (ID) diet from 0 to 6 mo of age, to reach 190 to 200 kg or 220 to 230 kg at 6 mo of age, respectively. Animals born after received ID until artificial insemination (AI). From 5.5 mo of age, blood samples were obtained from jugular vein every 10 d to determine plasma progesterone concentration. The plasma progesterone analyses were performed with AIA 360 robot. The intra- and inter-assay variabilities were 12.3 and 7.5%, respectively. Blood samples were collected until synchronization or AI. Single Anova analyses were performed through R Software. Puberty was detected on 56 animals, at an average age of 10.2 (±2.0) mo and 296 (±37) kg body weight (BW). Age varied between 6.2 and 14.4 mo, whereas BW was comprised between 224 and 369 kg. Because of huge ADG variations within feeding regimen and limited number of observations, no effect of SD or ID was noted on puberty onset. Puberty occurred earlier when average daily gain (ADG) before weaning (77 to 80 d of age on average) increased (9.7 vs. 10.8 mo when ADG varied from less than 700 g/d to 700 g/d or more respectively; $P < 0.05$). To a lesser extent, ADG from weaning to 4 mo of age also affected puberty onset. In agreement with previous published studies, this study indicates that enhanced growth program during lactating phase and/or early stages of rearing may affect puberty attainment.

Key Words: heifer, puberty, onset

T277 The effect of various dilutions, milk replacer dry matter, and volume amounts on calf growth and performance. T. J. Earleywine, B. L. Miller, W. S. Bowen Yoho*, and T. E. Johnson, *Land O' Lakes, Inc., Webster City, IA.*

Feeding an established volume of milk replacer (MR) solution without regard for dry matter (DM) by lowering the percentage solids is being done by producers. The objective of this study was to examine the effects of delivering a more dilute solution at the same volume on calf growth and performance. One hundred thirty-three (133) 3–10 d old Holstein calves with an average initial BW of 47.6 kg (SD = 2.21 kg) were shipped from Wisconsin to the Land O' Lakes Research Facility. Calves were randomly assigned according to BW and blood gamma globulin to one of 4 27% all milk protein/10% fat MR diets varying in dilution, MR DM, and volume amount. Days 8–49, treatments were as follows: High Solids, High DM, Low volume (HS/HDM/LV; 17.6% solids, 1.13 kg DM, 6.62 L solution/d); Medium Solids, High DM, Medium volume (MS/HDM/MV; 15% solids, 1.13 kg DM, 7.8 L solution/d); Medium Solids, Low DM, Low volume (MS/LDM/LV; 15% solids, 0.97 kg DM, 6.62 L solution/d); Low Solids, High DM, High volume (LS/HDM/HV; 12.6% solids, 1.13 kg DM, 9.2 L solution/d). Days 1–7, calves were offered the same % solids and 72% of MR DM stated above, with volume amounts adjusted accordingly. Calves were fed MR twice per day. Offering of MR was reduced by half, and calves fed once per d, during the last wk. Calf starter (22% crude protein, as fed basis) was fed ad libitum throughout this 49 d trial. Data were analyzed by Mixed Procedures of SAS. While there were no statistical differences ($P > 0.05$) in total BW gain, starter feed intake, or feed:gain, calves fed the MS/LDM/LV diet were numerically lower in total BW gain and numerically higher in starter feed intake when compared with calves on all other treatments. When considering offering a more dilute MR solution, it is important to deliver the same amount of MR DM to calves by offering more MR solution to support adequate growth of calves.

Table 1.

	MR Diet				
Item[1]	HS/HDM/LV	MS/HDM/MV	MS/LDM/LV	LS/HDM/HV	SE

T278 The effect of varying fatty acid profile on growth and performance of calves fed milk replacer. B. L. Miller*, T. J. Earleywine, W. S. Bowen Yoho, and T. E. Johnson, *Land O' Lakes, Inc., Webster City, IA.*

In 2 separate trials, the growth and performance of calves fed milk replacer (MR) varying in protein level, fat level, and fatty acid profile were examined. Thirty-five (35) and 67 (67) 3- to 10-d-old Holstein bull calves with average initial weights of 46.6 kg (SD = 2.83 kg) and 47.9 kg (SD = 2.79 kg) were shipped from Wisconsin to the Land O' Lakes Research Facility for trials 1 and 2, respectively. Calves were randomly assigned according to body weight (BW) and blood gamma globulin to their respective MR diet offered in a 17.6% solids solution. Calves on trial 1 were assigned to 1 of 2 MR diets: 28% crude protein (CP), 20% fat with lard as the primary fat source; 27% CP, 10% fat with medium-chain triglycerides (MCT) as the primary fat source. Calves on trial 2 were assigned to 1 of 3 diets: 28% CP, 20% fat with lard as the primary fat source; 27% CP, 10% fat with MCT as the primary fat source; 26% CP, 10% fat with MCT as the primary fat source. Calves were fed to provide 816 g DM/d during d 1 – 7, and 1135 g DM/d during d 8 – 42, in 2 feedings at 0600 and 1515 h. Calves were offered 567.5 g in one feeding at 0600 h during the last week. Calf starter (22% CP, as fed basis) was fed ad libitum throughout these 49 d trials. Data were analyzed by Mixed Procedures of SAS. For trial 1, calves fed a 28:20 MR with lard as the primary fat source were inferior ($P < 0.05$) in starter feed intake, MR consumption ($P < 0.05$), and body volume gain ($P < 0.05$), and tended ($P = 0.14$) to be inferior in total weight gain, compared with calves fed a 27:10 MR with MCT as the primary fat source. For trial 2, total weight gain did not differ among treatments. Calves fed a 28:20 MR were inferior ($P < 0.05$) in starter feed intake to calves fed a MR with lower CP and fat (26:10 and 27:10). Calves fed a 28:20 MR were superior in feed:gain when compared with calves fed the 26:10 MR, but did not differ from calves fed the 27:10 MR. Milk replacers with a modified fatty acid profile may allow for a reduction in protein and fat levels without negatively affecting growth and performance.

Key Words: calf, milk replacer, fatty acid

T279 Efficiency of IgG absorption in fresh or pasteurized colostrum of various qualities. S. L. Gelsinger*, C. M. Jones, and A. J. Heinrichs, *The Pennsylvania State University, State College.*

Previous data show improved IgG absorption in calves when fed pasteurized colostrum. However, this has not been compared using colostrum of very low or very high quality. This study was conducted to investigate this phenomena using colostrum of various qualities. Colostrum was sorted based on colostrometer measurement. This process was completed in summers of 2011 and 2012, and sorted colostrum was pooled to create 6 unique batches. Half of each batch was rebottled to be fed without heat treatment. The second half of each batch was heated to 60°C for 30 min, then subsequently cooled and bottled. All colostrum was frozen until fed. Colostrum treatments were analyzed for standard plate count, coliforms, non-coliform gram-negative bacteria, IgG1, and IgG2. Plasma samples were collected from 145 calves 48 h after birth and analyzed for IgG1, IgG2, total protein, and hematocrit. All IgG analysis was done using a bovine IgG1 or IgG2 ELISA and values were combined to calculate total IgG and apparent efficiency of absorption (AEA). Heat-treatment significantly reduced all types of bacteria. Colostral total IgG concentrations were 83.5, 89.7; 66.1, 52.4; 45.2, and 32.0 in the high, mid-range, and low batches from 2011, 2012, respectively. Plasma IgG levels and AEA were analyzed using Mixed procedure in SAS. Sex of calf, colostrum batch, treatment and batch by treatment interaction were included as fixed effects and calf within treatment was included as a random effect. As expected, calves fed colostrum containing more IgG attained higher plasma IgG1 and IgG2 concentrations at 48 h ($P < 0.05$). Heat treatment of colostrum increased plasma IgG ($P < 0.05$) and tended to increase AEA. Female calves tended to have greater total IgG concentrations than male calves ($P = 0.05$). Results of this study suggest that heat-treatment of colostrum increases absorption of IgG in colostrum of various qualities including very high and very low quality.

Key Words: colostrum, heat-treatment, calf

T280 Performance of crossbred Holstein bull and heifer calves slaughtered 8-month old. M. Vestergaard*[1], P. Spleth[2], A. Mikkelsen[3], C. F. Børsting[3], and M. Kargo[1,2], *[1]Aarhus University, Foulum, Denmark, [2]Knowledge Centre Agriculture, Aarhus, Denmark, [3]Cattle Research Centre, Tjele, Denmark.*

Most newborn bull calves of the Holstein (HOL) dairy breed in Denmark are raised intensively at specialized units and harvested at either 10 or 12–13 mo of age as young bulls. To be sold as veal in EU, the calf needs to be harvested before 8 mo. The market for rosé veal in EU requests a higher carcass conformation score (>4.5) than HOL bull calves can match. Use of sexed semen to produce HOL heifer calves on the genetically best cows allows for crossbreeding with beef breeds. The objective was to investigate if use of crossbreeding will produce offspring that can match the market requirement for rosé veal. A total of 12 purebred HOL bull calves (HOL), 12 beef × HOL bull (BULX) and 12 beef x HOL heifer (HEIX) calves were purchased at 4 wk of age. Two sires were used; one Limousine and one Belgium Blue (6 calves per crossbreeding group). Calves were fed milk replacer (850 g/d), grass hay and concentrate until weaning at 8 wk of age, and then gradually changed to a high-energy TMR based on concentrate pellets, corn-cob silage (35% of DM in TMR), ground barley, sugar beet pulp, and soybean and canola meal fed ad libitum until slaughter at 8 mo. The concentrate pellets (1.4 kg/calf/d) were removed from the TMR at 200 kg BW. Individual feed intake was recorded from 4 to 8 mo. Energy intake was not different between trt groups. At 4 mo, HOL, BULX and HEIX weighed 142, 154 and 140 kg (n.s.), ADG from 4 to 8 mo was 1.50, 1.68 and 1.46 kg/d ($P < 0.001$), BW at slaughter was 330, 368 and 323 kg ($P < 0.001$), and FCE was 4.2, 4.0 and 4.4 Scandinavian Feeding Units (= 7.89 MJ NEg) per kg gain for HOL, BULX and HEIX, respectively ($P < 0.02$). Dressing percentage increased from 51.3 in HOL to 55.5 and 52.8 in BULX and HEIX, respectively, leading to carcass weights of 162, 196 and 164 kg with conformation scores of 3.5, 6.5 and 5.5, respectively (both $P < 0.001$). No HOL but all 12 BULX and 11 out of 12 HEIX passed the 4.5 conformation score criteria. It is concluded that both crossbred male and female offspring of HOL cows can be utilized for rosé veal production in EU.

Key Words: veal, crossbreeding, growth

T281 Comparison of two nutritional programs from birth to 84 d of age in Holstein steers: Body composition, body weight, and stature. K. M. Daniels*[1], K. M. O'Diam[1], C. J. O'Diam[1], T. J. Earleywine[2], H. C. Puch[3], B. L. Miller[3], and J. A. Davidson[3], *[1]Department of Animal Sciences, Ohio Agricultural Research and Development Center, The Ohio State University, Wooster, [2]Land O'Lakes Animal Milk Products Co., Shoreview, MN, [3]Purina Animal Nutrition Center, Gray Summit, MO.*

To compare effects of 2 nutritional programs on body composition, BW, and stature in dairy calves from 0 to 84 d of age, Holstein steers (n = 12) were assigned to either conventional (Con) or full potential

(FP) feeding and were slaughtered at 28, 56, or 84 d of age. Con were fed 454 g DM/d of a 20:20 milk replacer (MR) and 18% CP starter. FP were fed 818 g DM/d of a 28:20 MR followed by increased feeding rate to 1136 g DM/d at d 10 of age and 22% CP starter. MR was offered twice daily from 0 to 44 d of age; calves were weaned (d 45) with 50% reduction in MR DM for 6 d. Starter was offered ad libitum from 0 to 84 d of age. Hip height, BW, body length and heart girth measurements were obtained every 2 wk. At slaughter, animals were processed into: carcass; head, hide, feet, and tail (HHFT); blood; and total viscera. Body composition (water, protein, lipid) was estimated by analysis of 9–11th rib sections. All data were analyzed with a mixed model; weekly data were analyzed with repeated measures. Regardless of age, FP weighed more, were taller, longer, and had larger heart girths than Con. Estimated carcass composition averaged 72.3% water, 18.7% protein, and 6.7% lipid. Regardless of age, body protein content tended to be greater (0.5%) in FP ($P = 0.09$). At 28 d of age, lipid content was 1.0% greater in FP, whereas at 84 d of age Con had 2.5% more lipid than FP ($P = 0.04$). Water content was not affected by diet, but decreased with increasing age ($P = 0.01$). FP tended to have greater protein:fat than Con, which is indicative of better lean gain (3.2 vs. 2.2; $P = 0.07$). As calves aged, percentage of final BW occupied by the carcass decreased ($P = 0.03$), whereas percentage occupied by viscera increased ($P = 0.01$). Nutritional program did not affect percentage of final BW occupied by: carcass, HHFT, blood, or total viscera. These averaged 53.8, 15.1, 5.2, and 25.9%, respectively. FP resulted in heavier and larger framed calves with fairly similar body composition as Con.

Key Words: dairy calf, body composition, nutrition

T282 Survival of *Bifidobacterium animalis* ssp. *lactis* BB-12 in yogurt drink is influenced by timing of probiotic addition. Z. Ba*, E. J. Furumoto, and R. F. Roberts, *Department of Food Science, Pennsylvania State University, University Park.*

Probiotic containing yogurts and yogurt-based drinks have become increasingly popular for their potential health benefits. Viability of the probiotic throughout the shelf life of these products is a critical quality parameter. The effect of time of bacterial addition into the product on survival has not been well studied. As part of an ongoing study designed to compare the efficacy of *Bifidobacterium animalis* ssp. *lactis* BB-12 (BB-12) delivered by yogurt-based smoothie drink and tablets on immune status, fecal transit time, and fecal microbiota, the timing of addition of the probiotic on survival of BB-12 in the yogurt drinks over 4 weeks of storage at 4°C was evaluated. The 2 yogurt drink treatments, (A) BB-12 added after yogurt fermentation and (B) BB-12 added before fermentation were formulated to have 23% total solids and <1% fat. The target concentration of BB-12 per 240-gram serving was log 10 ± 0.5 cfu, commonly considered an effective daily dose. Three bottles of each yogurt drink from 6 batches were analyzed. Population of BB-12 was determined by pour plating method on selective medium MRS-NNLP followed by anaerobic incubation at 37°C after 0, 1, 2, 3, and 4 weeks of storage at 4°C. No statistical difference in the population of BB-12 between treatments A and B was detected immediately following manufacture (wk 0) (initial counts of log 10.52 ± 0.05 cfu/serving and log 10.49 ± 0.14 cfu/serving, respectively). As expected the population of BB-12 declined throughout the shelf life of the products. However, the population decreased faster in treatment A than in treatment B resulting in a significant difference after 2 weeks of storage. This trend continued and at the end of shelf life the BB-12 concentration had decreased significantly in both treatment A (log 9.64 ± 0.06 cfu/serving) and treatment B (log 10.18 ± 0.13 cfu/serving) after 4 weeks of storage. The BB-12 survived significantly better in B than that in A ($P = 0.000$) indicating that BB-12 survives better when added before fermentation, possibly as a result of adaptation to the acidic environment.

Key Words: BB-12, survival, yogurt drink

T283 Pectin-whey protein microparticles containing probiotics: Release and survival of *Lactobacillus acidophilus* La5 in simulated gastrointestinal conditions. C. Gebara, K. S. Chaves, M. C. E. Ribeiro, F. N. Souza, C. R. F. Grosso, and M. L. Gigante*, *University of Campinas, Campinas, SP/Brazil.*

Once microparticles produced by ionotropic gelation are porous, the coating of particles with different materials has been proposed to increase the protective effect for the delivery of probiotics. The aim of this study was to evaluate the release and survival of *Lactobacillus acidophilus* La5 microencapsulated by ionotropic gelation with Ca^{2+} using pectin as wall material, and covered by electrostatic interaction with whey protein heat treated (80°C/30 min) or without heat treatment when exposed to conditions simulating the passage through the gastrointestinal tract. The simulated conditions were assayed with artificial gastric juice, at pH 3.0 with addition of mucin and pepsin at 37°C for 120 min, followed by artificial intestinal juice at pH 7.0 with addition of pancreatin for 300 min. A randomized block with 3 replications was used. The effect of time of exposure to simulated gastric juice and simulated intestinal juice on the viability of free and microencapsulated *Lactobacillus acidophilus* was assessed by ANOVA and the significant differences were evaluated by Tukey's test at 5% significance level. Microencapsulation conferred greater protective effect to *Lactobacillus acidophilus* La5 as compared with the free cells. However, the coating of pectin microparticles with whey protein did not confer additional protection to probiotics when exposed to simulated gastrointestinal conditions. The pectin microparticles remained intact when exposed at pH 1.2, 3.0 and after 300 min at pH 7.0. On the other hand, both microparticles coated with whey protein heat treated or without heat treatment have remained intact for 120 min exposure to simulated gastric juice but have disintegrated after 300 min exposure to simulated intestinal juice (pH 7.0). This occurrence suggests that the probiotics would be released in a different part of the intestinal tract whether delivered by one microparticle or another. Acknowledgments: FAPESP.

Key Words: probiotics, microencapsulation, microcapsules

T284 Influence of some medicinal spices on the bile tolerance of *Streptococcus thermophilus* ST-M5. M. Sanchez-Vega*[1] and K. Aryana[1,2], [1]*School of Animal Sciences, Louisiana State University Agricultural Center, Baton Rouge,* [2]*Department of Food Science, Louisiana State University Agricultural Center, Baton Rouge.*

Spices such as onion, garlic, turmeric, and ginger are known for their medicinal properties such as being antimicrobial, and their potential for the treatment of cancer and cardiovascular diseases. *Streptococcus thermophilus* is a culture bacterium having health beneficial effects. Bile tolerance is an important probiotic characteristic. Although most studies use non water soluble spice extracts, the effect of pure spice juice on bacterial performance is not known. The objective was to elucidate the effect of spices on the bile tolerance of *Streptococcus thermophilus* ST-M5. Bile tolerance of *S. thermophilus* was analyzed using MRS broth supplemented with 0.3% (wt/vol) oxgall and 1% (vol/vol) of freshly extracted spice juice. Sample without spice juice acted as a control. Samples were incubated at 37°C for 5 h, in which they were removed hourly for plating for plating. Growth was determined by plating every hour for a period of 5 h. *S. thermophilus* was incubated aerobically at 37°C for 48 h. Data were analyzed using Proc Mixed model with a Tukey adjustment of Statistical Analysis System. Experiments were conducted in triplicate. Counts at 0 and 1 h of incubation were 10 and 9 log cfu/mL respectively. None of the 4 spices showed any significant ($P > 0.05$) difference in counts when compared with control up to 1 h. After 2 h of incubation, there were significantly lower counts for garlic, with a reduction of 1.3 log cfu/mL when compared with control. At 3 h of incubation, all spices showed significant lower counts when compared with control, with an average reduction of 1.8 log cfu/mL, except for onion whose reduction was 1.4 log cfu/mL. After incubating for 4 and 5 h, all spices showed significant lower counts when compared with control, with a maximum reduction of 3.1 log cfu/mL for garlic and a minimum of 2 log cfu/mL for onion. Although these spices showed significantly lower counts, *S. thermophilus* was still viable, showing that these spices can be used alongside with this probiotic bacterium allowing health benefits from both sources.

Key Words: spice, probiotic

T285 Effect of month on the composition and quality of milk from Holstein cows in a hot-arid environment. J. Méndez*[1], M. Mellado[1], F. G. Véliz[1], M. A. de Santiago[1], J. E. García[1], and A. Zúñiga[1], [1]*Autonomous Agrarian University Antonio Narro, Saltillo, Mexico,* [2]*Autonomous Agrarian University Antonio Narro, Torreon, Mexico.*

This study was designed to evaluate the month of the year on the variation of milk composition and microbial content of intensively-managed Holstein cows in northern Mexico (26°N). The milk samples were obtained from about 3,200 cows, which were sampled 4 times per month from January to December of 2011 and 2012. Bacteriological analyses were performed daily in the bulk tank milk. The MIXED procedure of SAS with the PDIFF option was used to detect differences among mean monthly milk components, somatic cell counts and bacteriological measurements. Non-linear analyses were also performed to describe the monthly trend of milk composition and quality. Only month was accounted for in the models with year included as covariable. A quadratic (U-shaped; $r^2 = 0.86$) model best described the relationship between month of the year and total solids, with the highest ($P < 0.05$) value in November (12.27%) and the lowest in July (12.03). Also, a U-shaped trend ($Y = 3.23 + 0.22/1 + 0.08x - 0.001 x^2$; $r^2 = 0.95$) showed the best fit to the relationship between month and milk protein content, with the highest level (3.22%; $P < 0.01$) in December and the lowest (3.12%) in April. A clear decrease during the warmer months ($Y = 8.73–0.52x/1–0.058x-0.0001x^2$; $r^2 = 0.93$) was observed for non-fat solids but no differences among month for this variable was detected. Differences in the milk content of urea nitrogen (range 12.28–13.39 mg/dL), lactose (range 4.75–4.82%), fat (range 3.36–3.44), coliform bacteria counts (range 18.3–68.33 cfu/ml), standard microbial count and somatic cell counts (range 236,149–295,335 cells/mL) were not detected among months. The thermoduric strain of bacteria count showed a v-shaped tendency ($Y = 0.14–0.06 \cos(-0.02x + 0.14)$; $r^2 = 0.83$) with the highest ($P < 0.05$) values in the coldest months and the lowest values in the summer. This results show that, except for lactose, coliform bacteria counts and urea nitrogen milk content, all other milk components and microbiological variables showed a noticeable depression during the hottest month of the year.

Key Words: coliform, somatic cell count, milk protein

T286 Development of a pilot test system for demonstration and evaluation of CIP cleaning. Y. Yu* and R. Roberts, *Department of Food Science, The Pennsylvania State University, University Park.*

Cleaning in place (CIP) is widely used in the dairy industry. Electrolyzed oxidizing (EO) water offers an attractive alternative to traditional chemicals for cleaning and sanitation. EO water is produced via electrolysis of a dilute sodium chloride solution, which results in a sodium hydroxide solution (pH ~11.0 and ORP ~ 1168 mV) and an acidic solution (pH ~2.5, ORP ~ −850 mV and >100 ppm of chlorine). Walker et al. (2005) evaluated EO water as a cleaning agent for on-farm milking systems and found it to be effective in a cleaning/sanitizing system. The use of EO water in CIP applications for heated dairy processing systems has not been evaluated. In this project, a pilot scale system was constructed to allow evaluation and optimization of EO water as CIP agent for dairy processing equipment. The test system was composed of a 4-gallon double jacked stainless steel vessel, whose temperature could be controlled by running cooling or heating media through the jacket, a probe and microprocessor based chart recorder for monitoring temperature during fouling and cleaning, a variable frequency drive pump, and a static spray ball for CIP cleaning. A range of pump speeds were evaluated and it was determined a flow rate of 8.3 L/min provided adequate coverage for CIP cleaning of the system using a riboflavin removal method. A 4-step CIP procedure for the test system was developed. The effectiveness of cleaning was assessed using ATP bioluminescence and residual protein detection, which is comparable to a standard manual cleaning procedure. Results indicated the system would serve as a suitable test bed for optimization of CIP procedure using EO water. Preliminary experiments using EO water in a 4-step manual cleaning procedure suggested that EO water can serve as a suitable cleanser for dairy processing equipment. With the test system validated experiments are underway to optimize temperature and time required for cleaning the system soiled with cold milk and when soiled during heating of milk. Use of this test system to demonstrate principals of cleaning in a senior level dairy products processing course will also be presented.

Key Words: CIP, EO water

T287 Development of a fresh cheese model to evaluate novel antilisterials. M. L. Van Tassell*[1], L. Vazquez-Portalatin[2], S. R. Takhar[1], and M. J. Miller[1], *[1]University of Illinois at Urbana-Champaign, Urbana, [2]University of Puerto Rico at Mayaguez, Mayaguez.*

Hispanic-style fresh cheeses such as queso fresco are difficult to preserve without compromising delicate organoleptic properties. Inherently low salt content, neutral pH, and high water activity predispose such cheeses to carriage and proliferation of *Listeria monocytogenes.* Incorporation of novel antimicrobials into cheese-making processes for investigating antilisterial activity is complicated by manufacturing constraints. Consequently, few studies have focused on in situ testing of antilisterials in fresh cheeses despite evidence of discrepancies between in vitro and in situ efficacy of many antimicrobial compounds in food matrices. To allow for high-throughput testing of novel antilisterials incorporated into fresh cheeses directly, we have developed a small-scale laboratory queso fresco model that can be completed in a biosafety cabinet. Milk of variably scaled batches can be blended with desired antimicrobials and mixed with rennet before being divided into microcentrifuge tubes for incubation. Cheese production is carried out in vitro, including centrifugation to replace conventional pressing techniques. *Listeria* can be incorporated at any step to replicate diverse contamination scenarios and recovery from the final cheeses can be carried out with common selective media. We have validated this model with nisin and commercial fermentate, clearly demonstrating detection of listerial inhibition over a multi-week shelf-life. This model allows for rapid and convenient production of small-scale fresh cheeses for screening antilisterials in an appropriate food matrix.

Key Words: cheese, *Listeria*, antimicrobial

T288 Antimicrobial susceptibility profile and toxigenic genes detection in *Staphylococcus* spp. samples isolated from Brazilian artisanal cheeses. D. L. S. Oliveira[1], L. S. Carmo[2], L. B. Acurcio[1], R. D. Castro[1], F. M. Sant'Anna[1], C. F. A. M. Penna[1], M. O. Leite[1], L. M. Fonseca[1], S. H. C. Sandes[3], A. M. Silva[4], M. M. O. P. Cerqueira*[1], and M. R. Souza[1], *[1]Departmento de Tecnologia e Inspecao de Produtos de Origem Animal, Escola de Veterinaria, Universidade Federal de Minas Gerais, Belo Horizonte, Minas Gerais, Brazil, [2]Fundacao Ezequiel Dias, Belo Horizonte, Minas Gerais, Brazil, [3]Departamento de Genetica, Instituto de Ciencias Biologicas, Universidade Federal de Minas Gerais, Belo Horizonte, Minas Gerais, Brazil, [4]Universidade Federal de Sao Joao Del Rey, Sete Lagoas, Brazil.*

The objective of this study was to detect the presence of enterotoxin coding genes and analyze the antimicrobial susceptibility profile of 15 *Staphylococcus* spp. samples isolated from Serra da Canastra artisanal cheeses produced in Brazil. The bacterial identification was made through molecular techniques based on the amplification of a fragment of rDNA 16S gene. The detection of *sea*, *sec*, *sed* and *see* was carried

out by PCR-Multiplex and *seb* and *tst* by individuals PCR-Uniplex. Antimicrobial susceptibility profile was determined according to the disc diffusion method. The 15 samples of *Staphylococcus* spp. were identified as *S. aureus* ssp. *aureus* (67%), *S. saprophyticus* ssp. *bovis* (20%) and *S. warneri* (13%). No gene for synthesis of classic staphylococci toxins was identified in none of the analyzed samples. Regarding the antibiogram, the 15 tested samples presented, in general lines, low resistance to the 20 tested antimicrobials. All samples presented resistance to sulfonamide. Resistance was also observed to penicillin (80% of the samples), ceftazidime (60%) and oxacillin (40%). Although, for the other 16 tested antimicrobials, resistance rates were below 30%. A total of 26.7% of the samples were resistant to ciprofloxacin, tetracycline, ampicillin and amoxicillin, and 13.3% to chloramphenicol, sulfatrim and nitrofurantoin. The other tested drugs (vancomycin, gentamicin, clindamycin, eritromicin, imipenem, cefoxitin, amikacin, ceftriaxone and cefaclor) were efficient against 100% of the tested samples. Although *Staphylococcus* spp. tested samples were not able of producing enterotoxins and TSST-1, they can represent public health risk due to phenotypic resistance to most common antimicrobials used in animal and human therapies.

Key Words: *Staphylococcus*, PCR-multiplex, antimicrobial susceptibility

T289 Analysis of a genetically distinct strain of the monomorphic subspecies *Bifidobacterium animalis* ssp. *lactis,* the complete genome of *Bifidobacterium animalis* ssp. *lactis* ATCC 27673. J. R. Loquasto*[1], R. Barrangou[1,2], E. G. Dudley[1], B. Stahl[2], and R. F. Roberts[1], [1]*Department of Food Science, Penn State University, University Park,* [2]*DuPont Danisco USA Inc., Madison, WI.*

Bifidobacterium animalis ssp. *lactis* (BAL) is a widely consumed probiotic microorganism, commonly added to a variety of foods, including fermented dairy foods such as yogurt. Characteristics making this subspecies desirable for use as a probiotic include its perceived health benefits as well as technological advantages over organisms in the same genus. The genomes of 9 strains of this subspecies have been sequenced and are publicly available. Analysis of these genomes reveals very little genetic diversity leading to the term "monomorphic" being used to describe subspecies. In previous work, Delétoile et al. (2010) used multilocus sequence typing (MLST) to characterize several bifidobacterial species and revealed BAL ATCC 27673 had a unique MLST type. As part of an effort to assess the genetic diversity in the *B. animalis* ssp. *lactis* group, this strain was chosen for full genome sequencing. Following DNA isolation, 454 shotgun pyrosequencing was conducted, contigs were aligned and assembled using the genome of BAL DSM 10140 as a reference scaffold and the genome was closed using a combination of PCR and Sanger sequencing. The full genome of ATCC 27673 was 1,963,012 bp long, contained 1,616 genes, 4 rRNA operons and had a G+C content of 61.55%. Further analysis revealed 5 distinct genomic islands differing from other strains of the same subspecies. In 4 islands, either mobile genetic elements or phage elements are present. In island 5, the largest island, a novel CRISPR locus was identified. This locus contains 81 novel spacers different from any spacers observed in other strains of BAL. In addition BAL ATCC 27673 was found to contain a type I-E CRISPR-cas system, whereas all other strains of this subspecies contain a type I-U system. This analysis revealed ATCC 27673 represents a novel strain of *B. animalis* ssp. *lactis*, differing substantially from other stains of the subspecies. This work suggests that the 9 commercial strains sequenced to date may represent only a limited portion of the genetic potential of this subspecies.

Key Words: *B. animalis* ssp. *lactis*, probiotic

T290 Microbiological quality of nonfat dry milk and skim milk powder produced in the United States A. K. A. Ali*, K. E. Smith, K. J. Burrington, and J. A. Lucey, *Wisconsin Center for Dairy Research, University of Wisconsin–Madison, Madison.*

Microbiological quality of nonfat dry milk powder/skim milk powder (NFDM)/(SMP) is important as it can affect the quality of food products in which the powder is used as an ingredient. The objectives of this study were to determine the microbiological quality of domestically produced NFDM/SMP. In this study, 23 samples of NFDM/SMP were obtained from 4 US processors for analysis. Samples were 25 kg or 50 pound bags of powder of low, medium and high heat NFDM/SMP that have not been agglomerated or instantized and were approximately 6 to 9 mo old. Total bacterial count, aerobic thermophiles, thermoresistant bacteria, coliforms, yeasts and molds, as well as, bacterial spores including mesophilic aerobic, mesophilic anaerobic, thermophilic aerobic, and thermophilic anaerobic were determined. Powders were <10 cfu/g for coliforms, thermoresistant bacteria, yeasts and molds. Total bacterial count for powders had a range of 2.0–2.9 $\log_{10}$ cfu/g with differences due to powder manufacturer. Samples had a large variation in thermophilic aerobic bacteria numbers with a range of 2.1–4.8 $\log_{10}$ cfu/g. While the numbers of mesophilic aerobic spores and thermophilic anaerobic spores did not show notable variations, the numbers of thermophilic aerobic spores varied greatly with a range of $1 < -4.1$ $\log_{10}$ cfu/g. The high numbers of thermophilic aerobic spores observed with samples from some producers may be explained by their presence on the surfaces of the equipment and/or the formation of biofilms on stainless steel surfaces. There was no significant variation among powders based on heat classifications or between NFDM and SMP. The results of this work indicate that the microbiological quality of powders was source dependent regardless of heat classifications or whether the product was NFDM or SMP. Based on the results, powders from some manufactures may be better suited to low-spore count applications than powders from other producers.

Key Words: NFDM/SMP, bacterial spore, microbiological quality

T291 Real-time PCR and TTGE for rapid and sensitive detection of *Staphylococcus aureus* in Ras and Domiati cheese during ripening. S. Awad*, *Department of Dairy Science and Technology, Faculty of Agriculture, Alexandria University, Alexandria, Egypt.*

Microbial diversity in cheese is considered essential to the sensory richness and variety of traditional Egyptian cheeses. However, some members of these complex communities may also be responsible for cheese flavor defects or may constitute a health risk. Being able to characterize the microbial communities in raw milk and follow the dynamics of the entire populations throughout the cheese-making and ripening processes is therefore critical. *Staphylococcus aureus* is a bacterial pathogen considered a principal etiological agent of food poisoning. The aim of this study was to apply real-time PCR-based method (TaqMan RT-PCR) comparing with temporal temperature gradient electrophoresis (TTGE) technique to detect *S. aureus* in Doimiati and Ras cheeses during their ripening periods. In parallel, all cheese samples were examined to conventional methods to ensure the detection limit of 10^0 cfu per gram. In this study, *S. aureus* was detected in all Ras and Domiati cheeses after 2 mo of ripening by using TTGE. The results of real time PCR showed that the *S. aureus* could not be detected in fresh cheese samples using TTGE method but it detected in fresh cheese sample using real time PCR. The real time PCR method could be used for *S. aureus* detection as a faster, highly specific, and more sensitive alternative to microbiological method with the potential for providing of improved food-processing hygiene control.

Key Words: real-time PCR, TTGE, *Staphylococcus aureus*

T292 Development of a rapid SNP-typing assay to differentiate *Bifidobacterium animalis* ssp. *lactis* strains used in probiotic-supplemented dairy products. S. Lomonaco*[2], E. J. Furumoto[1], J. R. Loquasto[1], P. Morra[2], and R. F. Roberts[1], *[1]Department of Food Science, Penn State University, University Park, [2]Dipartimento di Scienze Veterinarie Università degli Studi di Torino, Grugliasco TO, Italy.*

Identification at the genus, species, and strain level is required when a probiotic microorganism is added to foods. Strains of *Bifidobacterium animalis* ssp. *lactis* (BAL) have been commonly used worldwide in dairy products supplemented with probiotic. However, strain discrimination is difficult, given the high degree of genome identity (99.975%) between different genomes of this subspecies. Typing of monomorphic species can be efficiently carried out by targeting informative single nucleotide polymorphisms (SNPs). Findings from a previous study analyzing both reference and commercial strains of BAL detected SNPs that could be used to discriminate 14 groups/strains. This abstract describes the development of a primer extension reaction (PER) assay targeting multiple SNPs that can allow strain differentiation of *B. animalis* ssp. *lactis*. Based on previous data, 7 informative SNPs were selected for further testing and a multiplex preliminary PCR was optimized to amplify the 7 DNA regions comprising the selected SNPs. Extension primers (EPs), annealing immediately adjacent to the selected SNPs, were tested in simplex PER to evaluate their performance. Twenty strains belonging to 13 groups were selected and PERs were carried out on according to manufacturer's instructions (SNaPshot Multiplex System from Applied Biosystems), with minor modifications. Fragment analysis was subsequently carried out in duplicate at the Penn State University Genomics Core Facility. Simplex PER mostly gave rise to a peak of the expected color, specific to the targeted SNP and 8 specific profiles could be observed, separating the most commonly used commercial strains. Further tests will be necessary to fully assess the discriminating capacity of each EPs and to optimize a multiplex PER assay able to simultaneously interrogate the selected SNPs. Such a novel multiplex PER approach can represent a simple, rapid, flexible SNP-based subtyping method for proper characterization and identification of commercial probiotic strains of BAL from fermented dairy products.

Key Words: *Bifidobacterium animalis* ssp. *lactis*, strain identification, SNaPshot

T237 Studying the microbiological safety criteria and quality related problems of the traditional Kishk Sa'eedi. S. Awad*[1], M. El Soda[1], A. Ahmed[1], I. Nagady[1], C. Mestres[2], and D. Pallet[2], *[1]Department of Dairy Science and Technology, Faculty of Agriculture, Alexandria University, Alexandria, Egypt, [2]CIRAD (Agricultural Research for Development), Montpellier Cedex 5, France.*

Kishk Sa'eedi is an indigenous food that is part of the rich food heritage of Egypt. The name "Kishk" refers to a group of popular fermented dairy cereal mix products common to Egypt and the Middle East within the framework of the European funded "AFTER" Project (African Food Tradition rEvisited by Research). The natural microflora in Kishk Sa'eedi were studied and characterized. An inventory of both the technological flora (lactic acid bacteria) and pathogenic germs (*Salmonella* sp., *Listeria* sp., *Clostridium* sp., *Staphylococcus aureus* coagulase positive, *Brucella* spp., yeasts, and molds) were analyzed in the final product. During the microbiological analysis of raw materials and final product, lactic acid bacteria that could potentially act as starter cultures were isolated and identified. The isolates were identified using rep-PCR as *Lactobacillus acidophilus, Lb. helveticus, Lb. del. bulgaricus, Lb. del. lactis, Lb. casei, Lb. paracasei, Lb. plantarum, Lb. rhamnosus, Lb. brevis, Lb. fermentum.* The technological criteria (stability of lyophilized, acidification, activity flavor development, antagonistic activities, slimy production, peptidase activity, antibiotic resistance and amines production) were determined for all isolates. Mixing cultures were selected to produce the second generation Kishk Sa'eedi.

Key Words: Kishk Sa'eedi, lactic acid bacteria, pathogenic bacteria

Nonruminant Nutrition: Amino Acids and Energy

T293 The National Animal Nutrition Program. G. L. Cromwell*[1], T. J. Applegate[2], D. C. Beitz[3], M. L. Galyean[4], M. B. Hall[5], M. D. Hanigan[6], J. Odle[7], W. P. Weiss[8], and C. Kirk Baer[9], *[1]University of Kentucky, Lexington, [2]Purdue University, West Lafayette, IN, [3]Iowa State University, Ames, [4]Texas Tech University, Lubbock, [5]USDA/ARS, Madison, WI, [6]Virginia Tech University, Blacksburg, [7]North Carolina State University, Raleigh, [8]The Ohio State University, Columbus, [9]U.S. Department of Agriculture, Washington, DC.*

The National Animal Nutrition Program (NANP), initiated in 2010, is supported as a National Research Support Project (NRSP-9) with Hatch funds administered by the US Department of Agriculture. Funds for NRSPs are drawn from the total federal allocation before the formula distribution to state agricultural experiment stations. The NANP focuses on addressing challenges facing researchers in animal agriculture and filling voids in the research and academic communities. An integrated and systematic approach is used to share, collect, assemble, synthesize, and disseminate science-based information, educational tools, and enabling technologies for agricultural animal nutrition, with emphasis on beef, dairy, swine, and poultry. The NANP also facilitates high-priority research across domestic agricultural species. The purpose of the NANP is to identify the current state of coordination and networking within animal nutrition; explore animal nutrition over time, across geographic locations, by topic, and by networks of collaborators in animal nutrition research; define high-priority animal nutrition issues; and address existing collaborations to facilitate solutions to these issues. The committee will interact with the National Research Council on critical national priorities in animal nutrition and provide a forum to address research support needs. The NANP consists of a coordinating committee (listed as authors) appointed by NRSP-9's Administrative Advisors (N. M. Cox, KY; B. W. Hess, WY; D. A. Benfield, OH; C. Faustman, CN). The coordinating committee oversees 2 additional committees: (1) a modeling committee that will improve the use of predictive technologies and tools, enable use of common software platforms, and work with researchers to develop and share models and modeling information; and (2) a feed composition committee that will assemble data and research resources on feed composition, foster communication among those collecting feed composition information, and improve efficiency and consistency in data collection and maintenance. Ongoing details regarding the activities and accomplishments of the 3 committees are posted on the NANP website: http://www.ca.uky.edu/nrsp-9/index.htm.

Key Words: animal nutrition, NANP, NRSP

T294 The National Animal Nutrition Program: Feed composition committee. P. S. Miller*[1], R. N. Dilger[2], W. P. Dozier[3], M. B. Hall[4], A. N. Hristov[5], V. R. Moreira[6], M. L. Nelson[7], N. R. St-Pierre[8], and W. P. Weiss[9], *[1]University of Nebraska, Lincoln, [2]University of Illinois, Urbana-Champaign, [3]Auburn University, Auburn, AL, [4]USDA/ARS, Madison, WI, [5]Pennsylvania State University, University Park, [6]Louisiana State University, Baton Rouge, [7]Washington State University, Pullman, [8]The Ohio State University, Columbus, [9]The Ohio State University, Wooster.*

A feed composition committee has been developed in conjunction with the National Animal Nutrition Program (NANP). This committee is supported and funded as a National Research Support Project (NRSP-9). The NRSPs are initiated by the use of Hatch funds administered by US Department of Agriculture and are drawn from the total federal allocation before the formula distribution to state agricultural experiment stations. The committee is moving forward with the following objectives: (1) Collect information on feed composition from the published literature and other critically evaluated sources and maintain a current collection of that information as a resource to the research community; (2) Develop a forum to exchange and collate information on methods of analysis, with links to sources and critiques to provide a resource to the research community and identify gaps in our ability to analyze feeds to stimulate development of new techniques; (3) Identify assays or methods that have or proven to have potential benefits to diet formulation. Thus, the overall approach of the committee is to gather data and information critical to the development of feed ingredient composition repositories for the major livestock species (beef, dairy, poultry, and swine). A major focus of the committee is to work with current and future National Research Council (NRC) committees to facilitate development and revision of ingredient databases for NRC nutrient requirement reports and to bring consistency to the databases used for the reports. Also, the committee is working closely with the NRSP-9 committee on modeling to support needs regarding ingredient composition data as model inputs. Presently, the committees' activities are posted on the NANP website: http://www.ca.uky.edu/nrsp-9/index.htm. The feed composition committee has initiated its work with data sets used by previous NRC species committees. Design of an overall database structure is currently underway. Input templates for the database have been developed for beef, dairy, poultry, and swine. The committee will solicit data from the scientific literature and industry sources focusing primarily on information derived from North America.

Key Words: feed composition, database

T295 Accuracy of predicting digestible energy of corn for growing pigs from various data sources. R. Allen, A. Hassen*, B. Smith, M. Hinds, C. Iiams, D. Rice, D. Sevenich, F. Owens, D. Jones, and T. Sauber, *DuPont Pioneer, Johnston, IA.*

The objective of the current study was to evaluate accuracy of predicting swine digestible energy (DE) of corn based on Near-Infrared Transmittance Spectroscopy (NIT) scans and models, cross-species relationships, and literature equations. DE content of 83 corn grain samples was determined from total collection of feces using uniform sets of barrows (16 to 18 kg initial BW) of similar genetic background. Diets contained 89.5% ground corn supplemented with casein, minerals and vitamins. Nitrogen-corrected apparent metabolizable energy (AME_N) for these 83 corn grain samples was determined with 3-wk old broiler chicks. DE and AME_N data were initially analyzed using mixed models. The model for AME_N analysis included fixed effects of study, corn source within study and random effects of block and error; the DE model included the same fixed effects as AME_N and random effects of run within study, room within study and run, pig within study and room and error. Check means were used as a covariate in each model. Data from 66 corn samples were used for model development; the remaining 17 were used for cross-validation based on stratified random sampling procedure. NIT spectra data from each whole grain sample were used to develop NIT based predictions of swine DE (NIT-DE) and poultry AME_N (NIT-AME_N). Models were then developed to predict swine DE from AME_N and NIT-AME_N. Simple linear equations proved adequate to predict swine DE from either AME_N or NIT-AME_N (R^2 and root mean square error (RMSE) ranged from 0.71 to 0.73 and 53 to 54 kcal/kg, respectively). Validation test showed a similar prediction capability from either AME_N or NIT-AME_N with correlation (r) between observed and predicted values ranging from 0.88 to 0.92, and RMSE from 43 to 52 kcal/kg. Direct NIT prediction of DE from spectra data (NIT-DE) showed a comparable fit (r = 0.91 and RMSE = 48 kcal/kg). Published literature equations when combined with wet chemistry analyses showed

the weakest fit to measured DE (r = 0.51; RMSE of 112 kcal/kg). Relative DE of corn grain samples for growing pigs can be calculated reliably from measurements of poultry AME_N, NIT-AME_N or direct NIT scans.

Key Words: swine, poultry, corn

T296 Energy and amino acid digestibility of camelina meal fed to finishing pigs. R. K. Kahindi*[1], T. A. Woyengo[2], P. A. Thacker[3], and C. M. Nyachoti[1], *[1]University of Manitoba, Winnipeg, MB, Canada, [2]University of Alberta, Edmonton, AB, Canada, [3]University of Saskatchewan, Saskatoon, SK, Canada.*

This experiment was conducted to determine the apparent ileal (AID) and standardized ileal (SID) AA digestibility as well as the DE and ME content of camelina meal fed to finishing pigs. Six ileal cannulated barrows (80.2 ± 7.5 kg BW) were fed 2 diets in a 2-period cross over design to give 6 replicates per diet. The diets were a corn-soybean meal-based basal diet formulated to meet NRC (1998) nutrient requirements for 50 to 80 kg pig as well as the basal diet with a portion of the AA-yielding ingredients (corn and soybean meal) replaced with 20% camelina meal. The basal diet was fed to determine nutrient digestibility and retention by the difference method. The SID of N and AA was calculated using published values for ileal basal endogenous AA losses from our laboratory and NE was calculated using values from proximate analysis. Titanium dioxide (0.3%) was included in the diets as an indigestible marker. The GE, CP, Lys, Met, Thr, EE, NDF, ADF and glucosinolate content of camelina meal (on a DM basis) were 5,130 kcal/kg, 38.08, 1.80, 0.68, 1.68, 11.90, 31.46, 20.30% and 36.30 µmol/g, respectively. The AID and SID of N for camelina meal were 58.30 and 65.20%, respectively. The SID values of Lys, Met and Thr for camelina meal were 57.89, 53.39 and 52.48%, respectively whereas the corresponding standardized ileal digestible contents on a DM basis for the same AA were 1.04, 0.36 and 0.84%, respectively. The DE, ME, and NE values for camelina meal were 4185, 3,857, and 1,951 kcal/kg, respectively. In conclusion, camelina meal can be used as an energy and AA source in swine diets and the SID AA and DE and ME values of camelina meal from the current study could be used when formulating diets to minimize N excretion and feed costs.

Key Words: camelina meal, digestibility, pig

T297 Effect of levels of digestible lysine and ractopamine on the performace of castrated pigs from 70 to 97 kg. D. O. Fontes*[1], I. S. Fernandes[1], D. M. S. Junior[1], L. P. O. Souza[1], B. O. Rosa[1], I. J. Silva[1], A. P. L. Brustolini[1], V. S. Cantarelli[1,2], and G. M. Salum[1], *[1]Federal University of Minas Gerais, Belo Horizonte, Minas Gerais, Brazil, [2]Federal University of Lavras, Lavras, Minas Gerais, Brazil.*

A total of 180 hybrid barrows (initial and final body weight of 70.8 ± 3.78 and 97 ± 7.3 kg) were used to evaluate the effects of ractopamine (RAC) and digestible lysine (Lys) levels on late finishing pig performance. Pigs were blocked by weight and time and randomly allotted to one of 15 dietary treatments in a 27d experiment. There were 2 pigs per pen and 6 pens per treatment. Pigs were fed corn and soybean meal based diets formulated to meet the NRC (1998) requirements, with the exception of digestible lysine which were adjusted to satisfy the level of treatments. Treatments were arranged as a 3 × 5 factorial with main effects of RAC (0, 5 and 10ppm) and digestible lysine (0.50, 0.65, 0.80, 0.95, and 1.1%). The diets were isocaloric (3,23 Mcal/kg) and isoproteic (12,6%). The levels of lysine were obtained by the addition of L-lysine-HCl and to meet the ideal protein concept, where necessary, supplementing the diets were the other essential amino acids. The parameters evaluated were BW, ADG, ADFI and G:F. Significant effect of digestible Lys was evaluated by the regression of the observed variable on digestible Lys level of diet while means of ractopamine supplemented animals were compared by SNK test at 10% probability level. Interaction was observed between lysine and ractopamine for BW, ADG and G:F ($P < 0.05$). No interactions were observed ($P > 0.05$) for ADFI and digestible lysine intake. The recommended level of digestible Lys was 0.8, 0.91 and 1.1% for diets without and with 5 and 10 ppm RAC respectively for best values of final BW and ADG. For G:F the values were 0.53, 0.96 and 0.98% of digestible Lys, respectively. Thus, considering the values obtained and the best data adjustment, it can be concluded that for the better performance of finishing barrows the digestible lysine requirement was 0.8, 0.96 and 1.1%, which corresponds to an intake of digestible lysine of 23.51, 28.04 and 32.57 g/day for diets without and with 5 and 10 ppm RAC, respectively.

Key Words: swine, amino acid, requirement

T298 Determination of digestible and metabolizable energy concentrations in oilseed meals fed to growing pigs. A. R. Son* and B. G. Kim, *Konkuk University, Seoul, Republic of Korea.*

An experiment was conducted to determine digestible energy (DE) and metabolizable energy (ME) concentrations in feed ingredients including sesame meal (SM), 3 sources of soybean meal (SBM), high-protein distillers dried grains (HPDDG), perilla meal (PM), cannola meal (CNM), copra meal (CM), corn germ meal (CGM), palm kernel expeller (PKE), and tapioca distillers dried grains (TDDG). Twelve barrows with an initial BW of 31.8 ± 2.7 kg were individually housed in metabolism crates equipped with a feeder and a nipple drinker. A 12 × 10 Youden square design was employed with 12 dietary treatments, 10 periods, and 12 animals. A basal diet mainly consisted of corn and SBM was prepared to contain 15.6% CP, 0.68% standardized ileal digestible Lys, 0.47% Ca, and 0.21% available P. Eleven additional diets were formulated to contain 30% of each test ingredient. The quantitative feed and feces method using Cr2O3 as an indigestible marker was used for fecal collection with 4-d adaptation and 4-d collection periods. The statistical model for the mixed procedure of SAS included dietary treatment as fixed variable, and animal and period as random variable. Values for the DE and ME in the 3 sources of SBM were greater ($P < 0.05$) than other test ingredients except HPDDG (Table 1). Values for DE:GE in the 3 sources of SBM were greater ($P < 0.05$) than all other test ingredients. In conclusion, SBM has greater energy concentrations than most oilseed meals and has greater energy digestibility than other oilseed meals fed to growing pigs.

Table 1. Nutrient composition (%) and energy values (cal/g) of test ingredients fed to growing pigs, as-fed basis

Ingredient	DM	CP	GE	DE	ME

T299 Energy value of dried distillers grains with solubles and oilseed meals for pigs. C. Kong* and O. Adeola, *Purdue University, West Lafayette, IN.*

The energy values of 3 dried distillers grains with solubles (DDGS) derived from corn, triticale and sorghum, and 3 oil seed meals including canola meal (CM), cotton seed meal (CSM), and sunflower seed meal (SSM) were determined in 2 studies. Twenty-four crossbred barrows with average initial BW of 28.0 kg were grouped by weight into 6 blocks with 1 pig per metabolism crate in each study. There were 4 diets in each experiment consisting of a corn-soybean meal reference (RD) diet and 3 test diets (TD). The TD consisted of each of 3 DDGS (Exp. 1), or 3 oil seed meals (Exp. 2) that partly replaced the energy yielding sources in the RD at 300 g/kg (Exp.1) or 200 g/kg (Exp. 2) such that same ratios were maintained for all energy ingredients across all experimental diets. The DE, apparent metabolizable energy (AME), and nitrogen-corrected AME (AME_n) of the test ingredients were determined by the difference method in 2 studies each consisting of a 5-d adjustment and 5 d of total but separate collection of feces and urine. The respective DM or GE of corn DDGS, triticale DDGS, sorghum DDGS, CM, CSM, and SSM were 918, 927, 904, 912, 907, and 898 g/kg; or 4,985, 4,913, 4,785, 4,616, 4,829, and 4,122 kcal/kg of DM. Addition of DDGS to RD in Exp. 1 decreased dietary DE, AME and AME_n of the TD. In Exp. 2, the respective energy values of the TD were not affected by the addition of oil seed meals to RD with SSM, which decreased ($P < 0.01$) the energy values. In conclusion the DE, AME and AME_n were 3,751, 3,559, and 3,361 kcal/kg of DM, respectively, for corn DDGS; 3,720, 3,537, and 3,315 kcal/kg of DM, respectively, for triticale DDGS; and 3,520, 3,355, and 3,228 kcal/kg of DM, respectively, for sorghum DDGS. Furthermore, the DE, AME, AME_n of SSM for pigs were 2,449, 2,253, and 2,071 kcal/kg of DM, which were lower ($P < 0.01$) than the energy values evaluated for CM and CSM at 3,577, 3,428, and 3,087 kcal/kg of DM, respectively for CM; and 3,281, 3,139, and 2,892 kcal/kg of DM for CSM.

Key Words: dried distillers grains with solubles, energy, pigs

T300 Amino acid digestibility in copra expeller and palm kernel expeller by growing pigs. A. R. Son*[1], Y. Hyun[2], J. K. Htoo[3], and B. G. Kim[1], *[1]Konkuk University, Seoul, Republic of Korea, [2]Farm Story Dodram B&F, Seoul, Republic of Korea, [3]Evonik Industries AG, Hanau, Germany.*

An experiment was conducted to determine the apparent ileal digestibility (AID) and the standardized ileal digestibility (SID) of crude protein (CP) and amino acids (AA) in copra expeller (CE) and palm kernel expeller (PKE) by pigs. The CE contained 89.9% DM, 20.2% CP, 7.1% ether extract, 54.4% NDF, and 6.7% ash; and the PKE contained 91.9% DM, 17.2% CP, 7.1% ether extract, 66.7% NDF, and 4.0% ash on an as-fed basis. Six boars fitted with a T-cannula in the distal ileum with an initial BW of 65.2 kg (SD = 5.4) were individually housed in pens equipped with a feeder and a nipple drinker. A replicated 3 × 3 Latin square design was employed with 3 dietary treatments, 3 periods, and 6 animals. Two experimental diets were prepared to contain 40% of the CE or PKE as the sole source of nitrogen. A nitrogen-free diet was formulated mainly based on cornstarch and sucrose to estimate the basal endogenous losses of CP and AA. All diets contained 0.5% chromic oxide as an indigestible index. The statistical model for the mixed procedure of SAS included dietary treatment as fixed variable and replication, animal within replication, and period within replication as random variable. The values for the AID of all indispensable AA except His and Lys in the CE were greater ($P < 0.05$) than in the PKE. The values for the SID of CP (67.6 vs. 52.8%), Arg (90.0 vs. 80.4%), Leu (78.5 vs. 72.9%), Met (82.1 vs. 75.6%), Phe (81.4 vs. 76.4%), Thr (64.4 vs. 55.4%), Trp (66.3 vs. 54.9%), and Val (77.8 vs. 71.6%) in the CE were greater ($P < 0.05$) than in the PKE. The values for the SID of Lys in the CE and PKE (40.3 and 39.1%, respectively) were relatively less than those of other indispensable AA. In conclusion, the digestibility of CP and most AA in the CE was greater than in the PKE, and the values for the AID and SID of Lys were less than other indispensable AA in the CE and PKE.

Key Words: protein supplement, standardized ileal digestibility, swine

T301 Digestible tryptophan:lysine ratios and different protein sources in diets for barrows from 70 to 95 kg. C. Pereira[1], M. Hannas*[1], H. Rostagno[1], L. Albino[1], R. Rodrigueiro[2], J. Htoo[3], and J. Barrera[4], *[1]Federal University of Viçosa, Viçosa, Minas Gerais, Brazil, [2]Evonik Industries, Health & Nutrition, Animal Nutrition Services, São Paulo, São Paulo, Brazil, [3]Evonik Industries AG, Health & Nutrition, Animal Nutrition Services, Hanau-Wolfgang, Germany, [4]University of Tolima, Tolima, Peru.*

The objective of this trial was to evaluate the performance of barrows fed with 2 digestible tryptophan:lysine (Trp:Lys) ratios (18% or 21%) and 2 diets with different protein sources (soybean meal – SBM or soybean meal, meat and bone meal and feather meal – SBM-MBM-FM) during the finishing phase (70 to 95 kg). A total of 96 barrows (69.26 ± 4.97 kg) were distributed in a completely randomized block design. The treatments were arranged as 2 × 2 factorial (2 diets with different protein sources × 2 digestible Trp:Lys ratios) with 12 replicates and 2 animals per pen. The diets were formulated to meet or exceed the nutritional recommendations. The experimental period lasted 24 d and the parameters evaluated were final BW, ADFI, ADG and G:F. The results were analyzed using ANOVA procedure. The test used was F at the 5% significance level. No interaction ($P > 0.05$) was found between diets with different protein sources and Trp:Lys ratios on animal performance. The diets with different protein sources had no effect ($P > 0.05$) on final BW, ADFI, ADG and G:F. There was no significant ($P > 0.05$) effect of digestible Trp:Lys ratio on G:F, however, barrows fed diets with 21% digestible Trp:Lys ratio had better final BW ($P < 0.02$), ADFI ($P < 0.01$) and ADG ($P < 0.01$) than those fed with 18% digestible Trp:Lys ratio. The use of 21% of digestible Trp:Lys in diets resulted in better performance of pigs from 70 to 95 kg. For pigs from 70 to 95 kg the Trp:Lys requirement is greater than 18%. Also, barrows fed diets with SBM or SBM-MBM-FM, formulated on digestible amino basis, showed similar performance during the finishing phase.

Table 1. Growth performance of barrows from 70 to 95 kg

	Ingredient			Dig. Trp:Lys, %			
Item	SBM	SBM-MBM-FM	$P <$ [1]	18	21	$P <$ [1]	CV, %
Final BW, kg	92.62	93.24	NS	91.71	94.20	0.02	3.09
ADFI, g	2732	2724	NS	2650	2810	0.01	5.90
ADG, g	983	989	NS	946	1028	0.01	7.99

T302 Digestible lysine and methionine + cystine levels on breast meat quality of broilers at 21 days old. C. H. F. Domingues*[1,3], K. F. Duarte[2,3], E. T. Santos[3], D. M. C. Castiblanco[3], T. C. O. Quadros[3], S. Sgavioli[3], J. C. R. Alva[3], T. G. Petrolli[3], O. M. Junqueira[4], and J. D. Messana[2,3], *[1]Fundacao de Amparo a Pesquisa do Estado de Sao Paulo FAPESP, Sao Paulo, SP, Brazil, [2]Coordenacao e Aperfeicoamento de Pessoal de Nivel Superior CAPES/PNPD, Brasilia, DF, Brazil, [3]Universidade Estadual Paulista Julio de Mesquita Filho, Jaboticabal, SP, Brazil, [4]Universidade Federal de Goias, Jatai, GO, Brazil.*

The aim of this study was evaluate different levels of digestible lysine and methionine + cystine on meat quality of pectoral muscle (Pectoralis major) of broilers at 21 d old. A total of 3,200 one-day-old male Cobb x Cobb 500 chicks were used, distributed in a completely randomized design in a factorial arrangement 2 × 5 (2 digestible lysine levels: 1.253 and 1.378% × 5 digestible methionine + cystine levels: 0.812, 0.860, 0.902, 0.947, and 0.992%) and 8 replicates of 40 birds each. At 21 d of age, 480 birds were culled to the achievement of sampling pectoral muscle, which were submitted to analysis of the following parameters of meat quality: Color (L* = lightness, a* = redness, and b* = yellowness), cook loss, shear force and pH values. There was no interaction ($P > 0.05$) of digestible lysine and methionine + cystine levels for any of the variables. There was an effect ($P < 0.05$) of digestible lysine levels on the meat color and shear force occurring highest rate of redness for birds that received the level of 1.253% digestible lysine when compared with those fed with diets containing 1.378% digestible lysine, while the opposite occurred with the shear force. The levels of digestible methionine + cystine did not influence ($P > 0.05$) the redness, yellowness, pH and cook loss of breast meat, however, there was a quadratic effect ($P < 0.05$) for lightness ($Y = 291.39 - 520.82x + 280.54x^2$, $R^2 = 0.94$), indicating 0.928% as the highest level of digestible methionine + cystine for this variable. It was observed a decreasing linear effect ($P < 0.05$) for shear force ($Y = 11.786 - 9.7403x$, $R^2 = 0.88$), with increased levels of digestible methionine + cystine feed. In conclusion, the results of this study suggest that diets with 1.253 and 1.378% digestible lysine levels improve redness and shear force respectively and 0.928% digestible methionine + cystine level improve the lightness.

Key Words: digestible amino acid, pectoral muscle, pH

T303 Determination of optimum amino acid to calorie ratio for grower and finisher pigs. A. Hassen*, B. Smith, C. Iiams, D. Rice, F. Owens, D. Jones, and T. Sauber, *DuPont Pioneer, Johnston, IA.*

Accurate diet formulation will minimize experimental error. This is critical for trials which require high sensitivity to experimental treatments. The objective of this study was to identify optimal corn-soy diet lysine:calorie ratios (LCR) for pigs reared in an environment that supports rapid growth (typically 0.9 to 1.25 kg/day from 25 to 120 kg BW). Individually-penned barrows (PIC Line 1055 females × Line 280 boars) were fed treatment diets in 3 growth phases: Grower (25 to 60 kg), Finisher1 (60 to 90 kg), and Finisher2 (90 to 120 kg). For each phase, diet ME was held constant and lysine concentration was increased in even increments of 0.11% across each of 6 treatments to achieve target ranges of 2.25 to 3.75 (grower), 1.75 to 3.25 (Finisher 1), and 1.25 to 2.75 (Finisher 2) for LCR (g lysine:Mcal ME). Twelve pigs were randomly assigned to each treatment in the Grower phase, and were fed to a constant BW before progressing to the next growth phase and dietary LCR treatment. Preceding phase dietary treatment was used as a blocking factor during re-randomization to the next set of 6 dietary treatments in each successive phase. Data within each phase were analyzed using linear and non-linear models to evaluate effects of treatment diets on gain-to-feed ratio (GF). Parameter estimates from linear models were used to estimate optimum GF and the corresponding LCR levels based on different approaches. For each phase, level of LCR produced a significant effect on GF and orthogonal contrasts of treatment effect suggested curvilinear relationships between GF and LCR. In all cases, the final prediction model included a concave-down quadratic curve; suggesting a unique maximum and a range of optimum animal performance values for the LCR used within each phase. Maximum GF (SE) for Grower, Finisher1, and Finisher2 were 0.57 (0.01), 0.44 (0.01), and 0.39 (0.01), respectively. The mean LCR at optimum performance ranged from 3.17 to 3.3, 2.41 to 2.80, and 2.11 to 2.45 for the respective phases. The estimates derived from the experiment will be used for formulation of diets for future trials in our facility.

Key Words: amino acid, energy, swine

T304 Digestible tryptophan:lysine ratios and different protein sources in diets for barrows from 30 to 65 kg. C. Pereira[1], M. Hannas*[1], H. Rostagno[1], L. Albino[1], R. Rodrigueiro[2], J. Htoo[3], and G. Viana[1], *[1]Federal University of Viçosa, Viçosa, Minas Gerais, Brazil, [2]Evonik Industries, Health & Nutrition, Animal Nutrition Services, São Paulo, São Paulo, Brazil, [3]Evonik Industries AG, Health & Nutrition, Animal Nutrition Services, Hanau-Wolfgang, Germany.*

A total of 96 barrows (30.14 ± 2.27 kg) were used to investigate the effects of 2 digestible tryptophan:lysine (Trp:Lys) ratios (18 or 21%) and 2 diets with different protein sources (soybean meal – SBM or soybean meal, meat and bone meal and feather meal – SBM-MBM-FM) on growth performance of barrows from 30 to 65 kg. Animals were distributed in a complete randomized block design and the treatments were arranged as 2 × 2 factorial (2 diets with different protein sources × 2 digestible Trp:Lys ratios) with 12 replicates and 2 animals per pen. The diets were formulated to meet or exceed the nutritional recommendations of Rostagno et al., 2011. The experimental period lasted 32 d and the parameters evaluated were final body weight (FBW), average daily feed intake (ADFI), average daily gain (ADG) and feed:gain ratio (F:G). There was no interaction ($P > 0.05$) between Trp:Lys ratios and the diets with different protein sources on pig performance. The SBM diet increased ADFI ($P < 0.03$), however, there was no effect ($P > 0.05$) of the experimental diets on FBW, ADG and F:G. Barrows fed 21% digestible Trp:Lys ratio had better ($P < 0.01$) FBW, ADG and F:G than those fed 18% Trp:Lys ratio. ADFI was not affected by Trp:Lys ratio ($P > 0.05$). Considering the performance of barrow from 30 to 65 kg, it is recommended the utilization 21% of digestible Trp:Lys ratio. Also, barrows fed diets with SBM or SBM-MBM-FM, formulated on digestible amino basis, showed similar performance during the growing phase.

Table 1. Growth performance of barrows from 30 to 65 kg

	Ingredient			Dig Trp:Lys, %			
Item	SBM	SBM-MBM-FM	$P <$ [1]	18	21	$P <$ [1]	CV
FBW, kg	64.13	63.55	NS	62.97	64.70	0.01	3.51

T305 Oral administration of amino acids as energy sources for newborn piglets. N. E. Manzke[1], L. B. Scapini[2], W. Loyola[3], M. Kutschenko[4], J. M. Fontana[5], E. T. Nogueira[4], E. G. Xavier[1], A. Coldebella[3], and G. J. M. M. Lima*[3], *[1]Universidade Federal de Pelotas, Pelotas, RS, Brazil, [2]Universidade Federal do Parana, Palotina, PR, Brazil, [3]EMBRAPA, Concordia, SC, Brazil, [4]Ajinomoto, Sao Paulo, SP, Brazil, [5]Granja Fontana, Charrua, RS, Brazil.*

Amino acids have been supplemented in diets due to their beneficial effects on performance, health and immune status. Some of these occur because they may be readily available sources of energy, especially to young animals, which may face malnutrition after birth. This study was carried out to evaluate the effects of glutamine (Gln), glutamic acid (Glu) and AminoGut (Amg) supplementation on performance, immune response and blood parameters. Forty-seven litters, selected based on genotype and parity, were distributed according to a complete randomized block design. Within each litter, 4 piglets were chosen with body weights close to litter average. Treatments consisted of daily intragastric applications of 4-mL doses containing one of the following: Placebo: distilled water; Gln: 2 g L-glutamine; Glu: 2 g L-glutamic acid; Amg: 2 g of the commercial mixture of L-glutamine and L-glutamic acid. Animals were supplemented with treatments along the first 7 d of life with the first dose provided to piglets just after colostrum consumption. There were no treatment effects ($P > 0.10$) on individual weight and weight gain of piglets. Amino acid supplementation increased ($P = 0.06$) the diameter of the papule produced by *Phaseolus vulgaris* lectin skin test at 24 h after intradermal injection, compared with Placebo (6.12 mm). Amg (8.68 mm) and Glu (8.09 mm) showed the highest response for this variable ($P < 0.05$), at the same time as Amg promoted higher cell-mediated immunity than Gln (7.16 mm, $P < 0.05$) when compared with Placebo by *t*-test. There were no differences in plasmatic levels of glucose ($P = 0.40$) and creatinine ($P = 0.49$) among treatments. However, serum urea was significantly higher ($P < 0.0001$) in animals supplied with Gln, when compared with Glu, Amg and Placebo. Glu and Amg also increased blood urea compared with the Placebo group. Higher blood urea levels verified in amino acid supplemented piglets may suggest that the amounts supplied are above requirements. Despite there were no significant responses on piglet weight, amino acid supplementation provided better cell-mediated immunity, with a higher reaction shown by animals receiving Amg and Glu.

Key Words: glutamine, glutamic acid, AminoGut

T306 Effect of dietary lysine to energy ratio on growth performance and sensory characteristics of indigenous Venda chickens. O. J. Alabi*, J. W. Ng'ambi, and D. Norris, *University of Limpopo, Mankweng, Polokwane, South Africa.*

The study determined the effect of dietary lysine to energy ratio on optimal productivity, carcass and sensory characteristics of indigenous Venda chickens aged 8–13 weeks. A completely randomized design was used. One hundred and 60 female indigenous Venda chickens (BW 362 ± 10 g) were allocated to 4 dietary treatments. Each treatment was replicated 4 times and each replicate had 10 chickens. Four maize-soybeans based diets were formulated. Each treatment had similar dietary lysine (12 g/kg DM) but different energy levels (11, 12, 13 and 14 MJ ME/kg DM), thus, forming 4 dietary lysine to energy ratios (L:E) of 1.09, 1.00, 0.92 and 0.86, respectively. Data on chicken productivity, carcass characteristics (as percentages of live weights) and meat sensory attributes were measured. These data were analyzed using one way ANOVA. A quadratic curve estimate model was used to determine dietary lysine to energy ratio for optimum growth rate, feed intake, FCR, metabolizable energy, N-retention, relative carcass and sensory characteristic values. Results showed that dietary lysine to energy ratio of 0.88 supported optimum growth rate (17.89 g/bird/day), heart weight (0.76%) and meat flavor (4 points out of a 5-point hedonic scale). While a ratio of 0.99 g/MJ ME supported optimum feed intake (109.92 g/bird/day), FCR (6.05 g feed/g live weight gain), metabolizable energy value (11.33 MJ ME/kg), N- retention (1.63 g/bird/day), carcass (87.18%), breast meat (20.36%) and drumstick (12.00%). A higher ratio of 1.05 optimized liver (2.27%), wing (11.29%), gizzard (5.40%) and fat pad (2.84%). Meat tenderness and juiciness (3.25 points each out of a 5-point hedonic scale) were optimized at a ratio of 1.07. Thus, dietary L:E level for chicken production optimization depended on the particular parameter of interest. These findings have many implications on ration formulation for female indigenous Venda chickens.

Key Words: growth performance, lysine to energy ratio, optimization

T307 Evaluation of dietary glutamic acid plus glutamine levels on the growth performance of piglets. D. Lescano[1], L. Albino[1], M. Hannas[1], S. Salguero[1], M. Kutschenko[2], E. Nogueira[2], and H. Rostagno*[1], *[1]Federal University of Viçosa, Viçosa, MG, Brazil, [2]Ajinomoto of Brazil Ajinomoto Animal Nutrition, São Paulo, SP, Brazil.*

A study was conducted to evaluate the utilization of 4 dietary levels of a commercial product containing glutamic acid plus glutamine (min 95%) in diets for weanling pigs (18 d) to 46 d old. A total of 44 piglets were randomly assigned in a completely randomized block design into 4 treatments, 5 replicates and 2 or 3 pigs per experimental unit. The treatments were: T1 = 0.0%; T2 = 0.4%; T3 = 0.8% and T4 = 1.2% glutamic acid (Glu) plus glutamine (Gln). Diets were based on corn, soybean meal, pre-cooked corn, dairy products, blood plasma, L-lysine, L-threonine and DL-methionine. The experimental period lasted 28 d and the parameters evaluated were body weight, weight gain, feed intake and feed conversion ratio. The addition of Glu plus Gln improved linearly ($P < 0.05$) daily feed intake (DFI) and feed conversion ratio (F:G) of the piglets. There were also linear ($P < 0.01$) and quadratic effects ($P < 0.04$) of dietary Glu plus Gln level on final body weight (FBW), total weight gain (TWG) and daily weight gain (DWG) of the piglets (Table 1). It is concluded that the best dietary Glu plus Gln level is 0.8% for weanling piglets from 18 to 46 days of age.

Table 1. Growth performance of weanling piglets from 18 to 46 days of age

	Glu plus Gln (%)				Regression

T308 Effect of different space allocation and energy levels on growth performance and nutrient digestibility in growing-finishing pigs. J. Li, J. P. Lee, and I. H. Kim*, *Department of Animal Resource & Science, Dankook University, Cheonan, Choognam, South Korea.*

This study was conducted to investigate the effects of different space allocation (SA) and dietary ME levels on growth performance, apparent total tract nutrient digestibility (ATTD) in growing-finishing pigs. Data were collected from 4 growing, early (1 to 5 wk) and late (6 to 10 wk) finishing pigs experiments conducted from 2010 to 2012, and each experiment lasted for 5 wk. In each experiment, growing pigs (BW = 27.10 ± 1.60 kg) and finishing pigs (BW = 67.43 ± 1.97 kg) were fed 2 ME levels of corn/soybean-meal based diets (growing phase:3400 vs. 3550 kcal/kg; finishing phase:3300 vs. 3450 kcal/kg) by addition of 3% soybean oil. Pigs were given 0.80 and 0.60 m^2/pig for growing phase, and 1.08 and 0.81 m^2/pig for finishing phase. All statistical analysis was conducted as 2 × 2 factorial arrangement using the GLM procedure of SAS (1996) with pen as the experimental unit. The probability level of $P < 0.05$ was regarded as statistically significant. In growing pig experiments, the effect of low SA decreased ($P < 0.05$) ADG, ADFI, and G:F. The high ME level decreased ($P < 0.05$) ADFI, increase ($P < 0.05$) G:F and ATTD of energy. There was an interactive effect between SA and ME on ADFI, with the pigs fed high ME diet and in greater SA had lower ($P < 0.05$) ADFI than those fed control diet in low SA. In early finishing pig experiments, pigs given low SA consumed less feed, grew slower and had lower G:F ($P < 0.05$). Feed intake were reduced with high ME diet compared with control diet ($P < 0.05$). The ADFI was lowered ($P < 0.05$) by the interaction effect of greater SA and high ME diet compared with control diet and low SA. Late finishing pigs given low SA had lower ADG, ADFI, and G:F. No effect ($P > 0.05$) of ME level and their interaction was observed to influence growth performance and nutrient digestibility. In conclusion, results indicated reduction in ADFI, ADG, and G:F for pigs given low SA; the addition of high ME diet were found to improve feed efficiency in growing and early finishing pigs. Higher ME level was able to counteract the detrimental effect of SA to a certain extent.

Key Words: energy level, growing-finishing pig, space allocation

T309 Effect of vitamin E supplementation on its hepatic concentration in broiler chicken. M. A. Pompeu*[1], N. C. Baião[1], L. J. C. Lara[1], V. M. Barbosa[3], J. S. R. Rocha[1], P. C. Cardeal[1], R. C. Andrade[1], C. E. Cunha[1], C. W. R. Gondim[1], and L. F. L. Cavalcanti[1,2], *[1]Universidade Federal de Minas Gerais, Belo Horizonte, Minas Gerais, Brazil, [2]Texas A&M, College Station, [3]Universidade Federal da Bahia, Salvador, Bahia, Brazil.*

The main goal of vitamin E (VE) supplementation on poultry diets is to ensure good performance and welfare, rather than to attend the nutritional requirements. The liver is the main regulator of the body's VE levels and it appears to be the major site of VE metabolism and excretion, making it a good indicator of VE's body status. This study aimed to evaluate the VE liver concentration (VELC, mg/kg) in broilers with 21 or 39 d of age, fed with increasing levels of VE supplementation. The initial phase (IP) comprehended the birth to 21 d of age in which 15 animals were supplemented with 5 levels (3 animals/level) of VE, to achieve diets concentrations of 10, 30, 50, 75 or 100 mg/kg of DM. Additionally, another 15 animals (3 animals/level) were fed with the same supplementation levels from 21 to 39 d of age during the growth phase (GP). At the end of each phase, the animals were slaughtered and their livers were collected. The VELC was assessed by HPLC. A linear cubic regression was fitted to the IP ($VELC = a+b \times D+c \times D^2+d \times D^3$), whereas nonlinear logistic model was fitted to the GP phase [$VELC = A \times (1-B \times e^{-k \times D})^{-1}$]; where, A = asymptote (mg/kg), B = constant related to the intercept (mg/kg), k = growth rate (1/mg/kg), D = VE concentration in the diet (mg/kg). For both phases, was observed an increase on VELC when VE levels were increased from 10 to 30 mg/kg. However, for IP it readily tended to a plateau (61.99 ± 13.3 mg/kg) until the highest VE level, when it abruptly reached 135.3 ± 28.6 mg/kg, justifying the fitted cubic model ($a = -20.2 \pm 18.1$, $b = 4.3 \pm 1.5$, $c = -0.08 \pm 0.03$, $d = 0.0005 \pm 0.0001$, $r^2 = 0.89$). For the GP this plateau was only achieved when the diet VE levels reached 50 mg/kg, with a VELC close to the estimated A parameter of the logistic model ($A = 112.6 \pm 9.8$, $B = -151.53 \pm 429.4$, $k = 0.15 \pm 0.1$, Residual SE = 23.73). For the IP, the VE supplementation above 75mg/kg seems to overload the liver metabolism capacity, resulting in VE accumulation, what did not happen in the GP. The observed plateaus may be related to a balance between liver requirement and utilization, and the decision of the exact VE diet levels below those plateaus should be made based on additional performance results.

Key Words: diet, poultry, tocopherol

T313 Effects of a dietary antioxidant blend and vitamin E on growth performance and meat quality in broilers fed a high oxidants diet. T. Lu*[1], R. A. Dalloul[1], J. Zhao[2], and A. F. Harper[1], *[1]Virginia Tech, Blacksburg, [2]Novus International Inc., St. Charles, MO.*

The aim of this study was to determine the effects of a dietary antioxidant (AOX) (Agrado Plus, Novus Inc.) and vitamin E (VE) on performance and meat quality in broilers fed a diet high in oxidants. Cobb 500 male broilers (n = 1200, d 0) were randomly distributed into 60 floor pens across 6 treatments with 10 replicate pens of 20 chicks each. Treatments included (1) NC [negative control, VE at 10 IU/kg, 3% oxidized oil, 3% high PUFA source], (2) VE (NC + VE at 200 IU/kg), (3) AOX (NC + AOX at 135 mg/kg), (4) VE+AOX (NC + VE at 200 IU/kg + AOX at 135 mg/kg), (5) SC (standard control, VE at 10 IU/kg, 3% fresh oil, no high PUFA), and (6) PC (positive control, SC + AOX at 135 mg/kg). Performance parameters were measured on d 10, 21 and 42 and carcass quality assessed on d 42 by measuring drip loss, pH, and lactate levels. Data were analyzed using Glimmix of SAS with Tukey's multiple comparison. Compared with the SC birds, the NC, VE, AOX, VE+AOX groups had larger BW (855.4, 859.4, 901.3 and 889.5 vs. 785.2 g), ADG (38.6, 38.8, 40.8 and 40.2 vs. 35.3 g) and ADFI (58.2, 58.6, 60.9 and 60.1 vs. 53.1 g) from d 0 through d 21 ($P < 0.05$). However, the growth of birds fed the VE treatment fell behind that of other treatments (NC, AOX, AOX + VE, SC and PC, $P < 0.05$) during the 42 d trial. The AOX fed birds (AOX and VE+AOX) had heavier BW and ADG from d 10 forward, except that the SC treatment had the highest ADG from d 22–42 ($P < 0.05$). The AOX birds had the best G:F on d 10 and d 42, or throughout the experiment ($P < 0.05$). The high oxidants diet induced a higher drip loss (2.63 vs. 1.33, 1.24, 2.56, 1.46 and 2.08%) in NC fed birds, which was associated with a lower ultimate pH (5.91 vs. 5.95, 5.96, 6.06, 5.98 and 5.88) and the highest lactate concentration (76.48 vs. 68.48, 64.69, 58.44, 60.73 and 74.00 mmol/g) compared with VE, AOX, AOX + VE, SC and PC ($P < 0.05$). In conclusion, dietary addition of AOX or AOX plus VE was effective in improving growth. The addition of AOX alone and high VE reduced drip loss, but VE may exert a pro-oxidant property in the finisher phase as measured by growth.

Key Words: broiler, antioxidant, PUFA

T314 Pig bone trait responses to maternal vitamin D intake depend on nursery diet vitamin D and P concentrations. L. A. Rortvedt-Amundson* and T. D. Crenshaw, *University of Wisconsin-Madison, Madison.*

In earlier experiments, kyphosis was induced and bone mineral density (BMD) was reduced in pigs produced by sows fed no supplemental vitamin D_3 or minimum levels (325 IU/kg). This experiment was designed to evaluate carryover effects of maternal vitamin D_3 (D) intake on pig bone traits as implied by earlier results. In 2 trials, gilts were fed 1 of 3 diets (n = 6, 8, or 9 gilts/treatment, respectively) with 0, 325, or 1750 IU D/kg from breeding through lactation. Using a nested design, pigs within a litter at weaning (23 ± 2 d) were assigned to pens and fed an adjustment diet with no supplemental D for 1 wk. Then for 4 wk, pigs were fed 1 of 4 nursery diets (arranged as a 2 × 2 factorial) with 0 (-D) or 280 (+D) IU D/kg, each with 95% (95P) or 120% (120P) of the P requirement. Pigs were killed before colostrum consumption at birth (n = 23), weaning (n = 22), and a subsample at the end of the nursery (n = 185) for DXA (GE Lunar Prodigy) scans to determine whole body bone mineral content (BMC, g/pig) and BMD (g/cm^2). Individual femurs were scanned. Femur BMC and BMD responses were similar to pig DXA responses. Live births per litter (n = 14.3, 14.4, 14.1) were not different among maternal treatments. At birth and weaning, no differences due to maternal diet were detected in pig BMC and BMD. Pig BMC and BMD responses to nursery diets were dependent upon maternal diets (maternal × nursery diet interaction, $P < 0.05$). The interaction confirmed a carryover effect of maternal diets. BMD was reduced in pigs fed –D120P but increased in pigs fed +D120P nursery diets if produced by gilts fed 0 or 325 IU D/kg. However, BMD increased in pigs fed –D120P nursery diets if produced by gilts fed 1750 IU D/kg. Thus, maternal dietary D intake affects neonatal bone traits at 8 wk of age even though maternal dietary responses were not evident in pigs at birth and weaning.

Table 1.

Item	Maternal diet	Nursery diets				SEM[1]
		−D95P	−D120P	+D95P	+D120P

T315 True total-tract digestibility of P in monocalcium phosphate for 15- and 25-kg pigs. H. Zhai* and O. Adeola, *Purdue University, West Lafayette, IN.*

Two experiments were conducted to determine the true total-tract digestibility (TTTD) of P in monocalcium phosphate using the regression method. Forty-eight barrows (initial BW 15.7 ± 1.53 kg) in Exp. 1 and 24 barrows (initial BW 25.2 ± 1.04 kg) in Exp. 2 were used in a randomized complete block design with 6 replicate pigs per dietary treatment. Eight dietary treatments were established in Exp. 1 by incremental addition of 3.5 g/kg of monocalcium phosphate to a 3.3 g P/kg corn-soybean meal-based diet. In Exp. 2, 4 dietary treatments were constituted by incremental addition of 2.4 g/kg of monocalcium phosphate to a 2.96 g P/kg corn-soybean meal-based diet. In both experiments, limestone was added accordingly to maintain a constant Ca:P ratio of 1.25:1 across all diets. A 5-d adjustment period preceded a 5-d total collection of feces, and ferric oxide was used as a marker to time the initiation and termination of fecal collection. The results of Exp.1 showed that dietary P intake, fecal P output, and digested P increased linearly ($P < 0.001$) with the increasing supplementation of monocalcium phosphate. The regression of daily digested P against daily P intake gave a TTTD of 67.5% for P in monocalcium phosphate. The results of Exp. 2 showed that dietary P intake, fecal P output, and digested P increased linearly ($P < 0.05$) with the increasing supplementation of monocalcium phosphate. Regressing daily digested P against daily P intake gave the TTTD of 84.3% for P in monocalcium phosphate. In conclusion, the TTTD of P in monocalcium phosphate was determined to be 67.5 and 84.3% for, pigs with BW of 15 and 25 kg, respectively.

Key Words: monocalcium phosphate, pig, true total-tract digestibility

Physiology and Endocrinology I

T316 Effects of supplementation with different PUFA during the postpartum periods influence ovarian follicle size and number in lactating dairy cows. E. Dirandeh*[1], A. Towhidi[1], Z. Ansari Pirsaraei[2], M. Ganjkhanlou[1], S. Zeinoaldini[1], T. Saberifar[1], A. Rezaei Roodbari[1], M. A. Roodbari Shahmiri[3], and A. R. Zarenezhad[3], *[1]University of Tehran, Karaj, Alborz, Iran, [2]Sari Agricultural Sciences & Natural Resources University, Sari, Mazandaran, Iran, [3]Mahdasht Milk & Meat Company, Sari, Mazandaran, Iran.*

The objectives were to determine if a diet enriched in α-linolenic acid (n-3), or linolenic acid (n-6) would influence ovarian function in lactating dairy cows. Thirty high-yielding multiparous Holstein dairy cows without clinical illnesses were blocked according to calving date and parity. Cows were assigned randomly to be fed: (1) soybean whole roast (S, n = 10), or (2) linseed (L, n = 10), or 3) palm oil as a source of mostly saturated fatty acids (FA), (C, n = 10) from calving until d 60 postpartum (dpp). Supplementation of FA was at 1.5% of dietary dry matter, and there was no difference between groups (mean ± SEM) in parity (3.0 ± 1.90) or BCS at calving (3.2 ± 0.07). At 30 and 44 d postpartum cows received an injection of PGF2α for estrous synchronization Ultrasound measurements of follicle numbers were performed in 30 cows (n = 10 per group) on alternate days, from the day that second PGF2α inject until the d 10 of next estrous cycle (d 0 = day of estrus). The characteristics and fate of the first follicular wave was monitored using a real-time linear scanning ultrasound diagnostic system (B mode; Pie medical, Falco 100; 8 MHz transducer). Data were analyzed using the MIXED procedure of SAS. Results showed that the ovulatory follicle on the day preceding estrus synchronization (before the first AI, d 0) was larger in groups S (16.14 ± 0.91 mm) and L (15.24 ± 0.75 mm) compared with C (13.20 ± 0.86 mm; $P < 0.05$) but there were no significant differences between groups S and L. Mean number of small follicles (<5 mm), medium follicle (5-10 mm) and diameter of subordinate follicle were not affected by diets ($P < 0.05$). Cows offered diet S and L had a greater ($P = 0.037$) total number of follicles, number of large (>10 mm) follicles and tended to have a greater ($P = 0.064$) than cows offered diet C. In conclusion, these data demonstrate that n-3 and n-6 fatty acids increased follicle size and number but there was no difference among type of supplemental fatty acid.

Key Words: dairy cow, follicle, ultrasonography

T317 Feeding n-6 fatty acids during 40 dpp and shift to n-3 fatty acids from 40 to 120 dpp can improve fertility in lactating dairy cows. E. Dirandeh*[1], A. Towhidi[1], Z. Ansari pirsaraei[2], M. Ganjkhanlou[1], S. Zeinoaldini[1], A. Rezaei Roodbari[3], M. A. Roodbari Shahmiri[3], and A. R. Zarenezhad[3], *[1]University of Tehran, Karaj, Alborz, Iran, [2]Sari Agricultural Sciences & Natural Resources University, Sari, Mazandaran, Iran, [3]Mahdasht Milk & Meat Company, Sari, Mazandaran, Iran.*

The objectives were to determine if a diet enriched in α-linolenic acid (n-3), or linoleic acid (n-6) would influence reproductive performance in lactating dairy cows. Ninety high-yielding multiparous Holstein dairy cows with overtly clinical illnesses were blocked according to calving date and parity. Cows were assigned randomly to be fed: (1) soybean whole roast (S, n = 30), or (2) linseed (L, n = 30), or 3) palm oil as a source of saturated fatty acid (C, n = 30) from calving until first estrus after d 40 postpartum (dpp) and then half of the cows in each treatment group were switched to receive either L or C from first estrus after d 40 to 120 dpp. There was no difference between groups (mean ± SEM) in parity (3.0 ± 1.90) or BCS at calving (3.2 ± 0.07). Pregnancy was evaluated at 40 d after AI, and pregnant cows had their pregnancy reconfirmed at 60 and days after AI. All of the reproductive responses (binary responses) were analyzed by Glimmix. Result showed uterine involution in cows fed soybean whole roast occurred 1.2 earlier than the other groups ($P < 0.05$). Heat detection rate was not different between groups. For SL (% 44) and LL (% 45) groups compared with other groups pregnancy rate to first insemination was higher ($P = 0.001$); pregnancy rate to all inseminations was higher ($P = 0.019$) in SL (% 80) group and lower in LC (% 57) and CC (% 47) groups compared with other groups ($P = 00.1$). Conception rate tended to be higher ($P = 0.03$) in SL (% 84) group compared with other groups. There was a lower rate of early (d 0 to 24) embryo survival in SC (% 18) and CC (% 25) group compared with other groups ($P = 0.12$). In conclusion, feeding n-6 fatty acids during 40 dpp and shift to n-3 fatty acids from 40 to 120 dpp can improve fertility in lactating dairy cows.

Key Words: dairy cow, n-6 and n-3 fatty acids, pregnancy losses

T318 Presynchronization with PGF_{2a} and GnRH on the same day, 7 d prior to Ovsynch, allowed for similar pregnancies/AI compared with Presynch-10/Ovsynch. J. P. Martins*[1], M. J. T. Acevedo[1], T. O. Cunha[1], C. Piterini[1], M. R. Yousuf[1], K. Nobis[2], and J. R. Pursley[1], *[1]Department of Animal Science, Michigan State University, East Lansing, [2]Nobis Dairy Farm, St. Johns, MI.*

Fertility of dairy cows treated with Ovsynch is enhanced when the 1st GnRH of Ovsynch induces ovulation on d 6 or 7 of the estrous cycle, and PGF_{2a} (PG) 1 wk later, induces luteolysis. Current pre-synchrony programs that allow Ovsynch to be initiated on d 6 or 7 of the estrous cycle can be either logistically challenging for reproductive management personnel or can significantly lengthen duration of the entire program. The hypothesis of this experiment was that simplification of a Presynch program through the combination of PG (0.5 mg cloprostenol) and GnRH (0.1 mg gonadorelin diacetate tetrahydrate) on the same day, 7 d before Ovsynch, would allow for similar pregnancies/AI compared with Presynch-10. Lactating dairy cows (n = 444) 41 to 47 DIM were assigned in a random fashion to 2 treatments within 1st and 2nd+ parities for 1st service. Control cows received Presynch-10/Ovsynch consisting of the following: PG −14 d – PG −10 d – GnRH −7 d – PG −56 h – GnRH −16 h - AI. Treated cows received PG and GnRH - 7d – GnRH - 7 d – PG −56 h – GnRH −16 – AI. All cows received a 2nd injection of PG 24 h after the PG of Ovsynch to enhance complete luteolysis. All cows received AI between 75 and 81 DIM. Blood was collected to assess circulating concentrations of progesterone, and number of corpora lutea were recorded using ultrasonography, on d of PG of Ovsynch. Pregnancies/AI at 28 d post-AI were similar in controls compared with treated cows (45 vs. 45%). There was no effect of treatment on parity. There were no differences in pregnancy/AI between 1st and 2nd+ parities when treatments were combined (47 vs. 44%). Serum concentrations of progesterone were different in 1st parity, and similar in 2nd+ parity, control vs. treated cows (5.9 vs. 5.1 and 6.28 vs. 5.96 ng/mL). Percent of cows with >1 CL at time of PG was greater in 2nd+ parity treated vs. controls (89 vs. 75) and not different in 1st parity cows (65 vs. 70). In summary, administering both PG and GnRH on the same day, 7 d before the start of Ovsynch, appears to be a simple alternative that keeps pregnancies/AI to that of Presynch-10/Ovsynch.

Key Words: dairy, Ovsynch, fertility

T319 Effect of cloprostenol during early corpora lutea development on circulating concentrations of progesterone in breeding age dairy heifers. J. P. Martins*, M. J. T. Acevedo, C. Piterini, T. O. Cunha, and J. R. Pursley, *Department of Animal Science, Michigan State University, East Lansing.*

As part of an overarching objective to create a low progesterone environment during growth of the pre-ovulatory follicle in heifers to determine the effect of low progesterone on fertility parameters, we tested the effect of cloprostenol administration on early corpora lutea (CL) function. Dairy heifers between 12 and 13 mo of age were pre-synchronized to ensure all heifers were on d 6 of the estrous cycle at the start of the Ovsynch program. Only heifers that responded to the following strategy with CL regression and ovulation determined using ultrasound were utilized: 0.5 mg cloprostenol (PG)–2d - 0.1 mg GnRH – 6d - GnRH (G1; 1st GnRH of Ovsynch). Heifers (n = 164) that responded to the pre-synchrony injections were randomly assigned to 4 groups: high progesterone control (HPC), low progesterone control (LPC), and treatments P2 and P3. LPC, P2 and P3 received PG 1 d after G1 to regress all d 7 CL. Heifers from these groups had 1 new CL growing during the treatment period. Groups P2 and P3 received treatments of PG 2 and 3 d after G1, respectively. HPC did not receive PG on d 1 following G1, thus had a mature and a new CL growing during the treatment period. Blood samples were collected in all heifers on d 7 and in a subset of heifers on d 1, 2, 3, 4 (n = 88) after G1 to analyze circulating concentrations of progesterone. Pre-ovulatory follicle size (12.9 ± 0.1 mm; $P = 0.9$) at G1 and mean progesterone concentrations on d 1 (3.40 ± 0.15 ng/mL; $P = 0.9$) did not differ between randomized groups. Mean serum progesterone concentrations on d 7 were 8.23 (±0.43), 2.52 (±0.35), 1.53 (±0.20), and 1.24 (±0.15) ng/mL for HPC, LPC, P2, and P3, respectively. HPC had greater ($P < 0.001$) concentrations of progesterone compared with LPC, P2 and P3 on d 2, 3, 4 and 7 following G1. LPC had greater progesterone concentrations on d 7 than P3 ($P = 0.01$) and tended to be greater than P2 ($P = 0.08$). In summary, cloprostenol treatments during early corpus luteum development reduced circulating progesterone concentrations to sub-normal luteal levels compared with both high progesterone and low progesterone controls.

Key Words: dairy heifer, corpora lutea, progesterone

T320 Comparison of 200 µg of GnRH versus 1000 IU hCG in Beefmaster and Brahman Cattle using an Ovsynch protocol. C. E. Ferguson*[1], G. Richey[1], A. McDuff[1], and D. J. Kesler[2], *[1]McNeese State University, Lake Charles, LA, [2]University of Illinois, Champaign-Urbana.*

Previous research has reported 200 µg dose of GnRH at time of AI can improve pregnancy rates in *Bos indicus*-influenced cattle. This experiment was designed to compare the effect of 1000 IU of hCG versus the increased dose of GnRH on pregnancy rate in *Bos indicus*-influenced cattle. In the study, 4 groups of cattle were used; pure-bred Brahman (BR) heifers (n = 64) between 14 and 18 mo of age from Texas, Beefmaster (BM) lactating mature cows (n = 29) ~60 d postpartum from Louisiana, BM lactating mature cows (n = 50) from Florida, and BM heifers (n = 50) between 14 to 18 mo of age from Florida. All females were synchronized using an Ovsynch + CIDR protocol. At 48 h following $PGF_{2\alpha}$ females were randomly selected to receive either 200 µg GnRH or 1000 IU hCG and then artificially inseminated (AI) 15 to 20 h later for BR heifers or ~12 h following treatment for BM heifers or cows. The BR heifers were bred later than BM heifers because they were inseminated with sex-sorted semen while BM heifers received conventional semen. Each group was evaluated via ultrasonography at ~30 d post-AI to determine pregnancy. Statistical analysis was performed in SAS and a chi-squared test was used to determine differences between pregnancy rates. There was no difference ($P > 0.05$) in pregnancy rates between 200 µg GnRH versus 1000 IU hCG in *Bos indicus*-influenced cattle. The pregnancy rates for BR heifers was (GnRH, 3/18, 8% versus hCG 7/39, 18%), for lactating BM cows (from LA) was (GnRH 17/30, 57% versus hCG 9/15, 60%), for lactating BM cows (from FL) was (GnRH 17/30, 57% versus hCG 11/20, 55%) and for BM heifers was (GnRH 12/25, 48% versus 13/25, 52%). There was a significant effect ($P < 0.05$) of time from GnRH or hCG to AI in BR heifers bred with sexed semen on pregnancy rates with 60% of all pregnancies occurring with AI 17 to 18 h post GnRH or hCG. These results indicate that 1000 IU hCG is a cost effective alternative to replace the use of 200 µg GnRH in timed-AI protocols for *Bos indicus*-influenced cattle.

Key Words: GnRH, hCG, Ovsynch

T321 Effect of prostaglandin $F_{2\alpha}$ on growth of *Mycoplasma bovis* associated with bovine mastitis. A. Ahmadzadeh*[1], L. Fox[2], M. McGuire[1], and K. Carnahan[1], *[1]University of Idaho, Moscow, [2]Washington State University, Pullman.*

Mycoplasma bovis (*M. bovis*) is a major pathogen that is inherently refractory to antibiotics. Certain fatty acids have been shown to inhibit the growth of mastitis pathogens such as *Staphylococcus aureus*. In vitro experiments were conducted to determine the effects of prostaglandin $F_{2\alpha}$ ($PGF_{2\alpha}$) on growth of *M. bovis*. Five strains of *M. bovis* bovine origin were selected for the study. Two strains were reference strains (ATCC 25025 and 25523) and the other strains were isolated from diseased cattle. Isolates were cultured and suspended in saline to achieve an optical density of 0.2 at 520 nm, a suspension of approximately 10^7 to 2×10^8 cfu/mL. Subsequently, *M. bovis* suspensions were incubated in special culture media containing $PGF_{2\alpha}$ (dinoprost tromethamine) at final concentrations of 0 (control), 2, 4, and 8 mg/mL, for 8 h at 37°C in triplicate. A sample from each treatment group was obtained and cultured for 10 d and bacterial growth assessed as cfu. Data were analyzed by ANOVA and the model included the effect of treatment, strain, and their interaction. Treatment affected ($P < 0.01$) *M. bovis* growth and mean cfu decreased with concentrations of $PGF_{2\alpha}$ at 4 and 8 mg/mL (43.6, 42.1, 24.3, 7.8 [±1.1] for 0, 2, 4, 8 mg/mL, respectively). However, an effect of treatment × strain on mean cfu was detected ($P < 0.05$), indicating that the effect of $PGF_{2\alpha}$ on bacterial growth was not consistent across strains. Overall, the 2 mg/ml $PGF_{2\alpha}$ decreased ($P < 0.01$) cfu only in 2 strains compared with control whereas 4 and 8 mg/mL $PGF_{2\alpha}$ decreased ($P < 0.05$) cfu in all strains compared with control. These results provide evidence, for the first time, that $PGF_{2\alpha}$, in the form of dinoprost tromethamine, has inhibitory effects on growth of *M. bovis*, and this bacteriostatic effect appears to be strain and dose dependent.

Key Words: *Mycoplasma*, prostaglandin $F_{2\alpha}$, bacteriostatic

T322 Inclusion of bovine somatotropin in fixed-time AI protocols for *Bos indicus* beef cows. J. P. Albuquerque[1], R. F. Cooke[2], H. P. Dias[1], I. C. Bueno[1], A. D. P. Rodrigues[1], and J. L. M. Vasconcelos*[1], *[1]UNESP - Faculdade de Medicina Veterinária e Zootecnia, Botucatu, São Paulo, Brazil, [2]Oregon State University, Eastern Oregon Agricultural Research Center, Burns.*

Two experiments evaluated the effects of bovine somatotropin (ST) on pregnancy per AI of lactating Nelore (*Bos indicus*) cows assigned to the following estrus synchronization + fixed-time AI (FTAI) protocol: 2 mg injection of estradiol benzoate and insertion of intravaginal progesterone releasing device (CIDR) on d 0, 12.5 mg injection of $PGF2_{\alpha}$ on d

7, CIDR removal in addition to 0.6 mg of estradiol cypionate and 300 IU of eCG on d 9, and FTAI on d 11. Pregnancy status was verified via transrectal ultrasonography 30 d after FTAI. Data were analyzed with the PROC GLIMMIX of SAS. In Exp. 1, 896 cows (primiparous, n = 371; multiparous, n = 525) were randomly assigned to receive, concurrently with FTAI, 1 of 3 treatments: 1) 167 mg injection (s.c.) of sometribove zinc (bST167; n = 304), 2) 333 mg injection (s.c.) of sometribove zinc (bST333; n = 298), or 3) no injection (control; n = 294). Control cows had reduced pregnancy per AI compared with bST167 ($P = 0.08$) and bST333 ($P = 0.05$) cows (42.1, 49.0, and 49.8% of pregnant/inseminated cows, respectively; SEM = 4.0%), whereas no differences were detected ($P = 0.88$) between bST167 and bST333 cows. In Exp. 2, 290 cows (primiparous, n = 81; multiparous, n = 209) were randomly assigned to receive 333 mg of sometribove zinc (s.c.) at the beginning of the estrus synchronization protocol and at FTAI (bST, n = 111), or no injection (control; n = 179). Pregnancy per AI was similar ($P = 0.94$) between bST and control cows (37.6 and 38.1% of pregnant/inseminated cows, respectively; SEM = 4.8%). Hence, administration of bovine ST at FTAI enhanced pregnancy per AI in Nelore beef cows, independently of parity or dose evaluated. Conversely, 2 injections containing 333 mg of sometribove zinc and administered at the beginning and end of the estrus synchronization + FTAI protocol failed to improve pregnancy per AI in Nelore beef cows. The reason for this latter outcome is unknown, but may be attributed to increased milk production, as well as excessive circulating IGF-I and insulin concentrations that impaired, respectively, synchrony between embryonic/maternal tissues and oocyte quality in bST cows.

Key Words: bovine somatotropin, beef cows, artificial insemination

T325 Establishment of primary culture of omasal epithelial cells from newborn calves and detection of function for peptide absorption. Q. B. Xu*[1,2], H. Y. Liu[1,2], Y. M. Xie[1,2], Y. M. Wu[1,2], and J. X. Liu[1,2], *[1]Institute of Dairy Science, College of Animal Sciences, Hangzhou, China. [2]MoE Key Laboratory of Molecular Animal Nutrition, Zhejiang University, Hangzhou, China.*

It has been proved that small peptides can be absorbed in bovine forestomachs, especially omasum. However, little information is available on small peptide absorption by bovine omasal epithelial cells (OE cells). In this study, the bovine omasal tissues obtained from newborn Chinese Holstein calves were digested with 2.5% trypsin solution to obtain the OE cells. The isolated cells were then cultured in DMEM medium containing 5% fetal bovine serum, 5 μg/mL insulin, 10 ng/mL epidermal growth factor and 1% penicillin-streptomycin. Morphological observation revealed that the cultured cells displayed a homogeneous epithelial cell-like morphology as cobblestone with few fibroblasts visible. The OE cells possessed morphological features of desmosomes, tight junctions and microvilli. Immunocytochemistry assay showed that the cultured cells were cytokeratin 18 positive, indicating that they were omasal epithelial cells. These cells had normal growth properties with corresponding growth curve, and could be stably cultured for 10 passages. The transcriptional expression of peptide transporter 1 gene was detected in OE cells. To evaluate their function for absorption of small peptides, the OE cells were incubated with glycylsarcosine under different conditions. The glycylsarcosine could be absorbed intact into the OE cells in vitro and the absorption was dependent on concentration, time and temperature. From these results, it is inferred that peptide transporter 1 may play an important role in peptide absorption in the OE cells, and that the culture system of OE cells can be served as a useful in vitro model to study absorption of small peptides in bovine omasum.

Key Words: bovine omasal epithelial cells, primary culture, small peptide absorption

T326 Prepartum supplementation of beef cows: Hepatic and muscle gene expression of the offspring at weaning. M. Carriquiry*[1], J. Laporta[1], F. Pereyra[1], A. Astessiano[1], G. Quintans[2], and R. Perez-Clariget[1], *[1]Facultad de Agronomia, UDELAR, Montevideo, Uruguay, [2]Instituto Nacional de Investigaciones Agropecuarias, Treinta y Tres, Uruguay.*

The effect of supplementation during the last month of gestation on plasma IGF-I, muscle fiber characteristics and hepatic muscle gene expression was examined on multiparous beef cow offspring. Cows, ranked by body weight (BW) and body condition score, were blocked by calving day and assigned randomly to control (CON) or supplement (SUP) treatments. All cows were grazing native pastures (1200 kg DM/ha, 8% CP, 67% NDF) and supplemented cows were offered (1 kg/100 kg BW, 4.5 kg/d) whole rice-bran (15.2% CP, 31.7% NDF, 15.1%EE) during the last 40 d of gestation. Blood samples were obtained at 30, 90 and 180 (weaning) days and liver and muscle biopsies were collected at weaning in 10 crossbred (Angus/Hereford; n = 5/treatment) male calves. Gene expression was measured by SYBR-Green real time PCR using ACTB and HPRT as internal control genes. Data were analyzed in a mixed model with treatment as a fixed effect and block as a random effect. Data were considered to differ when $P < 0.05$ and are reported as lsmeans ± SEM. Prepartum supplementation did not affect calf BW at birth (40 ± 4 kg) or at weaning (183.3 ± 3 kg). Plasma IGF-I was greater in SUP than CON offspring (160.4 vs. 117.3 ± 10.4 ng/mL). At weaning, Semitendinous muscle fiber density was greater in SUP than CON offspring (2.9×10^{-4} vs. $2.4 \times 10^{-4} \pm 0.3 \times 10^{-4}$ fiber/μm^2) while muscle diameter did not differ among calves (69 vs. 72 ± 1.6 μm). Expression of IGFBP3 mRNA was greater in the liver (0.65 vs. 0.46 ± 0.06) and less in muscle (0.10 vs. 0.28 ± 0.04) in SUP than CON offspring. Neither liver nor muscle expression of GHR, IGF1 and INSR mRNA differed among treatments. Muscle expression of PPARγ mRNA was greater in SUP than CON offspring (0.11 vs. 0.04 ± 0.02) but SREBF1 mRNA did not differ among calves. Results of this experiment suggest that prepartum supplementation of beef cows in rangeland conditions would enhance growth and muscle adipogenesis potential in male calves.

Key Words: beef cattle, nutrition, fetal programming

T327 Morphometry of the tubular compartment in insulated boar testis. K. Yagoda*[1], F. Melo[2], and J. Parrish[1], *[1]University of Wisconsin-Madison, Madison, [2]Federal University of Goias Campus Jatai, Jatai, Goias, Brazil.*

Elevated ambient temperature is associated with summer infertility in boars. The aim of this study was to evaluate the effects on the testis of short-term scrotal insulation using morphometric analysis. One boar was used as a control and the other boar's scrotum was insulated in a sack for 48 h. The insulation procedure has been shown to increase scrotal temperature by 1.8°C. Testes sections were collected, fixed in Karnovsky solution, dehydrated, and embedded in Epon. Two-micrometer-thick sections from each sample were stained with 1% toluidine blue/sodium borate. All statistical methods were done using an ANOVA test and all values are presented as the mean ± standard deviation. We measured in the control and insulated boar, respectively, the volume density by counting 2880 points on a grid and found the percentages of interstitium (28.8 ± 0.1 vs. 33.7 ± 0.1, $P = 0.0705$), and seminiferous tubules (71.2 ± 0.2 vs. 66.3 ± 0.2, $P = 0.63$) did not differ. We measured the seminiferous tubule diameters (in microns) in 30 cross sections in each boar (214.9 ± 17.5 vs. 216.3 ± 16.2, $P = 0.747$) and found no difference. In contrast, the heights of epithelium in 30 cross sections (59.3 ± 6.2 vs. 53.5 ± 8.1, $P = 0.0029$) was different. We counted cell populations in 9 stage 1 cross sections and only found a difference in the preleptotene/

leptotene primary spermatocytes (13.1 ± 2.5 vs. 8.7 ± 1.6, $P = 0.0004$). In the insulated boar we observed a high density of cells in the lumen and small round vacuoles in the basal compartment. The lowered height of epithelium could be associated with greater cell loss during the thermal injury in the insulated boar. The preleptotene/leptotene primary spermatocytes appear to be the first cells affected by the heat, and had we allowed more time to pass after the insulation this effect would have been seen in the later cell stages. Morphometric analyses realized in this study showed that the scrotal insulation impaired the testicular function and affect the spermatic production.

Key Words: scrotal insulation, reproduction, spermatogenesis

T328 Impact of increased oxidative stress through excessive accumulation of adipose tissue on circulating adiponectin concentrations in dairy cows. S. Häussler*[1], S. P. Singh[1], L. Laubenthal[1], L. Locher[3], J. Winkler[2], U. Meyer[2], S. Dänicke[2], and H. Sauerwein[1], *[1]Institute of Animal Science, Physiology and Hygiene Group, University of Bonn, Bonn, Germany, [2]Institute of Animal Nutrition, Friedrich-Loeffler-Institute (FLI), Braunschweig, Germany, [3]University of Veterinary Medicine, Foundation, Hannover, Germany.*

Adipokines play an important role in regulating energy metabolism and glucose homeostasis. Fat accumulation (FA) correlates with systemic oxidative stress that may dysregulate the production of adipokines. We are interested in the insulin-sensitizing adipokine Adiponectin (Aq); the objective of our present study was to investigate the effect of excessive FA on oxidative stress and on circulating Aq concentrations in cows. Non-pregnant, nonlactating, pluriparous German Holstein cows (n = 8) were gradually adapted to a high-energy ration (corn-grass-silage with increasing the proportion of corn silage), including a successive increase of the proportion of the concentrate feed (within 6 wk from 0% up to 60% of the dry matter of the daily ration). Within 20 wk, the mean body weight (BW) increased from 540 ± 56.8 kg to 792 ± 81.7 kg; body condition score (BCS, 5-point scale) rose from 2.31 ± 0.35 to 4.53 ± 0.39. Subcutaneous fat from the tail head region was biopsied every 8 wk. Cryosections (14 µm) were prepared, fixed in acetone and stained with hematoxylin. Adipocyte sizes (μm^2) were determined in 100 randomly selected adipocytes. Blood samples were collected monthly; serum Aq concentrations were measured by ELISA (Mielenz et al. 2013). Derivatives of reactive oxygen metabolites (dROM) were photometrically quantified in serum using *N*,*N*,diethyl-1,4-phenylendiamine as chromogen. Data (means ± SEM) were analyzed using ANOVA and Pearson correlations. Serum Aq concentrations (µg/mL) decreased gradually throughout the FA period (41.3 ± 1.76 to 31.1 ± 0.72; $P = 0.006$). Serum Aq concentrations were negatively correlated with BCS ($r = -0.724$, $P < 0.001$), BW ($r = -0.573$, $P = 0.004$), and adipocyte size ($r = -0.475$, $P = 0.022$) and tended to be related with dROM ($r = -0.372$, $P = 0.073$). Increased dROM concentrations (from 49.9 ± 9.24 up to 113 ± 14.5 µg H_2O_2 equivalents/mL) indicating mitochondrial dysfunction as a result of excessive FA, were accompanied by decreased concentrations of the insulin-sensitizing adipokine Aq.

Key Words: adiponectin, reactive oxygen species, dairy cows

T329 The effect of heat stress on lipolytic response of bovine primary adipocytes. M. P. Faylon*[1], L. H. Baumgard[1], R. P. Rhoads[2], and D. M. Spurlock[1], *[1]Iowa State University of Science and Technology, Ames, [2]Virginia Polytechnic Institute and State University, Blacksburg.*

Heat stress (HS) has an enormous economic impact on the global dairy industry, and recent research indicates lipid metabolism is altered in lactating cows experiencing HS. In particular, basal and stimulated lipolytic responses are severely blunted in multiple species during HS. Thus, we hypothesized that HS directly affects adipose tissue by diminishing its response to lipolytic signals. Bovine primary adipocytes were isolated from 5 multiparous Holstein cows in late lactation and cultured at either 42C (HS) or 37C (thermal neutral, TN). Isoproterenol (ISO) was administered at varying concentrations and glycerol release was measured as an indicator of lipolytic response. A dose response curve to ISO was determined under HS and TN conditions for adipocytes isolated from each cow, and differences in the curve-fitting parameters between HS and TN treatments were compared using paired-samples *t*-test. Likewise, the abundance of several lipolytic proteins in relation to HS was evaluated. Adipocytes exposed to HS had an elevated maximal response to ISO (106.9% increase, $P = 0.024$), and were more sensitive to lipolytic stimulation by ISO ($P = 0.02$) compared with cells cultured at TN. Basal lipolytic response was not different between HS and TN cells ($P > 0.05$). At a high ISO concentration, a significant decrease in lipolytic response was observed for HS but not TN cells, suggesting potential downregulation of β-adrenergic receptors in HS but not TN cells. Thermal treatment also increased phosphorylation of hormone sensitive lipase (HSL) at Ser^{563}, confirming increased activation of the PKA pathway under HS conditions. The increased sensitivity of HS cells to lipolytic stimuli was unexpected, as in vivo data previously reported a diminished response to lipolytic signals. Further investigation is warranted to understand the relationship between the in vitro results and the effect of HS on lipid metabolism in vivo.

Key Words: heat stress, adipose tissue, lipolysis

T330 Once-daily milking during a feed restriction does not alter transcription of key lipid metabolism genes in adipose tissue of grazing dairy cows. T. M. Grala[1], J. R. Roche[1], C. V. C. Phyn[1], A. G. Rius[1], R. H. Boyle[1], R. G. Snell[2], and J. K. Kay*[1], *[1]DairyNZ, New Zealand, [2]University of Auckland, New Zealand.*

Study objectives were to investigate the effect of once-daily (1×) milking, at 2 feeding levels, on transcription of key lipid metabolism genes in adipose tissue of grazing dairy cows. Multiparous cows (n = 120) were grazed on pasture and milked twice daily (2×) from calving until 34 ± 6 d in milk (mean ± SD). Cows were then allocated to one of 4 treatments in a 2 × 2 factorial arrangement. Treatments were imposed for 3 wk and consisted of 2 feeding levels (adequately fed; AF, consuming 14.3 kg DMI/cow per d, or underfed: UF, consuming 8.3 kg DMI /cow per d) and 2 milking frequencies (2× or 1×). After the 3-wk treatment period, all cows were AF and milked 2×. Adipose tissue was collected from 12 cows per treatment at wk −1, 3, and 5 relative to treatment start, RNA extracted and transcript abundance of genes involved in lipid metabolism quantified. At the end of the 3-wk treatment period, transcript abundance of genes involved in glyceroneogenesis, glycerolipid synthesis and fatty acid (FA) transport, synthesis, and oxidation were greater ($P < 0.05$) in AF cows milked 1× compared with all other treatments. There was no effect of feeding level on the expression of genes involved in FA oxidation. Additionally, there was no effect of milking frequency on the expression of genes involved in lipid metabolism in UF cows. At wk 5, when all cows had returned to AF and 2× milking for 2 wk, there were no consistent differences in transcript abundance of lipid metabolism genes between treatments. In conclusion, milking cows 1× during a 3-wk nutrient deficit did not alter lipid metabolism compared with 2× milking; however, 1× milking in AF cows upregulated genes associated with FA synthesis, storage and oxidation. These data indicate that by wk 3 of

a feed deficit, lipostatic mechanisms, such as reduced milk production and limited lipolysis, prevented excess body tissue mobilization in UF cows. Furthermore, lipostatic mechanisms, such as greater FA oxidation, prevented excessive adipose deposition in AF cows milked 1× that were in an improved energy state.

Key Words: once-daily milking, nutrition, lipid metabolism

T331 GPR109A mRNA abundance in two different fat depots of dairy cattle considering nicotinic acid and transition period related changes. P. Friedrichs[1], L. Locher[2], K. Huber[2], S. Dänicke[3], H. Sauerwein*[1], and M. Mielenz[1,4], *[1]Institute of Animal Science, Physiology & Hygiene Unit, University of Bonn, Bonn, Germany, [2]Department of Physiology, University of Veterinary Medicine, Hannover, Germany, [3]Institute of Animal Nutrition, Friedrich-Loeffler-Institute (FLI), Federal Research Institute for Animal Health, Braunschweig, Germany, [4]Leibniz Institute for Farm Animal Biology (FBN), Department of Nutritional Physiology, Dummerstorf, Germany.*

The G-protein coupled receptor (GPR) 109A is predominantly expressed in adipocytes and mediates anti-lipolytic effects. We aimed to determine if nicotinic acid (NA), a known agonist of GPR109A influences the expression of this receptor in subcutaneous (SC) and retroperitoneal (RP) adipose tissue (AT) of dairy cattle. Likewise we studied time-dependent changes and differences of GPR109A mRNA abundance between both AT. For this, 20 pluriparous German Holstein cows were divided into a NA (n = 10) and a control group (n = 10). The animals from the NA group received a NA supplement (Lonza, Basel, Switzerland; 24 g/d) from d 1 until d 21 postpartum. The SCAT from tail head and RPAT were biopsied at d −21, 1 and 21 relative to calving. GPR109A mRNA abundance was quantified by qPCR. The statistical analyses were performed with SPSS 20.0 (SPSS Inc., Chicago, IL, USA) using ANOVA for analysis of the single tissues and Mann-Whitney U test for comparison of both AT. The mRNA abundance was not different between the NA versus control group neither in SCAT nor in RPAT. Thus, groups were pooled for further analyses. In both tissues GPR109A expression was independent of time. Comparing the mRNA abundance from pooled data of all sampling dates between both tissues yielded 1.51-fold higher values in RPAT than in SCAT ($P = 0.001$). When comparing both fat depots within the individual sampling times, RPAT showed 1.46-fold higher expression of GPR109A than SCAT on d −21 ($P = 0.014$) and 1.75-fold higher on d 21 ($P = 0.015$), but we detected no significant difference between both tissues at d 1. In conclusion, neither NA treatment nor time affected the mRNA expression of GPR109A in SCAT and in RPAT, respectively. The different GPR109A mRNA abundances between SCAT and RPAT confirmed our earlier works and indicate different importance for lipolysis and energy mobilization in both fat depots.

Key Words: adipose tissue, nicotinic acid, GPR109A

T332 Evaluation of the Idexx pregnancy detection assay for milk samples. B. Lawson*[1], D. Ray[1], K. Velek[2], E. Martel[2], R. Linscott[2], P. McCoy[1], M. Tate[1], J. Lawrence[2], and W. Silvia[1], *[1]University of Kentucky, Lexington, [2]Idexx Laboratories Inc., Westbrook, .*

The objective of this experiment was to assess the accuracy of the Idexx pregnancy detection assay for milk samples. Lactating Holstein cows (n = 17) were bred by timed artificial insemination. Pregnancy was evaluated by ultrasonography at 37, 65 and 93 d after breeding. Milk samples were collected on d 2 after insemination and at weekly intervals either 1) through d 58 post insemination if the cow was not pregnant on d 37 or 2) through d 93 if the cow was found pregnant. Plasma and milk samples were shipped to Idexx Laboratories Inc. to measure pregnancy associated glycoproteins (PAGs) using an ELISA. This ELISA classifies samples as (1) nonpregnant (NP; PAG concentration below a low critical threshold), (2) pregnant (P; PAG concentration above a high critical threshold) or (3) requiring recheck (RR; PAG concentration between the low and high thresholds). The Idexx staff was not informed of pregnancy status. Seven cows were pregnant by ultrasound on d 37, 65 and 93. All of these cows were classified as P using the milk PAG ELISA on d 30 and 37. Ten cows were found to be open by ultrasound on d 37. All 10 were classified as NP on d 30 and 37. A total of 70 samples were collected from the 7 pregnant cows from d 30 to 93 postinsemination. Using the milk PAG ELISA, 65 (93%) of these samples were classified as P, 5 as RR and 0 as NP. A total of 50 samples were collected from the 10 cows found not pregnant by ultrasound on d 37. In the milk PAG ELISA, 48 (96%) were classified as NP, 2 as RR and 0 as P. A total of 120 milk samples were collected on d 30 or after from these 17 cows. Sixty-five samples were classified P. All of these were from the 7 pregnant cows (positive predictive value: 100%). Forty-eight samples were classified as NP, all from nonpregnant cows (negative predictive value: 100%). Seven samples were classified as RR, 5 from pregnant cows and 2 from nonpregnant cows. We conclude that the milk PAG ELISA identifies pregnant and nonpregnant cows with a high degree of accuracy as early as 30 d after insemination.

Key Words: bovine, milk, pregnancy

T333 Gestational form of supplemental selenium (Se) affects gene expression in the newborn calf testis. II. Spermatogenesis. C. R. Skees*, P. J. Bridges, J. D. Patterson, and J. C. Matthews, *Department of Animal and Food Sciences, University of Kentucky, Lexington.*

In states with Selenium (Se)-deficient soils it is necessary for cattle producers to supplement Se in livestock feed rations. The objective of this study was to determine how inorganic versus organic forms of maternal dietary Se supplementation affect the expression of genes known to affect spermatogenesis in the newborn bull calf testis. Twenty-four Angus-cross cows managed under a standard forage-based cow calf production setting were randomly assigned (n = 8) to 1 of 3 treatment groups: sodium selenite (inorganic, ISe; Prince Se), Sel-Plex (organic, OSe; Alltech) or a 50/50 mix of ISe/OSe (mix). Cows were given ad libitum access to a commercial mineral mix that contained 35 ppm of Se beginning 4 mo before breeding through to calving. Thirteen bull calves were born (ISe n = 5, OSe n = 4, Mix n = 4) and castrated within 48 h of birth. Total RNA was extracted from small pieces of whole testis collected at castration. A microarray analysis was performed using bovine 1.0 ST arrays (Affymetrix) and the data set analyzed by one way ANOVA followed by a post hoc pairwise comparison (*t*-test). Overall, 1112 genes were affected ($P < 0.05$) by Se treatment, including 13 known to be involved with spermatogenesis: Ift52, Acvr1, Tlr3, Mapk14, Egf, Npr1, Raf1, Lep, Ldha, Meis1, Cdk5r1, Ccnd2 and Nphp1. When compared ($P < 0.05$) to ISe (the standard supplementation regimen) the expression of mRNA for Npr1, Lep, Nphp1 and Ccnd2 was increased, and Raf1 decreased, in testis of calves born to OSe supplemented cows, whereas mRNA for Egf and Ldha increased, and Tlr3, Mapk14 and Meis1 decreased, in testis from calves born to Mix supplemented cows. The relative ($P < 0.05$) content of mRNA for Ift52, Acvr1, Tlr3, Mapk14, Npr1, Lep, Meis1, Ccnd2 and Nphp1 was greater, whereas Raf1, Ldha and Cdk5r1 mRNA was lesser, in testis of calves born to OSe vs Mix supplemented cows. Our results provide evidence that the gestational source of dietary Se

affects development of the neonatal calf testis. Whether dam gestational form of supplemental dietary Se affects spermatogenesis and fertility of mature bulls requires investigation.

Key Words: selenium, spermatogenesis, testis

T334 Effect of implants on steroidogenic capacity of bovine granulosa cells. A. D. Stapp*[1], C. A. Gifford[1], K. B. Parker[1], B. I. Gómez[1], D. M. Hallford[2], and J. A. Hernandez Gifford[1], *[1]Oklahoma State University, Stillwater, [2]New Mexico State Universty, Las Cruces.*

Feedlot heifers are often implanted with steroids to increase growth efficiency thereby altering hormone profiles and changing the milieu in which ovarian follicles develop. Because granulosa cell (GC) culture is commonly used and often bovine ovaries are collected from abattoirs with no record of implant status, the objective of this study was to determine if the presence of anabolic and estrogenic steroids during bovine GC development affects FSH-regulated steroidogenesis. Sixteen feedlot heifers were assigned to 1 of 3 treatments: non-implanted (n = 5), and Revalor 200 for 30 d (30 d; n = 5) or 90 d (90 d; n = 6). At slaughter, paired ovaries were collected and small follicle (1 to 5 mm) GC were isolated from each pair and incubated with PBS (n = 16) or 100 ng/mL FSH (n = 16) for 24 h. Effects of FSH treatment on real-time PCR analysis of gene expression and hormone concentrations were analyzed using GLM procedure of SAS. Efficacy of treatment was confirmed by increased ($P < 0.01$) concentrations of medium estradiol in FSH-treated cells (62.31 ± 9.16 pg/mL) compared with PBS-treated controls (14.81 ± 9.16 pg/mL). Treatment with FSH tended to increase steroidogenic acute regulatory protein ($P = 0.09$) mRNA expression in GC of implanted heifers (−0.84 ± 0.56 and −1.79 ± 0.52) compared with non-implanted females (−0.21 ± 0.56). Similarly, P450 side chain cleavage ($P = 0.07$) tended to increase in response to FSH in GC of heifers implanted (2.89 ± 0.29 and 3.04 ± 0.27) compared with non-implanted heifers (1.99 ± 0.33). However, no difference in mRNA expression of 3-β-hydroxysteroid dehydrogenase ($P = 0.57$) and aromatase ($P = 0.23$) were demonstrated in implanted or non-implanted heifers. Medium estradiol concentrations of GC treated with FSH were similar ($P = 0.11$) between implanted (88.8 and 80 ± 21 pg/mL) and non-implanted heifers (80 ± 19.24 pg/mL). Similarly, FSH-mediated progesterone did not differ among treatment groups ($P = 0.22$). Results indicate follicles developing in the presence of high androgenic and estrogenic steroids tend to have an impaired ability to respond to FSH stimulation of the steroidogenic enzymes but not subsequent steroid production.

Key Words: granulosa cells, implant, steroidogenesis

T335 Effects of heat stress and plane of nutrition on liver insulin responsiveness in lactating cows. G. Xie*[3], M. V. Skrzypek[1], S. R. Sanders[1], L. H. Baumgard[2], and R. P. Rhoads[3], *[1]University of Arizona, Tucson, [2]Iowa State University, Ames, [3]Virginia Tech University, Blacksburg.*

Multiparous cows (n = 12; parity = 2; 136 ± 8 DIM, 560 ± 32 kg BW) housed in climate chambers were fed a TMR consisting primarily of alfalfa hay and steam-flaked corn. Cows were subjected to 2 experimental periods (P): (1) thermoneutral conditions (18°C, 20% humidity) with ad libitum intake (TN for group 1, WF for group 2) for 9d and (2) either heat-stress (HS) conditions (cyclical temperature 31.1–38.9°C, 20% humidity: min THI = 73, max THI = 80.5) fed for ad libitum intake (n = 6), or TN conditions, pair-fed (PF) with a HS animal (n = 6) for 9d. Rectal temperature (Tre) and respiration rate (RR) were measured thrice daily at 0430, 1200 and 1630h. Study objectives were to evaluate hepatic insulin responsiveness during HS and PF. Liver biopsies were obtained immediately before and after an insulin tolerance test (ITT) on the last day of each period. Insulin receptor β (IRβ), insulin receptor substrate 1 (IRS-1), Akt/protein kinase B (AKT) and phosphorylated AKT (P-AKT) were measured by Western blot analyses. During P2, HS increased Tre and RR by 1.48°C and 2.4-fold, respectively ($P < 0.01$). HS reduced ($P < 0.01$) DMI by 8 kg/d and by design PF cows had similar intake reductions. Milk yield was decreased similarly (30%) in HS and PF cows and both groups entered into a similar (−4.5 Mcal/d) calculated negative energy balance during P2. Compared with P1 ($P < 0.05$), basal glucose levels increased (5%) in PF cows, but decreased (5%) in HS cows during P2. The ITT caused a more rapid glucose disposal in P1 compared with P2 ($P < 0.05$), but glucose clearance did not differ between environments in P2. Protein abundance of IRβ remained constant during each period. The protein level of IRS-1 was lowered ($P < 0.05$) by insulin in WF only. Insulin increased P-AKT protein content in each period ($P < 0.05$) except PF. Abundance of AKT tended to decrease ($P = 0.057$) only in PF. Phosphorylation ratio of AKT increased 120% in each period ($P < 0.05$) after insulin infusion. These results indicate that liver insulin responsiveness remains unchanged despite mild systemic insulin resistance during HS and reduced nutrient intake.

Key Words: heat stress, insulin, liver

T336 Progesterone, TNF-α, IGF-1, and $PGF_{2\alpha}$ concentrations in blood plasma of beef cows within 14 days after transfer of embryos. J. Copeland*[1], J. Batton[1], E. J. Cuadra[1], T. H. Elsasser[2], B. Johnson[3], J. E. Larson[4], M. C. Mason[1], and J. Yoonsung[5], *[1]Alcorn State University, Alcorn State, MS, [2]USDA ARS, Bovine Functional Genomics Laboratory, Beltsville, MD, [3]Coastal Plain Branch Experiment Station, Newton, MS, [4]Mississippi State University, Mississippi, [5]Prairie View A&M University, Prairie View, TX.*

Lactating beef recipient cows previously synchronized for estrus were randomly assigned to one of 4 treatments to assess the magnitude in progesterone (P_4) rise and its effects on TNF-α, IGF-1 and $PGF_{2\alpha}$ after transfer of embryos. Cows exhibiting estrus received an embryo in the uterine horn ipsilateral to CL 7 d post-estrus. Cows received either no treatment (Control, n = 16), a CIDR (Controlled Internal Drug Release) (CIDR, n = 16), an injection of 1000 IU of hCG (hCG, n = 15) or an injection of 100 µg of GnRH (GnRH, n = 15) at the time of embryo transfer. Blood samples were taken from all cows immediately on d 0 (day of transfer), 7, and 14 for analysis of P_4, TNF-α, and IGF-1. Blood samples for determination of 13,14-dihydro-15-keto $PGF_{2\alpha}$ (PGFM) were collected from half the animals in each treatment group on d 7 and the remaining half on d 14; samples were collected every 15 min for 2 h on both days. Data was analyzed using the SAS MIXED procedure. Pregnancy 60 d after embryo transfer was 56.2, 62.5, 46.7 and 6.7% for the control, CIDR, hCG and GnRH respectively. P_4 was higher ($P < 0.05$) in cows receiving hCG compared with other groups on d 7. Cows, whether pregnant or not at diagnosis, had an increase in P_4 from d 0 to 7 and a decline ($P < 0.05$) in P_4 from d 7 to 14. Non-pregnant cows had an overall decline in P_4 and TNF-α from d 0 to 14 ($P < 0.05$). Treatments did not affect TNF-α. No significant differences ($P > 0.05$) in IGF-1 were observed among treatment groups and between pregnant and non-pregnant cows. While PGFM increased ($P < 0.05$) from d 7 to 14 in cows receiving the CIDR and hCG, concentrations in the hCG group were only higher than those observed in the GnRH ($P < 0.05$) on d 14. Contrary to the non-pregnant cows, no significant differences were observed in concentrations of PGFM between samples collected

every 15 min in the pregnant cows on d 14 ($P < 0.05$). Regardless of pregnancy status, cows had a significant decline in P_4 during the second week after the transfer of an embryo; additionally, $PGF_{2\alpha}$ seems to be steadier in pregnant cows than in non-pregnant cows during that same period.

Key Words: embryo, P4, $PGF_{2\alpha}$

T337 Effect of an essential fatty acid (EFA)-deficient diet on luteal and uterine function in pseudopregnant (PSP) rats and prostaglandins (PG) E1, E2, and F2a (PGF2a, PGE1; PGE2) in nonpregnant (NP) and pregnant (P) ewes. C. W. Weems*[1], Y. S. Weems[1], and R. R. Magness[2], *[1]Dept. of Human Nutrition, Food, and Animal Sciences, University of Hawaii, Honolulu, [2]Dept. of Obstetrics and Gynecology, University of Wisconsin, Madison.*

PGF2a is the uterine luteolysin, but PGE1 or PGE2 are antiluteolysins and prevent luteolysis. PGE1 or PGE2 prevent a natural or induced luteolysis. The precursor for PGF2a and PGE2 is arachidonic acid (AA) and di-homo-gamma linolenic acid (DHGLA) for PGE1. The objective of EXPT 1 was to assess length of PSP and fatty acid (FA) profile by GLC in control 7 EFA deficient PSP rats. A control or EFA-free diet was fed to rats from weaning on d 21. EXP 2 objective was to measure uterine weight on d 9 in control and EFA-deficient PSP rats treated with Vehicle, PGE1, PGE2, or PGE1+PGE2 intrauterine at deciduomata (DCR) induction. PSP length was analyzed by a one-way ANOVA and data in Expt. 2 by a 2 × 2 × 4 CRD for ANOVA. EXPT 3 objective was to measure PGF2a, PGE1 and PGE2 in caruncles and uterine blood by HPLC and RIA on d 13 in NP and P ewes (n = 10 each). EXPT 3 data were analyzed by a one-way ANOVA. An EFA-deficient diet increased ($P < 0.05$) PSP length (12.1 ± 0.5 vs. 17.1 ± 0.6 d), decreased AA 78% ($P < 0.05$), and increased ($P < 0.05$) DHGLA (133%). Uterine weight of DCR rats was lower ($P < 0.05$) in EFA deficient PSP rats (3.2 ± 0.2 vs. 5.9+0.6 g). PGF2a in uterine blood was lower ($P < 0.05$) in EFA-deficient rats (1.9 ± 0.6 vs. controls 11.2 ± 0.21). Uterine weight in PGE1, PGE2, or PGE1+PGE2 at induction of DCR increased ($P < 0.05$) more in PGE2 than PGE1 in EFA-deficient PSP rats (78% vs. 1%). PGF2a in uterine blood was lower in EFA-deficient rats (1.9 ± 0.6 vs. controls 11.2 ± 0.21). PGE1 and PGE2 in caruncles increased ($P < 0.05$) in P ewes on d 13 NP PGE1 (4.7 ± 0.5 ng/g); NP PGE2 (11.7 ± 1.4 ng/g); P PGE1 (12.5 ± 2.3 ng/g), and P PGE2 (24.3 ± 5.1 ng/g). PGF2a, PGE1, and PGE2 in uterine blood of NP ewes averaged 7.3 ± 0.2, 1.2 ± 0.4, and 2.6 ± 0.5 and PGF2a, PGE1, and PGE2 in P ewes averaged 9.9 ± 1.2, 11.6 ± 1.6 and 16.5 ± 2.1. In summary, an EFA deficiency increased PSP and decreased the DCR response in PSP rats. Both PGE1 and PGE2 increases in P ewes support PGE1 and PGE2 as antiluteolysins. Deceased contributors: Hal Behrman and Dorothy Cope.

Key Words: EFA, PSP rats, ewe

T338 Effects of FSH stimulation on β-catenin accumulation in bovine granulosa cells. K. B. Parker*[1], C. A. Gifford[1], A. D. Stapp[1], B. I. Gomez[1], D. M. Hallford[2], and J. A. Hernandez Gifford[1], *[1]Department of Animal Science, Oklahoma State University, Stillwater, OK, USA, [2]Department of Animal and Range Sciences, New Mexico State University, Las Cruces, NM, USA.*

Regulation of estradiol (E_2) biosynthesis by FSH requires the transcriptional co-factor β-catenin (CTNNB1). Increased abundance of CTNNB1 is demonstrated in large antral follicles with greatest concentrations of intra-follicular E_2. In bovine granulosa cells (GC), FSH increases CTNNB1 and protein kinase B (AKT) protein, and WNT2 mRNA expression. These data indicate FSH regulates CTNNB1 through the canonical WNT or AKT signaling pathways. The objective of this study was to elucidate AKT's role in CTNNB1 accumulation. Bovine GC were pre-incubated with AKT inhibitor (LY294002; LY) for 30 min, then cultured with or without FSH for 24 h (n = 4). Total protein was collected for analysis by Western blot. Relative abundance of protein was analyzed using one-way ANOVA procedure of SAS. Expectedly, LY reduced total AKT abundance ($P = 0.05$) and ablated phosphorylated AKT protein. Inhibition of AKT signaling with LY alone ($P = 0.13$) or in combination with FSH ($P = 0.16$) tended to reduce CTNNB1 protein compared with control and FSH-treated GC. Progesterone (P_4) media concentrations did not differ among treatment groups ($P = 0.52$); however, numerical reduction in P_4 was demonstrated in LY compared with FSH-treated GC. Inhibition of AKT reduced ($P < 0.01$) production of FSH-mediated E_2 production. A subsequent study was conducted to investigate whether a known AKT stimulator, IGF-I, could also mediate CTNNB1 accumulation (n = 4). Bovine GC treated with FSH had greater CTNNB1 compared with control and IGF-I groups ($P = 0.01$). Though, FSH did not increase P_4 ($P = 0.42$), IGF-I alone and in combination with FSH increased ($P < 0.01$) P_4 to 161.8 and 185.9 (±13) ng/mL, respectively. Estradiol concentrations were 93 pg/mL for control, and addition of IGF-I alone or in combination with FSH increased E_2 to 280 and 343 (±65) pg/mL, respectively. Data demonstrate that AKT is required for FSH-induced accumulation of CTNNB1 and steroid synthesis. However, IGF-I stimulation of AKT increased steroid production but not CTNNB1 accumulation indicating AKT is necessary for FSH-induced accumulation of CTNNB1, and CTNNB1 is not required for IGF-I induction of steroidogenesis.

Key Words: FSH, granulosa cells, β-catenin

T339 Combined effect of cytological endometritis and cyclicity on fertility of dairy cows. A. Vieira-Neto*[2], W. R. Butler[3], R. O. Gilbert[3], and K. N. Galvão[1], *[1]University of Florida, Gainesville, [2]Universidade do Estado de Santa Catarina, Lages, SC, Brazil, [3]Cornell University, Ithaca, NY.*

Anovulation is associated with cytological endometritis (CTE); therefore, the negative association of either condition with fertility could be confounded by the other. The objective was to evaluate if both cyclicity and CTE would be negatively associated with fertility. Holstein cows (n = 403) from 5 dairies in upstate New York were used. Cyclicity was characterized by serum progesterone concentration ≥1.0 ng/mL at 21, 35, or 49 DIM. CTE was characterized by the presence of ≥4% neutrophils on the uterine cytology performed at 49 DIM. Time to pregnancy up to 300 DIM was analyzed using the PHREG and LIFETEST procedure of SAS. The PHREG model included the effects of cyclicity, CTE, interaction between cyclicity and CTE, parity, body condition score, calving season, PGF treatment, and herd. An interaction between cyclicity and CTE was observed ($P = 0.02$), and 4 dummy variables were created based on the permutation of cyclicity and CTE: Cyclic with CTE (CycCTE; n = 118), cyclic without CTE (CycHealthy; n = 205), anovular with CTE (AnovCTE; n = 34), and anovular without CTE (AnovHealthy; n = 46). Compared with CycHealthy cows, AnovCTE [hazard ratio (HR) = 0.54; CI = 0.34–0.88; $P = 0.01$] and AnovHealthy (HR = 0.69; CI = 0.47–1.00; $P = 0.05$) cows had decreased hazard of pregnancy, and CycCTE tended (HR = 0.79; CI = 0.60–0.1.02; $P = 0.07$) to have decreased hazard of pregnancy. CycHealthy cows were the most fertile as evidenced by the fact that they had the shortest median time to pregnancy (122 d). On the other hand, AnovCTE had the longest median time to pregnancy

(180 d), while CycCTE and AnovHealthy were intermediate (159 and 171 d, respectively). In summary, cyclicity and uterine health statuses are both important for fertility in dairy cows. Both, anovulation and presence of CTE were negatively associated with fertility, and when combined, they had an additive negative effect.

Key Words: cyclicity, cytological endometritis, fertility of dairy cows

T340 Effect of propionate, palmitate and insulin on chemerin gene expression in monolayer cultures of bovine hepatocytes. S. G. Roh*[1], S. Kitayama[1], Y. Suzuki[1], K. H. So[1], K. J. Yi[1], E. Yamauchi[1], S. Haga[2], and K. Katoh[1], *[1]Lab of Animal Physiology, Graduate School of Agriculture Science, Tohoku University, Sendai, Miyagi-ken, Japan, [2]NARO Institute of Livestock and Grassland Science, Japan.*

Chemerin, an adipokine, gene was highly expressed in adipose and liver tissues of Japanese Black cattle, and TNF-α increased the expression of chemerin and chemerin receptor in cultured bovine adipocytes. However, it is not known about the regulatory factors on gene expression of chemerin in cultured bovine hepatocytes. The objective was to investigate the effect of propionate, palmitate and insulin on chemerin mRNA expression in in vitro cultured bovine hepatocytes prepared from preweaning and postweaning cattle. The caudate lobes of liver tissues were sampled from Japanese Black cattle (3-week, 3- and 5-mo-old). The collagenase solution was recirculated through the caudate lobe to collect cells in the medium. The cells were seeded and cultured for 48 h. The cells were washed 3 times with fresh medium and cultured for an additional 6 h in serum-free medium. Then the medium was exchanged with fresh serum-free medium in the presence or absence of propionate (0.1, 1 m*M*), palmitate (50, 100, 250 μ*M*) and insulin (1, 10, 100 n*M*) for 24 h and total RNA was extracted from the cells for analysis of chemerin mRNA. Data were analyzed by 2-way ANOVA using PROC GLM (SAS Inst. Inc.). Values are representative of at least 2 separate series of cultures (5 to 6 replicates per each treatment). Propionate treatment (1 m*M*) reduced ($P < 0.05$) the expression levels of chemerin gene in cultured hepatocytes of 3-wk-old cattle by 40%, while it increased ($P < 0.05$) the expression in 5-mo-old cattle by 1.3-fold. Palmitate (100 μ*M*) did not change the expression level of chemerin mRNA in hepatocytes of 3-week-old cattle ($P > 0.1$), while it increased ($P < 0.05$) the expression in 3-mo-old cattle by 1.4-fold. Insulin (100 n*M*) decreased ($P < 0.05$) the levels of chemerin gene expression in 3-wk- and 3-mo-old cattle by 65% and 20%, but not in 5-mo-old cattle. The expression of chemerin gene was differently controlled by propionate, palmitate and insulin treatments in hepatocytes, and between preweaning and postweaning animals, indicating that chemerin may play a role on nutrient metabolism associated with development.

Key Words: bovine, hepatocyte, weaning

T341 Gene expression in Holstein bull testicular testis after scrotal insulation. J. R. Schindler* and J. J. Parrish, *University of Wisconsin, Madison.*

Holstein bulls (n = 9, approximately 5 years old) were used to study the effects of heat stress on testis gene expression. Bulls were split into a control, insulated, and insulated and recovered groups. Tissue from the control group was harvested without insulation and from the insulated group immediately following insulation for 48 h. Semen was collected from the recovered group for 2 weeks prior, and for 45 d after insulation (3 d per week). Semen was analyzed for nuclear shape (Fourier Harmonic Analysis) to confirm that a heat stress event occurred. The mean harmonic amplitude 1 increased on d 19 post insulation compared with pre-insulation (mean ± SEM, 0.196 ± 0.017 vs. 0.171 ± 0.003; $P < 0.05$). The mean harmonic amplitude 3 increased on d 19, 21, 23, 26, and 28 post insulation compared with pre-insulation (mean ± SEM, 0.173 ± 0.012, 0.170 ± 0.012, 0.179 ± 0.016, 0.185 ± 0.017, and 0.167 ± 0.013 vs. 0.145 ± 0.003; $P < 0.05$). The mean harmonic amplitude 5 increased on d 19 post insulation compared with pre-insulation (mean ± SEM, 0.153 ± 0.012 vs. 0.132 ± 0.003; $P < 0.05$). A mixed effects model was used to compare the control days to each day, post-insulation. Changes in harmonic amplitudes are consistent with previous results. Total RNA from the testis of the control and insulated groups was extracted and microarray analysis was done using a Nimblegen 385K custom bovine expression array. Using a targeted approach, a subset of 200 genes in the array was investigated. The subset was constructed using a National Center for Biotechnology Information search of genes involved in heat stress, apoptosis, DNA repair, and hypoxia. Six genes in the insulated group were statistically different from the control: Cytochrome C-testis, BCL2L13, Dynein, RPS6KB1, OBFC2A, and TIMP-2. These 6 genes were subjected to a validation experiment using qRTPCR. Only TIMP-2 showed a trend for a difference with a 122% decrease in expression from the control ($P = 0.06$) using a mixed effects model. Decreased TIMP-2 expression in the testis would lead to an increase in remodeling of the extracellular matrix in interstitial space and/or the seminiferous epithelium.

Key Words: bull, heat stress, gene expression

T342 Effect of induction of ovulation, early in lactation, on uterine health and fertility in dairy cows. J. H. Bittar*[1], P. Pinedo[3], K. E. Hencken[1], C. C. Barbosa[1], M. Gobikrushanth[1], S. Croyle[1], C. A. Risco[1], A. Vieira-Neto[2], J. E. Santos[1], and K. N. Galvão[1], *[1]University of Florida, Gainesville, [2]Universidade do Estado de Santa Catarina, Lages, SC, Brazil, [3]Texas A&M University, Amarillo.*

Objective was to evaluate the effect of GnRH early postpartum on induction of ovulation, uterine health and fertility in dairy cows. Holstein cows without a CL at 17 ± 3 DIM (n = 255) were randomly assigned to receive an injection of GnRH (n = 128) at 17 ± 3 DIM and at 20 ± 3 DIM or to remain as controls (n = 127). Cows had their ovaries scanned by ultrasonography (US) twice a week for a total of 4 US. Ovulation was characterized by the appearance of a corpus luteum (CL) ≥ 20mm in any US or when a CL < 20mm appeared in 2 consecutive US. Clinical (CE) and cytological endometritis (CTE) were diagnosed at 35 ± 3 DIM. Data was analyzed using the LOGISTIC and PHREG procedure of SAS adjusting for the effect of parity, calving related problems, metabolic problems, or metritis. Cows receiving GnRH had increased ovulation (71.1 vs. 43.3%; $P < 0.001$). GnRH treatment (GTRT) did not affect the prevalence of CE (26.2 vs. 20.8; $P = 0.41$) or CTE (30.9 vs. 32.8; $P = 0.29$). Cows having calving problems (39.7 vs. 17.5%; $P = 0.004$) and metritis (39.7 vs. 16.2%; $P < 0.001$) had increased prevalence of CE. Metritis (39.7 vs. 16.2%; $P < 0.001$) also increased the prevalence of CTE (50.7 vs. 23.5%; $P < 0.001$). An interaction between GTRT and ovulation after GTRT (GTRT × Ov) showed that treated cows that ovulated had decreased CTE compared with cows that did not ovulate (25.6 vs. 43.2%; $P = 0.05$), but ovulation did not affected ($P = 0.88$) CTE in control cows. GTRT did not affect conception rate (CR) at 32 (42.2 vs. 43.3%; $P = 0.74$) or 74 d after AI (37.5 vs. 35.4%; $P = 0.26$), or pregnancy loss (11.1 vs. 18.2%; $P = 0.30$). The interaction GTRT × Ov showed that treated cows that ovulated had increased CR at 74 d compared with cows that did not ovulate (42.9 vs. 24.3%; $P = 0.05$), while there was no difference ($P = 0.57$) in control cows. The interaction GTRT × Ov showed that treated cows that did not ovulate had decreased hazard of pregnancy up to 300 DIM compared with cows that ovulated (HR = 1.9; $P = 0.01$), or control

cows that did (HR = 1.8; $P = 0.03$) or did not ovulate (HR = 1.9; $P = 0.01$). GnRH treatment early postpartum increased ovulation; however, it failed to improve uterine health or fertility.

Key Words: ovulation, uterine health and fertility, dairy cow

T343 Temporal gene expression profiling of liver from peripartal dairy cows during spring and summer. H. Akbar[1], U. Bernabucci[2], L. Basiricò[2], P. Morera[2], and J. J. Loor*[1], *[1]University of Illinois, Urbana, [2]Università degli Studi della Tuscia, Viterbo, Italy.*

Thermal stress during hot seasons renders dairy cattle more susceptible to metabolic disease, including liver lipidosis. Hepatic transcriptome-wide changes during heat stress remain unknown. We examined temporal gene expression profiles during the dry period and early lactation in liver of 12 Holstein cows that calved in the spring (SP, March to April) or summer (SU, June to July) using a whole-transcriptome bovine microarray (Agilent) and quantitative RT-PCR (qPCR). Liver tissue was harvested at −30, 3, and 35 d relative to parturition. The 23 target genes selected for qPCR were associated with heat shock response (HSP70A1A, HSTF1), fatty acid oxidation (CPT1A, PPARA, ACOX1), hepatokines (FGF21, ANGPTL4), esterification and VLDL assembly (MTTP, APOB100, DGAT1, SREBF2), glucose metabolism (PC, PCK1, PDK4), and inflammation and stress (TNF, GPX1, SOD1, SOD2, SAA3, HP, HAMP). The ANOVA model included day, season, and day × season as fixed effects, and cow within season as the random effect. Statistical difference for interaction and main effects was declared significant at $P < 0.05$. Results from qPCR revealed a 2-fold increase in expression of HSP70A1A in SU between −30 and 3 d. In contrast, expression of HSTF1 between −30 and 3 d increased 20-fold in SP and 7-fold in SU. Despite the 6- to 11-fold increase in CPT1A between −30 to 3 d in SU and SP, SU was associated with lower overall expression (~2-fold) of CPT1A and also PPARA and ACOX1. Except for MTTP, expression of APOB, DGAT1, and SREBF2 was 2- to 6-fold greater overall in SP than SU. The gluconeogenic enzyme PCK1 increased 14-fold from −30 and 3 d in SP but decreased 2-fold in SU. Expression of acute-phase proteins increased > 60-fold between −30 and 3 d regardless of season, but there was greater overall expression (~40-fold) in SU. Overall, results revealed that during hot seasons the liver transcriptome in peripartal cows is markedly altered and likely contributes to the susceptibility of those cows to develop disease.

Key Words: heat stress, transition cow, transcriptomics

T344 Chronic uterine infusion of melatonin or melatonin receptor antagonist during mid-gestation alters ovine placental nitrites and superoxide dismutase activity. K. E. Brockus*[1], L. E. Camacho[2], K. A. Vonnahme[2], and C. O. Lemley[1], *[1]Mississippi State University, Mississippi State, [2]North Dakota State University, Fargo.*

Previous data from our laboratory showed an increase in umbilical artery blood flow in ewes infused with melatonin (MEL), while in contrast MEL receptor antagonist (luzindole, LUZ) infusion decreased blood flow. The objectives of the current experiment were to determine maternal and fetal concentrations of total nitrites (an index of nitric oxide production) and placental superoxide dismutase (SOD) activity following a 4 week uterine infusion of MEL (n = 5), LUZ (n = 5), or vehicle control (CON; n = 4). Singleton pregnant ewes were implanted with Alzet osmotic pumps (Durect Co; 2.5 μL/h infusion of 1 mg/mL MEL or LUZ) under the perimetrium of the gravid uterine vascular network on d 62 of gestation. This infusion model resulted in local delivery of MEL to the fetus as evident by a 25% increase in maternal MEL concentrations vs. a 125% increase in fetal MEL concentrations. On d 90 of gestation maternal blood samples were collected, ewes were euthanized, umbilical cord blood samples were collected (combination of umbilical artery and vein), and placentomes were separated and frozen for later determination of tissue levels of nitrites or SOD activity. Total nitrites in maternal serum were not different ($P > 0.50$) across all treatments; however, total nitrites in umbilical cord serum were increased ($P < 0.03$) in both LUZ and MEL vs. CON dams. Placental concentrations of nitrites in the caruncle were increased in LUZ and MEL vs. CON dams, while cotyledon nitrites were not different ($P > 0.10$) across all treatments. Caruncle SOD activity was increased ($P < 0.05$) in MEL dams vs. CON and LUZ; however, cotyledon SOD activity was not different ($P > 0.30$) across all treatments. The results from the current study show an increase in placental antioxidant enzyme activity following chronic uterine MEL infusion, which may be mediating the previously observed increase in umbilical artery blood flow. Moreover, placental nitric oxide production may be increased in both LUZ and MEL infused dams irrespective of the previously observed differences in umbilical artery blood flow.

Key Words: melatonin, nitrites, superoxide dismutase

T345 Follicular dynamics in Holstein heifers subjected to 5-d protocols to synchronize ovulation. H. Ayres*[1,3], L. M. Vieira[1], R. M. Ferreira[1], E. O. S. Batista[1], R. V. Sala[1], J. P. Barbuio[3], F. P. Rennó[1], J. E. P. Santos[2], and P. S. Baruselli[1], *[1]Department of Animal Reproduction, University of São Paulo, São Paulo, Brazil, [2]Department of Animal Sciences, University of Florida, Gainesville, [3]MSD Animal Health, São Paulo, Brazil.*

Three experiments (Exp) were designed to evaluate follicular dynamics in Holstein heifers treated with 5-d protocols to synchronize ovulation. Protocols differed in the source of progesterone (P4), the use or not of GnRH on d 1 of the protocol and type of ovulatory stimulus. In Exp1, heifers received a P4-releasing intravaginal device on D0 and were assigned to receive (n = 12) or not (n = 12) 0.1mg gonadorelin (GnRH; Fertagyl, Merck). On D5, the P4 device was removed and 0.53 mg cloprostenol (PGF; Ciosin, Merck) were administered followed by 0.1 mg GnRH 48 h later. In Exp2, heifers received a protocol similar to Exp1, except that on D0 they were assigned to receive a P4 device and no GnRH (n = 13), a Norgestomet implant (Crestar, Merck) and no GnRH (n = 11), or a norgestomet implant combined with GnRH (n = 12). In Exp3, heifers received a norgestomet implant on D0, which was removed on D5. PGF was administered on D5 and heifers were assigned to receive either 1mg estradiol benzoate (EB, Gonadiol, Merck AH; n = 11) 48 h or GnRH (n = 12) 72 h later. Ultrasonographic evaluations of the ovaries were performed using a 5-MHz linear transducer. Continuous data were analyzed by ANOVA and for binary data by logistic regression (GLIMMIX, SAS). In Exp1, the use of GnRH on D0 did not affect follicular growth and synchronization of ovulation. In Exp2, the use of norgestomet implant without GnRH on D0 anticipated ovulation (76.4 ± 4.3) compared with P4 device (98.5 ± 4.1; $P = 0.003$) and norgestomet implant with GnRH was similar a both. Regardless the use of GnRH on D0, norgestomet implant-treated heifers had larger diameter of the ovulatory follicle (OF) (13.6 ± 0.4) than P4 device-treated heifers (12.3 ± 0.4; $P = 0.01$). As for the ovulatory stimuli, both GnRH and EB had similar ovulation rates (100 and 91.7%, respectively; $P = 0.90$). When P4 was administered via intravaginal insert use of GnRH at the beginning of the protocol did not improve synchronization of follicle growth. However, when norgestomet was the source of P4, administration of GnRH increased the diameter of the OF and synchronized ovulation compatible with insemination at 72 h after implant removal.

Key Words: follicle dynamic, Holstein heifer, progesterone

T346 Associations between plasma anti-Müllerian hormone (AMH) and fertility responses of seasonally calving grazing dairy cows. E. S. Ribeiro*[1], R. L. A. Cerri[2], R. S. Bisinotto[1], F. S. Lima[1], L. F. Greco[1], A. Morrison[3], A. Kumar[3], W. W. Thatcher[1], and J. E. P. Santos[1], *[1]Department of Animal Sciences, University of Florida, Gainesville,, [2]Department of Land and Food Systems, University of British Columbia, Vancouver, BC, Canada, [3]Ansh Labs Inc., Webster, TX.*

The objective was to investigate associations between plasma AMH and fertility of grazing dairy cows subjected to synchronized AI on the first day of a 100-d breeding season. Lactating cows (n = 1,237) in 2 farms had estrous cycles presynchronized and were enrolled in a timed AI (TAI) protocol (GnRH on d −8, $PGF_{2\alpha}$ on d −3 and −2, and GnRH + AI on d 0). All cows received the first AI on the same day (study d 0). Blood was sampled on d −8 and analyzed for AMH using a chemiluminescence immune assay (AnshLite Bovine AMH CLIA). From d 19 to 34, detection of estrus was performed daily and cows were re-inseminated. On d 35, bulls were placed with cows for 65 d of breeding. Concentrations of AMH were affected ($P < 0.01$) by breed and lactation number. Concentrations were higher for Jersey cows, followed by crossbreds and then Holsteins (337 vs. 298 vs. 264 pg/mL). Cows on lactations 2 and 3 had higher ($P < 0.05$) AMH than those on lactations 1 and > 3 (342 and 328 vs. 257 and 273 pg/mL). Plasma AMH was related negatively (AOR = 0.93; $P = 0.01$) with estrous expression at TAI. The odds of detecting a cow in estrus at timed AI reduced 7% per every 100 pg/mL increase in plasma AMH. Nevertheless, AMH was not associated with detection of estrus and re-insemination after first AI. Plasma AMH was not associated with pregnancy per AI (P/AI) for the TAI, but tended ($P = 0.10$) to be positively related to P/AI for the second AI performed after estrous detection (AOR = 1.07) and pregnancy for natural service (AOR = 1.07). Non-pregnant cows at the end of 100-d breeding period had lower ($P = 0.05$) plasma AMH than those that became pregnant (252 vs. 310 pg/mL). In conclusion, concentrations of AMH in plasma were associated with reduced expression of estrus at TAI but not later in the breeding period. Plasma AMH was not associated with fertility of cows subjected to synchronized ovulation, but was associated with fertility of cows that failed to become pregnant to TAI and were subsequently bred on estrus (AI on estrus + natural service). Synchronization of ovulation might override associations of AMH and fertility of lactating grazing cows.

Key Words: AMH, dairy cow, reproduction

T347 Comparison of four methods to determine pregnancy success in beef cattle. G. A. Perry*[1], M. F. Smith[2], and K. G. Pohler[2], *[1]Department of Animal Science, South Dakota State University, Brookings, [2]Division of Animal Science, University of Missouri, Columbia.*

Transrectal ultrasonography has been available for several years, but accuracy is dependent upon a well-trained technician. More recently, blood tests to determine pregnancy have become commercially available. Therefore the objective of this study was to compare the accuracy of determining pregnancy status on d 30 after fixed-time AI among: transrectal ultrasonography, visual observation for return to estrus, and 3 different blood tests. Beef heifers (n = 42 and 69 at location 1 and 2, respectively) and cows (n = 102 at location 1) were synchronized using the PG 6-d CIDR protocol with FTAI at 66 to 72 h after CIDR removal concurrent with an injection of GnRH. EstroTect estrus detection patches were placed on animals (6 or 19 d after AI at location 1 and 2, respectively) and estrus was monitored twice daily until d 30. On d 30, pregnancy status was determined by transrectal ultrasonography and blood samples were collected. Blood samples were sent to Genex, University of Missouri (UM), and BioTracking for determination of pregnancy status. Data were analyzed using the GLIMMIX procedures of SAS with herd as a random effect. When compared with transrectal ultrasonography there was no difference ($P = 0.14$) for assay sensitivity (ability to correctly identify pregnant animals; 99, 98, 94, and 95% for estrous detection, Genex, UM, and Biotracking). There was a tendency ($P = 0.09$) for decreased specificity (ability to correctly identify non-pregnant animals; 82, 67, 82, and 87% for estrous detection, Genex, UM, and Biotracking). There was no difference in the positive predictive value ($P = 0.20$; likelihood a pregnant animal was called pregnant) or negative predictive value ($P = 0.29$; likelihood a non-pregnant animal was called not pregnant) among tests (90 and 99%, 83 and 97%, 89 and 89%, and 92 and 91% for estrous detection, Genex, UM, and Biotracking). Furthermore, there was no difference ($P = 0.25$) in the overall accuracy of the test (percent of time correctly identified; 92, 86, 89, and 92%, for estrous detection, Genex, UM, and Biotracking, respectively). Therefore, several options are available to determine pregnancy status in cattle.

Key Words: fixed-time AI, pregnancy status, blood test

T348 The relation of two apoptosis-related proteins (bax and bcl-2) to adipocyte cell size in bovine adipose tissue. D. Germeroth[1], M. Steyer[2], T. Ettle[3], M. Rodehutscord[2], H. Sauerwein[1], and S. Häussler*[1], *[1]Institute of Animal Science, Physiology and Hygiene Group, University of Bonn, Bonn, Germany, [2]Institute of Animal Nutrition, University of Hohenheim, Hohenheim, Germany, [3]Bavarian State Research Center for Agriculture, Institute of Animal Nutrition and Feed Management, Grub, Germany.*

Programmed cell death (apoptosis) in adipose tissue (AT) is related to adipocyte size. The initiation and regulation of apoptosis can be mediated by the intrinsic pathway through mitochondria. Members of the Bcl-2 protein family, e.g., bcl-2 (anti-apoptotic) and bax (pro-apoptotic) are key regulators involved in this mitochondrial pathway. Our objective was to evaluate whether adipocyte size and the mitochondrial pathway are related in bovine AT. Therefore, Simmental heifers (n = 39) from 2 feeding trials with a mean BCS of 4.0 ± 0.13 (scale 1–5) were examined and AT from the tail head region was biopsied. Cryosections were cut (12–14 µm) and stained with Mayer's hematoxylin, adipocyte area (μm^2) of 100 randomly selected cells per section was evaluated. For immunohistochemistry, sections were fixed in ice-cold acetone at room temperature (RT). Endogenous peroxidase activity and unspecific binding sides were blocked with 0.3% H_2O_2 (15 min, RT) and normal goat serum (1:10, 20 min, RT), respectively. Sections were incubated with monoclonal mouse antibodies against human bax (1:30, RT) and human bcl-2 (1:30, 4°C) over night. Afterward, sections were incubated with biotinylated polyclonal goat antibodies against mouse IgG (1:200) and peroxidase-labeled streptavidin (1:1000) both for 30 min at RT. Staining was achieved by 3-amino-9-ethylcarbazol, counterstaining was done by Mayer's hematoxylin. Bovine placenta (6 µm) served as control. Data (means ± SEM) were evaluated using Spearman correlations. The mean adipocyte size was 6,833 ± 295 μm^2. The mean portions of bax and bcl-2 positive cells were 6.45 ± 0.67% and 12.74 ± 1.31%, respectively. Adipocyte size was positively correlated with bax ($r = 0.571$, $P < 0.001$) and bcl-2 ($r = 0.654$, $P < 0.001$) as well as the portion of bax to bcl-2 ($r = 0.632$, $P < 0.001$). The presence of both apoptosis-related proteins indicates that the mitochondrial pathway of apoptosis functions in bovine AT. Both bax and bcl-2 were related to adipocyte size. The amount of anti- and pro-apoptotic parameters was similar. Therefore, we assume that the mitochondrial pathway leading to apoptosis is not initiated.

Key Words: adipocyte size, dairy cows, Bcl-2 family

T349 Niacin increases adiponectin secretion in differentiated bovine preadipocytes in vitro via G-protein coupled receptor 109A. C. Kopp[1], S. P. Singh[1], H. Sauerwein*[1], and M. Mielenz[2], *[1]Institute of Animal Science, Physiology & Hygiene Unit, University of Bonn, Bonn, Germany, [2]Leibniz Institute for Farm Animal Biology (FBN), Department of Nutritional Physiology, Dummerstorf, Germany.*

Adiponectin (AdipoQ), an insulin-sensitizing adipokine, is involved in regulating energy homeostasis and lipid metabolism by increasing fatty acid oxidation in liver and glucose uptake in adipocytes of monogastrics. The G-protein coupled receptor 109A (GPR109A) is involved in downregulating lipolysis not only by its endogenous ligand β-hydroxybutyrate but also by pharmacological doses of Niacin (NA). In rat adipocytes, increased AdipoQ secretion in response to stimulation with NA was attributed to GPR109A signaling. In cattle, corresponding data are missing. Our objective was thus to examine the effect of NA on AdipoQ secretion and the involvement of GPR109A in bovine adipocytes. A primary cell culture system using differentiated preadipocytes was established. Subcutaneous adipose tissue was collected from 5 Holstein-Friesian dairy cows. Stromal-vascular cells were isolated, pooled and seeded at 2500 cells/cm^2. Preadipocytes after 12 d of differentiation were used. After starvation, cells were incubated either with 100 ng/mL pertussis toxin (PTX), a nonselective G-protein uncoupling agent, or PBS for 16 h to characterize the NA mediating pathway. Afterward cells were treated with NA (10 or 15 μ*M*) for 12 or 24 h or with PBS as controls, respectively. The AdipoQ concentrations in the cell culture supernatants were quantified by ELISA (Mielenz et al., 2013, doi:10.1016/j.domaniend.2012.10.004). Statistical analyses were performed using ANOVA with Bonferroni post hoc tests. Data are given as means ± SEM. The concentrations of AdipoQ for both NA doses and durations of NA treatment were increased ($P \leq 0.001$) to maximal 306 ± 11 ng/mL compared with controls (48 ± 2 ng/mL). Pre-incubation with PTX reduced ($P \leq 0.001$) the response to NA to maximally 2.2 fold higher concentrations than in the controls. Our results of NA stimulated AdipoQ secretion from differentiated bovine adipocytes together with the dampened increase after PTX treatment point to GPR109A as mediating at least partially the NA stimulated increase of AdipoQ secretion in cattle.

Key Words: bovine adiponectin, niacin, G-protein coupled receptor 109A

T350 Effect of storage time on the viability of cryopreserved bovine spermatozoa. A. I. Gallegos*[1], S. A. Ericsson[1], H. D. Blackburn[2], S. F. Spiller[2], B. J. Warnock[1], M. K. Meador[1], M. W. Smith[1], and P. H. Purdy[2], *[1]Sul Ross State University, Alpine, TX, [2]USDA-ARS-National Animal Germplasm Program, Fort Collins, CO.*

Long-term cryopreserved semen viability can affect the National Animal Germplasm Program's (NAGP) sampling strategy and ability to reconstitute livestock populations. Therefore, the purpose of this project was to determine if prolonged storage of cryopreserved sperm affects cell viability. Cryopreserved sperm samples from 12 Hereford bulls were utilized from the NAGP repository. These samples were separated into groups based on storage time of 40–50, 30–39, 20–29 or 10–19 yr. The percentage of progressively (PMS) and total motile sperm (TMS), curvilinear velocity (VCL), and beat cross frequency (BCF) was obtained using computer assisted sperm analysis. Flow cytometric analysis and specific fluorescent stains were utilized for the following viability assessments: FITC PNA – percent live non-acrosome reacted sperm (LNARS); propidium iodide – percent membrane intact sperm (MIS); Yo-Pro-1 - cell membrane integrity/ non-apoptotic sperm (NAS); merocyanine 540 (M540) - percent of sperm with relatively ordered membranes (ROM); and the combination of Yo-Pro-1 with M540 for assessment of membrane phospholipid order (MPO). Differences in measures of sperm viability were assessed using ANOVA with a fixed effect model that included the effects of storage time, type of cryopreservation diluent (milk or egg yolk), and their interaction. Significant differences were not observed for the main effects or for the interaction term (Table 1). These results demonstrate that bovine sperm viability was not affected as a result of the storage time in liquid nitrogen. These results suggest sample deterioration is not occurring and need not be a factor for consideration in collection development and sample utilization.

Table 1. Mean values of stored sperm viability

	Storage (yr)				
Measure	40+	30–39	20–29	10–19	SEM
PMS (%)	6	15	12	11	1.7
TMS (%)	26	45	48	39	3.3
VCL (μm/s)	134	167	164	148	7.9
BCF (Hz)	36	35	32	31	1.3

T351 Effect of exogenous eCG during the first or second service during the Ovsynch protocol upon the pregnancy per insemination of lactating Holstein cows. K. G. Gonzalez-Garcia*[1], C. Leyva[1], C. A. Cancino[1], J. L. Morales[1], M. Mellado[2], F. G. Veliz[2], and C. A. Meza-Herrera[3], *[1]Universidad Autonoma Agraria Antonio Narro Unidad Laguna, Torreon, Coahuila, Mexico, [2]Universidad Autonoma Agraria Antonio Narro, Saltillo, Coahuila, Mexico, [3]Universidad Autonoma Chapingo, URUZA, Bermejillo, Durango, Mexico.*

The aim of this study was to evaluate the effect of eCG during Ovsynch protocol upon the pregnancy per insemination in dairy cattle. Lactating Holstein cows (n = 200) from a dairy herd in northern Mexico, were divided into 2 groups (n = 100 each). Females from both groups were treated according to the Ovsynch protocol (d0 GnRh, d7 PgF2α, d9 GnRh, d10 AI). However, while one group received 400 IU of eCG on d 7 of the protocol, the other group was defined as the control group; all animals in both groups were inseminated at first service. In the second part of experiment, those cows diagnosed as non-pregnant (n = 48), were used to evaluate the effect of a second Ovsynch protocol with (n = 21) and without (n = 27) application of eCG. Those cows injected with eCG but diagnosed as non-pregnant, served as control to the non-pregnant, non-eCG-injected in the first part of treatment. All cows were inseminated at fixed time. Pregnancy diagnosis was performed by rectal palpation at d-39. The pregnancy per insemination of both groups was compared using a chi-squared test (SYSTAT 10 (Evenston, ILL, USA, 2000). The results of the pregnancy per insemination of cows subjected to Ovsynch with and without eCG are included in Table 1. Results suggest that injection of eCG in the first or second service does not improve the pregnancy per insemination in lactating Holstein cows in northern Mexico.

Table 1. Effect of eCG injection at first or second service during Ovsynch protocol on the pregnancy per insemination in Holstein cows

Group	First service (no.)	Pregnancy per AI (%)	Second service (no.)	Pregnancy per AI (%)
eCG	100	21[a]	21	23.8[a]
Control	100	17[a]	27	40.7[a]

[a]Means with different superscripts in each column differ significantly ($P > 0.05$).

Key Words: eCG, Ovsynch protocol, pregnancy

T352 Visual analytics of bovine nutriphysiogenomics datasets. M. J. Khan*[1], M. Welge[1,2], C. Bushell[1,2], M. Berry[1,2], L. Gatzke[1,2], and J. J. Loor[1], *[1]University of Illinois, Urbana, [2]National Center for Supercomputing Applications, Urbana, IL.*

High-throughput microarray technology has provided a wealth of information on the dynamism of the transcriptome in key tissues of dairy cattle during key life stages such as the transition from pregnancy to lactation. With the advent of next-generation sequencing technology and its application in bovine bioscience, high-dimensional data are becoming more prevalent. The research of transcriptome data mining has relied on the use of software which places strict limits of the feature dimensionality, utility, and comprehensibility of analysis. The objective of this study is to develop new, innovative visual and interactive techniques for effectively studying, exploring and experimenting with the data to help form and confirm hypothesis. Technique development is focused on the use of statistical and machine learning tools and approaches in support of data driven biology that are required to underpin and enable modern nutriphysiogenomics research. Five different data sets including cow performance and transcriptomics of mammary gland, adipose tissue and liver were used. Mammary data encompass d −30, −15, 1, 15, 30, 60, 120, 240 and 300 relative to parturition. Adipose data encompass −65, −42, −14, 1, and 14 d in cows fed control or a moderate-energy diet prepartum. Liver data encompass −65, −30, −14, 1, 14, 30, and 49 d in cows fed control, moderate-energy, or underfed energy prepartum. Specifically we are applying approaches in the following areas 1) analyzing and interrogating microarray and next-generation sequencing data sets; 2) extracting quantitative features from large and complex data sets; 3) capturing variation and linking biological processes to phenotypic traits; 4) supporting knowledge-discovery in biological data using visualization approaches. These approaches will allow the researcher to extract relevant features to explain phenotypic behavior. These include the use of "small-multiples" each visually representing the distribution of the data, the display of gene expression amplification for comparison over time and tissues, and techniques that support the exploration of "what if scenarios" to produce alternative phenotypic outcomes.

Key Words: bioinformatics, nutrition, transcriptomics

T353 Effect of vitamin E and R-carnitine on beef cattle finishing performance and profitability. E. Ponce-Cruz[1], J. R. Garduño-Juárez[1], G. Aranda-Osorio*[1], O. Hernandez-Mendo[2], J. C. Garcia-Ortiz[1], M. Cordoba-Alvarez[1], and J. M. Monzon Armenta[1], *[1]Universidad Autonoma Chapingo, Texcoco, Mexico, [2]Colegio de Postgraduados, Montecillo, Mexico.*

The aim of this study was to evaluate the effect of vitamin E and R-carnitine supplementation on feedlot performance of beef cattle and profitability. Twenty-four commercial crossbred (*Bos taurus* × *Bos indicus*) young bulls initially weighing 425.3 ± 31.3 kg were used, which were homogenously divided into 4 groups and randomly assigned to the following treatments: (T1) Control (no supplement added), (T2) vitamin E (3,000 IU/animal/d) for 71 d, (T3) R-carnitine (5 ppm) for 45 d, and (T4) combination of T2 and T3. Cattle received a reception management (identified, vaccinated, dewormed, vitamined and implanted). They were housed in individual pens. The chemical composition of the basal diets was: 13.13% CP; 1.79 and 1.16 Mcal/kg of NEm and NEg, respectively, 11.16% CF, and Ca:P of 1.94. A completely randomized design with the GLM procedure of SAS was used, and when statistical differences were observed, a Tukey test was carried out. The response variables were: dry matter intake (DMI), average daily gain (ADG), feed conversion (FC), feed efficiency (FE) and benefit/cost ratio (BC). There were found not differences ($P > 0.05$) among treatments in any of the variables evaluated, with mean of 12.25 kg/animal/d, 1.65 kg, 7.85 kg, 0.134 g/kg, for DMI, ADG, FC, and FE, respectively. The BC was slightly better for the vitamin E and R-carnitine treatments (1.07) than for the control treatment (1.05). The inclusion of vitamin E at 3,000 IU/hd/d showed not to have negative effect on feedlot performance, thus, it could be used as an antioxidant for beef. R-Carnitine at 5 ppm does not improved animal performance, thus the concentration probably must be increased to find a positive response.

Key Words: bullock, additive, feedlot performance

T354 Influence of prepartum dietary energy on cow and progeny performance. T. B. Wilson*, D. B. Faulkner, and D. W. Shike, *University of Illinois, Urbana-Champaign.*

The objectives of this study were to evaluate the effects of prepartum dietary energy on cow performance, lactation, and reproduction, as well as progeny performance and carcass traits. Spring-calving, mature cows (n = 106; BW = 690 ± 76 kg) were blocked by BW and allotted to 2 dietary treatments: 1) 93% ground hay and 7% dried distillers grains plus solubles (REQ), or 2) 50% corn bran and 50% ground cornstalks (HE). Treatment diets were formulated to be isonitrogenous with REQ and HE providing 100% and 125% of TDN requirements, respectively, and were fed from 90d prepartum to calving. All cows were fed a common diet postpartum. Cow BW and BCS were recorded at 90d prepartum, 24h post-calving, and breeding. Milk production was estimated by the weigh-suckle-weigh technique at 65 ± 9 and 120 ± 9d of age. Calf BW was measured at birth and at weaning (120 ± 9d of age). Calves (n = 86) were fed a common feedlot diet 28d after weaning and individual feed intake was monitored using GrowSafe. Progeny were harvested in 3 groups to target a 12th rib fat thickness of 1.3 cm, determined via ultrasound. From 90d prepartum to breeding, change in BW was greater ($P < 0.01$) for cows fed HE and BCS change tended ($P = 0.07$) to be greater. Birth BW tended ($P = 0.10$) to be heavier for calves born to cows fed HE with no increase ($P \geq 0.18$) in dystocia. There was no effect ($P \geq 0.43$) of dietary treatment on milk production or conception rates. Marbling score, measured via ultrasound, was greater ($P = 0.03$) at weaning for calves born to cows fed HE. Calf weaning BW, initial feedlot BW, final BW, and days on feed were not affected ($P \geq 0.12$) by cow treatment. Feedlot DMI and ADG were not different ($P \geq 0.20$); however, calves born to cows fed REQ tended ($P = 0.06$) to be more efficient. There was no effect ($P \geq 0.29$) of cow treatment on calf mortality or morbidity. Although marbling score was different at weaning, there was no effect ($P \geq 0.20$) of cow treatment on final marbling score or other progeny carcass traits. Feeding cows 125% of TDN requirement from 90d prepartum to calving increased cow BW change with no effect on conception rates, or progeny health, growth and DMI.

Key Words: prepartum, energy, progeny

T355 Effect of ration composition on income over feed cost and milk yield. M. H. Buza*, L. A. Holden, R. A. White, and V. A. Ishler, *The Pennsylvania State University, University Park.*

Feed is the greatest expense in the cost of milk production. With volatility in feed and milk markets, income over feed cost (IOFC) may be a more advantageous measure of profit than feed cost per cow. The objective of this study was to evaluate the effects of ration cost and ingredient composition on IOFC and milk yield. The Pennsylvania State Extension Dairy Team IOFC tool was used to collect data from 91 Pennsylvania farms from 2009 to 2011 and determine IOFC per cow per day. The data collected included average milk yield, milk income, purchased feed cost, ration ingredients, ingredient cost per ton, and amount fed. Feed costs were based on market values rather than on-farm cost. Actual costs were used for purchased feed. Mean lactating herd size was 169.4 ± 10.55, and milk yield was 31.7 kg ± 0.19. Mean IOFC was $7.71 ± 1.006 ranging from -$0.33 in March, 2009 to $16.60 in September, 2011. Data was analyzed using a one-way ANOVA in SPSS. Values were grouped by quartiles and analyzed by individual year and all years combined. Purchased feed cost per cow per day averaged $3.16 ± 1.07 from 2009 to 2011. Milk yield and IOFC did not significantly differ with purchased feed cost, suggesting that purchased feed cost per cow was not a key factor in high milk yield or IOFC. Intermediate levels of forage cost between $1.45 and $1.97 per cow per day resulted in the highest ($P < 0.01$) average IOFC of $8.19 and the highest ($P < 0.05$) average milk yield of 32.3 kg. This suggests that optimal ration formulation was key to increasing milk yield and IOFC. Total feed costs in the top quartile ($6.27 or more per cow per day) resulted in the highest ($P < 0.01$) IOFC showing that minimizing feed cost per cow per day did not result in the highest IOFC. In 2010, the IOFC was highest ($P < 0.01$) at $8.09 for dairies that fed one or more by-products. Intermediate levels of forage cost and higher levels of total feed cost per cow per day resulted in both higher milk yield and higher IOFC suggesting that profit margin was affected by more than just feed cost per cow.

Key Words: income over feed cost, profitability, dairy management

T356 Evaluation of Kemtrace brand chromium propionate on milk production by Holstein cows under heat stress conditions in Pennsylvania. J. Ferguson*, *University of Pennsylvania, Kennett Square.*

A field trial was conducted from June through October 2012 on an 800-cow Holstein dairy in Pennsylvania to evaluate the effect of Chromium Propionate (CrPr, KemTRACE Chromium Propionate 0.4%, Kemin

Industries Inc., Des Moines, IA) on milk production by second lactation and greater cows between 14 and 150 DIM. Two parallel treatment groups, Control (no CrPr) and CrPr (supplemented to provide 8 mg Cr/h/d), were populated by random assignment one wk before trial start. Subsequently, cows leaving the post-fresh group entered treatment groups on an alternating basis while cows with the greatest DIM were removed to maintain pen size at 104 to 116 cows. At the trial start, pre-fresh (−21 d to calving) and post-fresh (≤14 d postpartum) groups received CrPr, supplemented to provide 8 mg Cr/h/d. Data for milk yield, milk components, and DIM were analyzed using PROC MIXED in SAS. The model included fixed effects for treatment, time, DIM, and the interaction of treatment by time, and the random effect of cow within treatment group. Milk yield, kg/h/d, was greater (48.8 vs. 46.2, $P < 0.0001$) for CrPr cows compared with control cows. Milk fat % was lower (3.63% vs. 3.75%, $P < 0.001$) for CrPr cows compared with control cows, but milk fat yield, kg/h/d, was not different (1.76 vs. 1.71, $P > 0.10$). Milk protein % was not different (2.90% vs. 2.91%, $P > 0.10$) between treatment groups, but milk protein yield, kg/h/d, was greater (1.41 vs. 1.33, $P < 0.02$) for CrPr cows compared with control cows. For cows randomized to treatment at the trial start, CrPr supplementation supported 3.6 kg more milk/h/d ($P < 0.05$) than cows receiving no CrPr during heat stress. A treatment by time interaction existed where cows supplemented for <4 wk with CrPr before entering treatment groups were not different ($P > 0.05$) in milk yield between treatments, and cows supplemented for >4 wk with CrPr before entering treatment groups produced 4.8 kg/h/d more milk ($P < 0.05$) from wk 3 to 11 postpartum. These results suggest CrPr supplementation from −21 d pre-fresh through 150 DIM may help maintain milk yield during periods of heat stress.

Key Words: heat stress, chromium, milk yield

T357 Evaluation of KemTRACE brand chromium propionate on reproductive performance of Holstein cows in Pennsylvania. J. Ferguson*, *University of Pennsylvania, Kennett Square.*

A field trial on an 800-cow Holstein farm in Pennsylvania evaluated the effect of Chromium Propionate (CrPr, KemTRACE Chromium Propionate 0.4%, Kemin Industries Inc., Des Moines, IA) on reproductive performance. The trial was conducted from January to October 2012; the dairy was naïve to supplemental Cr. Lactating cows received 8 mg Cr/h/d as CrPr in a base corn mix. Reproductive performance over the previous 6 years served as a baseline for treatment comparisons, and binomial trend analysis with Chi-Square values was used to compare changes in conception rate (CR). Body condition score (BCS) was assessed on post-fresh and high group cows before and during CrPr supplementation and compared by Chi-Square test. Pregnancy rate (PR), determined by life-test method using 21-d intervals post-calving, had increased from 17% in October 2006 to a plateau of 27% from January 2010 through December 2011. This improvement corresponded to an increase in first service CR (FSTCR) from 30% to 45%, which plateaued with the PR. Second, 3rd and 4th service CR were typically below 30% over this period. Following initiation of CrPr supplementation in January, PR began to increase in March, and continued to increase to 31.5% by July and remained over 30% through October. The FSTCR remained at 45%, but 2nd, 3rd, and 4th insemination CR increased from 25, 28, and 33% to 32, 37, and 45%, respectively. The binomial trend for CR from 1st to 4th service was significantly reduced ($P < 0.05$) from a chi-squared value of 11.9 in January to 6.8 in October. Changes in CR for repeat services were not associated with transition cow health, parity or milk yield. Mean BCS for post-fresh cows was similar ($P = 0.22$) from January to May (3.5 vs. 3.5, ± 0.02 SEM), but mean BCS in high group cows significantly increased ($P = 0.023$) over the same period (2.5 vs. 2.8, ± 0.03 SEM). In conclusion, based on the improvement in BCS and the increase in CR for repeated services, the results would suggest that CrPr supplementation ameliorated negative energy balance in cows possibly associated with failure to conceive at FSTCR and with lower CR for subsequent services.

Key Words: reproduction, chromium, dairy

T358 Supplementation with soybean oil increases milk fat and improves milk fatty acid profile in heat-stressed dairy goat. S. Hamzaoui*[1], A. A. K. Salama[1,2], G. Caja[1], E. Albanell[1], and X. Such[1], *[1]Group of Ruminant Research (G2R), Universitat Autonoma de Barcelona, Bellaterra, Spain, [2]Animal Production Research Institute, Dokki, Giza, Egypt.*

In a previous work we observed that heat-stressed goats suffered reductions in milk yield, milk fat, and milk protein. Supplementation with soybean oil may be a useful way to enhance milk quality. Eight multiparous Murciano-Granadina dairy goats (42.8 ± 1.3 kg BW; 99 ± 1 DIM) kept in metabolic cages were used in a replicated 4 × 4 Latin square design with 4 periods; 21 d each (14 d adaptation, 5 d for measurements, and 2 d transition between periods). Goats were allocated to one of 4 treatments in a 2 × 2 factorial arrangement. Factors were no oil (C) or 4% of soybean oil (S), and thermal neutral (TN; 15 to 20°C) or heat stress (HS; 12 h/d at 37°C and 12 h/d at 30°C) conditions. This resulted in 4 treatment combinations: TN-C, TN-S, HS-C, and HS-S. The humidity was maintained at 40 ± 5%. Feed intake, milk yield, milk composition, milk fatty acids, and digestibility were measured. Compared with TN, HS goats had lower ($P < 0.05$) feed intake, milk yield, and milk protein. Soybean oil increased ($P < 0.01$) milk fat by more than 30% and conjugated linoleic acid (CLA) by more than 360%. The Soybean oil supplementation increased milk fat with the same magnitude regardless the ambient temperature. Goats under HS had 5 to 9 points greater ($P < 0.05$) digestibility coefficients than TN goats. In conclusion, feeding soybean oil to heat-stressed dairy goats was a useful way to increase milk fat, CLA, without any effects on intake, milk yield, or milk protein content.

T359 Effects of dietary sea urchin shell powder supplementation on growth performance and ammonia emissions in broilers. C. M. Kim[1], S. C. Kim[2], S. M. Amanullah[2], D. H. Kim[3], H. J. Lee[3], J. H. Choi[4], and I. H. Choi*[5], *[1]Division of Science Education, Chemistry Education Major, Daegu University, Gyeongsan, South Korea, [2]Department of Animal Science (Inst. Agric. & Life Sci.), Gyeongsang National University, Jinju, South Korea, [3]Division of Applied Life Science (BK 21), Gyeongsang National University, Jinju, South Korea, [4]Department of Chemistry, Hanyang University, Seoul, South Korea, [5]Department of Companion Animal & Animal Resources Science, Joongbu University, Geumsan, South Korea.*

A 4-wk trial was conducted to evaluate the effect of diet supplementation with sea urchin shell powder and vitamin D on growth performance and ammonia fluxes in broilers. A total of 240 broiler chickens (Arbor Acres) were allocated in 4 treatments with 3 replicates of 20 birds and fed diets supplemented with 0 (control), 0.1% (T1) and 1.0% (T2) sea urchin shell powder or 1% (T4) vitamin D. The feeding program consisted of a starter diet until 3 wk of age and a finisher diet until 4 wk of age. All broilers and feed were recorded for calculation of growth performance at 1 and 28 d. A 100 g litter sample was collected weekly from 4 random locations within each pen to measure pH. Ammonia fluxes of 4 different sampling locations sampling location were analyzed using a multi-gas analyzer. During the experimental period, there were significantly differences ($P < 0.05$) among all treatments with and no sea urchin shell powder (0.1% and 1%) or vitamin D (1%) in body weight, feed intake, and feed conversion (feed:gain ratio), except for initial body weight. Litter pH values in treatments with 0.1% and 1% sea urchin shell powder and 1% vitamin D (pH 5.87 to 6.77) were significantly lower ($P < 0.05$) than the control treatment (pH 7.60 to 7.73) at 2 through 4 wk. Ammonia fluxes were reduced by 0.1% and 1% sea urchin shell powder and 1% vitamin D treatment ($P < 0.05$) at 2 and 4 wk. When compared with the controls at 4 weeks (25.11 ppm), 0.1%, and 1% sea urchin shell powder (17.78 ppm and 15.67 ppm) and 1% vitamin D (18.11 ppm) resulted in reduction ammonia fluxes form litter by as much as 29.2%, 37.6%, and 27.9%, respectively. Based on the results of this experiment, adding 0.1% and 1% sea urchin shell powder to poultry diets holds great promise for feed additive in broilers or for reduction in environmental impacts, suggesting that a decrease in ammonia fluxes was chiefly related to the lower litter pH.

Key Words: sea urchin shell powder, growth performance, ammonia

T360 Effect of oral supplementation with colostrum and cross-fostering on gilt's litter performance focused on low birth weight piglets. R. Muns*[1], C. Silva[2], X. Manteca[1], and J. Gasa[1], *[1]Servei de Nutrició i Benestar Animal (SNiBA), Departament de Ciència Animal i dels Aliments, Universitat Autònoma de Barcelona, Barcelona, Catalonia, Spain, [2]Departamento de Zootecnia, Universidade Estadual de Londrina, Londrina, Paraná, Brazil.*

The experiment studied the effect of oral supplementation of small piglets, born weighing less than 1.35kg (CON: control group; COL: 15 mL of sow colostrum fed within 4 h after birth), and the effect of cross-fostering 24 h after farrowing on litter performance (litters fixed at 11 piglets, with 3 piglets being born weighing less than 1.35 kg, HL; or with all the piglets being born weighing less than 1.35 kg, LL). Fourteen litters from primiparous sows with 154 piglets (81 small piglets) were used. Litters were allocated to 1 of the 4 treatments: CON-HL, CON-LL, COL-HL, COL-LL. Piglets were weighed on d 1 and 19 postpartum. Mortality was recorded. Data was analyzed using GLIMMIX procedure of SAS with litter as experimental unit and treatment effects and their interaction introduced in the model. At d1, gilts did not differ for litter average piglet BW or CV of litter BW, although HL gilts had quantitatively higher litter average piglet BW than LL gilts (1.52 vs. 1.23 ± 0.028 kg; $P = 0.214$). As expected, HL gilts had higher litter average piglet BW than LL gilts at d 19 (5.43 vs. 4.38 ± 0.267 kg; $P < 0.001$), in addition, LL gilts increased litter average piglet BW when combined with COL rather than with CON (4.81 vs. 3.96 ± 0.153kg; $P = 0.035$). Compared with CON, COL supplementation reduced CV of litter BW at d19 ($P = 0.076$), especially when combined with LL (18.9 vs. 10.1 ± 1.37%; for CON-LL and COL-LL respectively; $P = 0.025$). No small piglets died in HL litters during lactation, and CON-LL nearly doubled COL-LL small piglet mortality rate (8.0 vs. 4.6 ± 0.67%) although such differences were not significant. Allocating small piglets in the same litter through cross-fostering reduced litter growth with numerical negative effect on mortality. Nevertheless, colostrum supplementation of small piglets to improve growth and survival is especially recommended in litters fixed with all of the piglets being small.

Key Words: pig, colostrum, cross-fostering

T361 Forage intake by grazing lactating cows kept in creep-feeding system. V. R. M. Couto*[1], M. F. Paulino[2], N. F. De Paula[2], E. Detmann[2], S. C. Valadares Filho[2], I. M. De Oliveira[2], I. F. S. Maciel[2], C. H. A. Cabral[2], E. Arnhold[1], and J. J. R. Fernandes[1], *[1]Universidade Federal de Goias, Goiania, Goias, Brazil, [2]Universidade Federal de Vicosa, Vicosa, Minas Gerais, Brazil.*

The objective was to evaluate the milk production, the change in body weight (BW) and body condition score (BCS), forage intake, and digestibility of dietary components by lactating Nellore or crossbred cows, with zebu blood predominance, kept under creep-feeding system from 4 to 8 mo of lactation. Forty-one cows and their respectively calves were used. Each set (dam and calf) was randomly assigned to one of 5 supplementation strategies of energy-protein supplement, as follows: control (without energy and protein source, mineral mixture only fed ad libitum), T250 (0.250 kg/animal), T500 (0.500 kg/animal), T750 (0.750 kg/animal), and T1000 (1.000 kg/animal). The forage DM intake, as well as other dietary components were not ($P > 0.10$) affected by treatments and was on average 10.171 kg/day or 22.734 g/kg of BW. No differences were observed ($P > 0.10$) for total digestible nutrients (TDN) intake by the cows with increasing levels of supplementation of the offspring. The digestibility of organic matter, crude protein and neutral detergent fiber did not differ ($P > 0.10$) among treatments. A quadratic effect was observed ($P < 0.10$) for variation of BW gain with a maximum gain of cows when the calves are supplemented with 0.598 kg of concentrate. There was an increase in BW ($P < 0.10$), on average 13.8 kg in cows which calves were supplemented, to the control treatment, this variation was only 1.9 kg throughout the experimental period. There was a linear decrease in milk intake as it provided the concentrate to calves ($P < 0.02$) for each kg of supplement provided to offspring, 2.088 kg of milk was no longer consumed by these calves. The supplementation of suckling calves with protein-energy sources results in lower milk production by the dams and consequently allows an increase in BW of the cows.

Key Words: *Brachiaria decumbens*, energy supplementation, protein supplementation

T362 Heart rate and energy expenditure in pure and crossbred beef cows grazing two allowances of native pastures in Uruguay. A. Espasandin*[1], P. Batista[1], P. Soca[1], M. do Carmo[2], and M. Carriquiry[1], *[1]School of Agronomy, Udelar, Paysandu, Uruguay, [2]INIA-Tacuarembo, Tacuarembo, Uruguay.*

There is information that have demonstrated that heart rate (HR) is an appropriated estimator of energy Expenditure (EE, or heat production) in dairy and beef cows. The objective of this work was to estimate the EE from HR in multiparous beef cows of 2 genotypes: purebred Angus and Hereford (PB), and crossbred F1 (AH and HA; CB) grazing high (HI) or low (LO) forage allowances (6 and 10 kg DM/100 kg LW/day, respectively) of native grasslands in Uruguay. The HR (beats/min) was measured in 24 beef cows (4/treatment) during 5 consecutive days in the summer (lactation period) and registered with individual radio transmitters each 15 s. The EE was estimated using predefined equations relating O_2 pulse and HR and assuming a constant value of O2 uptake-bit between and within cows (HR/day × 0.343 mL O_2/(beat × kg $LW^{0.75}$) × (21.47 J/mL O_2) × (1440 min/day)/1000 J/kJ). The effects of cow genotype, forage allowance and their interaction were analyzed by ANOVA and adjusted Tukey LSmeans were obtained. The HR and EE were affected ($P < 0.05$) by cow genotype, forage allowance and their interaction. CB and LO cows had greater ($P < 0.05$) EE than PB and HI (1174 ± 85 and 1160 ± 72 for CB and LO, vs. 920 ± 59 and 933 ± 74 kJ/day/kg$LW^{0.75}$ for PB and HI, respectively). Those values result as consequence of greater ($P < 0.05$) HR (109 ± 8 and 107.7 ± 7 vs. 86 ± 6 and 87 ± 7 bits/minute). However, the HR was greater ($P < 0.05$) for CB-LO than PB-HI, PB-LO and CB-HA (133 ± 12, 85 ± 8, 83 ± 8 and 86 ± 11 kJ/day/kg$LW^{0.75}$, respectively). The greater EE probably were related to the longer daily grazing time, and consequently dry matter intake, in these cows.

Key Words: beef cow, energy expenditure, forage allowance

T363 Effect of forage allowance on individual and per area production of primiparous beef cows grazing Campos native pastures. M. Claramunt[1], M. Carriquiry[3], and P. Soca*[2], *[1]Facultad de Veterinaria, Universidad de la Republica, Paysandu, Uruguay, [2]Facultad de Agronomia, Universidad de la Republica, Paysandu, Uruguay, [3]Facultad de Agronomia, Montevideo, Uruguay.*

The objective of this study was to evaluate 2 levels of forage allowance (FA) on forage mass (FM) and productivity of primiparous beef cows grazing Campos native pasture. The study took place in Facultad de Agronomía, Uruguay (31°S 57°W). Eighty primiparous cows were assigned to a completely randomized experiment of 2 FA in spatial replication on 2 blocks during 2 years. The experiment started in autumn −150 d postpartum (dpp) and finished 190 dpp. Annual FA averaged 6 and 10 kg DM/100kg liveweight (LW)/d for low (L) and high (H) FA, respectively. The grazing system was continuous. Cow BW and FM were measured monthly and used to adjust FA using the "put and take" method. At 82 ± 12 dpp, cows were exposed to bulls for 80 d. Calf suckling was restricted with a nose plate for 12 d and cows were offered 2 kg/d during 20 d of whole rice middling at 76 ± 12 dpp. Pregnancy diagnosis (PRE) was performed at 205 ± 12 dpp. To use PRE in individual production a reduction of 10% was applied to include calf losses from pregnancy to weaning. Calf weaning weight was adjusted to 205 d (CW). Individual production (kgLW/cow) was calculated as PRE × CW. SR (kgLW/ha) was calculated with testers plus grazers cows × testers weight/plot area. Production/ha was calculated as SR in animal units (380 kg/cow) × individual production. The experimental unit was the plots and group of cows for FM and animal measurements, respectively. Effect of FA on PRE was analyzed by generalized linear mixed model using the logit link function for a binomial distribution. CW and SR were analyzed using a generalized linear model and repeated measurements respectively. Greater FA improved FM (L = 1212 vs. H = 1474 ± 33 kg/ha, $P < 0.004$), PRE (L = 0.6 vs. H = 0.9 ± 0.04; $P = 0.07$) and CW (L = 175 vs. H = 194 ± 16 g, $P < 0.05$). FA did not affect SR but values were quite different (L = 437 vs. H = 339, $P < 0.12$). However H FA increased production/ha (L = 100 and H = 138 kg/ha). In conclusion, greater FA increased production and reproduction of primiparous cows grazing Campos native pastures.

Key Words: forage allowance, stocking rate, beef cow

T364 Natural occurrence of mycotoxins and toxigenic fungi on corn and sorghum silage in Sao Paulo State, Brazil. C. A. R. Rosa*[1,2], L. A. K. Keller[1,2], M. Aronovich[3], and L. R. Cavaglieri[4], *[1]University Federal Rural of Rio de Janeiro (UFRRJ), Seropédica, RJ, Brazil, [2]Conselho Nacional de Pesquisas Científicas (CNPq), Belo Horizonte, MG, Brazil, [3]Agricultural Development Company of the Rio de Janeiro State (PESAGRO), Niteroi, RJ, Brazil, [4]Universidad Nacional de Río Cuarto (UNRC), Rio Cuarto, Cordoba, Argentina.*

Silage is a common widespread practice to preserve forages in Brazil. Poor storage conditions can lead to mold contamination and mycotoxin production. The aim of this study was to establish the occurrence of toxigenic fungal species and to determine aflatoxins (AFs), ochratoxin A (OTA), fumonisin B_1 (FB_1) and deoxinivalenol (DON) in corn and sorghum silages intended for bovines before and after fermentation in farms located São Paulo State in Brazil during period of 2009 to 2012. Fungal counts were done by surface-spread method and toxigenic ability of isolates strains was evaluated with in vitro conditions. AFs and OTA natural contamination was determined by TLC and HPLC. DON and FB_1 was determinate by ELISA. Total fungal counts were generally high (molds that exceeded 1×10^4 cfu/g). *Aspergillus flavus*, *Penicillium citrinum*, and *Fusarium verticillioides* were the prevalent toxigenic strains were isolated. Aflatoxin levels differed ($P < 0.0001$) from 2 to 45 µg/kg and from 2 to 100 µg $kg^{-1\ in}$ pre and post-fermentation samples, respectively (Table 1). OTA, FB_1 and DON levels found in pre-fermentation samples were higher than in post-fermentation (Table 1). Mycotoxins and toxigenic fungi are present before and after fermentation in silages. Aflatoxin B_1 (AFB_1) increased during storage whereas OTA, FB_1 and DON had a little decrease. Determination of mycotoxin levels and their frequency of occurrence in corn and sorghum silage (the main substrates used in Brazil) are important to provide information so that the assessments of risk for animal feed and livestock environment can be made.

Table 1. Mycotoxin levels found in silages samples before and after fermentation (pre- and postfermentation)

Sample	Mycotoxin	Contamination frequency (%)	Level range (µg/g)	Samples exceeding regulation limits[1] (%)
	AFB_1	31	0.002 – 0.045	0
	OTA	9.5	2.00 – 30.00	100
	FB_1	20	0.31 – 2.00	0
Prefermentation	DON	26	0.50 – 2.00	0
	AFB_1	40	2.00 – 100.00	84
	OTA	7	4.47 – 20.39	100
	FB_1	30	0.32.- 2.00	0
Postfermentation	DON	20	0.30 – 1.00	0

[1]Limits: 0.02 µg/g AFB_1 (GMP, 2008), 0.25 µg/g OTA, 50 µg/g FB_1, 12 µg/g DON (EU, 2006).

Key Words: aflatoxin, feedstuffs, mycotoxin

Teaching/Undergraduate and Graduate Education: Teaching and Learning Tools for Animal Sciences

T377 A learner-centered approach to teaching animal reproduction. J. Moro-Mendez*, *EARTH University, Guacimo, Limon, Costa Rica.*

The objective of this study was to develop a method to assess the learning of animal reproduction and artificial insemination (AI) by students enrolled in EARTH University. The student population comes from 25 countries (Africa, Caribbean, Latin America, and the United States). Within the curriculum there are animal science courses, one being Animal Reproduction and Lactation. This second-year course is based on a student-centered approach and combines hands-on practices and theory aimed at facilitating the understanding of reproductive physiology as well as the acquisition of skills, such as AI, body condition scoring, animal welfare assessment, and heat detection. The course is given to 2 groups (approximately 27 students each) from January to May and 2 other groups from September to December. From January 2011 to December 2012, a total of 213 students were evaluated with a questionnaire at the beginning and end of each session to obtain an objective evaluation of their knowledge and skills related to animal reproduction. Grades were analyzed by a one-way ANOVA to determine the effectiveness of the course. The mean grades of the first and second questionnaires were different ($P < 0.05$), 2.7 and 8.1, respectively (in a scale from 1 to 10). At the beginning of each session, 9.5% of the students reported to have some knowledge and/or limited practice of semen thawing and AI; in contrast, the written evaluation showed that 98% of the students did not know how to properly handle frozen semen, or how to perform AI. At the end of the sessions 82% of the students were able to correctly execute each step of the AI process. A group of 23 cycling Brahman cows was synchronized, and students randomly selected from 2 groups (September–December 2012) were assigned to inseminate them in November 2012. After a period of 35 d, 8 cows (34.8%) did not return to heat and were deemed pregnant. It was concluded that the course allowed students the acquisition of a working knowledge of animal reproduction and AI. Additionally, the evaluation tool provided for an objective assessment of the student learning outcome.

Key Words: student-centered, reproduction physiology, artificial insemination.

T378 Targeting global competencies in animal sciences: Reproduction cases on Mexico. J. J. Parrish* and R. L. Monson, *University of Wisconsin, Madison.*

A global perspective is essential to success of the modern animal scientist. Students are unlikely to take specific courses in global competencies or do not have the flexibility. It is essential that a global perspective be incorporated into the required courses in animal sciences. In the fall of 2011 we initiated case study work in a required Reproductive Physiology course dealing with Mexico. Products were a website that presented background and solutions to the case, and a public service announcement related to the case but targeted at a Mexican audience. Results were from evaluations of the project in the fall 2012 semester. The global learning outcomes we sought to address were (1) critical thinking skills and application to solving problems related to a foreign country, (2) communication skills and in particular, strategies to communicate in a language other than English, and (3) appreciation of ethical issues in global agriculture as they relate to reproduction manipulation. The overall impacts we expected to have on students were (1) understanding how theory applies to application in the novel environment of a new culture and ethical system, (2) empathize with individual that have differences based on culture and ethnicity, and (3) development of human capacity for competitiveness in global agriculture. Survey questions were scored on a 1 – 5 scale with 1 being not successful, 3 being somewhat important and 5 being very successful (n = 84). The mean ± SEM scores indicate that the project increased global awareness/competency (3.71 ± 0.11); use of electronic communication tools (3.26 ± 0.13); appreciation of ethical issues in a global agriculture (3.94 ± 0.10); critical thinking ability (4.06 ± 0.11); empathy for individuals whose differences are based on culture, social-economic status, and/or ethnicity (3.92 ± 0.11); and preparedness for understanding global issues in agriculture (3.96 ± 0.11). The approach encouraged students to investigate Mexico, utilize both verbal and written communication skills and appreciate challenges faced in the management of reproduction in Mexico.

Key Words: case studies, international, reproduction

T379 Evaluation of relationships between questions on the IDEA survey for university and animal science courses. M. J. Anderson, K. J. Stutts, M. M. Beverly*, and S. F. Kelley, *Sam Houston State University, Huntsville, TX.*

The Individual Development and Educational Assessment (IDEA) survey is a mechanism that uses student feedback to assess and improve teaching, learning, and the higher education process. The IDEA survey contains questions pertaining to course objectives, teaching methods and styles, and a description of the course with the goal of determining the quality of the instructor and overall course. The objective of this study was to determine relationships among questions on the survey and to determine if differences existed between animal science courses and all other courses offered at the university. Data from 27,430 courses (238 animal science courses) taught over a 6-year period at Sam Houston State University were used in this study. Correlations were calculated between all questions on the survey to determine if relationships existed between each of the individual questions for both university (Univ) and animal science (AnSc) courses. Questions which pertained to the amount of work, assignments, and overall course difficulty (questions 33–35), were not strongly correlated ($r < 0.70$; $P < 0.01$) to any other survey questions for Univ or AnSc courses. Additionally, for AnSc courses, questions concerning the desire to take the course regardless of the instructor and students' workload compared with other courses (questions 37 and 39) were not strongly correlated ($r < 0.70$; $P < 0.01$) to any other survey questions. For Univ courses, questions pertaining to instructor abilities and progress toward specific objectives (questions 1–32) were consistently strongly linked ($r > 0.70$; $P < 0.01$) to each other. However, for AnSc courses, this association between questions 1–32 was weaker than the association observed for Univ courses. These correlations indicate that students in animal science have a different perception of courses than the university student body as a whole. As instructors in animal science, it is our obligation to identify how our students differ from the rest of the university and adjust our teaching styles to accommodate those differences.

Key Words: undergraduate teaching, IDEA, animal science

T380 Implementation of a hybrid-flexible instructional model in the animal sciences—Technical considerations to optimize student educational experience. M. C. Chakerian*, T. A. Evans, B. A. Wenner, R. W. Flood, M. R. Hendrick, H. N. Zerby, and J. M. Osborne, *The Ohio State University, Columbus.*

Instructors of the animal sciences writing course Animals in Society redesigned it to utilize technology to enhance the student learning experience (funded by the OSU Office of Distance Education and eLearning). The priority was to provide students flexibility for how and where they attended lectures, while considering student preferences for in-person engagement with the instructor and/or lack of confidence in technology skills. Increased class size, limited access to large lecture halls, and issues with student movement on the Columbus campus due to conversion to a semester system contributed to the need for course attendance options. The Hybrid-Flexible (Hy-Flex) Instructional Model is a course framework that allows students to choose daily to attend lecture in-person or synchronously online. Elements of the delivery system were selected for compatibility with classroom infrastructure and the OSU course management system, cost to students, and ease of use by instructors and students. Based on these criteria, Adobe Connect and Poll Everywhere were selected; an activity was designed for students to test the technologies before course implementation. In autumn 2012, 94 students consented to participate in a research study. At the start of the term, 8% of students noted they would always/almost always attend class online, while 79% indicated they planned to attend mostly/always in person. At the conclusion of the course, 72% reported attending always/almost always online, while 21% reported attending almost always/always in person. Attendance data support student perception. For the term, 19% of students attended online less than 20% of the time and 64% attended online greater than 60% of the time. The problem most frequently reported by students attending online was wireless access in their location. Student perception of satisfaction and comfort with technology utilized both exceeded 85%. Results suggest that the technologies employed satisfied the criteria to support student engagement with the course and provided a highly acceptable alternative for students.

Key Words: technology, online, anytime/anywhere learning

T381 Student perception of horsemanship skills after completion of a horse judging course. M. Nicodemus*, T. Bova, and B. Tisdale, *Mississippi State University, Mississippi State.*

Through thorough consideration horse judging officials form an opinion concerning the ranking of horse show classes they are judging and this is done using their past horse experience. Through collegiate horse judging courses students develop the experience needed to judge. This experience is often based on observations of horse show classes, but it usually does not include the students performing the activities associated with the class they are judging; and thus, study objective was to determine if through the observational activities during a collegiate horse judging course students gain a perceived ability to be able to perform the classes they are judging. A 19 question survey was given to students (n = 20) at the start and end of a collegiate horse judging course with questions focused on the students' perceived ability of their horsemanship skills using a Likert scale of 1–5 with higher scores indicating a higher perceived ability to perform the horsemanship activity. Average scores were determined for each question and analyzed by a one-way ANOVA to determine the influence of the course on perceived horsemanship abilities. All questions showed score improvement with 3 questions resulting in significant increase of scores ($P < 0.05$) in which these questions focused on more advanced pattern work on the ground and under saddle, which were all topics covered in the course. None of the questions resulted in an average score of 5 as the highest score was 4.5 given for 2 questions for the final course survey focused on basic ground handling and health care activities. By the end of the course, the lowest score was 3.1 with the question focusing on advanced riding activities specific to society-type breeds in which these breeds and their associated classes such as native costume, liberty, and saddle seat were not covered in this course. In conclusion, while the learning objectives of a collegiate horse judging course are not focused on developing horsemanship skills, the students' perception of their horsemanship abilities may be improved by the development of their abilities to judge the classes associated with these horsemanship activities.

Key Words: horse judging, horsemanship

T382 Reorganization of experiential learning activities into a single multi-section course. A. C. Dilger*, L. Redman, and W. L. Hurley, *University of Illinois, Urbana.*

Encouraging students to engage in out-of-the-classroom learning experiences is a long-standing priority in the Department of Animal Sciences at the University of Illinois. Recently, experiential learning opportunities fulfilling this curriculum requirement were organized under one multi-section course. Students are required to complete a memorandum-of-agreement with a faculty supervisor outlining their proposed activity, learning objectives, and work product to demonstrate their learning. Considerable flexibility was maintained within this organization so that students can pursue a wide range of experiences. This reorganization provides the opportunity to evaluate the breadth of the students' experiential learning activities. From the summer 2012 through spring 2013, 185 students (39% of the animal sciences majors) completed 238 experiences supervised by 38 different faculty supervisors. Students engaging in multiple experiences accounted for 17.7% of the total, with 14.3% engaging in 2 experiences and 3.4% engaging in 3 to 5 experiences. Students earned 1 (49.2%), 2 (29.8%), 3 (13.0%), or 4 h (8.0%) of credit for experiences across an array of activities. The majority of experiences involved undergraduate research (33.2%). A substantial number of experiences reflected a companion or exotic animal interest including internships at a local county humane society (18.9%), companion animal spring break trip (13.4%), working with a veterinarian (8.0%) and interning at zoos, sanctuaries or rescue organizations (3.0%). Other experiences included teaching assistance in the required animal handling course (8.0%), on-campus special projects (4.2%) and internships with agriculture groups (1.7%) or companies (1.7%). Study abroad accounted for 3.8% of the experiences. Organization of diverse experiential learning opportunities under one course number with multiple sections provides important information about the range and nature of opportunities in which students engage. This allows the department to further enhance the value of experiential learning to its students.

Key Words: experiential learning, course organization, undergraduate

T383 Effect of correcting missed exam questions (regrading) as a learning tool in physiology courses. J. Winkler*, A. Sexten, A. Rhodes, and T. Rozell, *Kansas State University, Manhattan.*

Teaching large lecture courses presents many challenges for enhancing and monitoring student learning using exams. One technique that may improve student learning and provide more individualized opportunities for instructor feedback is the use of an exam "regrading" exercise. Students in ASI 533, Anatomy and Physiology, at KSU have the opportunity to correct exam questions and receive up to half credit for

points originally missed. This assignment allows students an opportunity to correct misconceptions soon after the exam, with an incentive of receiving credit to improve their overall score. The objective of this study was to determine whether performance on the regrade assignment is predictive of the comprehensive final exam and overall grades in the course. To meet this objective, original exam scores, regrade scores, final exam scores, and overall course scores were analyzed by ANOVA (n = 999). Data have been compiled over the past 7 years, beginning in the fall of 2005. Students doing at least one exam regrade had significantly greater mean final exam scores and overall course grades ($P < 0.05$). The results varied from year to year, but in most years students that did regrades for at least 3 exams had greater final exam and overall course grades ($P < 0.05$) than those doing no regrades. From our results it appears that the exercise of going through exam questions missed soon after the test and explaining the correct answer is valuable for student comprehension and likely retention of basic concepts, as assessed by the comprehensive final exam and overall course grades.

Key Words: student learning, exam regrades, comprehension

Graduate Student Competition: ADSA Dairy Foods Division Oral Competition

14 Tracking heat-resistant, spore-forming bacteria in the milk chain: A farm-to-table approach. M. Estrada*, J. Stratton, and A. Bianchini, *University of Nebraska-Lincoln, Lincoln.*

Thermoduric spore-forming bacteria *Bacillus* and *Paenibacillus* spp. can survive processing and refrigerated conditions causing spoilage of fluid milk, limiting the shelf life of the product beyond 14 d. The objective of this study was to evaluate the fluid milk chain for *Bacillus* and related genera to identify their potential sources. Raw milk, pasteurized milk and environmental samples representing the farm-to-table continuum were collected in the spring of 2012 from a dairy farm and a medium-size processing plant in the Midwest, supplied exclusively by that farm. Environmental samples from the dairy farm included feed, drinking water, bedding material, manure, milking parlor wash water, teat cloths and sponges (milking clusters and teats). Environmental samples from the processing plant included rinse water (tanks and mixer), and swabs (filler's surface and nozzles). Environmental and raw milk samples were heat-treated at 80°C for 12 min to eliminate vegetative cells. Pasteurized milk samples were evaluated for quality and, along with heat treated samples, stored at 6°C for 21 d. Samples were enumerated for microbial load and the plates used for bacterial isolation throughout storage. Colonies with the distinct morphology of *Bacillus* spp. were isolated and characterized using a subtyping method based on the DNA sequence of their rpoB gene. A total of 34 different rpoB allelic types representing *Bacillus* (99% of isolates) and *Paenibacillus* spp. (1%) were identified among 72 bacterial isolates. The *Bacillus* spp. clade was represented mainly by *B. licheniformis* (40% of isolates), *B. pumilus* (33%) and *B. subtilis* (14%). Two allelic types were identified in both raw and pasteurized milk, indicating the raw milk supply as a possible source of these bacteria. Six allelic types were found in milk and environmental samples (farm and processing plant), suggesting that these bacteria can enter the fluid milk chain from different sources. This data will help in the development of intervention strategies for controlling spoilage by spore-formers and extending the shelf life of pasteurized milk.

Key Words: HTST milk, spore-formers, subtyping

15 Pulse electric fields treatment maintains the antiproliferative activity of the milk fat globule membrane on colon carcinoma cells. S. Xu*[1], M. Walkling-Ribeiro[2,1], M. W. Griffiths[2,1], and M. Corredig[1], *[1]University of Guelph, Guelph, ON, Canada, [2]Canadian Research Institute for Food Safety (CRIFS), Guelph, ON, Canada.*

The milk fat globule membrane (MFGM) components have antiproliferative activities against colon cancer cells. The present work investigated the effect of processing of the cream on the antiproliferative activity of MFGM. Unheated cream and commercially pasteurized cream were collected from a local dairy immediately after separation. Pulsed electric fields (PEF) with 37 kV/cm field strengths for 1705 μs was applied to unheated cream, at 50°C and 65°C. The electrode gap was 0.21 cm and the flow rate of cream was 25 mL/min. PEF control treatments were carried out at 50°C and 65°C for 3min, the passage time in PEF chamber to mimic the effect of heating. For comparison, the unheated cream was also heat treated at 5 different temperature/time combinations: 50°C/10 min, 60°C/2 min, 60°C/10 min, 70°C/30 s and 70°C/2 min. After processing, all cream was processed to butter, and MFGM isolates were obtained from buttermilk using centrifugation at 70,000 × *g* for 45min at 15°C. The antiproliferative activity of extracts was tested on human adenocarcinoma HT-29 cells, incubated for 24 h then stimulated with 0.4, 0.2, or 0.1 mg/mL various MFGM isolates for another 24 h. Cell proliferation was tested using a colorimetric method (BrdU). All samples heated below 70°C showed significant cell reduction ($P < 0.05$, using ANOVA) from control at the highest 2 concentrations, with 70°C/30 s sample only at the highest concentration. The 70°C/2 min sample even helped cell growth, comparable to the commercially pasteurized sample. There was a reduction up to 52% in cell proliferation in PEF samples, with no significant difference compared with PEF controls, suggesting electrical field itself did not affect the anticarcinogenic activity of MFGM. Commercially pasteurized samples and heat treated samples showed a decrease in bioactivity. PEF did not change the phospholipids composition compared with PEF controls, while heating showed protein-protein interactions and a decrease in phospholipids as measured by ^{31}P NMR. PEF may be a promising process to maintain valuable bioactivity in the MFGM.

Key Words: milk fat globule membrane (MFGM), anticarcinogenic activity, pulsed electric field (PEF)

16 Effect of the heating of whey proteins in the presence of milk fat globule membrane extract or phospholipids from buttermilk. M. Saffon*[1], R. Jiménez-Flores[2], M. Britten[3], and Y. Pouliot[1], *[1]STELA Dairy Research Center, Institute of Nutrition and Functional Food (INAF), Laval University, Quebec City, QC, Canada, [2]Dairy Products Technology Center, California Polytechnic State University, San Luis Obispo, [3]Food Research and Development Center (FRDC), Agriculture and Agri-Food Canada, St-Hyacinthe, QC, Canada.*

Previous work suggests that phospholipids from buttermilk were involved during the heat-induced formation of protein aggregates from whey and buttermilk proteins. It was hypothesized that "free" phospholipids from buttermilk initiates the formation of whey proteins aggregates. Whey protein isolate (WPI) was dispersed in water to a concentration of 5% protein (w/v), and the pH was adjusted to both 4.6 and at 6.8. Solutions were heated to 65°C or 80°C for 15 min under constant stirring. Milk fat globule membrane (MFGM) extract isolated from whey buttermilk or commercial phospholipids (PL) powders were dispersed in the WPI solutions at 1.0% (w/v) before heating. The aggregate composition was characterized with Ellman's reagent (free thiols), SDS-PAGE electrophoresis, thin layer chromatography (TLC), and 3-dimensional confocal laser-scanning microscopy (CLSM). All experiments were performed in triplicate and the concentration of free thiol groups were tested according to a factorial design. Addition of phospholipids or MFGM extract did not significantly affect the liberation of free thiol groups of whey proteins but delayed the loss of the native form of major whey proteins by 5 min at pH 6.8. TLC profiles showed no trace of phospholipids after 20 min of heating WPI-PL mixtures at 80°C at pH 4.6. CLSM images confirmed that only a few interactions occurred between whey proteins and MFGM proteins/phospholipids in the whey solution, while the interactions were frequent in the presence of MFGM extract or phospholipids. Overall, our results show evidence that phospholipids from buttermilk are involved in the formation of protein aggregates through the MFGM fragments at 65°C, whereas they can directly interact with the proteins at 80°C. Results allow the consideration of

new potential applications for the use of dairy products that are rich in phospholipids such as regular or whey buttermilks.

Key Words: buttermilk, phospholipid, aggregation

17 Effect of ultra-high pressure homogenization on physicochemical properties of pasteurized skim milk. M. S. Mohan*, R. Ye, and F. Harte, *Department of Food Science and Technology, University of Tennessee, Knoxville.*

Recent developments in material science and engineering enabled us to study the effect of ultra-high pressure homogenization (HPH; up to 500 MPa) on the physicochemical properties of milk. We report the effect of HPH of pasteurized skim milk (0 to 500 MPa followed by immediate chilling) on pH, apparent casein micelle size (dynamic light scattering; pH 2 to 10), turbidity (absorbance at 550 nm; pH 2 to 10), heat stability (120°C; pH 6.3 to 6.7), viscosity (flow curve), and viscoelasticity after rennet addition (G′; 90 min, 1Hz, 0.1% strain). All HPH milks were stable for more than 10 d without visible coagulation. The pH of all except 500 MPa milk were slightly higher (up to 0.13 pH units) than 0 MPa milk (pH 6.81). Maximum casein micelle size was observed after HPH of milk at 500 MPa (ca. 500 nm) compared with 0 MPa milk (ca. 250 nm) at pH 5. However, 500 MPa milk remained stable above this pH and coagulated together with the other milks below pH 5. From pH 6 to 8 the casein micelle size of 500 MPa milk decreased until it was same as 0 MPa milk at pH 9 and 10. Although the absorbance of 0 MPa was higher than 500 MPa milk at pH 8 to 10, indicating differences in particle size and absorbance observations, the trend was similar for both measurements at pH 6 and 7. At normal milk pH (6.6 and 6.7) all the HPH milks remained stable for 24 min at 120°C. With increase in pressure the casein micelles were first partially broken down (at 100 MPa), re-aggregated (until 400 MPa) and then re-dispersed (at 500 MPa), confirmed by microscopic image and particle size analysis. The rennet coagulation of 500 MPa milk did not occur even after 90 min. Overall, 500 MPa pressure did not significantly affect the pH, heat and shelf stability of milk, but altered the viscosity and renneting properties. Further understanding these changes will enable the novel use of HPH milk proteins as ingredient in products including cheeses.

Key Words: high pressure homogenization, pasteurized skim milk, casein micelle

18 Performance of modified milk protein concentrates in model high-protein nutrition bars. J. Banach*, S. Clark, and B. Lamsal, *Iowa State University, Ames.*

The nutritional value and flavor of milk protein concentrates (MPC) are desirable for high-protein nutrition (HPN) bar applications. However, rapid hardening and crumbly texture upon incorporation limit its use. Extrusion and toasting were used to modify MPC at 80% protein (MPC80) and performance was evaluated in model HPN bars. MPC80 was extruded in a twin-screw co-rotating extruder at 2 ramped temperature profiles with die temperatures of 65 or 120°C. Extrudates were dried and finely ground (<250 mm). Toasting of MPC80 was done in a convection oven at 75 or 110°C for 4 h. Model bars contained 30% protein, 22% glycerol, 19% palm kernel stearin, 12% maltitol syrup, 10% high-fructose corn syrup, and water. Dough was sealed into cylindrical molds and in water activity sample cups, and stored at 22, 32, or 42°C. Bar texture (hardness, fracturability, and shear), water activity, and color change were measured over 42 d. Disulfide bond formation in bars was studied with sodium dodecyl sulfate PAGE (SDS-PAGE). Sample means were compared with Tukey's adjusted *P*-value ($P < 0.05$). Toasted MPC80 in bars had texture similar to unmodified MPC80 (control). Bars prepared with MPC80 extruded at 65°C were significantly softer than bars made with control MPC80. Significant difference in hardness and fracturability between bars formulated with MPC80 extruded at 120°C and those prepared with control MPC80 was intermittent. Water activity of the bars increased slightly during storage, but remained less than 0.65, which assured shelf stability. Total color change was limited at 22°C storage, but increased significantly at 32°C and 42°C. Non-reduced SDS-PAGE showed that the whey protein in bars prepared with extruded MPC80 was not soluble on Day 0; its solubility under reduced conditions indicated that disulfide bonds were formed before bar manufacture. Internal protein aggregation did not occur because free sulfhydryls were previously reacted, and thus low temperature (65°C) extrusion of MPC80 may improve performance in HPN bars.

Key Words: milk protein concentrate, high-protein nutrition bar, texture

19 Concentration of milk by ultrafiltration modifies the acid-induced gelation properties of casein micelles. Y. Li* and M. Corredig, *University of Guelph, Guelph, ON, Canada.*

Membrane filtration is a widespread unit operation in dairy technology, and little is understood on how concentration by ultrafiltration (UF) and diafiltration (DF) may change the processing functionality of the casein micelles. This study investigated the acid (gluconoδ-lactone, 1.3% wt/wt for control; 1.8% wt/wt for 2×; 3.0% wt/wt for 4×, at 40°C) induced gelation behavior of milk concentrated by UF and DF with and without heat treatment at 80 ± 1°C for 15 min. Measurements of soluble and insoluble calcium by ion chromatography suggested that there was a lower amount of colloidal calcium phosphate in the casein micelles concentrated (4 ×) by UF compared with those in single strength milk. In addition, the amount of colloidal calcium in the heated concentrated milk was significantly lower than for unheated concentrated milk. Size exclusion chromatography on the soluble fraction demonstrated that DF caused compositional changes in the serum fraction compared with UF. The processing history (DF, UF and heating) strongly affected the gelation behavior of the concentrated milk: The gelation pH, measured by rheology and diffusing wave spectroscopy, significantly increased with the extent of concentration ($P < 0.05$, as measured by ANOVA), due to a reduction in the interparticle distance and because of the changes occurring to the soluble fraction. Concentrated samples formed significantly ($P < 0.05$) stiffer gels than control milk because of an increased amount of linkages in the network. DF milk showed a significantly higher gelation pH compared with the UF milk at the same volume fraction. In addition, compared with UF milk, heated DF milk had even higher pH of gelation, but no significant difference in the gel stiffness (pH = 4.6) between the 2 treatments. This work clearly demonstrated for the first time that UF and DF changes the composition of the soluble fraction, and affects the acid induced behavior of concentrated milk.

Key Words: concentrated milk, unheat and heat treatment, gelation behavior

20 The effects of sodium reduction, with and without KCl, on blue cheese. A. Pataky*[1], S. Rankin[2], Z. Vickers[1], and T. Schoenfuss[1], *[1]University of Minnesota, Saint Paul, [2]University of Wisconsin, Madison.*

Blue cheese contains approximately 400 mg sodium per 28-g serving, twice the amount found in Cheddar. Salt is essential to blue cheese ripening and microbial safety. Because blue cheese is often surface-salted, the effects of sodium reduction may be more noticeable in the center of the cheese wheel. The purpose of this study was to evaluate the effects of sodium reduction (25%) on blue cheese composition, flavor, sensory, and proteolytic properties with and without the use of potassium chloride (KCl) at 2 locations in the cheese wheel. Three-kg wheels of pasteurized milk blue cheese were produced from 2,100 kg of milk (in duplicate), and 3 salting treatments were applied to randomly selected wheels. Salt was applied by % weight of the wheel in the following treatments: Control (C; 3.5 wt% NaCl), reduced sodium (R; 2.63 wt% NaCl), and reduced sodium with KCl (RK; 2.63 wt% NaCl, 1.17 wt% KCl). Wheels were evaluated monthly during 5 mo of aging, sampling both inner and outer portions of the cheese wheel. Sodium and potassium concentrations, fat, moisture, pH, a_w, volatile free fatty acids, and extent of proteolysis (as measured by free amino acids) were measured. Sensory attributes (aroma, taste, aftertaste) and volatile flavor chemicals were measured at mo 3 and 5. Salt reductions of 24% and 21% in RK and R, respectively, were achieved. The water activity of C and RK treatments was 0.935 at 5 mo of age. R was higher (0.945). A greater extent of proteolysis was observed in R compared with C. A descriptive sensory panel found higher overall flavor intensity and "waxy" aroma in the inner portion of the cheese compared with outer portions ($P = 0.013$), and in RK when compared with C ($P = 0.036$). Concentrations of medium chain fatty acids were higher in RK than C. Flavor volatiles associated with blue cheese were found in higher concentrations in RK treatment, specifically 2-octanone, 2-nonanone, butanoic acid, and 2-hexanone. A consumer panel (n = 95) ranked overall liking for all treatments similarly, and higher texture liking for RK. Reduction in sodium with and without KCl produced consumer-acceptable blue cheese despite sensory and compositional differences.

Key Words: sodium reduction, blue cheese, KCl

21 Improving the quality of low sodium Cheddar cheese. M. Ozturk*[1], S. Govindasamy-Lucey[2], J. J. Jaeggi[2], M. E. Johnson[2], and J. A. Lucey[1,2], *[1]University of Wisconsin, Madison, [2]Wisconsin Center for Dairy Research, Madison.*

Low Na cheeses often exhibit acidic and bitter flavor and pasty texture. We proposed that starter-induced acidity could be prevented by decreasing microbial activity by the application of high hydrostatic pressure (HHP), and by increasing curd buffering with use of ultrafiltration (UF) retentates. Camel chymosin was used as a coagulant to reduce proteolysis and thus bitterness. Three types of low Na (0.8% NaCl) cheeses were manufactured: non-UF fortified, no HHP applied; UF fortified (17.2 ± 0.6% TS), no HHP applied; and UF fortified, HHP (500 MPa for 3 min applied at 1 d). Regular salt (2% NaCl) non-UF fortified, no HHP applied cheese was also manufactured. Average composition of all cheeses was 36.3 ± 1.4% moisture, 33.8 ± 0.8% fat, and 25.4 ± 0.8% protein. Analysis was performed at 4 d, 2 wk, 1, 3 and 6 mo after cheese manufacture. Cheese functionality during ripening was assessed using texture profile analysis (TPA) and dynamic low-amplitude oscillatory rheology. Quantitative descriptive analysis was conducted with 9 trained panelists to evaluate texture and flavor attributes using a 15 point scale. Pressure treated low Na cheese had ~1.5, and ~3 log lower starter culture numbers than all samples at 4 d and 2 wk, respectively. Cheese milk retentate fortification and HHP treatment resulted in low Na cheeses with significantly ($P < 0.05$) higher acid/base buffering capacity and pH values. For low Na cheeses, retentate fortification significantly ($P < 0.05$) increased cheese firmness measured at 4 d of ripening; however, by 1 mo all low Na cheeses exhibited similar hardness values, which were lower than regular salt cheese. Pressure treatment significantly ($P < 0.05$) increased maximum loss tangent (meltability) and decreased melt temperature. Sensory results indicated only very slight bitterness (<2 out of 15 point scale) development for all cheeses during 3 mo of ripening. Pressure treated and UF-fortified cheese was rated significantly ($P < 0.05$) lower in acidity during ripening. Pressures of 500 MPa and milk retentate fortification could be used to improve the quality of low Na cheese.

Key Words: high pressure processing, low sodium cheese, milk retentate

22 Influence of depletion flocculation and continuous phase viscosity on the stability of sodium-caseinate-stabilized emulsions. Y. C. Liang*[1,2], H. Patel[3], L. Matia-Merino[2], A. Q. Ye[4], G. Gillies[1], and M. Golding[2,4], *[1]Fonterra Research and Development Centre, Palmerston North, New Zealand, [2]Institute of Food, Nutrition and Human Health, Massey University, Palmerston North, New Zealand, [3]Dairy Science Department, South Dakota State University, Brookings, [4]Riddet Institute, Massey University, Palmerston North, New Zealand.*

Creaming has a detrimental effect on the quality of a protein-rich oil-in-water emulsion because the emulsion tends to separate into a droplet-rich phase and a droplet-poor phase during aging, which reduces its visual appearance and mouthfeel. We explored the stability and rheological properties of sodium-caseinate-stabilized emulsion. The formation of the transient gel network was studied by microstructure, and by large and small deformation rheology. Sodium caseinate was reconstituted to a 3% (wt/wt) solution. Corn oil (60% wt/wt) was mixed with the protein solution. The mixture was homogenized to yield a stock emulsion, which was then mixed with stock caseinate (20% wt/wt), xanthan gum (2% wt/wt), and maltodextrin (40% wt/wt) solutions to produce final 30% oil-in-water emulsions containing 2 to 10% caseinate, 0.01 to 0.2% xanthan gum, and 5 to 20% maltodextrin, respectively. The pH was adjusted to 6.8 ± 0.04 for all model emulsions. All the samples were prepared separately in duplicates. The emulsions displayed 2 types of behavior. At 1.5 to 4% caseinate, the emulsion separated rapidly, whereas a droplet network with stronger attractions formed slowly at high concentrations (5 to 10%), arresting the phase separation transiently. Small deformation rheology showed that the development of the transient droplet network depended markedly on the unadsorbed caseinate concentration. Droplet rearrangements were possibly influenced by both the strength of the depletion force and the continuous phase viscosity at high caseinate concentrations. Interestingly, droplet network was weakened with the addition of maltodextrin, with a stabilizing mechanism that differed from the prediction that the low shear viscosity will prevent phase separation of the emulsion. The understanding of the development of caseinate-induced droplet network provides a mechanism capable of controlling the creaming behavior of emulsion. We find a good correlation between visual observation and small deformation rheology. More stable samples exhibit a longer droplet network formation time than the less-stable ones.

Key Words: caseinate, depletion flocculation, stability

23 High feed efficiency for milk is associated with high feed nitrogen efficiency in dairy cows. C. Arndt*[1], M. A. Wattiaux[1], J. M. Powell[2], and M. J. Aguerre[1], *[1]Department of Dairy Science, University of Wisconsin, Madison, [2]USDA-Agricultural Research Service, US Dairy Forage Research Center, USDA-ARS, Madison, WI.*

Greater feed N efficiency for milk N could enhance dairy farm profits and reduce manure N excretion and environmental risks. The objective was to evaluate relationships between feed efficiency for milk (FEmk, kg milk/kg DMI) and measures of feed N efficiency in dairy cows. Eight pairs of mid-lactating cows (primiparous or multiparous <16 DIM apart within each pair) with high and low FEmk of 1.78 and 0.98 kg/kg, respectively, were fed a TMR (47% DM) consisting of 28% corn silage, 27% alfalfa silage and 45% concentrate, containing 16% CP and 28% NDF (DM basis) for at least 4 weeks. During a 3-d period TMR, feed refusals, milk, total feces and total urine were measured, sampled daily and analyzed for N concentrations. Data were analyzed as a randomized complete block with cow pairs as blocks and FEmk as treatment. High FEmk cows had 15% greater N intake (NI), 32% greater fecal N (FN) excretion and 5% lower apparent N digestibility than low FEmk cows (see Table 1). Despite similar digested N high FEmk cows secreted 1.9 times more N in milk than low FEmk cows, yet urine N (UN) and manure N (FN + UN) excretion were similar. High FEmk cows had greater feed N efficiencies (30% of NI secreted as milk N) than low FEmk cows (19%). Also, high FEmk cows excreted 45% less manure N/milk N and manure UN to FN ratio was 30% lower than in low FEmk cows. High FEmk cows were more feed N efficient due to metabolic rather than digestive processes. Selection for high FE cows may increase feed energy utilization as well as feed N utilization and decrease risk of manure ammonia and nitrous oxide emissions due to reduced manure UN to FN ratio.

Table 1.

Item	FEmk1		SEM	*P*-value
	High	Low

24 Tumor necrosis factor-α injection promotes liver inflammation and decreases gluconeogenesis in early lactation dairy cows. K. Yuan*[1], J. K. Farney[1], L. K. Mamedova[1], L. M. Sordillo[2], and B. J. Bradford[1], *[1]Kansas State University, Manhattan, [2]Michigan State University, East Lansing.*

The first week of lactation in dairy cows is characterized by substantial metabolic stress and high rates of metabolic disorders. We hypothesized that inflammation may contribute to these problems. Therefore, we tested whether administering an inflammatory cytokine, recombinant bovine tumor necrosis factor-α (TNFα), affects liver inflammation, gluconeogenesis, and metabolism during this period. Thirty-three Holstein cows (9 primiparous and 24 multiparous) were randomly assigned to 1 of 3 treatments at parturition. Treatments were 0, 1.5, or 3.0 μg/kg BW TNFα, and were administered once daily by subcutaneous injection for the first 7 d of lactation. Plasma samples were collected daily for analysis of metabolites and hormones, and liver samples were collected on d 7 for triglyceride and qPCR analyses. Glucose turnover rate was determined by a U-^{13}C-glucose dilution technique on d 7 to estimate gluconeogenic rate. Data were analyzed using mixed models with repeated measures over time and significance was declared at $P < 0.05$ and tendencies at $P < 0.10$. Preplanned contrasts evaluating control vs. TNFα treatments and low vs. high doses were evaluated. The TNFα treatments increased ($P < 0.01$) concentrations of plasma haptoglobin, but did not affect plasma insulin, nonesterified fatty acids, glucose, β-hydroxybutyrate, triglyceride, 3-methylhistidine, or liver triglyceride. Plasma TNFα concentrations tended to be increased when quantified 16 h after daily TNFα administration. Few plasma eicosanoids were affected by treatment, but surprisingly, TNFα administration decreased prostaglandin D_2 and leukotriene D_4 concentrations. Hepatic carnitine palmitoyltransferase 1a transcript abundance increased in a TNFα dose-dependent manner. Plasma glucose turnover rate tended to be decreased 18% by TNFα administration, suggesting impaired glucose production. Taken together, these results indicate that administration of TNFα daily for the first 7 d of lactation increased hepatic inflammation, tended to decrease gluconeogenesis, but did not affect liver triglyceride accumulation or lipid metabolism in dairy cows.

Key Words: gluconeogenesis, metabolism, tumor necrosis factor-α

25 Efficacy of on-farm use of ultraviolet light for inactivation of bacteria in milk for calves. S. L. Gelsinger*, A. J. Heinrichs, C. M. Jones, R. J. Van Saun, C. M. Burns, and H. R. Lysczek, *The Pennsylvania State University, State College.*

UV light has been suggested as an alternative method to heat for bacterial inactivation in milk for calves. However, limited data are available to show the efficacy of this method. Thus, the objective of this study was to investigate the efficacy of on-farm UV (UV) light treatment in reducing bacteria levels in waste milk used for feeding calves. Samples were collected from 9 Pennsylvania herds, twice daily for 15 d, both before and after UV light treatment (n = 60 samples per farm). All samples were analyzed for standard plate count (SPC), coliforms (C), non-coliform gram-negative bacteria (NC), environmental and contagious streptococci (ES and CS, respectively), coagulase-negative staphylococci (CNS), *Streptococcus agalactiae* (SAG), and *Staphylococcus aureus* (SA) count. Log reduction and percentage log reduction were calculated. Data were analyzed using the proc mixed procedure in SAS. UV light treatment significantly reduced all types of bacteria ($P < 0.001$). Weighted least squares means for log reductions (percentage log reduction) were 0.78 (23%), 1.06 (61%), 1.12 (42%), 1.38 (56%), 1.86 (93%), 1.09 (38%), and 1.24 (21%) for SPC, C, NC, ES, CS, CNS, and SA, respectively. Prior to UV light treatment 30% of samples had SPC <10,000 cfu/mL and 17%

of samples had C <10 cfu/mL. These percentages increased to 74% and 47% for SPC and C, respectively following treatment with UV light. A percentage log reduction of 50% has been suggested as a goal for calf milk pasteurization and has been shown to be achievable with heat pasteurization. Others have suggested maximum bacterial counts of 10,000 cfu/mL for SPC, 5,000 cfu/mL for ES, CS, and NC, and <10 cfu/mL for C. A percentage log reduction of 50% was achieved in 3 of 7 bacteria types, and 116 samples (43%) contained bacterial levels within the suggested limits after UV light treatment. Overall results of this study suggest that UV light treatment is not an acceptable alternative to heat pasteurization systems for bacterial inactivation in milk for use in calf feeding.

Key Words: ultraviolet light, milk, calf health

26 Fatty acid profile differs between organic and conventionally produced milk independently of sampling time. B. H. Schwendel*[1], P. C. H. Morel[2], T. J. Wester[2], M. H. Tavendale[1], C. Deadman[3], B. Fong[3], N. M. Shadbolt[2], A. Thatcher[2], and D. E. Otter[1], *[1]Food Nutrition & Health Team, Food & Bio-based Products Group, AgResearch Grasslands, Palmerston North, New Zealand, [2]Animal Nutrition Group, Institute of Veterinary, Animal and Biomedical Sciences, Massey University, Palmerston North, New Zealand, [3]Fonterra Research Centre, Palmerston North, New Zealand.*

Many differences reported in fatty acid (FA) composition between organic and conventionally produced cow's milk can be explained by the differing amounts of fresh forage and concentrates fed in the 2 systems. Comparisons in most previous studies were made between grazed organic cows and housed conventional cows. Our study investigated differences between organic and conventional milk produced using year-round pasture grazing utilized in New Zealand for both systems. FA composition was measured in milk sampled on 4 occasions during morning and evening milking in spring and autumn. Samples were taken from 24 cows selected randomly from the Massey University organic herd and compared with 26 cows from the corresponding conventional herd grazed and managed similarly at the same location. Thirteen out of 25 analyzed FA were influenced by season ($P < 0.001$), while one-third of the FA were different due to time of milking ($P < 0.001$). In addition, one-third were also different between production systems ($P < 0.001$). Variation observed in FA is illustrated using selected polyunsaturated FA. For example, linoleic acid (LA) and α-linolenic acid (ALA) were greater in organic milk while conjugated linoleic acid (CLA) and docosahexaenoic acid (DHA) were greater in conventional milk ($P < 0.001$; Table 1). Also, an interaction between system and milking time was observed for docosapentaenoic acid (DPA) and LA, where levels were greatest in conventional milk in the evening and were lowest in organic milk in the morning ($P < 0.005$). Our results confirm widely described reports that FA profile is affected by sampling time, however, we also showed an effect due to production system, even when cows are kept on pasture continuously.

Table 1. Effect of system, stage of lactation, and time on selected fatty acids

Fatty acid	System		Season		Time				
(g/100g)	Conventional	Organic	Spring	Autumn	am	pm	System	Season	Time
LA	0.81	0.92	0.72	1.01	0.87	0.86	***	***	NS

27 An in vitro assessment of the antibacterial effects of plant essential oils. K. A. E. Mullen*, A. R. Lee, R. L. Lyman, S. P. Washburn, and K. L. Anderson, *North Carolina State University, Raleigh.*

In the growing organic dairy industry, there is need for non-antibiotic treatments for mastitis. Plant essential oils have anecdotal efficacy for treatment of mastitis in dairy cattle. The potential mechanism of action of essential oils in mastitis therapy has not been well studied. The objective of the current study was to evaluate the antibacterial activity of the essential oil components of Phyto-Mast, an herbal intramammary mastitis treatment, against 3 mastitis-causing pathogens (*Staphylococcus aureus*, *Streptococcus uberis*, and *Staphylococcus chromogenes*). The essential oils evaluated were *Thymus vulgaris*, *Gaultheria procumbens*, *Glycyrrhiza uralensis*, *Angelica sinensis*, and *Angelica dahuricae*. Broth dilution testing according to CLSI standard protocol was performed using ultra-pasteurized whole milk. Controls included milk only (negative control), milk + bacteria, and milk + penicillin-streptomycin (positive control, at 1 and 5% dilutions). Essential oil of *T. vulgaris* was tested by itself and not in combination with other oils because of its known antibacterial activity. The other essential oils were tested alone and in combination for a total of 15 treatments, each replicated 3 times and tested at 4, 2, 1, and 0.5% to simulate concentrations achievable in the pre-dry off udder quarter. Of all the individual essential oils tested, only *T. vulgaris* oil had consistent antibacterial activity against all 3 pathogens tested, and activity was seen at or above 2%. *T. vulgaris* essential oil completely inhibited bacterial growth in all replications of 2% or greater concentration. Though the combinations of oils did not show typical dose-response effects, some concentration levels were consistently antibacterial across all 3 replications. Our results indicate that only *T. vulgaris* essential oil has consistent antibacterial activity. Further evaluation of the physiological effects of essential oils on mammary tissue is recommended.

Key Words: essential oil, mastitis, antibacterial

28 Low doses of recombinant bovine somatotropin (rbST) enhance fertility of dairy cows. E. S. Ribeiro*[1], R. G. S. Bruno[2], A. M. Farias[2], J. A. Hernandez-Rivera[2], G. C. Gomes[1], R. Surjus[1], G. Sasser[3], D. H. Keisler[4], W. W. Thatcher[1], T. R. Bilby[2], and J. E. P. Santos[1], *[1]Department of Animal Sciences, University of Florida, Gainesville, [2]Texas A&M AgriLife Research and Extension, Stephenville, [3]BioTracking LLC, Moscow, ID, [4]Department of Animal Sciences, University of Missouri, Columbia.*

Objectives were to evaluate the effects of a single or 2 low doses of rbST on plasma hormone concentrations and fertility in dairy cows. Lactating Jersey and crossbred cows (n = 1,493) from 2 farms were inseminated for first AI postpartum on estrus. On the day of AI (study d 0), cows were blocked by parity and assigned randomly to receive a single placebo injection at AI (control), a single treatment injection with 325 mg of rbST at AI (S-bST), or 2 treatment injections with 325 mg of rbST administered at AI and 14 d later (T-bST). Blood was collected twice weekly and plasma analyzed for concentrations of GH, IGF-1, insulin, progesterone, and pregnancy-specific protein B (PSPB). Pregnancy was diagnosed on d 31 and 66. Ultrasonographic morphometry of conceptuses were performed on d 34 and 48. Data were analyzed using PROC GLIMMIX of SAS according to data distribution. Treatment with bST increased plasma concentrations of GH (control: 3.5 vs. S-bST: 6.4 vs. T-bST: 7.6 ng/mL; $P < 0.01$) and IGF-1 (control: 64.1 vs. S-bST: 77.4 vs. T-bST: 98.5 ng/mL; $P < 0.01$) from d 3 to 31, and increments were extended in T-bST. Treatments did not affect concentrations of insulin, progesterone and PSPB. However, a distinction in plasma PSPB between pregnant and non-pregnant cows ($P < 0.01$) occurred earlier for bST-treated cows (on d 21) than for controls

(on d 24). Pregnancy per AI, amniotic vesicle and embryo/fetus sizes were all increased by T-bST compared with control and S-bST (Table). In conclusion, administration of 325 mg of bST on d 0 and 14 relative to AI increased concentrations of GH and IGF-1, enhanced conceptus size, and improved fertility of dairy cows.

Table 1. Effect of bST treatments on fertility and conceptus morphometry

Item	Treatment			*P*-value
	Control	S-bST	T-bST	
Pregnant, %				
d 31	35.6^{b}	37.5^{ab}	43.1^{a}	0.08
d 66	29.9^{b}	29.2^{b}	38.0^{a}	0.01
Pregnancy loss, %	12.6^{ab}	19.1^{a}	8.6^{b}	0.04
Amniotic vesicle length, mm				<0.01
d 34	12.5±0.6^{B}	12.5±0.6^{B}	13.9±0.6^{A}	
d 48	29.3±0.8^{b}	28.5±0.8^{b}	31.8±0.8^{a}	
Embryo/fetus crown-rump length, mm				<0.01

29 Individual cow risk factors for development of ketosis in lactating dairy cattle. J. L. Gordon*[1], T. F. Duffield[1], T. H. Herdt[2], D. F. Kelton[1], and S. J. LeBlanc[1], *[1]University of Guelph, Guelph, ON, Canada, [2]Michigan State University, East Lansing.*

The purpose of this study was to determine risk factors at the cow level that lead to ketosis. Records from cows in 5 herds enrolled in 3 field trials on subclinical ketosis treatment were collected for evaluation. In all trials, study herds were visited once a week and cows between 3 and 16 DIM that had not been previously diagnosed with ketosis or a displaced abomasum or enrolled in the study were tested for blood β-hydroxybutyrate (BHBA) concentration using an electronic hand-held meter (Precision Xtra; Abbott). Electronic records were also collected at each visit. Information on previous lactation days carried calf (DCC), days dry (DDRY), days open (DOPN) and milk yield, as well as current parity was available for 1414 multiparous cows. DDRY was categorized into normal (30–60 d) long (>60 d) and short (<30 d) and parity as 2 or ≥3. Ketosis was defined as ≥ 1.2 mmol/L BHBA in whole blood using the Precision Xtra. Ketosis incidence was 35% overall, with incidence in Herd A at 15%, Herd B 30%, Herd C 32%, Herd D 38%, and Herd E 39%. Previous lactation total milk and 305ME had no effect on ketosis risk (P = 0.7–0.9), whether expressed as an absolute value or deviation from herd average. DDRY category also had no effect on ketosis risk (P = 0.3–0.8). DCC and DOPN were significantly associated with ketosis risk, controlling for herd and parity. An increase of 21 DOPN and a decrease of 10 DCC increased the odds of ketosis 1.3 (1.1–1.6, P = 0.003) and 1.2 (1.1–1.4, P = 0.01) times respectively. Controlling for parity, DOPN, and DCC, there were differences between herds in ketosis risk. In 1 herd, the trial was performed 2 years in a row and 334 cows were tested both years. Being diagnosed with ketosis the first year increased the odds of ketosis the second year by 2.2 times (1.4–3.4, P = 0.001) in this herd. There were no interactions between the risk factors. Herd, and ketosis and time to pregnancy in the previous lactation are associated with ketosis risk in lactating dairy cattle.

Key Words: ketosis, risk factor

30 Postnatal changes in gut bacteria and mucosal immune system development in dairy calves. N. Malmuthuge*[1], G. Liang[1], T. B. McFadden[3], P. J. Griebel[2], and L. L. Guan[1], *[1]Department of Agricultural, Food and Nutritional Science, University of Alberta, Edmonton, AB, Canada, [2]Vaccine and Infectious Disease Organization, Univ. of Saskatchewan, Saskatoon, SK, Canada, [3]Divison of Animal Sciences, University of Missouri, Columbia.*

Gut microbial establishment plays a vital role in development of the host mucosal immune system. However, there is limited knowledge on how postnatal establishment of the gut microbiome influences development of mucosal immune responses in dairy calves. This study investigated the relationship between the gut bacteria and mucosal immune responses over time. Small intestinal (mid jejunum, distal jejunum, ileum) tissue and digesta samples were collected from d 0 (n = 3), 1 (n = 6), 3 (n = 6) and 6 (n = 6) week old calves and quantified total bacteria, *Lactobacillus* and *Bifidobacterium* sp. as well as mucosal expression of bovine toll-like receptors (TLR), and immune-regulatory genes. Multivariate ANOVA of bacterial population and gene expression data revealed that calf age exerts a joint effect on bacterial density and mucosal immune responses. Total bacterial density in the small intestine of 6-wk-old calves (4.0 ± 2.0 × 10^{10} copies of 16S rRNA gene) was significantly higher than that of d 0 calves (7.3 ± 2.0 × 10^{8} copies/g). The prevalence of *Lactobacillus* sp. was lower in d 0 and 6-wk-old calves (>1%) compared with 1-wk (7.1%) and 3-wk (5.7%) old calves. In contrast, *Bifidobacterium* were prevalent than *Lactobacillus* at all ages with peak prevalence (21.2%) observed in 3-wk-old calves. Expression of TLR 1 to 10, except TLR9, was age dependent and expression of most TLRs was lowest in d 0 calves. Strong correlations were observed between total bacterial density and TLR expression levels but these associations varied with age. Mucosal expression of IL8 and IL10 was significantly higher in 1 and 3-week-old calves compared with d 0 and 6-week-old calves and cytokines expression was positively correlated with *Lactobacillus* and *Bifidobacterium* populations but not with total bacteria, signifying these specific bacterial species may associate with postnatal mucosal immune regulation. The present study revealed that gut bacterial density and mucosal immune system change significantly within the first weeks of life and changes in gut bacteria may influence the immune development during the early life of dairy calves.

Key Words: gastrointestinal tract, bacteria, mucosal immunity

31 Management of dairy goats during the transition between lactations. G. Zobel*[1], K. Leslie[2], D. M. Weary[1], and M. A. G. von Keyserlingk[1], *[1]Animal Welfare Program, University of British Columbia, Vancouver, BC, Canada, [2]Population Medicine, University of Guelph, Guelph, ON, Canada.*

Dry-off and the onset of the new lactation are key periods of risk for intramammary infections, but little work to date has examined how management of this transition affects dairy goat health and welfare. To guide such research, it is helpful to describe management practices currently employed. The aim of this study was to determine the practices of dairy goat milk producers in Ontario, Canada. The survey was sent by mail to all 229 licensed farms of which 67 responded (i.e., response rate of 29%). Analyses are descriptive and all results are presented as means ± SD. On average, farms milked 203 ± 125 goats, with an average lactation length of 330 ± 99 d (1st lactation) and 386 ± 168 d (2+ lactations). The most common breeds were Saanen (66 ± 25%) and Alpine (28 ± 21%). The majority of producers (79%) ranked days until kidding and milk production as their top deciding factors when choosing to drying-off their goats; interestingly, 83% had no ability to record individual milk production. Furthermore, although the average

dry period cited was 53 ± 11 d, nearly 20% of the farms noted that does are occasionally milked for over 600 d, regardless of pregnancy status. They cited the top reasons for skipping a dry period as persistent milk production, even when pregnant (71%) and continuing to milk because the doe had not been bred in the current year (17%). Two respondents indicated that they did not dry-off their goats at all. To induce dry-off, 40% of producers reported restricting access to feed, while water restriction was used on 4 of the farms. Interestingly, not all producers felt diet had a major effect on dry-off, with 26% reporting no change in feeding practices. Intramammary antibiotic and teat sealer use was minimal (17% and 2%, respectively) despite producers expressing that they were "moderately or extremely concerned" about subclinical and clinical mastitis (28% and 35%, respectively). These results suggest the need for research to determine the effects of the large variety of dry-off methods being used by producers, including extended lactations and skipped dry periods in dairy goats.

Key Words: does, dry-off, udder health

32 Comparison of NRC and industry dietary trace mineral standards for yearling feedlot steers. C. J. Berrett*, J.J. Wagner, K. L. Neuhold, E. Caldera, and T. E. Engle, *Colorado State University, Fort Collins.*

Effect of trace mineral (TM) concentration and source on yearling feedlot steer performance, carcass characteristics, and liver TM status, were determined utilizing 360 crossbred steers (initial BW = 350 ± 4.0 kg). Steers were blocked by initial BW and randomly assigned to one of 4 treatments (10pens/treatment; 9 hd/pen). Treatments consisted of (1) negative control (NC), no supplemental TM (basal diet contained 7.65 mg Cu/kg DM, 50.5 mg Zn/kg DM, 27.7 mg Mn/kg DM, and 0.12 mg Co/kg DM); (2) basal diet supplemented with 10 mg Cu/kg DM from $CuSO_4$, 30 mg Zn/kg DM from $ZnSO_4$, 20 mg Mn/kg DM from $MnSO_4$, 0.50 mg I/kg DM from EDDI, 0.10 mg Se/kg DM from Na_2O_3Se, and 0.10 mg Co/kg DM from $CoCO_3$ (NRC); (3) basal diet supplemented with inorganic forms of Cu, Zn, Mn, EDDI, Se and Co at consulting nutritionist recommendations (CNI, 20, 100, 50, 0.50, 0.20, and 0.20 mg of mineral/kg DM, respectively); and (4) basal diet supplemented with 66.6% inorganic and 33.4% organic Cu, Zn, Mn and Co, and inorganic forms of I and Se at iso-concentration to consulting nutritionist recommendations of treatment 3 (CNO). All steers were fed a high concentrate steam-flaked corn-based diet for 154 d. Steers were individually weighed on d −1, 0, 35, 121, 153, and 154. Continuous data were analyzed on a pen mean basis using a mixed model appropriate for a randomized block design (fixed effects = treatment and time; random effect = replicate). Categorical data were analyzed utilizing GLIMMIX (fixed effect = treatment; random effect = replicate). Initial and final BW, ADG, DMI, F:G and G:F ratios and calculated net energy recoveries were similar ($P > 0.23$) across treatments. Subcutaneous adipose tissue depth, HCW, KPH, yield grade, marbling score, and quality grade were similar across treatments ($P > 0.17$). Final liver Zn, Mn, Se, and Co concentrations were similar across treatments ($P > 0.37$). Under the conditions of this experiment, it appears that basal dietary concentrations of Cu, Zn, Mn, and Co were adequate for growth and performance of finishing yearling feedlot steers.

Key Words: beef cattle, feedlot, trace mineral

33 Effects of BovaZyme WP enzyme supplementation on frothy bloat and performance in stocker cattle grazing winter wheat. W. E. Pinchak*[1], D. W. Pitta[1,2], J. Miller[1], G. M. Shipp[3], and J. D. Fulford[1], *[1]Texas A&M AgriLife Research, Vernon, [2]School of Veterinary Medicine University of Pennsylvania, Kennett Square, [3]Texas A&M AgriLife Research, Amarillo.*

Frothy bloat is the major non-pathogenic cause of mortality and depressed performance in cattle grazing hard red winter wheat in the southern Great Plains. Value-added bloat intervention strategies mitigate direct bloat effects, while enhancing performance in non-bloated animals as well. Frothy bloat occurs when rumen bacteria produce extra-cellular, low gas permeable, polysaccharide biofilms. These biofilms interconnect with fluid and particle phase rumen contents to entrap fermentative gases and disrupt eructation. Supplementation with exogenous enzymes could decrease the rate and extent of polysaccharide formation, thereby decreasing bloat severity and duration. An in vitro experiment utilizing rumen fluid from bloated and non-bloated rumen cannulated steers and 4 levels of BovaZyme WP (York Ag Products Inc., York, PA) was conducted. BovaZyme supplementation to rumen fluid reduced ($P < 0.001$) foam strength, time of foam collapse, biofilm and viscosity. Subsequently, a grazing experiment was conducted utilizing 65 cross-bred heifers (avg. initial wt. = 191 kg) with 3 replicate groups of mineral Control and mineral + BovaZyme supplemented herds (10 to 12 hd) stocked at 1 ha/hd. During the study period, 58 of 65 head (89%) experienced at least one bloat event. The number of head that experienced bloat more than 4 d was greater ($P < 0.10$) in Control than in BovaZyme herds (7.0 d and 4.7 d respectively). Conversely, the percentage of head observed with bloat score 1 (minor bloat) was greater ($P < 0.10$) in BovaZyme than in Control herds (34.7% and 19.3% respectively). Collectively, BovaZyme supplementation decreased the severity and duration of bloat under the conditions of this experiment. Total gain and ADG for the grazing period was greater ($P = 0.1003$) for the BovaZyme supplemented mineral group than for the mineral only Control group at 6.71kg and 0.07 kg/hd/d, respectively. Results from these preliminary experiments support the use of BovaZyme in a complete mineral supplement as a value-added bloat mitigation chemistry. Further research is warranted across multiple years to validate the results of this research.

Key Words: biofilm

34 Individual ad libitum intake of mineral mix by beef cows is less than NRC recommendations and form of selenium (Se) in mineral mix affects Se levels of cows and suckling calves. J. D. Patterson*, W. R. Burris, J. A. Boling, and J. C. Matthews, *University of Kentucky, Lexington.*

This project was conducted to determine (1) individual ad libitum intake of mineral mix by beef cows managed under a year-long, fall-calving, forage-based production regimen and (2) if form of Se in mineral mix affected blood Se levels of cows and suckling calves. In August 2011, 24 late-gestation (6 to 8 mo) Angus-cross cows (2.7 ± 0.8 yr; BW = 585 ± 58 kg) were blocked by BW and randomly assigned (n = 8) to a mineral supplement treatment (TRT) containing 35 ppm Se as either inorganic (ISe; sodium selenite), organic (OSe; SEL-PLEX), or a 1:1 combination of ISe:OSe (Mix). Cows commonly grazed a 10.1 ha Kentucky-31 tall fescue pasture and had individual ad libitum access to TRT using an in-pasture Calan gate system. Cows calved from September to November and calves had common ad libitum access to creep feed and a mineral supplement that lacked Se. Cow jugular blood was taken at 28-d intervals (13 periods) and calf blood taken with cows' from birth through weaning. Data were analyzed using mixed models with main effects of experimental period, TRT, and their interaction evaluated. Main effect means were separated using the pdiff option. Pearson's partial correlation coefficient was calculated to assess linear associations between cow and calf blood Se levels. Cow mineral intake (g/d) was affected ($P < 0.0001$) by period, with Periods 1–3 (92.2 ± 6.7) > Periods 4, 9, 12 (56.3 ± 7.0) > Periods 5–8, 10, 11 and 13 (36.2 ± 6.9); but not ($P = 0.24$) by cow Se TRT. Cow blood Se (0.115 to 0.229 ± 0.01 μg/mL) was affected by Period ($P < 0.0001$), Se form ($P = 0.001$), and their interaction ($P = 0.03$), with ISe = Mix < OSe for Periods 3, 7, 8, 10, 12; ISe < Mix < OSe for Periods 9 and 11; and ISe = Mix = OSe for Periods 1, 2, 4–6. Calf blood Se (μg Se/mL) was correlated (r = 0.63, $P = 0.0001$) with cow blood Se and was affected by ($P < 0.0001$) cow Se TRT, with ISe (0.07 to 0.11) < Mix (0.10 to 0.15) = OSe (0.16 to 0.19). In conclusion, ad libitum cow mineral intake (54.7 g/d) was 36% less than NRC recommendations (85 g/d) and cow Se TRT affected cow and calf blood Se levels.

Key Words: cow, mineral intake, selenium

35 Effects of dietary ferric ammonium citrate on performance and carcass quality of beef cattle fed 20, 40, or 60% distillers grains with solubles. M. E. Drewnoski[2], S. J. Morine*[1], and S. L. Hansen[1], *[1]Iowa State University, Ames, [2]University of Idaho, Moscow.*

Previously, the addition of ferric ammonium citrate (FAC) to high S diets was found to decrease hydrogen sulfide (H_2S) concentrations. The objective of this experiment was to determine the effects of feeding FAC to steers fed varying concentrations of dried distillers grains plus solubles (DDGS) on steer performance, mineral status, and carcass quality. Angus-cross steers (n = 128) were assigned to one of 6 treatments, composed of 3 concentrations of DDGS in the diet (20, 40, or 60% of diet DM; 0.28, 0.41, 0.54% dietary S respectively) and one of 2 levels of FAC (0 or 300 ppm of added Fe). Treatments were replicated in 5 pens (20, 40% DDGS) or 6 pens (60% DDGS). During the 98 d study H_2S concentrations were measured on d 0, 7, 14, 21, and 95 at 6 h post feeding. Steer DMI was linearly and quadratically affected ($P \leq 0.02$) by increasing inclusion of DDGS, with no differences between 20 and 40% DDGS-fed steers, and lesser DMI by 60% DDGS-fed steers. Steer ADG was linearly decreased ($P < 0.01$) as DDGS inclusion increased, primarily due to the lesser ADG of steers consuming 60% DDGS. Increasing DDGS linearly increased ($P < 0.01$) ruminal concentrations of H_2S. Inclusion of FAC did not affect ($P \geq 0.21$) ADG, DMI, G:F (study means: 1.67 kg/d, 11.05 kg/d, and 0.15, respectively) or ruminal H_2S concentrations. Inclusion of FAC or increasing DDGS did not affect ($P \geq 0.32$) ribeye area, backfat, or KPH. Inclusion of FAC tended to increase HCW ($P = 0.10$), while increasing DDGS linearly decreased HCW ($P = 0.03$). Increased inclusion of DDGS had a quadratic effect ($P = 0.03$; 423, 443, and 413 for 20, 40, and 60% DDGS, respectively) on marbling score, and the inclusion of FAC increased ($P = 0.05$) marbling score. Liver Cu averaged 233 ppm and tended ($P = 0.06$) to be decreased by increasing DDGS, and was decreased ($P < 0.01$) by FAC addition, but was not decreased to the point of deficiency. Results of this study suggest 40% DDGS is the optimal inclusion in finishing cattle diets and including FAC in diets does not affect steer gains, but may increase HCW and marbling scores of cattle fed high S diets.

Key Words: cattle, dried distillers grain, iron

36 Feeding ferric citrate to decrease risk of sulfur toxicity: effects on trace mineral absorption and trace mineral status of steers. M. E. Drewnoski*[2] and S. L. Hansen[1], *[1]Iowa State University, Ames, [2]University of Idaho, Moscow.*

We have previously shown that adding ferric Fe to diets in the form of ferric ammonium citrate will decrease ruminal hydrogen sulfide concentrations and thus may reduce risk of S toxicity when feeding elevated levels of S. However, Fe can have negative effects on absorption of other trace minerals such as Cu, Mn and Zn. Therefore, this study was designed to determine the effect of supplementing 300 mg/kg DM of ferric Fe in high S diets on trace mineral absorption and trace mineral status of cattle. Eighteen Angus cross steers (370 ± 9.5 kg) were individually fed 1 of 3 high concentrate diets: (1) a moderate sulfur diet (MS; 0.3% S), (2) a high sulfur diet (HS; 0.5% S), or (3) HS plus 300 mg/kg of ferric Fe from ferric ammonium citrate (HS+Fe). Steers were adapted to diets for 7 d in individual pens and then moved into metabolism crates for a 5 d crate adaptation followed by a 5-d period of total fecal collection to determine apparent absorption of Cu, Fe, Mn and Zn. Steers were then moved back to individual pens and fed diets for an additional 56 d to determine effects on performance. Liver biopsies were conducted before the start of the trial and again at the end of the trial to determine trace mineral status. During the collection period DMI was greater ($P < 0.02$) for MS than HS and HS+Fe, which did not differ ($P = 0.87$). However, the apparent absorption of Cu, Fe, Mn and Zn were not affected ($P \geq 0.14$) by treatment. Additionally, after 73 d of consuming diets there were no effects of treatment ($P \geq 0.28$) on liver concentrations of Zn, Mn or Fe. However, steers fed the MS had greater ($P < 0.01$) liver Cu (273 mg/kg DM) than did those fed HS or HS+Fe. Liver Cu of steers fed HS (156 mg/kg) did not differ ($P = 0.44$) from those fed HS+ Fe (136 mg/kg), suggesting that the reduced liver Cu was due to the increased dietary S. The 56 d ADG of steers did not differ ($P = 0.45$) among treatments and were 2.33, 2.15, 2.11 kg/d (SEM ± 0.125) for MS, HS and HS+Fe, respectively. In this study, feeding 300 mg/kg ferric Fe in a high S diet did not appear to affect trace mineral absorption or status of steers.

Key Words: copper, iron, sulfur

37 Phytonutrients or calcified marine algae as natural alternatives to monensin in beef feedlot diets. F. M. Hagg*[1,2], L. J. Erasmus[2], R. H. Van der Veen[1], E. Haasbroek[2], S. Taylor[3], and C. Oguey[4], *[1]Allied Nutrition, Pretoria, South Africa, [2]University of Pretoria, Pretoria, South Africa, [3]Celtic Sea Minerals, Cork, Ireland, [4]Pancosma, Geneva, Switzerland.*

Public concern regarding possible antibiotic resistance led to the evaluation of a mixture of phytonutrients (XT) containing capsicum oleoresin, cinnamaldehyde and eugenol, and a commercial buffer (AB), containing *Lithothamnium calcareum* (calcified marine algae), as natural alternatives to monensin (MON) in beef cattle. The objective of the study was to determine if XT or AB can successfully replace MON in commercial beef feedlot diets. In Trial 1 (Experimental trial) 180 recently weaned male beef cattle (±225 kg) were randomly allocated to one of 3 treatments: 1) Monensin (21 – 33 mg/kg DM); 2) XT (XTRACT 7065, Pancosma) at 1.0 – 1.2 g/head/day; 3) AB (Acid Buf; Celtic Sea Minerals) at 0.6% of DM. Same basal diets (ME = 10.6 – 11.7 MJ/kg DM) were used during 4 different feeding periods, with only MON, XT or AB inclusion differing between diets. Six pens, with 10 animals each, were randomly allocated to each treatment for a period of 119 d. In Trial 2 (Commercial trial), 1170 recently weaned male beef cattle (±225 kg) were used in a similar design, but for each treatment 3 pens, with 130 cattle per pen, were randomly allocated, with a trial period of 115 d. Growth, feed intake and health parameters were measured. Statistical analyses were done with one-way ANOVA (ANOVA). In Trial 1 there were no differences ($P > 0.05$) in DMI, FCR or ADG between treatments. In Trial 2, ADG was increased (1.77 vs. 1.70 kg/d) when XT replaced MON ($P < 0.05$) and there was a tendency ($P = 0.09$) toward improvement of ADG when AB replaced MON. DMI tended to be increased ($P = 0.09$) by XT (10.05 kg/d) compared with MON (8.96 kg/d). Overall performance expressed as FCR was not affected when either AB or XT replaced MON ($P > 0.2$). Percentage of healthy animals was reduced ($P < 0.05$) when AB replaced MON, however growth performance was not impaired. Percentage of healthy rumens was improved ($P < 0.01$) when either XT (76.3%) or AB (49.2%) replaced MON (27.1%). Results suggest that both XT and AB could be used to replace MON in commercial beef feedlot diets without impairing animal performance.

Key Words: calcified marine algae, monensin, phytonutrients

38 Interaction between supplemental zinc and zilpaterol in feedlot steers. C. L. Van Bibber-Krueger*, K. A. Miller, C. C. Aperce, C. A. Alvarado-Gilis, J. M. Gonzalez, and J. S. Drouillard, *Kansas State University, Manhattan.*

Interactive effects of supplemental zinc (Zn) and zilpaterol hydrochloride (Zil) were evaluated in feedlot steers (n = 40; initial BW 653 kg ± 14) to determine the effect on feedlot performance, blood constituents, and carcass traits. The study was conducted as a randomized complete block with a 2 × 2 factorial treatment arrangement. Steers were blocked by BW and randomly assigned to treatments. Factors consisted of supplemental Zn (60 or 300 mg/kg), and Zil (0 or 8.3 mg/kg) concentrations in the diet. Zil was fed for 21 d followed by a 3-d withdrawal. Cattle were housed in partially-covered individual feeding pens equipped with automatic waterers, fence-line feed bunks and supplied an ad libitum diet once daily. Plasma samples were collected d 0 and 21 to assess changes in zinc, urea nitrogen (PUN), glucose, and lactate concentrations, and serum samples were collected d 21 to assess IGF-1 concentration. On d 24 cattle were weighed, transported 450 km to a commercial abattoir for harvest, and HCW and incidence of liver abscesses were recorded. Carcass data were collected after 24 h of chilling. Data were analyzed as a mixed model with Zn, Zil, and Zn × Zil as fixed effects, block as a random effect, and steer as the experimental unit. No interaction or effects of Zn or Zil ($P > 0.05$) were observed for IGF-1 concentration. Interactions between Zn and Zil were observed for changes in plasma glucose and lactate ($P < 0.05$). No interaction between Zn and Zil was observed for PUN concentration, but PUN decreased over time with Zil ($P < 0.05$). There were no effects of Zil or Zn on ADG, DMI, final BW, feed efficiency, HCW, LM area, backfat, KPH, quality grade, or incidence of liver abscesses ($P > 0.05$), though Zn numerically improved marbling and tended ($P = 0.08$) to improve proportion of carcasses grading USDA Choice. Feeding Zil decreased yield grade ($P < 0.05$) without compromising marbling score ($P > 0.05$) and tended to increase LM area ($P = 0.07$). In conclusion, increasing dietary concentrations of zinc does not affect response to zilpaterol, but feeding zilpaterol alters circulating concentrations of blood constituents associated with muscle accretion.

Key Words: IGF-1, lactate, plasma urea nitrogen

39 Influence of supplementing vitamin C to cattle fed a high sulfur diet late in the finishing period on meat color and tenderness. D. J. Pogge*, S. M. Lonergan, and S. L. Hansen, *Iowa State University, Ames.*

The objective of this study was to determine the effects of supplementing a rumen-protected vitamin C (VC) for approximately 102 d before harvest on meat color, tenderness, and nutrient content of longissimus dorsi (LD) collected from cattle receiving a 0.55% S diet. Angus-cross steers (n = 140) were blocked by initial BW (432 ± 0.4 kg), stratified within blocks by ultrasonographic initial intramuscular fat (3.6% ± 0.06), and assigned to treatments (5 steers per pen, 7 pens per treatment), including: 1) no VC control (CON), 2) 5 g VC·h^{-1}·d^{-1} (5VC), 3) 10 g VC·h^{-1}·d^{-1} (10VC), and 4) 20 g VC·h^{-1}·d^{-1} (20VC). Cattle were harvested by block on d 91 (n = 40), d 105 (n = 40), and d 112 (n = 60). Three, 1.27 cm steaks (n = 136) were removed from each carcass after a 24 h chill. One steak was displayed under retail-simulated lighting at 2°C and color analysis was conducted on d 1, 2, 3, and 7; and after 7-d of display Warner-Bratzler shear force (WBSF) was determined. Separate steaks were analyzed for hydroxyproline, VC, vitamin E (VE), and cholesterol. For all analyses pen (n = 7 per treatment) was the experimental unit. The supplemental VC intake (g·h^{-1}·d^{-1}) averaged 5.1 (5VC), 10.1 (10VC), and 20.2 (20VC). Inclusion of VC resulted in a lesser ($P < 0.01$) L* than CON, and VC supplemented treatments did not differ from one another ($P \geq 0.46$). No differences among treatments ($P \geq 0.30$) in WBSF values, a* and b*, or hydroxyproline content of LD muscle were noted. However, WBSF values tended to be negatively correlated with a* ($R = -0.33$; $P < 0.08$). The VC content of the LD was not different ($P \geq 0.48$), but the inclusion of VC increased ($P < 0.01$) VE content of LD compared with CON (1.24, 1.71, 1.45, and 1.53 µg/g tissue ± 0.07, for CON, 5VC, 10VC, and 20VC, respectively). Cholesterol content of LD demonstrated a quadratic response ($P < 0.01$), CON (54.4), 5VC (57.4), 10VC (59.8), and 20VC (54.9 mg/100 g ± 1.4). Under the conditions of our study, supplementation of VC to steers fed a high S diet late in the finishing period did not influence color stability or WBSF, but increased VE content of LD.

Key Words: cattle, sulfur, vitamin C

40 Effect of a supplemental zinc complex on beef cattle performance and plasma and liver trace mineral concentrations. O. N. Genther* and S. L. Hansen, *Iowa State University, Ames.*

The objective of this experiment was to determine the effect of a supplemental zinc (Zn) complex (ZnC) on steer performance and plasma and liver trace mineral concentrations. Forty-one steers (380 ± 5.3 kg) were fed a finishing diet of 61% ground corn, 23% dried distillers, 14% corn silage, 2% micronutrients, and 60 mg supplemental Zn/kg diet DM (as Zn sulfate). Steers were assigned to 1 of 4 treatments for 86 d: Zn0: no supplemental ZnC (n = 6), Zn30: 30 mg Zn/kg from ZnC (n = 12), Zn60: 60 mg Zn/kg from ZnC (n = 12), and Zn90: 90 mg Zn/kg from ZnC (n = 11). Individual DMI was recorded daily, body weights were taken on d 0, 1, 28, 56, and 86, and ultrasound measurements were taken on d 0 and 86. Steer was the experimental unit and DMI, ADG and G:F were analyzed as repeated measures. Steer DMI (11.3, 11.4, 11.0 and 11.0 ± 0.17 kg for Zn0, Zn30, Zn60 and Zn90, respectively) was not affected ($P > 0.20$) by treatment. However, Zn60 ADG was greater (2.2 kg/d) than Zn90 (1.9 kg/d; $P < 0.05$), tended to be greater than Zn30 (1.98 kg/d; $P < 0.10$) and was not different from Zn0 (2.05 ± 0.07 kg/d; $P > 0.10$). The Zn60 steers had greater G:F and final BW than Zn30 and Zn90 (G:F: 0.197, 0.174 and 0.168 ± 0.007, respectively; $P < 0.05$; final BW: 571, 547, 543 ± 5.6 kg, respectively; $P < 0.05$), and were not different from Zn0 (G:F: 0.180 ± 0.008; $P > 0.10$; final BW: 554 ± 7.8kg; $P > 0.10$). Day 86 ultrasound-determined ribeye area and intramuscular fat were not affected by treatment ($P > 0.20$). Steers receiving the Zn60 diet had greater d 86 back fat than Zn90 (1.47 and 1.17 cm, respectively; $P < 0.05$) but were not different from Zn0 and Zn30 (1.32 and 1.32 ± 0.07 cm, respectively; $P > 0.10$). Plasma Cu and Fe, and liver Zn and Cu concentrations were not affected by treatment ($P > 0.20$). Plasma Zn tended ($P < 0.10$) to be higher in Zn90 than Zn0 and Zn60 (1.48, 1.30, 1.35 ± 0.04 mg/L, respectively) and no treatments were different from Zn30 (1.44 mg/L). During the 86 d finishing period Zn60 steers performed better than Zn30 or Zn90, and were similar to Zn0 steers.

Key Words: cattle, growth, zinc

41 Influence of lipid-extracted algae on intake and digestibility of a concentrate diet. M. K. Beckman*, L. N. Tracey, C. L. Shelley, K. L. Norman, K. H. Marchetti, E. J. Scholljegerdes, C. A. Löest, S. A. Soto-Navarro, and S. L. Ivey, *New Mexico State University, Las Cruces.*

The co-product resulting from the oil extraction of microalgae, intended for biofuel production, may be of interest to ruminant producers as a proteinaceous feedstuff. The objective of this study was to determine the influence of lipid extracted algae (LEA) on feed intake and digestibility of a concentrate diet. We hypothesized that an isonitrogenous addition of LEA in a concentrate diet fed to sheep would yield results similar to that of dried distillers grains with solubles (DDGS). Fifteen crossbred wether lambs (46 ± 7.1 kg BW), fitted with ruminal and duodenal can-

nulas, were used in a completely randomized design. Lambs were fed twice daily at 110% of previous 3 d DMI. Treatments included: 1) lipid extracted algae diet (CP 16.3%; NDF 23.4%, DM basis; ALGAE) and 2) dried distillers grains with solubles diet (CP 15.7%; NDF 22.3%, DM basis; DGS). Animals were adapted to treatments for 10 d followed by a 6 d sample collection period. Treatment did not influence OM, NDF, or CP intake ($P \geq 0.21$). Ruminal and total tract OM digestibility was lower in animals consuming ALGAE compared with DGS (78.6 vs 83.6 ± 1.77%, $P = 0.05$ and 81.0 vs 86.8 ± 1.38%, $P < 0.01$, respectively). There was no treatment influence on lower tract OM digestibility ($P = 0.93$). Ruminal N digestibility was unaffected by treatment ($P > 0.10$), however N digestion in the total tract was lower for sheep fed ALGAE versus DGS (76.0 vs 86.1 ± 1.49%; $P < 0.01$). Additionally, total tract NDF digestion was greater for DDGS treated lambs, than for those consuming LEA (76.6 vs 70.5 ± 2.19%; $P = 0.05$). There was a tendency ($P = 0.09$) for ALGAE fed animals to show increased microbial efficiency over those fed DGS. Ruminal pH, NH_3, and VFA concentrations did not differ by treatment ($P \geq 0.34$). These data may indicate that LEA is palatable in ruminant diets. However, reduction in digestibility of OM, N and NDF when LEA is added compared with DDGS is concerning and warrants further investigation.

Key Words: biofuel, digestibility, sheep

42 The effect of *Aspergillus oryzae* extract on feedlot performance and carcass merit in yearling steers fed steam-flaked corn based finishing diets. K. A. White*[1], J. J. Wagner[1], T. E. Engle[1], D. R. Woerner[1], R. K. Peel[1], T. C. Bryant[2], J. S. Jennings[3], and K. M. Brennan[3], *[1]Animal Sciences Department, Colorado State University, Fort Collins, [2]JBS Five Rivers Cattle Feeding, Greeley, CO, [3]Alltech Inc., Nicholasville, KY.*

Crossbred yearling steers (n = 270) averaging 319 ± 7.11 kg initial BW were utilized in a randomized block design experiment to evaluate the effects of supplementing a steam-flaked corn based finishing diet with *Aspergillus oryzae* extract containing α-amylase activity on feedlot performance and carcass characteristics. Steers were ranked by weight and allocated into 15 weight block replicates. Within each weight block replicate, steers were randomly assigned to 1 of 2 treatments resulting in 9 steers per pen. Treatments consisted of: 1. Amaize (AMZ; 5 g/head daily providing 750 fungal α-amylase units/g, Alltech Inc. Nicholasville, KY) and 2. Control (CON; providing 5 g/head daily of a corn meal placebo). All cattle were fed for 149 d and 2 individual and 1 pen weight were collected on d 32, 69, and 105, respectively. Final BW and ADG were similar ($P > 0.10$) across treatments. Dry matter intake and gain to feed (G/F) ratios were similar ($P > 0.10$) across treatments throughout the entire study. From d 106 through slaughter, there was a tendency ($P > 0.11$) for G/F ratio to be greater for AMZ supplemented cattle as compared with CON. Hot carcass weight was similar ($P > 0.60$) across treatments. The distribution of HCW among light, average, and heavy weight categories ($P > 0.75$) and longissimus muscle area ($P = 0.17$) did not vary by treatment. Fat depth over the 12th rib ($P = 0.06$, 1.24 vs. 1.35 cm) and Yield grade calculated from carcass measurements ($P = 0.12$, 2.81 vs. 2.98 units) tended to be lower while dressing percentage tended ($P = 0.06$, 63.0 vs. 62.6%) to be greater for the AMZ vs. CON supplemented cattle. Liver abscess rates were lower ($P < 0.01$) for CON (3.8%) vs. AMZ (15.8%) supplemented cattle. Under the conditions of this experiment, results indicate that AMZ supplementation has minimal effects on live cattle performance but may improve dressing percentage.

Key Words: amylase, beef feedlot, carcass merit

43 Effect of supplementing gestating and lactating beef cows with supranutritional concentrations of vitamin D on cow production and pre-weaning growth of the calf. J. P. Schoonmaker*[1], M. Engstrom[2], K. N. Condron[1], C. N. Shee[1], and R. P. Lemenager[1], *[1]Purdue University, West Lafayette, IN, [2]DSM Nutritionals, Parsippany, NJ.*

Angus × Simmental cows (n = 156, age = 4.7 yr, BW = 639 ± 12.4 kg, BCS = 5.2 ± 0.07) were allotted by BW, BCS, and breed to 4 treatments to determine the effect of supranutritional vitamin D during gestation and/or lactation on milk production and composition, reproductive efficiency, and pre-weaning progeny growth. At 173 d in gestation, cows were allotted to 2 pastures and fed a molasses based vitamin/mineral block formulated to provide 6300 IU D daily (LD) or 100,000 IU D daily (HD). At the mid-point of calving season cows were placed on lactation treatments and fed LD or HD in drylot. Treatments were arranged as a 2 × 2 factorial: LD in gestation, followed by LD (LDLD) or HD (LDHD) in lactation, or HD in gestation followed by LD (HDLD) or HD (HDHD) in lactation. Treatments concluded at breeding (79 d postpartum; DPP) and cattle were commingled and managed as a group until weaning which occurred at 188 DPP. At 69 and 79 DPP milk production and composition was assessed on 10 cows per treatment. Categorical and continuous data were analyzed with the GLIMMIX and MIXED procedures of SAS, respectively. Cows fed HD during gestation were 29.6 kg heavier at the end of the gestation period ($P = 0.02$), whereas cows fed HD during lactation were 26.0 kg lighter at study termination ($P = 0.04$). Cow weight at weaning ($P > 0.69$) and BCS ($P > 0.29$) did not differ. Conception rates were lowest for LDHD cows (interaction, $P = 0.04$) and overall pregnancy rates tended ($P = 0.06$) to be greater for cows fed HD during gestation. Milk production was lower ($P = 0.03$) for cows fed HD during gestation but did not differ due to D during lactation ($P = 0.79$). Milk protein was lowest for LDHD cows (interaction; $P = 0.01$). Milk fat tended ($P = 0.10$) to be lower for cows fed HD during lactation. Calf birth weight did not differ among treatments, however, HD during gestation tended to decrease calving difficulty ($P = 0.07$) and to produce heavier calves at weaning ($P = 0.08$). In conclusion, feeding supranutritional D during gestation improves cow weight and reproductive efficiency and may benefit the offspring.

Key Words: beef, developmental programming, vitamin D

Bioethics Symposium I: The Hunger Games: Should "Big Ag" Be Left Standing?

44 "Valuing" alternative agricultural systems: What do consumers perceive about different labels and where do they get their information? N. J. O. Widmar*, C. Croney, and M. G. S. McKendree, *Purdue University, W. Lafayette, IN.*

Consumers today are interested in not only what they buy, but how it was made and who/what was affected. What are consumer's preferences surrounding attributes such as organic, animal-friendly and all-natural? Who do consumers trust for information on socially-relevant agriculture debates, such as animal welfare? Consumer's tastes, preferences, and values are highly variable and heterogeneous. Determining which agricultural system is ethically superior to another is complicated, especially without consensus on what makes a production method or system "good." Even consumers' interpretations of simple labels such as all-natural vary widely; survey respondents report that they associate such labels with improved animal welfare practices, no antibiotics, no hormones, no preservatives added, improved taste and improved food safety. As labels such as "all-natural" appear, it is important for producers to understand what they are perceived to mean, and how and to what extent purchasing them aligns with a consumer's values. For example, does such a label suggest improved welfare or a food safety enhancement? Along with perceptions, the consumer's knowledge base, information sources, and past experiences may also influence their demand for alternative practices. Consumers asked where they seek animal welfare information relied on HSUS and PETA, and to a lesser extent, federal government agencies and "other." More recently, when asked this question with the option to select not having any source for animal welfare information, the majority (55%) selected no source. As debates continue about what animal agriculture should look like, it is important to recognize that deficits of trusted sources of objective information, combined with underlying value notions may explain why consumers' purchasing behavior may or may not reflect their stated preferences. Understanding the value that consumers place on various systems and their attributes and the basis for forming their opinions enables constructive discussion surrounding how agricultural industries can meet consumers' demands, and do so profitably.

Key Words: consumer demand, preference

45 Farm size and animal welfare. D. M. Weary* and M. A. G. von Keyserlingk, *Animal Welfare Program, Faculty of Land and Food Systems, University of British Columbia, Vancouver, BC, Canada.*

Concerns about the welfare of farm animals often revolve around the issue of farm size. Many critics suggest that animals on larger farms are less likely to receive individual attention and instead are treated only as units of production, and that the shift to larger farms results in a decline in standards of care and ultimately in the quality of life for animals. In this talk we outline the historical background of this criticism, drawing parallels with the earlier debate over the shift from an agrarian to an industrial society. We also argue that farm size influences different aspects of animal welfare in different ways. For example, larger farms may permit more specialized and professional management of animal health, but make it difficult to provide access to pasture for dairy cows. We also review the limited empirical literature linking farm size and welfare and conclude that available research provides little support for any simple relationship. In conclusion, increases in farm size provide opportunities to improve the welfare of farm animals but also create welfare risks. Policy and advocacy efforts, instead of trying to reverse the increase in farm size, would be better directed toward generalizing the welfare benefits and minimizing the risks.

Key Words: natural living, professionalism, industrial agriculture

46 Can the fox guard the hen house? Can big corporations be socially responsible? T. Grandin*, *Colorado State University, Fort Collins.*

Three factors make big food corporations socially responsible. They are the (1) top leader's ethical principles, (2) a health emergency, and (3) activists that expose serious problems. During a 40-year career working with big corporations, I have observed animal welfare switching from an abstract nuisance that is delegated to the legal or public relations department to a real issue. This occurred when top executives went on tours of farms and slaughter plants. They saw reality; many things were acceptable but there were bad practices that needed changing. Since 1999, there have been huge improvements in animal handling in large slaughter plants. The improvement started when big restaurant chains started auditing animal welfare. Activist pressure was an initial stimulus, but the long-term motivator was top executives getting their "eyes opened." Industry organizations responded by developing guidelines and I have served on many committees. Sometimes the worst producers get on the committees to weaken standards. Large corporations can be socially responsible but many of them will need some outside pressure to prevent the worst abuses. On the other hand, big corporations are not the evil empire depicted by activists. Reality is always somewhere in the middle.

Key Words: animal welfare, social responsibility, welfare standard

47 Bioethical implications of retailer decisions and agreements with activists: HSUS-UEP Agreement. J. C. Swanson*, *Michigan State University, East Lansing*

The objective of this talk is to examine the ethical challenges that have occurred through activist pressure on food retailers, use of state initiatives, and industry-led change that have led to the HSUS-UEP historic agreement. During the last 15 years, social and political activism has instigated change to standard food animal production practices, including transport and slaughter. In the 1990s, animal activist organizations directly engaged the food retail sector to promote social responsibility for the welfare of animals used in the supply chain. Major food retailers responded by forming advisory committees, developing policies, and setting standards for their supply chain using market access as leverage for change. In the mid-2000s, the game changed. Social pressure on food retailers was coupled with the citizen referendum and successfully codified housing standards in several states. The targets were housing systems utilizing battery cages, sow gestation stalls, and stalls for veal calf production. A patchwork of legislation emerged. Each state-negotiated law left affected animal industries with serious production and market access issues. Most affected by the differences in state laws was the US egg industry. In 2011, the United Egg Producers (UEP) and the Humane Society of the United States (HSUS) mutually agreed to pursue federal legislation to set a common baseline for egg production within the United States.

Key Words: bioethics, animal welfare, agreements

48 Population structure and identification of lineages in a Brazilian Guzerat metapopulation. J. C. C. Panetto*[1], M. G. C. D. Peixoto[1], G. G. Santos[1], F. A. T. Bruneli[1], R. S. Verneque[1], M. A. Machado[1], A. L. S. Azevedo[1], D. R. L. Reis[1], L. A. Silva[1], A. A. Egito[2], and M. R. S. Carvalho[3], *[1]Embrapa Gado de Leite, Juiz de Fora, MG, Brazil, [2]Embrapa Gado de Corte, Campo Grande, MS, Brazil, [3]Universidade Federal de Minas Gerais, Belo Horizonte, MG, Brazil.*

Guzerat (*Bos primigenius indicus*) cattle was included in the FAO list of breeds to be conserved by means of management due to its beef and dairy potentials under various, especially harsh, environmental conditions. This study aimed to ascertain the population structure and the identification of distinct lineages in a metapopulation of the Guzerat breed in Brazil. Blood samples were collected from 664 animals in 15 seedstock herds in the country, including 5 herds with selection focused on beef, 9 herds in dual purpose systems and one closed herd with selection exclusively for dairy purposes. Genomic DNA was extracted from these samples and a panel of 21 microsatellites was selected for the Guzerat breed, according to their polymorphism information content (PIC). F-Statistics were used to estimate differentiation among subpopulations (F_{ST}) and the degree of reduction in heterozygosis due to non-random mating within subpopulations (F_{IS}). Lineages were determined by cluster analysis with a Bayesian approach with increasing numbers of inferred populations, assuming an admixture model based on the correlations between allelic frequencies. PICs ranged from 0.57 to 0.88, with a mean of 0.75. There was a large variation among herds on F_{IS} (values ranged between −0.109 and 0.061) indicating that some herds were more inbred than others. Average F_{ST} for this metapopulation was 0.034 ± 0.002. The closed dairy herd was the most differentiated among all (average pairwise F_{ST} = 0.052). The pairwise F_{ST} matrix demonstrated that, in general, the dual purpose herds were less differentiated within the entire metapopulation, when compared with the studied beef herds. Cluster analysis resulted in the identification of 6 lineages. Among them, 3 lineages included mostly animals from dual purpose herds, 2 lineages included mainly animals from beef herds, and one lineage included animals from dairy or dual purpose herds. One practical consideration is that the existence of herds with different purposes has contributed to the genetic structure of this breed. This project was supported by FAPEMIG.

Key Words: cluster analysis, genomic DNA, population structure

49 Genetic relationships among milk production and teat and udder scores in cows sired by seven prominent beef cattle breeds. L. A. Kuehn* and H. C. Freetly, *USDA-ARS, US Meat Animal Research Center, Clay Center, NE.*

Milk production and teat and udder quality are key components to lifetime cow productivity in commercial beef cattle. Our objective was to determine genetic relationships and breed differences for milk production and teat and udder quality in young and mature cows. Cows (n = 602) were crosses of F_1 cows and bulls (F_1^2) ; the F_1 parents resulted from matings of industry Angus, Hereford, Red Angus, Charolais, Gelbvieh, Limousin, and Simmental bulls with base Hereford, Angus, and MARC III composite cows. These F_1^2 cows were produced in 3 seasons and evaluated as 2 yr olds after their first calf and again as 5 yr olds. Milk production was measured approximately 100 d after parturition using the weigh-suckle-weigh method. Teat size and udder suspension were scored on a 9-point subjective scale in which 5 was considered an optimum. Genetic correlations and breed effects were derived from MTDFREML using a mixed model with fixed season, calf sex (for milk production), and breed and heterosis covariates and random effects of animal and error. Heritability estimates for 2 and 5 yr teat score, 2 and 5 yr udder score, and 2 and 5 yr milk production were 0.27, 0.31, 0.14, 0.32, 0.32 and 0.49. Genetic correlations among the same trait measured in different years were high (0.79 to 0.84). Similar to heritability estimates, correlations with udder score at 2 yr were lower than for other score traits likely indicating greater error in phenotyping udder suspension at 2 yr. Correlations between score traits and milk production were low and not significantly different than zero. Teat size was smallest in Charolais and largest in Simmental across years. Udder suspension was most optimal in Charolais. No breed effects were detected for milk production. This result is counter to breed effects generally observed on maternal effects for weaning weight in national cattle evaluation. Selection for these traits may lead to increased lifecycle productivity in beef cattle due to decreased culling on udder conformation.

Key Words: cow productivity, beef cattle, milk production

50 Genetic parameters for udder quality in Hereford cattle. H. L. Bradford*, D. W. Moser, J. M. Bormann, and R. L. Weaber, *Kansas State University, Manhattan.*

Udder quality is an important trait for beef producers because udders affect cow longevity and calf performance. The objective of this study was to estimate the genetic parameters for udder quality in Hereford cattle. The Beef Improvement Federation recommends collecting subjective scores on udder suspension and teat size. Prior to these guidelines, the American Hereford Association (AHA) recorded an overall score, which combines all udder characteristics into a single score. In all cases, scores ranged from 1 to 9 with a score of 9 considered ideal. Records on 78,556 animals and a 3-generation pedigree with 196,540 animals were obtained from the AHA, Kansas City, MO. These records contained repeated observations for overall score (n = 126,753), suspension (n = 61,758), and teat size (n = 61,765). Data were modeled using a multiple trait animal mixed model with random effects of additive genetic and permanent environment and with fixed effects of age and contemporary group (herd-year-season). Variances were estimated with ASREML 3.0. Heritability estimates (standard errors) of overall score, suspension, and teat size were 0.32 (0.01), 0.31 (0.01), and 0.28 (0.01), respectively. These results showed udder quality was moderately heritable, agreeing with previous research. The phenotypic correlations (standard errors) between teat size and suspension, overall score and teat size, and overall score and suspension were 0.64 (0.003), 0.31 (0.01), and 0.31 (0.01), respectively. Of the records for suspension and teat size, 57% had the same score for both traits. The genetic correlations (standard errors) between teat size and suspension, overall score and teat size, and overall score and suspension were 0.83 (0.01), 0.72 (0.02), and 0.70 (0.02), respectively. The genetic correlations between traits were extremely strong, indicating that these records were different measures of the same trait. In addition, differentiating between suspension and teat size might be difficult for producers.

Key Words: beef cattle, genetic parameter, udder score

51 Phenotypic relationships between docility and reproduction in Angus heifers. K. L. Otteman*[1], J. M. Bormann[1], K. C. Olson[1], J. R. Jaeger[1], S. Johnson[1], B. Downey[2], D. M. Grieger[1], J. W. Waggoner[1], D. W. Moser[1], and R. L. Weaber[1], *[1]Kansas State University, Manhattan, [2]Cowney Ranch Inc., Wamego, KS.*

Reproductive success is economically relevant in beef cattle operations, and may be influenced by temperament. The objective of this study was to elucidate the phenotypic relationships between docility and first service AI conception rate in heifers. Data (n = 337) collected from 3 cooperator herds in Kansas at the start of the synchronization protocol and included exit velocity (EV), chute score (CS), fecal cortisol (FC), and blood serum cortisol (BC). Statistical analysis was done using logistic regression with 30 d pregnancy rate as the dependent variable. The model included the fixed effect of contemporary group, and the covariates FC, BC, EV, CS, weight, and age. Correlation coefficients were also calculated between all continuous traits. Pregnancy rate ranged from 34% to 58% between herds. Blood cortisol positively correlated with EV (r = 0.22, $P < 0.01$), negatively correlated with age (r = −0.12, $P < 0.03$), and tended to be negatively correlated with weight (r = −0.10, $P = 0.09$). Exit velocity was positively correlated with CS (r = 0.24, $P < 0.01$) and negatively correlated with weight (r = −0.15, $P < 0.01$) and age (r = −0.12, $P < 0.03$). Chute score negatively correlated with age (r = −0.14, $P < 0.01$), and as expected, age and weight were moderately positively correlated (r = 0.42, $P < 0.01$). In general, older, heavier animals had better temperament, as indicated by lower BC, EB, and CS. The power of our test could not detect any significant predictors of 30 d pregnancy for the combined data from all ranches. When the data was divided by ranch, however, chute score ($P < 0.03$) and weight ($P < 0.01$) were both found to be significant predictors for 30 d pregnancy for ranch 1. Fertility is a complex trait that is dependent on many factors; our data suggest that docility is one factor that warrants further investigation.

Key Words: beef cattle, fertility, docility

52 Docility and heifer pregnancy heritability estimates in Angus heifers. K. L. Otteman*, J. M. Bormann, D. W. Moser, and R. L. Weaber, *Kansas State University, Manhattan.*

The objective of this study was to determine the genetic control of docility and reproduction in heifers as measured by pregnancy rate. Data included weaning contemporary group information, yearling contemporary group information, sex, docility score, yearling weigh date, age of dam, breeding contemporary group, age at first breeding, pregnancy check results, and first service sire. A subjective chute scoring system was used as the basis of their genetic evaluation for docility. Pedigree information included 508,015 animals over 30 generations. Contemporary groups were formed by the concatenation of weaning contemporary group, yearling contemporary group, and breeding contemporary group. Heritabilities were computed from estimates of genetic and residual variance components computed using ASReml 3.0 (VSN International, Hemel Hempstead, UK). Heifer pregnancy variance components were estimated from a univariate threshold model, with pregnancy outcome as the dependent variable, animal and contemporary group as random effects, and age at first breeding as a covariate. The heritability of heifer pregnancy was estimated to be 0.16 ± 0.02. Docility was fit as a univariate, linear animal model with docility score as the dependent variable, and animal and contemporary group modeled as random effects. The heritability for docility score was estimated to be 0.22 ± 0.03. Low to moderate heritability on these traits indicates that slow but definite genetic improvement can be made by selection on heifer pregnancy and docility.

Key Words: genetics, docility, reproduction

53 The effect of sire breed on birth weight, preweaning ADG, and adjusted 205-d weight of calves from commercial Angus dams mated to Angus, Braunvieh, and Hereford sires. C. L. Ferring*, G. A. Hansen, and J. P. Cassady, *North Carolina State University, Raleigh.*

The objective of this study was to assess the effects of breed of sire on birth weight, preweaning ADG, and adjusted 205-d weight. Angus (n = 58), Hereford (n = 37), and Braunvieh (n = 41) sires were randomly mated to commercial Angus cows (n = 184, 75% or greater Angus). Hereford and Braunvieh sired calves should express 100% heterosis. Data were available for 389 calves born from 2003 to 2011 at the Tidewater Research Station in Plymouth, NC. Male calves were castrated by 5 mo of age. Calves were not creep fed and never implanted. The GLM Procedure of SAS was used. The model included fixed effects of sire breed, age of dam, sex of calf, and calf birth year. Gestation length, calculated based on the day a cow was bred by AI and the day she calved, was included as a covariate. Age of dam and sex of calf affected birth weight, pre-weaning ADG, and adjusted 205-d weight ($P < 0.01$). Calf birth year affected preweaning ADG and adjusted 205-d weight ($P < 0.01$). A 1-d increase in gestation length increased birth weight by 0.19 kg ($P < 0.01$), increased preweaning ADG by 0.12 kg ($P < 0.05$), and decreased adjusted 205-d weight by 0.42 kg ($P < 0.06$). Sire breed affected birth weight ($P < 0.01$). Angus, Hereford, and Braunvieh sired calves had average birth weights of 34.6, 36.9, and 37.4 kg, respectively. Effects of sire breed on preweaning ADG and adjusted 205-d weight were not statistically significant. Birth weight, preweaning ADG, and adjusted 205-d weight increased as age of dam increased up to 5 years of age. In summary, breed of sire influenced birth weight but did not affect preweaning ADG and adjusted 205 d weight. These results are surprising in that heterosis did not result in significantly heavier calves at weaning.

Key Words: beef cattle, crossbreeding, growth

54 Breed × sex effects on birth weight in Brahman-Simmental embryo transfer calves. J. A. Dillon*[1], R. M. Thallman[2], J. O. Sanders[1], and D. G. Riley[1], *[1]Texas A&M AgriLife Research, College Station, [2]US Meat Animal Research Center, Clay Center, NE.*

Brahman cross calves exhibit unusual inheritance of birth weight: Brahman-sired crossbreds out of *Bos taurus* females are heavier with greater difference between sexes than calves of the reciprocal cross. The objective of this work was to compare birth weight in various crosses of Brahman, Simmental, and Simbrah. Embryo transfer (ET) calves (n = 2,486) were born in central Texas from 1984 – 1990 and were 1/4, 3/8, 1/2, 5/8, or 3/4 Brahman produced by multiple types of matings, dependent upon the breed group. Data were analyzed with an animal model, with 6,061 animals in the pedigree. Fixed effects investigated included contemporary group (n = 36; combinations of year, birth season, and location), sex of calf, breed group (n = 5), and linear covariates of direct expected breed heterozygosity (HET) and proportion of Brahman in the sire (BIS). Random effects included additive genetic and maternal permanent environmental (of the recipient dam); maternal genetic did not improve likelihood values and was not included in the final model. The regression coefficient for HET was 11.2 ± 3.52 kg ($P = 0.02$). The regression coefficient for BIS was 7.7 ± 1.04 kg ($P < 0.001$). There was a breed group by sex interaction detected ($P < 0.001$). Males were heavier ($P < 0.05$) than females in 1/4, 3/8, and 3/4 Brahman groups. Among females, 3/4 Brahman calves had lower ($P < 0.05$) birth weights than all other breed groups. In male calves, 1/2 and 3/4 Brahman calves had lower ($P < 0.05$) birth weights than all other groups. The estimate of heritability for birth weight from these data was 0.34 ± 0.05. Maternal permanent environmental variance as a proportion of phenotypic variance was 0.34 ± 0.09.

Proportion Brahman in the sire relative to proportion Brahman in calf significantly influences birth weight in Brahman-Simmental crosses produced by ET. This effect is not consistent with standard models used in genetic evaluation, but is consistent with the mechanisms of genomic imprinting, early (before ET) embryonic maternal effects, and/or X chromosome effects.

Key Words: birth weight, Brahman, non-Mendelian inheritance

55 Phenotypic and genetic correlations as well as linear relationships of performance, carcass, feed efficiency, and economic characteristics of beef feedlot steers. K. M. Retallick*[1], D. B. Faulkner[2], S. L. Rodriguez-Zas[1], J. D. Nkrumah[3], and D. W. Shike[1], *[1]University of Illinois, Urbana, [2]University of Arizona, Tucson, [3]Pfizer Animal Genetics, Kalamazoo, MI.*

Several feed efficiency measures are being investigated including: feed conversion ratio in terms of feed:gain (FCR), residual feed intake (RFI), residual BW gain (RG), and residual intake and BW gain (RIG). These traits have production efficiency potential since they include feed intake inputs and production outputs. The objective of this study was to investigate 1) how these measures of efficiency affect one another and their heritability estimates and 2) relate measures of efficiency both genetically and phenotypically to feedlot cattle performance, carcass, and economic characteristics. All feed efficiency traits were favorably correlated genetically and phenotypically to each another. Heritability estimates were moderate ranging from 0.22 to 0.38 ± 0.10. Feed conversion ratio was genetically correlated to RG and RIG at −0.97 and −0.95, respectively. Feed conversion ratio was also highly correlated with growth traits therefore an increase in weight led to a more desirable FCR. A genetic increase in carcass value was associated with a more desirable FCR due to an increase in HCW. As expected due to genetic correlation to FCR, similar affects were shown for RG. A unit reduction in DMI yielded a 0.42 improvement in RFI and genetic results were similar. As designed, RIG reduced DMI similar to RFI and increased ADG similar to RG. Marbling was correlated phenotypically to RG and RIG at −0.08 and −0.09, respectively and correlated genetically to RFI and RIG at 0.59 and −0.59, respectively. This indicated that marbling decreased as measures of feed efficiency improved; however, the linear regression slope was small which indicated only a small decrease in marbling. As a result, carcass value was still favorably correlated with RG (r = 0.15) and RIG (r = 0.10) and not correlated to RFI. As profitability increased for steers, all feed efficiency measures improved.

Key Words: feedlot feed efficiency, genetic relationship, phenotypic relationship

56 Genotype by environment interaction effects on crossbred lambs at finishing. G. C. Márquez*[1], W. Haresign[2], M. H. Davies[3], R. Roehe[4], L. Bünger[4], G. Simm[4], and R. M. Lewis[1,4], *[1]Virginia Tech, Blacksburg, [2]Aberystwyth University, Aberystwyth, UK, [3]ADAS Rosemaund, Preston Wynne, UK, [4]Scottish Agricultural College, Edinburgh, UK.*

Accounting for genotype by environment interactions (GE) in genetic evaluations is important because animals may not perform predictably across environments. The purpose of this study was to investigate GE on full body weight (FWT), ultrasonic muscle (UMD) and fat (UFD) depth at finishing in crossbred lambs. Data on 6,325 lambs sired by Charollais, Suffolk, and Texel rams were obtained. The experiment was done between 1999 and 2002 on 3 farms in the UK. In total 89 sires (selected from the top or bottom 10% on a selection index that increased carcass lean weight while keeping fat constant) were mated to 1,984 ewes of 2 types (Bluefaced Leicester × 2 hill breeds). Most rams were used for 2 successive mating seasons, with some rotated among farms to create genetic links. Lambs were reared on pasture and assessed for fat cover until they reached a target of 11% subcutaneous fat, and then were weighed and ultrasonically scanned for fat and muscle depth. The UFD data were log-transformed to approach normality. All models included the fixed effects of sire index category, lamb sex and birth year, age of dam, and birth-rearing category. Subcutaneous fat at finishing was a covariate for FWT and UMD, and age at finishing for UFD. An additive genetic effect was fitted with a pedigree-based relationship matrix among lambs. Six genetic groups were fitted (3 sire breeds, 2 dam breed types, 1 maternal grandsire breed). For FWT a random rearing dam effect was fitted, which was unimportant for UFD or UMD ($P > 0.2$). The GE in the data was first investigated by fitting a random sire by farm interaction term. Likelihood ratio tests indicated that GE defined variation ($P < 0.001$). The ratio of interaction variance to total variance for FWT, UMD, and UFD was 0.07 ± 0.02, 0.11 ± 0.02, and 0.22 ± 0.03, respectively. Additionally, data from the 3 farms were fitted as separate but correlated traits. Heritabilities differed in the 3 farms ($P < 0.01$). Genetic correlations among farms were generally high, as were rank correlations of sire EBV (0.7–0.9). This indicates that, especially for scanning traits, GE should be considered in robust genetic evaluation programs.

Key Words: genetics by environment interaction, sheep

57 Tolerance of the maternal immune system to the fetal semi-allograft. M. G. Petroff*, S. M. Alam Khorshed, C. Linscheid, and S. Jasti, *Department of Anatomy and Cell Biology, University of Kansas Medical Center, Kansas City, KS.*

Pregnancy has often been likened to an allograft due to the genetic differences between the mother and her baby. Upon the discovery of the major histocompatibility complex antigens in the 1950s it was reasoned that in order for the mother to tolerate the fetus, the 2 must somehow prevent or suppress an immune response that could result because of their immunogenetic differences. Initial hypotheses of how the mother could tolerate the semiallogeneic fetus included maternal immune suppression, immunological immaturity of the fetus, and physical separation of the mother and fetus. The last 60 years of research have enlightened us greatly in the mechanisms by which this paradoxical situation flourishes; to varying degrees, all of Sir Peter Medawar's hypotheses regarding the fetal "allograft" are true. The trophectoderm-derived placental trophoblast provides the physical interface between mother and baby, and although this tissue restricts expression of major histocompatibility complex molecules, there is no shortage of paternally-inherited minor histocompatibility antigens. These minor antigens, when mismatched between organ donor and recipient, cause chronic allograft rejection in transplantation; in pregnancy, minor antigens are expressed by the trohpoblast, and are detected and robustly tolerated by the maternal immune system. We have hypothesized that paternally-inherited as well as placenta-specific antigens are detected by the maternal immune system as a result of trophoblast expression, and moreover, by virtue of shedding of copious amounts of trophoblast microvesicles and exosomes into the maternal blood. The detection of feto-placental antigens by maternal CD4+ and CD8+ T lymphocytes occurs as a muted immune response that is controlled by placental factors co-expressed with the antigens. Despite this highly controlled lymphocyte response to the fetus, maternal memory T cells develop and can persist in women for decades. Although the physiological ramifications of these persistent T cells are not understood, they may include effects on long-term health of mothers. Supported by NIH R01HD045611 and P01HD049480.

Key Words: pregnancy, placenta, trophoblast

58 The immune system in CL formation/angiogenesis/lymphangiogenesis and its role in establishment of pregnancy. A. Miyamoto*[1], K. Shirasuna[2], S. Haneda[1], T. Shimizu[1], and M. Matsui[1], *[1]Obihiro University of Agriculture and Veterinary Medicine, Obihiro, Japan, [2]Jichi Medical University, Tochigi, Japan.*

The establishment of pregnancy needs a well-balanced regulation in endocrine and immune systems and involves interactions among conceptus, oviduct/uterus and CL. In particular, the optimal rate of increase in plasma P4 during the first 1wk after ovulation is critical for the conceptus growth, leading to successful in pregnancy in cattle. Events involved in maternal recognition of pregnancy (MRP) may commence before 1wk from AI, as interferon-stimulated genes (ISGs) and IL10 mRNA expressions in circulating immune cells increase in pregnant cows. To regulate optimal endocrine condition in this narrow time window, CL should develop rapidly with active angiogenesis/lymphangiogenesis. Major angiogenic factors VEGF and FGF2 work in developing CL, but may also act as chemoattractant to PMN. Indeed, PMNs were observed at highest number in new CL with highest IL8 expression, and PMN secrete IL8 to induce active angiogenesis/lymphangiogenesis in CL. The findings led us to hypothesize functional polarization of neutrophils (proinflammatory N1 vs. anti-inflammatory N2). It is interesting that on d 5 after AI circulating PMN exhibit upregulated expression of ISGs, and that PMN in CL are stimulating luteal angiogenesis, both of which are physiological prerequisites for occurrence of pregnancy. During later phase of MRP, the conceptus secretes a large amount of interferon-tau (IFNT), thereby preventing CL regression. Likely IFNT reaches CL and acts on acquisition of PG-resistance. New lymphangiogenesis stimulated by IFNT may occur at MRP without any new angiogenesis in cows. Taken into account that PGE2 is also upregulated in CL at MRP, some shifting of local immunity toward immune tolerance may occur in CL of early pregnancy. Interestingly, persistent CL (non-pregnant) and CL of early pregnancy showed similar mRNA expression, but differed in higher expression of Foxp3 mRNA in CL of pregnancy. Elucidating the immune system for earlier MRP together with local regulation of CL development utilizing immune system may help in understanding physiology and pathophysiology of early pregnancy in cows.

Key Words: corpus luteum, angiogenesis/lymphangiogenesis, early pregnancy

59 Effects of maternal obesity on placental and gut inflammation and immune function. M. Zhu*[1], H. Wang[2], M. Du[3], and S. P. Ford[2], *[1]School of Food Science, Washington State University, Pullman, [2]Department of Animal Science, University of Wyoming, Laramie, [3]Department of Animal Science, Washington State University, Pullman.*

Obesity in pregnant women is a growing public health concern, which negatively affects fetal development and has long-term effects on offspring health. The placenta mediates nutrient transport to fetuses and is a source of inflammatory cytokines. Maternal obesity in sheep induces placental inflammation as indicated by enhanced expression of inflammatory cytokines including tumor necrosis factor (TNF)-a, interleukin (IL)-6, IL-8 and IL-18, and exaggerated c-Jun N-terminal kinase (JNK)/c-Jun and nuclear factor kappa-light-chain-enhancer of activated B cells (NF-kB) inflammatory signaling pathways. Accompanying placental inflammation, maternal obesity induces an inflammatory response in the late gestation fetal large intestine of sheep, manifested by elevated expression of TNF-a, IL-1β, IL-6, IL-8, and monocyte/macrophage chemotactic protein-1 (MCP-1), as well as macrophage markers, CD11b, CD14, and CD68 in the fetal gut. In addition, we observed that inflammation persisted in offspring gut of obese mothers. Using non-obese diabetic (NOD) mice, we further demonstrated that offspring born to obese mothers had higher gut epithelial permeability, called "leaky gut," which is one of the main etiological factors for several common diseases including inflammatory bowel diseases, Type I diabetes and related autoimmune diseases. In agreement with increased gut permeability, we showed that maternal obesity resulted in an increased incidence of Type I diabetes, as evidenced by a severe lymphocyte infiltration and destruction of pancreas islets in the offspring of obese NOD mice. In summary, maternal obesity induces inflammation in the placenta and fetal gut, which has long-term effects on offspring gut immunity, likely pre-disposing offspring to inflammatory bowel diseases, type 1 diabetes and other autoimmune diseases. (Supported by NIH 7R15HD073864–02; USDA 2008–35203–19084; 2009–65203–05716).

George C. Fahey Companion Animal Nutrition Symposium I: Effect of Dietary Format on Nutrition, Food Management, and Food Safety

60 Introduction—Defining natural pet foods. K. R. Kerr*, *Department of Animal Sciences and Division of Nutritional Sciences, University of Illinois, Urbana.*

Many pet owners are choosing alternative diets for their dogs and cats. Therefore, it is not surprising that more and more pet food packaging contains words like "holistic," "natural," "organic," "real meat," "no preservatives," and a multitude of other claims. In 2009, it was estimated that 249 new natural products were available in the pet market, up from 154 new natural products in 2007. While the pet food market is benefiting from the current natural and organic trends, the definitions of these terms are either vague or misunderstood by consumers, allowing a multitude of products to be categorized and purchased under these terms. We have invited some of the field's most reputable speakers, who have first-hand experience with researching, marketing, formulating, and managing the safety of natural pet foods.

Key Words: companion animal, nutrition

61 From wild to captive diets: Metabolic flexibility of cats. A. Verbrugghe*, *Ontario Veterinary College, University of Guelph, Guelph, ON, Canada.*

The domestic cats' wild ancestors (*Felis silvestris*) are known to be obligate carnivores, consuming prey which are high in protein, moderate in fat, and contain only minimal amounts of carbohydrates. Evolutionary events adapted the cat's metabolism and physiology to this diet strictly composed of animal tissues, which led to unique digestive and metabolic peculiarities of protein, carbohydrate, fatty acid, and vitamin metabolism. Cats have a high protein requirement and are unable to adapt hepatic catabolic enzyme activity to a low protein diet. Cats also have a higher requirement for essential amino acids such as arginine, methionine, cysteine and taurine. Carbohydrate digestion is characterized by a very low salivary amylase activity, a rather low intestinal amylase activity and a non-adaptive sugar transport system across the intestinal brush border. Moreover, hepatic glucokinase and glycogen synthase activity are limited, while hepatic gluconeogenic enzymes are upregulated. The modern domestic cat (*Felis catus*) still closely resembles its wild ancestor. Although the carnivore connection of domestic cats is well recognized, little is known on the precise nutrient profile to which the digestive physiology and metabolism of the cat has adapted throughout evolution. Data from dietary habits of feral cats combined with compositional data of the consumed prey species revealed a typical diet containing a crude protein, crude fat and nitrogen-free extract content on dry matter basis of 63.1, 20.1 and 8.9%, respectively. Still a distinct difference must be made between the optimal diet composition and nutrient requirements. Also this diet composition did not discriminate between reproduction and maintenance nor accounted for disease or other physiological states. It can be argued that the shift from an obligatory meat based diet to a pet food with higher carbohydrates levels places the cats' metabolism under stress and might have unwanted negative health effects in the long-term, especially when accompanied by a shift from an outdoor environment to an indoor lifestyle and a decreased physical activity.

Key Words: feline nutrition, metabolism

62 What is natural? Marketing versus science of natural pet diets. P. R. Buff*, R. A. Carter, and J. H. Kersey, *The Nutro Company, Franklin, TN.*

In recent years, the natural segment of pet foods has grown steadily from $2.0 billion in 2008 to $3.9 billion in 2012. This growing trend may be attributed to anthropomorphism of dogs and cats as 63% of pet owners consider their pets to be family members. The term natural when used to describe pet foods or pet food ingredients has been defined by the Association of American Feed Control Officials (AAFCO). The regulation requires at a minimum the pet food is preserved with natural preservatives. However, pet owners consider natural as something different than the AAFCO definition. Pet owner perception of natural pet food is variable and includes the following; organic, less additives, no by-products, no added preservatives and high protein. Much of the trend in natural pet food focuses on ingredients with a rise in grain free, human grade and organic claims. However, the research behind the benefit of these natural ingredients may be lacking. Where evidence exists, some natural pet foods focus on structure-function claims to provide nutritional benefits linked to natural ingredients. New food formats have emerged in recent years, evolving from only extruded and canned diets to formats such as frozen, freeze-dried and baked. The processing of pet food can affect digestibility, nutrient bioavailability and safety. Some trends have focused on evolutionary diet formulation based on wild species. Domestic cats have been shown to prefer a macronutrient profile similar to wild cats. However, dogs prefer a diet different than wolves, with a macronutrient profile of approximately 30% of their caloric intake from protein. This may be attributed to recent data showing dogs have evolved much different than wolves in their ability to metabolize carbohydrates as dogs are scavengers rather than hunters. Future opportunities include the integration of sustainability with natural pet foods. The challenge is to match the consumer demand and provide natural nutrition to pets while reducing the impact on the environment. The market for natural pet food continues to grow as pet owners are becoming closer to their pets than previous generations and more aware of their pets' diet.

Key Words: nutrition, natural, pet food

63 Potential health benefits of phytochemicals in pets. P. Nguyen*[1], B. Paragon[2], H. Hazewinkel[3], V. Leray[1], G. Blanchard[4], S. Serisier[5], and A. André[1], *[1]National College of Veterinary Medicine, Food Science and Engineering Nantes-Atlantique (Oniris), Nantes, France, [2]National Veterinary School of Alfort, Maisons-Alfort, France, [3]Utrecht University, Utrecht, the Netherlands, [4]Animal Nutrition Expertise, Antony, France, [5]Royal Canin R & D, Aimargues, France.*

In addition to the chemicals used as "usual" nutrients, plants contain secondary metabolites that are involved in adaptation to environment, defense against 'predators' and pathogens, and regulation of symbiosis and seed germination. These phytochemicals include phenolics, alkaloids, carotenoids, and organosulfur compounds. Although some are toxic when consumed, others may be associated with health benefits, including anti-mutation, anti-carcinogenesis, anti-oxidation and anti-angiogenesis properties. For the most part, their bioactive potency is low, but they may induce significant

effects when consumed daily over the long-term. Higher doses of phytochemicals can be provided in the form of nutraceuticals that are often phytochemical-enriched extracts or phytochemicals-like compounds synthetized and/or modified so that to increase their bioavailability and efficacy. The health effects of phytochemicals particularly concern age-related diseases, such as cardiovascular and neurodegenerative diseases, diabetes, osteoporosis, and several types of cancer. They have also been shown to improve obesity-related metabolic disturbances, especially low insulin sensitivity, and low-grade inflammation, as well as dyslipidemia. As phytochemicals are very numerous, several mechanisms of action can be involved, including the increase of the total antioxidant power, or modifications of gene transcription through activation of nuclear receptors or epigenetic modifications. For companion animals, less evidence is available as regards phytochemical efficacy than for humans and rodents from in vivo clinical and experimental trials, and in vitro studies. In pets, phytochemicals would improve insulin resistance, aging cognition impairment, osteoarthritis, carcinomas, urolithiasis, atopic dermatitis, and 'antioxidants' would improve immunological status. Some studies have concerned the bioavailability and tissue distribution of some phytochemicals but most often clinical studies are missing. It is known, however, that more is not always better. Moreover, we raise the question of how phytochemicals act, and that of the metabolic basis for 'dietary' supplementation of diets supposed to be balanced and meeting dietary 'requirements'.

Key Words: phenolic compound, carotenoids, plant secondary metabolite

64 Ramifications of the food safety modernization act on the pet food industry, along with new technologies to control salmonella in pet food. C. Knueven*[1] and G. Aldrich[2], *[1]Research and Development, Jones-Hamilton Co., Walbridge, OH, [2]Grain Science & Industry, Kansas State University, Manhattan.*

In 2007 there were 2 very significant food safety events in the pet food industry; one a chemical economic adulterant (melamine-cyanuric acid) and one a microbial pathogen (*Salmonella schwarzengurnd*). They each carried over into the human food chain and subsequently garnered enough attention of Congress to sweep pet food safety into the legislation crafted for the Food Safety Modernization Act of 2011. Since that time pet food manufacturers, equipment suppliers, laboratories, and ingredient suppliers have been gearing up for what they expect to be new rules regarding safety and traceability in the production of foods for companion animals. The new rules should be published by mid-summer 2013 and are expected to mirror the recently published cGMP rules for human foods. Diligence regarding testing has been expanding since 2007 with more than 99 recall events identified for various pet foods and treats during the period from 2008 to the present. While many of these events were due to mixing or labeling errors, the one large element generating great concern is the zero tolerance for pathogens such as Salmonella. For this there are several strategies being developed to bring contamination under control. This discussion will further discuss the requirements for facilities to conduct a hazard analysis, implement risk-based preventive controls, monitoring procedures, corrective actions, verification and recordkeeping steps to remain in compliance with the act. It will also provide an insight into new technologies and results from research on mitigation strategies for pathogen reduction and control and their influence on companion nutrition and food management.

65 The effect of feeding rumen-bypass protein on milk yield and composition in Irish dairy cows. M. R. Sheehy*[1,2], F. J. Mulligan[1], P. A. McLaughlin[2], O. Brennan[2], S. Taylor[2], and A. G. Fahey[3], *[1]School of Veterinary Medicine, University College Dublin, Dublin, Ireland, [2]Devenish Nutrition Ltd., Belfast, UK, [3]School of Agriculture and Food Science, Dublin, Ireland.*

Inclusion of rumen-bypass proteins in dairy cow diets is a standard management practice in many areas around the world. However, supplementing diets with rumen-bypass protein is not standard practice with a typical perennial ryegrass based Irish diet. Therefore the objective of this study was to determine if supplementing rumen-bypass protein would alter milk yield and composition for cows fed this diet type. Holstein-Friesian dairy cows (n = 112) were balanced for DIM, pre-experimental milk yield, and milk composition and assigned to either a control (n = 58) or a rumen-bypass protein (n = 54) treatment. Cows were put into 2 large pens and after each milking the cows rotated into a new pen to account for environmental effects in the shed. Cows were fed rumen-bypass protein in individual stanchions. Therefore cow is considered the experimental unit. The trial was carried out over a 10 wk period and on weekly intervals yield was recorded and milk composition was determined (fat yield and %, protein yield and %, lactose yield and %). All data were analyzed in SAS with a repeated measures mixed model. The fixed effects included treatment, parity (1 to ≥5), week (1 to 10), and the interactions between treatment and parity, and treatment and week. Days in milk, genetic potential for milk production, and the covariates of production for milk yield and composition −2, −1, and +1 week of the trial were included in the model. Cow within treatment was included in the model as a random effect. Cows fed the bypass protein had significantly greater milk yield ($P < 0.01$), protein yield ($P < 0.05$), protein % ($P < 0.01$), and a tendency to have an increase in lactose yield ($P < 0.10$). There were significant differences between the rumen-bypass protein and control treatments for fat yield, fat percentage, or lactose percentage. In conclusion bypass protein supplementation in the diet resulted in increased milk yield, and protein yield and composition for cows fed typical Irish forages. Therefore supplementation of rumen-bypass protein in Irish dairy systems may improve milk yield and protein production.

Key Words: milk composition, milk yield, rumen-bypass protein

66 Rescue from diet-induced milk fat depression in monensin-supplemented dairy cows. D. E. Rico*[1], A. W. Holloway[2], and K. J. Harvatine[1], *[1]The Pennsylvania State University, University Park, [2]Elanco Animal Health, Greenfield, IN.*

Sixteen Holstein cows were used in a crossover design to investigate the effect of monensin (MN) on the recovery from milk fat depression (MFD). MFD was induced at the start of each period by feeding a low fiber, high oil diet with monensin (Rumensin 90, Elanco Animal Health) for 10 d. A recovery phase of 18 d followed where cows were fed a high forage, low oil diet (31.2% NDF and no oil). Treatments during recovery were (1) control (no MN supplementation) or (2) monensin administered as a topdress at a rate of 450 mg/cow/d. Dry matter intake was observed daily and milk yield and composition and milk fatty acid (FA) profile were measured every 3 d during recovery. Data were analyzed as repeated measures and tested control vs MN at each time point. There was no effect of monensin on DMI or yield of milk, protein, and lactose ($P > 0.05$). Milk fat concentration and yield increased progressively during recovery in both treatments. However, there was no treatment by time interaction for milk fat yield ($P > 0.10$). Monensin decreased milk fat yield from d 6 to 15 (12% on average; $P < 0.05$), but was the same as control on d 18. There was a treatment by time interaction for milk fat concentration ($P < 0.10$), which was decreased by MN only on d 3 and 6. The yield of milk de novo synthesized FA increased progressively in both treatments and was not affected by treatment. Similarly, yield of 16C FA increased progressively, but was decreased by MN on d 6 and 9. Preformed FA yield was lower in the MN group from d 6 to 15 (13.9%; $P < 0.05$), but was not different from control on d 18. Importantly, milk FA concentration of trans-10 C18:1 and trans-10, cis-12 CLA rapidly decreased in both groups, however, MN slightly increased trans-10 C18:1 concentration on d 15 and 18 (21% of FA; $P < 0.01$). Monensin feeding reduced the rate of recovery from MFD predominantly through a delayed recovery of preformed FA, although a similar level of recovery was achieved by d 18. Monensin supplementation has minimal effect on recovery of normal rumen biohydrogenation and de novo fatty acid synthesis during recovery from MFD by correction of dietary NDF and PUFA concentration.

Key Words: dairy cows, milk fat depression, monensin

67 Behavior of dairy cattle housed on differing freestall bed types compared with cattle kept at pasture. J. Lau[1], J. K. Margerison*[1], M. Hedley[1], D. Horne[1], J. Hanley[1], N. Powell[2], and A. Shilton[2], *[1]Institue of Agriculture and Environment, Massey University, Palmerston North, New Zealand, [2]School of Engineering & Advanced Technology, College of Sciences, Massey University, Palmerston North, New Zealand.*

This research aimed to compare differing types of free stall beds on the lying time of dairy cattle and compare this with animals grazed at pasture. Three groups of 12 adult dairy cattle, of similar age, live weight and condition score were offered access overnight to; pasture (P) or were housed in free stalls that were fitted with sand beds (S) or dual chamber water beds (W). All housed cows were offered each bed type in a changeover design, with a 5 d house acclimatization period, followed by a 3 d behavior measurement and a 5 d rest period on pasture. Each day cows were grazed for 4 h, waited to be milked for 2 × 2 h and were either housed or grazed for 16 h overnight. During the training period all cows adapted quickly to lying in deep litter sand beds (0.61 (±0.05) days). During the 3 d of 24 h behavior measurement, cows lay in water beds for significantly less time, and stood fully in and half in beds for significantly longer compared with sand beds, while there was no significant difference between sand beds and cows at pasture (Lying: 11.1; S: 11.1; W: 9.9 (0.71) h/d). More cows housed on water beds lay in the alley (3) compared with cows housed on sand beds (0). Cows quickly adapted to lying in sand beds, despite not having used freestall housing previously. Cows housed on sand beds lay down for similar amount of time as cows kept at pasture. Cows housed on water beds lay down for significantly less time than cows on sand beds and more lay in the ally, and stood for longer and often stood half in the beds.

Key Words: housing, pasture, dairy

68 Effects of amount of palmitic and stearic fed to mid-lactation dairy cows on intake, milk yield, and diet digestibility. D. N. Lobão da Silva*[1], R. S. Younker[2], and N. B. Litherland[1], *[1]University of Minnesota, Saint Paul, [2]Milk Specialties, Eden Prairie, MN.*

Dietary supplementation with stearic and palmitic acid can increase energy available for dairy cows when energy intake constrains milk yield. Questions still remain regarding the impact of carbon chain length (pure stearic or palmitic acid) of saturated fatty on DMI, milk production, and milk fat yield. The objectives of this study were to determine if pure stearic or palmitic acid fed at 2.5% and 5% of total diet DM would affect DMI, milk yield, milk components and DM digestibility. Forty (n = 8) multiparous cows at 219 ± 10 DIM, producing 33 ± 1.8 kg of milk/d were randomly assigned to 1 of 5 treatments for 6 wk with a 5-d adaptation period. Data were analyzed by PROC MIXED with model containing effect of treatment and random effect of cow within treatment. Treatments were: TMR with 0% fat of diet DM Control (C); 2.5% stearic (S2.5); 5% stearic (S5); 2.5% palmitic (P2.5); 5% palmitic (P5). Diets were 17% CP, 28% NDF, 22% starch, and varied only in ether extract (4.1, 6.5, 8.8, 6.5, 8.8 %) for C, S2.5, S5, P2.5 and P5, respectively. There were no treatment effects on DMI, energy intake, or milk yield. Due to high summer temperatures (35°C) during this study, cows were heat stressed (93 THI) with low DMI. Higher energy diets from fat source did not alleviate the effects of heat stress on production.

Table 1.

	Treatment						
Variable	C	S2.5	S5	P2.5	P5	SEM	*P*-value
Calculated supplemental FA intake, g/d	0.0	452.4	932.7	466.1	847.5	32.1	<0.001
DMI, kg/d	18.8	18.1	18.7	18.6	16.9	0.9	0.57
Energy intake, Mcal/d	29.3	30.3	33.5	30.9	30.7	1.5	0.50
3.5% FCM, kg/d	23.5	25.1	27.6	27.1	25.2	1.6	0.35
Fat yield, g/d	0.8	0.9	1.0	1.0	0.9	0.1	0.28

Key Words: milk production, palmitic acid, stearic acid

69 Effects of dietary starch content and corn particle size on intake, digestion and milk production by dairy cows. S. M. Fredin*, S. J. Bertics, and R. D. Shaver, *University of Wisconsin, Madison.*

An experiment was conducted to evaluate the effects of dietary starch concentration and corn particle size on intake, ruminal fermentation, digestibility, and milk yield, composition and component yields. Eight ruminally-cannulated multiparous Holstein cows (96 ± 8 d in milk at trial initiation) were randomly assigned to a 2 × 2 factorial arrangement of treatments in a replicated 4 × 4 Latin square design with 21-d periods. Treatments were finely (F; mean particle size = 552 µm) and coarsely (C; 1270 µm) ground dry shelled corn in normal (NS) and reduced (RS) starch rations fed as TMR. The NS and RS rations contained 27 and 18% starch (DM basis), respectively, by partially replacing corn with soy hulls. Milk samples were collected at both milkings on d 16 and 17 and rumen fluid 4 times daily at 2-h intervals on d 18–20 such that the samples represented a 24-h feeding cycle. Fecal samples were collected 2 times daily on d 18–20. Apparent total tract DM digestibility (DMD) was estimated using indigestible NDF as a marker. Data were analyzed using the MIXED procedure of SAS. Mean DMI (23.2 kg/d) was unaffected by treatment. Cows fed NS produced 1.9 kg/d more milk (41.0 vs. 39.1 kg/d; $P = 0.03$) and 0.06 kg/d of milk protein (1.18 vs. 1.12 kg/d; $P < 0.01$) than cows fed RS. There tended ($P = 0.06$) to be an interaction for milk fat yield with greater yield for NSF and RSC. The DMD, ruminal VFA (mM) and ammonia (mg/dL) were unaffected by treatment. Cows fed F had greater ruminal propionate (20.0 vs. 18.9 mol/100 mol; $P < 0.001$) and lower acetate: propionate ratio (3.45 vs. 3.68; $P < 0.001$) and pH (6.27 vs. 6.33; $P = 0.04$). Average rumen pH was above 5.8 for all treatments. Feeding normal starch diets increased milk and protein yields and finely ground corn increased ruminal propionate concentration.

Key Words: digestion, particle size, starch

70 Effect of time of storage on ammonia nitrogen concentration and ruminal in vitro starch digestibility of high moisture corn—A field survey. L. F. Ferraretto*, R. D. Shaver, and P. C. Hoffman, *University of Wisconsin-Madison, Madison.*

The objectives of the study were to (1) determine relationships between HMC ammonia-N, DM, pH and soluble CP concentrations and 7-h ruminal in vitro starch digestibility (IVStarchD), and (2) evaluate the effects of storage time on HMC pH, ammonia-N, soluble CP and IVStarchD measurements. Month of submittal was assumed to be associated to length of time in storage. To achieve these objectives a data set comprised of 2,685 HMC samples, within 50 to 80% DM, from Dairyland Laboratories Inc. (Arcadia, WI) and Cumberland Valley Analytical Services Inc. (CVAS, Maugansville, MD). Ammonia-N and soluble CP were reported as % of CP. Data evaluating the effects of month of submittal were analyzed using Proc Mixed in SAS with month as a fixed effect and laboratory as a random effect. Regressions to determine linear relationships between IVStarchD and ammonia-N, soluble CP, pH and DM content were performed using Proc Reg in SAS. Statistical significance and trends were declared at $P \leq 0.05$ and $P > 0.05$ to $P < 0.10$, respectively. IVStarchD increased from October to September of the following year, with October/November values 6%-units lower than May through September values. Similar results were observed for ammonia-N and soluble CP with an increase from 3.5% or 30% in October to 6.6% or 48% in August, respectively. The pH of HMC decreased from 4.6 in October to 4.3 in August of the following year. Ammonia-N was positively related to soluble CP ($R^2 = 0.92$) and StarchD ($R^2 = 0.53$). The DM content of HMC was negatively related ($R^2 = 0.58$) to IVStarchD with a decrease of 0.4%-units in IVStarchD per 1%-unit increase in DM. Combined, ammonia-N and DM provided good predictions of IVStarchD (Adj. $R^2 = 0.66$). The pH of HMC was negatively related to ammonia-N ($R^2 = 0.61$), soluble CP ($R^2 = 0.56$) and IVStarchD ($R^2 = 0.43$). Increasing ammonia-N, soluble CP and IVStarchD values suggest that HMC may need up to 8 mo to achieve maximum starch digestibility. Furthermore, ammonia-N and DM content are good indicators of starch digestibility in high moisture corn.

Key Words: high moisture corn, ammonia, starch digestibility

71 Using a systems model approach to assess the potential effect of changes in gene expression in adipose tissue of dairy cattle on production and reproductive efficiency. S. Shields and J. McNamara*, *Washington State University, Pullman.*

Variation in efficiency is a function of genetic, physiological and nutritional control in several organs and systems, including adipose tissue. To identify key physiological control points of metabolic flux and reproductive functions in dairy cattle, an existing metabolic model was used and expanded to include reproductive cycling, follicular growth, and steroid clearance. Our objective was to relate transcription of mRNA in adipose and liver which control metabolism, and potentially, reproductive processes and efficiency. The model describes substrate sensitivity

and maximum velocity for lipogenesis, esterification and lipolysis in adipose and gluconeogenesis and protein synthesis in the liver. Data from late gestation through 56 DIM on nutrient intake, milk output, adipose lipid, visceral and body protein and lipid, adipose metabolism and gene transcription in adipose and liver were collected. Genes coding for lipogenic pathways, as well as rates of lipogenesis decreased, but rates of lipolysis increased without increased mRNA abundance. In the liver, several genes of glucose, fatty acid and amino acid metabolism increased. In the simulation study, we altered the Vmax and Ks for lipogenesis, lipolysis, gluconeogenesis and protein synthesis, and milk production and intake were allowed to vary in response. Milk production ranged from 38.3 to 38.9 kg/d, body fat change from −0.07 to 0.4 kg/d, maintenance energy 22.0 to 25.4 Mcal/d and efficiency of milk energy as a percent of ME from 44.3 to 49% (at 56 DIM). Changing rates of lipogenesis, lipolysis, gluconeogenesis and protein synthesis did not affect milk production or feed intake, but altered milk fat percentage and maintenance costs and varied postpartum interval to first ovulation approximately 3 d. Increases in metabolic rate increased rates of estrogen and progesterone degradation. This model may be used to help interpret genomic and transcriptomic data to pinpoint the most effective ways to select and manage for changes in productive and reproductive efficiency.

Key Words: efficiency, systems model, adipose tissue

72 Effects of feeding millet silage cultivars on performance of lactating dairy cows. T. Brunette*[1], B. Baurhoo[2], and A. Mustafa[1], *[1]McGill University, Ste-Anne-De-Bellevue, QC, Canada, [2]Belisle Solution Nutrition, St-Mathias, QC, Canada.*

Fifteen lactating Holstein cows were used in a replicated 3x3 Latin square experiment to determine the effects of feeding regular and high water soluble carbohydrate (WSC) millet silages on the performance of dairy cows. Dietary treatments (68:32 forage:concentrate ratio) were a corn silage diet (control, CS), a regular millet silage diet (RM), and a high WSC millet silage diet (SM). Experimental silages constituted 37% of each diet DM. Three ruminal-fistulated cows were used to determine the effect of dietary treatments on ruminal fermentation and total-tract nutrient utilization. Relative to corn silage, regular and high WSC millet silages contained 37% more CP, 66% more NDF, and 67% more ADL. Cows fed CS consumed more ($P < 0.05$) DM (24.4 kg/d) and starch (5.7 kg/d), and less ($P < 0.05$) NDF (7.9 kg/d) than cows fed RM or SM. Millet silage type had no effect on DM (22.8 kg/d), starch (3.7 kg/d) and NDF (8.7 kg/d) intakes. Feeding RM relative to CS reduced ($P < 0.05$) milk yield (32.7 vs. 35.2 kg/d), ECM (35.8 vs. 38.0 kg/d) and SCM (32.7 vs. 35.3 kg/d). However, cows fed SM had similar milk yield, ECM, and SCM relative to cows fed CS or RM. Milk efficiency was not affected by dietary treatments. Milk protein concentration was greatest for cows fed CS, intermediate for cows fed SM, and lowest for cows fed RM ($P < 0.05$). Milk concentration of SNF was reduced ($P < 0.05$) while MUN was greater ($P < 0.05$) for cows fed RM than for those fed CS. However, millet silage type had no effect on SNF and MUN concentrations. Furthermore, concentration of milk fat, lactose and TS were not affected by silage type. Ruminal pH was greatest for cows fed SM, intermediate for cows fed RM, and lowest for cows fed CS ($P < 0.05$), while ruminal NH_3-N was lower ($P < 0.05$) for cows fed CS than for those fed RM or SM. Total-tract digestibility of DM (67.9%), NDF (53.9%), CP (63.3%) and GE (67.9%) were not influenced by dietary treatments. It was concluded that cows fed CS performed better than those fed RM or SM likely due to the higher starch and lower NDF intakes. However, no major differences were noted between the 2 millet silages.

Key Words: millet silage, milk production, ruminal fermentation

73 Variability in the concentrations of free and esterified fatty acids in corn silage and byproduct feeds. C. M. Klein[1], J. C. Ploetz[1], T. C. Jenkins[2], and A. L. Lock*[1], *[1]Michigan State University, East Lansing, [2]Clemson University, Clemson, SC.*

This study examined the concentration of fatty acids (FA) as either free FA (FFA) or esterified FA from corn silages and byproduct feeds. Total lipids were extracted and lipid classes separated with solid-phase extraction cartridges. Esterified fractions were combined following separation, which resulted in a single esterified FA fraction and a FFA fraction. For corn silage samples (n = 75), DM (%), NDF, starch, and CP (all % DM) ranged from 35.3 ± 4.2, 36.5 ± 3.9, 36.4 ± 3.9, and 7.1 ± 0.7 (mean ± SD), respectively. Total FA ranged from 1.6 to 3.6% DM (mean 2.5 ± 0.3% DM). Esterified FA ranged from 1.2 to 2.8% DM (mean 2.0 ± 0.3% DM) and FFA ranged from 0.3 to 0.8% DM (mean 0.5 ± 0.1% DM). Esterified FA accounted for 69 to 86% (mean 80 ± 4%) and FFA 13 to 31% (mean 20 ± 4%) of total FA. Esterified FA (% DM) were positively correlated with starch concentration (r = 0.35, $P = 0.001$), whereas FFA (% DM) were positively correlated with lactic acid concentration and corn silage processing score (CSPS), and negatively correlated with in vitro starch digestibility. Multiple regression analysis identified 4 factors (CSPS, lactic acid, starch concentration, and in vitro starch digestibility; all $P < 0.05$) that explained 41% of the variation in the proportion of total FA as FFA. Concentration of esterified FA in distillers grains (n = 27), canola meal (n = 21), and cottonseed (n = 12) was 11.0 ± 1.7, 6.1 ± 5.1, and 18.4 ± 3.5% DM, respectively. Concentration of FFA was 1.2 ± 0.2, 0.9 ± 1.7, and 1.2 ± 1.7% DM, respectively. Ether extract (% DM) values for byproducts agreed with esterified FA plus FFA concentrations ($R^2 = 0.95$). Furthermore, in a dual-flow continuous fermenter study, soy FFA increased the accumulation of total *trans* 18:1 and *trans*-10 18:1 by 28 and 48% (both $P < 0.05$), respectively, when compared with soy oil (both at 1.5% DM). In conclusion, there is considerable variation in total FA concentration of corn silages and byproduct feeds and a variable proportion of these FA are present as FFA. Results suggest that FFA may negatively affect rumen biohydrogenation to a greater extent when compared with esterified FA.

Key Words: byproduct feed, corn silage, dietary fatty acid

76 Effects of milking frequency on integrin signaling in mammary glands of dairy cows. R. Murney*[1], K. Stelwagen[2], T. T. Wheeler[1], J. K. Margerison[3], and K. Singh[1], *[1]AgReserach Limited, Ruakura Research Centre, Hamilton, New Zealand, [2]SciLactis Limited, Waikato Innovation Park, Hamilton, New Zealand, [3]Massey University, Palmerston North, New Zealand.*

In dairy cows, short-term changes of milking frequency (MF) in early lactation can have an immediate and a long-term effect on milk yield. The effect is controlled locally within mammary glands and is thought to be a function of secretory mammary epithelial cell (MEC) number and/or activity. Attachment to the extracellular matrix (ECM) via β_1-integrin is required for both MEC survival and function. Focal adhesion kinase (FAK) mediates the intracellular signaling of integrins. In this study we investigated if ECM/β_1-integrin signaling in MEC is affected by changes in MF. Ten multiparous cows (5 ± 2 DIM) were unilaterally milked for 14 d; udder halves were either milked once a day (1×) or 4 times a day (4×). On d 14, biopsy samples were collected from both rear quarters and mRNA and protein were analyzed by real time RT-PCR and Western blot, respectively. The cows were then milked twice daily (2×) for the remainder of lactation. By the end of the treatment period the 4×-milked udder halves were producing 2-fold ($P < 0.001$) more milk than the 1×-milked udder halves and continued to produce 15% ($P < 0.01$) more milk than 1×-udder halves once returned to 2× milking. Relative secretory activity was estimated by determining mRNA levels of the major milk proteins, αS_1-casein, β-casein and α-lactalbumin, which were increased in the 4×-samples, 8-, 9-, and 12-fold, respectively ($P < 0.01$). Signal transducer and activator of transcription 5 (STAT5) phosphorylation was dramatically ($P < 0.001$) higher in the 4×-tissues, while protein levels for β_1-integrin and FAK were 5- ($P < 0.001$) and 40-fold ($P < 0.001$) higher in 4×-tissues, respectively. Furthermore, STAT5-phosphorylation correlated strongly with the protein abundance of both β_1-integrin ($r = 0.78$, $P < 0.001$) and FAK ($r = 0.86$, $P < 0.001$). The data indicate that β_1-integrin and FAK proteins may be involved in the regulation of milk production in differentially milked bovine mammary glands.

Key Words: milking frequency, cell signaling, β_1-integrin

77 Prolactin-inhibitor cabergoline enhanced the mammary remodeling during drying-off in dairy cows. M. Boutinaud*[1], N. Isaka[4], A. Deflandre[4], E. Gandemer[1,2], P.-G. Marnet[2,3], F. Dessauge[1,2], and V. Lollivier[2,3], *[1]INRA, UMR 1348 PEGASE, Saint Gilles, France, [2]AGROCAMPUS UMR 1348 PEGASE, Rennes, France, [3]Université Européenne de Bretagne, Rennes, France, [4]CEVA Santé Animale, Libourne, France.*

In ruminants, the early phase of drying-off is a period of intense mammary gland remodeling that has great consequences on the next lactation and that is marked by the cessation of prolactin (PRL) release. To assess the effect of PRL inhibition on mammary remodeling, 14 Holstein dairy cows were injected with a single i.m administration of 5.6 mg cabergoline (n = 7) or placebo (n = 7) just after the last milking before drying-off. Mammary biopsy samples were collected one week before drying-off (D-6), at D1 and D8 and used for zymography analyses. Mammary secretion samples (290 mL) were collected using a teat-cannula once during lactation (D-6) and at D1, D2, D3, D4, D8 and D14 after the drying-off. The mammary secretion samples were used for SCC, Na^+, K^+ and BSA determinations and zymography analyses. Mammary epithelial cells (MEC) were purified from mammary secretions after centrifugation and immunocytochemical binding. Blood samples were collected before and after the morning mammary secretion collection for PRL determination. Cabergoline treatment decreased the blood PRL level from D1 to D8 compared with control treatment ($P < 0.001$). SCC was 2.4 fold higher in cabergoline treated cows than in control cows ($P < 0.01$). In addition, cabergoline induced an increase in MEC count ($P = 0.04$) with a reduction of their viability on D3 and D4. No significant cabergoline effect was observed on Na^+ and BSA except a tendency for a higher K^+ content in the mammary secretions of cabergoline treated cows ($P = 0.06$ at D1), suggesting a small increase in the tight junction opening in the mammary gland. In mammary tissue, cabergoline increased the activity of MMP-2 (matrix metalloproteinases) after drying-off (1.4 fold, $P \leq 0.01$). In mammary secretion, cabergoline increased the activity of MMP9 (1.7 fold, $P < 0.05$). Cabergoline treatment was efficient to enhance the extracellular matrix mammary remodeling, the MEC exfoliation and the migration of somatic cells responsible for the mammary gland remodeling. The mammary gland remodeling induced by the lower plasmatic PRL concentration may only be in part explained by a higher tight junction opening.

Key Words: cow, drying-off, prolactin

78 Efficacy of cabergoline to reduce udder pressure and milk leakage after dry-off in dairy cows. S. Bertulat*[1], N. Isaka[2], A. Deflandre[2], A. Lopez[2], T. Hetreau[3], and W. Heuwieser[1], *[1]Clinic for Animal Reproduction, Freie Universität Berlin, Berlin, Germany, [2]CEVA Santé Animale, Libourne, France, [3]Centre d'élevage Lucien Biset, Poisy, France.*

A recent study demonstrated a relationship between high milk yield, high udder pressures (PRE) and elevated stress levels after dry-off and revealed an animal welfare concern regarding current dry-off strategies. Cabergoline inhibits prolactin release and is approved to treat false pregnancies in bitches. The objective of this study was to evaluate the efficacy of cabergoline to reduce PRE and milk leakage after dry-off. Two hundred sixty-three high-yielding (≥16 kg milk/d) dairy cows were enrolled 7 d before (d −7) and followed up until 14 d (d 14) after dry-off. Cows were milked twice daily until dry-off (d 0) and treated with a single i.m. injection of 5.6 mg cabergoline (CAB; n = 130) or placebo (PLA; n = 133) after last milking (controlled, randomized and blinded study design). PRE was measured 4 d before (i.e., before and after milking) and 1, 2, 3, 7, 10 and 14 d after dry-off using a hand-held dynamometer (Penefel DFT 14; Bertulat et al., 2012). Udder firmness was assessed manually using a 4-point firmness score (0 = flabby, 3 = very hard; Gleeson et al., 2007). Milk leakage was recorded on d −4, d 1, d 2, d 3 and d 7, respectively. Data were analyzed using Chi^2 or Fisher exact test to compare qualitative variables and two-sample *t*-test for quantitative variables. After dry-off PRE increased in both groups, but was lower ($P < 0.05$) on d 1 and d 2 in CAB (d 1 = 0.79 ± 0.35 kg; d 2 = 0.93 ± 0.45 kg) than PLA cows (d 1 = 1.16 ± 0.6 kg; d 2 = 1.07 ± 0.49 kg). PRE on d 1 exceeded values measured on d -−4 before milking in 53.2% of PLA, but only 26.2% of CAB cows ($P < 0.001$). Moreover, cows in PLA group were more likely ($P < 0.05$) to have an udder firmness score of 3 than CAB cows on d 1 (27.9% vs. 67.2%), d 2 (41.5% vs. 54.9%) and d 3 (27.1% vs. 42.1%), respectively. The percentage of cows with milk leakage during the 1st wk after dry-off was also lower in CAB (10.2%) compared to PLA (19.8%) cows (P = 0.03). Our data provide evidence that a single injection of cabergoline

reduced PRE and firmness after dry-off and decreased the prevalence of milk leakage. Further research is warranted to evaluate, if cabergoline is able to reduce stress and alleviate pain after dry-off.

Key Words: cabergoline, dry-off, udder pressure

79 The effects of continuous light on milk yield, milk composition, IGF-1 and prolactin in dairy cows. S. Ferneborg*[1], E. Ternman[1], A. A. K. Salama[2], G. Caja[2], and S. Agenäs[1], *[1]Department of Animal Nutrition and Management, Swedish University of Agricultural Sciences, Uppsala, Sweden, [2]Group of Ruminant Research (G2R), Universitat Autonoma de Barcelona, Bellaterra, Spain.*

Light improves the lactational performance (feed intake and milk yield) of dairy cows. When long (16h) and short (8h) photoperiods are compared the higher milk yield in the 16h photoperiod seems to be mediated by higher secretion of IGF-1 and prolactin (PRL). Continuous lighting, on the other hand, is not recommended since no positive effect is seen on milk yield. However, it is often used as an on-farm management tool to keep cow activity high in intensive production systems with automatic milking. In calves, decreased levels of PRL have been seen in 24h light compared with 16h light, but the effect of 24h light on IGF-1 is unknown. In this pilot study, the short-term effects of 2 different light treatments on milk yield, milk composition, IGF-1 and PRL secretion were examined. Five lactating Swedish Red dairy cows were daily subjected to 24–0 (continuous light) or 4–20 (light 0930 to 1330) light-dark treatments in a changeover design. Cows were adapted to the treatments for 60h before recording and sampling started. Milking was performed at 12h intervals, and milk samples were collected at each milking for milk composition analysis. Blood samples were taken through a permanent jugular cannula hourly over a 36h sampling period, frozen and analyzed for IGF-1 (IMMULITE immunoassay) and PRL (ELISA). Neither milk yield (26.8 ± 5.2 L/d) nor milk composition differed between treatments, but plasmatic IGF-1 concentrations were greater ($P < 0.05$) in the 4–20 vs. 24–0 cows (133 ± 2 vs. 124 ± 2 ng/mL). Moreover, IGF-1 levels were greater ($P < 0.05$) during the circadian night than during the circadian day in the 4–20 cows and tended to be greater ($P < 0.10$) in the 24–0 cows. The secretory pattern of PRL differed between treatments, with an increase in secretion 1 min after the start of milking for 4–20 vs. 24–0 cows (124 ± 13 vs. 78 ± 8 ng/mL; $P < 0.05$), while basal concentrations did not differ between treatments. In conclusion, short-term continuous light did not change basal PRL, but decreased IGF-1 levels in plasma without changing milk yield or milk composition. Further research will explore the effects of continuous light on milk production and welfare of dairy cows.

Key Words: photoperiod

80 Timing of first milking and colostrum feeding affect serotonin (5-HT) concentrations in cows and calves. J. J. Gross[2], J. Laporta[1], R. M. Bruckmaier[2], and L. L. Hernandez*[1], *[1]University of Wisconsin, Madison, [2]University of Bern, Bern, Switzerland.*

Hormonal signals differentially regulate the timing of parturition, as well lactogenesis and potentially colostrum formation in the mammary gland. Serotonin (5-HT) has been determined to be a homeostatic regulator of lactation. To this end, we performed an experiment in which we manipulated the timing of first milking to investigate the effects on 5-HT concentrations in the maternal and calf circulation, as well as colostrum composition. Twenty cows were randomly assigned to 2 groups: control (CON) milked for the first time 4 h post-calving, and a treatment (TRT) group that were milked for the first time approximately 1 d before calving, and were milked 4 h post-calving. Maternal blood samples were collected for 4 d pre-partum, 3 times daily, and one blood sample was taken 4 h after parturition. Calves were fed 2 L of colostrum from their respective dam that was collected at their first milking, either 1 d before parturition (TRT) or 4 h post-calving (CON) 4 h after birth. Calf blood samples were collected 4 h after birth (before colostrum feeding), 12 h after birth, and at 3 wk of age. Colostrum samples were collected from the entire udder. 5-HT was analyzed in serum and colostrum samples. Circulating 5-HT concentrations were significantly higher in CON cows when compared with TRT cows ($P < 0.0001$). Colostrum 5-HT concentrations were increased in TRT cows compared with the CON ($P = 0.0165$). Finally, calves born to TRT cows had increased circulating 5-HT concentrations compared with the CON on all dates evaluated, with the greatest increase being at 3 wk of age. These data suggest that 5-HT plays a role in regulating colostrum composition, and may be of importance to the calf. Further research should be conducted in an attempt to separate the roles of circulating 5-HT from that produced within the mammary gland.

Key Words: serotonin, lactation, colostrum

81 Essential amino acid deficiencies and imbalances regulate milk protein synthesis through mTOR signaling in lactating bovine mammary glands. J. Doelman*[1], R. V. Curtis[2], M. Carson[1], J. J. M. Kim[2], J. P. Cant[2], and J. A. Metcalf[1], *[1]Nutreco Canada Agresearch, Guelph, ON, Canada, [2]Department of Animal and Poultry Science, University of Guelph, Guelph, ON, Canada.*

Part of the mechanism by which essential amino acids (EAA) stimulate milk protein synthesis may be through effects on mammalian target of rapamycin (mTOR) signaling in the mammary gland. To determine the effect of imbalance and deficiencies of EAA on mammary mTOR signaling, 6 early-lactation, rumen-fistulated dairy cows (102 ± 4 DIM) were abomasally infused for 5 d with either saline, EAA, EAA less methionine, EAA less phenylalanine, EAA less histidine, or EAA less tryptophan in a 6 × 6 Latin square design. The EAA infusion rates were based on the EAA content of 1000 g/d casein. Cows were fed a TMR with a forage to concentrate ratio of 65:35 to provide 100% of the NE_L requirement and 65% of the metabolizable protein requirement. Mammary tissue was collected by biopsy on the final day of each experimental period for quantification of signaling protein activity. Milk protein yield increased 22% during the EAA infusion, compared with saline ($P < 0.001$), while methionine, phenylalanine and histidine deficiencies decreased milk yield by 15.7, 23.6, and 22.6%, respectively, compared with EAA ($P < 0.001$). Additionally, milk protein concentration was 0.36, 0.37 and 0.25 percentage points lower during methionine, phenylalanine and histidine deficiencies, respectively ($P < 0.001$). Immunoblot analysis showed increased phosphorylation of ribosomal protein S6 kinase (S6K1) in response to methionine deficiency ($P < 0.04$), while the phosphorylation state of eukaryotic initiation factor 2B (eIF2B) was decreased in all treatments relative to saline ($P < 0.04$). These results indicate that milk protein synthesis is sensitive to the supply of methionine, histidine, and phenylalanine, specifically. S6K1 and eIF2B appear to be sensitive to the supply of total EAA, yet their activation during EAA deficiency did not stimulate milk protein yields.

Key Words: milk protein, essential AA, mTOR signaling

82 Effects of arginine concentration on the in vitro expression of casein and mTOR pathway related genes in mammary epithelial cells from dairy cattle. M. Z. Wang*[1,2], B. L. Xu[1], H. R. Wang[1], D. P. Bu[2], J. Q. Wang[2], and J. J. Loor[3], *[1]College of Animal Science and*

Technology, Yangzhou University, Yangzhou, Jiangsu, China, [2]State Key Laboratory of Animal Nutrition, Institute of Animal Science, Chinese Academy of Agricultural Sciences, Beijing, China, [3]Department of Animal Sciences and Division of Nutritional Sciences, University of Illinois, Urbana.

Arginine is a conditionally-essential amino acid that is taken up by bovine mammary gland in excess of its output in milk. In this study we evaluated the effects of arginine level on the expression of casein and signaling pathway-related genes in mammary epithelial cells. The treatments (applied for 24 h) were designed to be devoid of Arg 0X (control; 0.00 mg/L), resemble the profile of Arg in casein (Arg 1X; 278.00 mg/L), be deficient, Arg 0.25X (69.50 mg/L) and Arg 0.5X (139.00 mg/L), or be in excess of the amount in casein, Arg 2X (556.00 mg/L), Arg 4X (1,112 mg/L), and Arg 8X (2,224 mg/L). The expression of CSN1S, CSN3 and mTOR in the experimental groups was higher than those of the control group ($P < 0.05$). Except for Arg 0.25X and Arg 8X ($P > 0.05$), the expression of CSN1S2, CSN2 and JAK2 in other experimental groups was higher ($P < 0.05$) than those in the control group. Except for Arg 8X ($P > 0.05$), the expression of STAT5 in the other experimental groups was higher than those of the control group ($P < 0.05$). It was also observed that, except for Arg 0.5X, S6K expression was higher in other experimental groups than the control group ($P < 0.05$). In contrast, except for Arg 0.25X, the other experimental groups resulted in lower 4EBP1 expression than the control group ($P < 0.05$). Among groups, the expression of CSN1S1, CSN1S2, CSN2, CSN3, JAK2, STAT5, mTOR and S6K gene was highest with Arg 2X ($P < 0.05$); the reverse was true for 4EBP1 gene, with the lowest expression in this group ($P < 0.05$). Taken together, arginine appears to play an important role in the transcriptional regulation of casein genes and mTOR related genes in bovine mammary epithelial cells.

Key Words: arginine, casein expression, mammary epithelial cell

83 Enhancing mammary involution during early stages of the dry period by infusing mammary serum amyloid A3. A. Domenech[1], S. Parés*[1], A. Bach[1,2], and A. Arís[1], *[1]Department of Ruminant Production, Institut de Recerca i Tecnologia Agroalimentàries (IRTA), Torre Marimon, Caldes de Montbui, Barcelona, Spain, [2]Institució Catalana de Recerca i Estudis Avançats (ICREA), Barcelona, Barcelona, Spain.*

The aim of this study was to evaluate the potential of recombinant mammary serum amyloid A3 (M-SAA3) in the improvement of the dry period in dairy cows by stimulating the immune system and epithelial regeneration. At dryoff, immediately after the last milking, the 4 quarters of 9 cows were treated as follows: 1 quarter infused after drying with 1 mg of M-SAA3 (MS3), another quarter infused with 80 ng of LPS (LP) to reproduce the possible effect of LPS traces in purified recombinant fraction, and the other 2 contralateral quarters were infused with saline solution as a negative control (CTRL). Mammary secretions (MS) were obtained just before treatment and at 0800 h during the 3 consecutive days. MS was analyzed for somatic cell count (SCC), fat, protein, and the activity of involution promoters such as metalloproteinases (MMP). Also, in vitro experiments were performed to test the effect of M-SAA3 on primary mammary cells challenged with *S. aureus* and on bovine dendritic cells. Cytokine concentrations were evaluated by qPCR. Data were analyzed using a mixed-effects linear model in the in vivo experiment and by ANOVA in the in vitro study. The activity of MMP-9 during the 3 d of the in vivo experiment was greater ($P < 0.0001$) in MS3 than in the other treatments, and there was a numerical increase in SCC at d 2 compared with LP and CTRL. MS fat and protein were increased ($P < 0.01$ and $P < 0.1$, respectively) in the MS3 treatment compared with LP and CTRL. Results for qPCR of the in vitro experiment showed activation and maturation of the dendritic cells and an increase ($P < 0.05$) in the expression of IL-8 ($6 \times 10^{-3} \pm 0.3 \times 10^{-3}$ vs. $3.9 \times 10^{-4} \pm 3.8 \times 10^{-4}$) in primary mammary cells. Moreover, M-SAA3 decreased by 25% the infection of mammary cultures with *S. aureus*. In conclusion the M-SAA3 shows a clear potential to improve the early stages of the dry period, independently of LPS traces, not only stimulating the mammary gland involution and immune system but also reducing bacterial infection.

Key Words: dry period, immune, infection

84 Lack of circulating serotonin (5-HT) in TPH1-deficient mice down-regulates serum calcium and mammary gland gene expression of calcium transporters. J. Laporta*, K. E. Merriman, S. Weaver, C. Cronick, T. L. Peters, and L. L. Hernandez, *University of Wisconsin, Madison.*

Serotonin (5-HT) is a homeostatic regulator of lactation and is known to play a role in calcium homeostasis. 5-HT is synthesized in a 2-step reaction from L-tryptophan (L-TRP), with the rate-limiting step catalyzed by tryptophan hydroxylase (TPH1) to form 5-hydroxytryptophan (5-HTP), which is then further converted to 5-HT by aromatic amino acid decarboxylase. We recently demonstrated increasing circulating 5-HT up-regulates mammary gland expression of calcium transporters in rats. To demonstrate that 5-HT is responsible for regulating calcium transport in the mammary gland, we performed an experiment in lactating mice that are genetically deficient for TPH1 (−/−, n = 7) and compared them to wild-type mice (+/+, n = 7). On d 1 and 10 of lactation blood samples were collected to measure serum 5-HT and calcium concentrations. All animals were euthanized on d10 of lactation and mammary gland tissue was harvested. Total RNA was isolated from mammary gland tissue to measure the mRNA expression of TPH1, 5-HT transporter (SERT) and the following calcium transporters: plasma membrane Ca^{2+} ATPases 1 and 2 (PMCA1, 2), sodium-Ca^{2+} exchanger 1 (NCX1), secretory Ca^{2+} ATPase 1 and 2 (SPCA1, 2), and sarco(endo)plasmic reticulum Ca^{2+} ATPase 2 (SERCA2), by real-time RT-PCR. Total protein was also isolated from mammary gland tissue to measure 5-HT content. Serum 5-HT concentration were decreased in the −/− dams compared with +/+ dams on both d1 and 10 of lactation ($P < 0.036$) as was mammary gland 5-HT content on d10 of lactation ($P = 0.0039$). Serum calcium was decreased on both d1 and 10 of lactation in −/− dams compared with +/+ dams ($P < 0.023$). Mammary gland TPH1 and SERT mRNA expression was decreased in −/− dams compared with +/+ dams ($P < 0.011$). Mammary gland mRNA expression of NCX1, SERCA, SPCA1 and 2, PMCA1 and 2, were decreased in −/− dams compared with +/+ dams ($P < 0.038$). These results demonstrate that 5-HT is critical for regulation of circulating calcium concentrations and calcium transport within the mammary gland during lactation.

Key Words: serotonin, calcium, lactation

85 Importance of progesterone and prolactin profiles, and of parturition on the composition of colostrum obtained before and after parturition. J. J. Gross[1], E. C. Kessler[1], V. Bjerre-Harpoth[2], and R. M. Bruckmaier*[1], *[1]Veterinary Physiology, Vetsuisse Faculty University of Bern, Bern, Switzerland, [2]Department of Animal Science, Aarhus University, Foulum, Denmark.*

Progesterone (P4) and prolactin (PRL) are key regulators that mediate the initiation of both parturition and onset of lactation including colostrum formation. The hypothesis was tested that colostrum formation is regulated by changes of P4 and PRL but independent of the actual time

of parturition. To achieve this goal, 23 multiparous cows were randomly assigned to 2 groups: control (PP, postpartum only, n = 11) milked for the first time 4 h post-calving, and a treatment (AP, ante- and postpartum, n = 12) group that was already milked approximately 1 d before calving and again at 4 h after parturition. Colostrum yield before and after parturition was recorded and proportional samples were analyzed for total IgG, fat, protein and lactose. Blood samples for the analyses of P4 and PRL were collected at 8 h intervals for 4 d pre-partum until calving, and another sample was taken at 4 h after parturition. Total IgG mass increased with increasing time span between the P4 drop and first milking ($P < 0.05$). Total IgG mass and milk yield tended to increase with decreasing time span between PRL peak and first milking ($P < 0.1$), and also with increasing time between parturition and first milking ($P < 0.1$). Protein concentration in colostrum decreased with increasing interval between drop of P4 and PRL peak ($P < 0.05$). Milk yield, fat, protein and lactose concentration did not differ between PP and AP at the first milking. However, total IgG mass was higher in AP than in PP ($P < 0.05$) which is obviously due to the low milk yield in AP. In AP cows, milk protein decreased between pre- and postpartum milking, while lactose concentration increased ($P < 0.05$). In colostrum obtained at 4 h postpartum, milk fat was increased in AP compared with PP, while protein, total IgG concentration and mass were decreased ($P < 0.05$). Milk yield and lactose were not different between AP and PP at 4 h postpartum. These data suggest that synthesis and secretion of constituents into first colostrum do not only depend on changes in PRL and P4.

Key Words: colostrum, composition, lactogenesis

86 Feeding entrainment of the mammary circadian rhythm in FVB mice. L. Ma*, Y. Ying, A. Clarke, P. Bartell, and K. J. Harvatine, *Penn State University, University Park.*

Food entrainment of adipose and liver circadian rhythms is well established, but little is known about the regulation of the circadian rhythm of the mammary gland. Food entrainment of circadian rhythm of milk fat synthesis was investigated in wild-type FVB mice. Treatments were ad libitum feed intake and 7 h feed restriction during the day (DR; 1100 to 1800 h) or night (NR; 2300 to 0600 h) from d 7 to 14 of lactation. Dam intake and body weight and litter gain were recorded 2×/d. On d 14 of lactation, dams were euthanized at 0600, 1200, 1800, or 2400 h (n = 6 per treatment per time point) and dam mammary tissue and pup stomach milk clots were collected. Data were analyzed using ANOVA with treatment, time, and the interaction of treatment and time as fixed effects and second by fitting to a cosine function with a 24 h period for rhythm analysis. In control mice, no overt rhythm was observed for feed intake, milk fat synthesis or mammary gene expression, which is expected as FVB mice commonly do not express a robust circadian rhythm. Dams from DR treatment consumed more than 70% of daily intake during the dark phase, while NR mice consumed more than 76% of daily intake during the light phase (treatment by time, $P < 0.01$). Litters from DR and NR gained the most weight during the light (65%) and dark (72%) phase, respectively (treatment by time $P < 0.01$). Day restriction entrained a rhythm in de novo milk FA synthesis and the peak (amplitude 1.57 and 4.52% FA for DR and NR, respectively) was advanced about 10 h for NR ($P < 0.01$). Inverted rhythms (shifted by 11.3 h) were also observed for preformed FA between DR and NR treatments ($P < 0.01$). The mammary expression of core clock genes (BMAL1, CRY1 & 2, and PER1 & 2), lipogenic regulators (SREBP1c and Spot 14), and milk fat synthetic enzymes (FASN and SCD1) showed a rhythm in the mice with restricted feeding and the phase was shifted by 5.5 to 12.3 h ($P < 0.01$). In conclusion, timing of feed intake entrains the circadian rhythm in the mammary gland and milk fat synthesis by entraining the expression of mammary clock genes as well as regulators and enzymes involved in milk fat synthesis.

Key Words: FVB mice, feed restriction, circadian rhythm

87 Proteomic profiling of bovine mammary gland response to milk removal or increased milking frequency indicates roles for prolactin and leptin signaling. M. G. H. Stevens*[1], E. H. Wall[2], P. A. Bentley[3], A. Ruiz-Sanchez[3], and T. B. McFadden[1,3], *[1]University of Missouri, Columbia, [2]University of Vermont, Burlington, [3]University of Alberta, Edmonton, AB, Canada.*

Milking dairy cattle 4-times (4X) instead of twice-daily (2X) during early lactation increases milk yield and persistency. Our objective was to identify physiological processes involved in the mammary response to milk removal or increased milking frequency. Six cows were assigned at parturition to unilateral frequent milking (2X milking of left udder half, 4X milking of right udder half) and biopsies were taken from both udder halves at 5 DIM. In the first study (n = 2) the effect of milk removal was investigated by taking biopsies immediately after milking only the 4X udder half. In the second study (n = 4) biopsies were obtained at 2.5h after milking both udder halves to quantify the sustained effect of 4X. Proteins were quantified by iTRAQ and proteomes of paired udder halves were compared. Proteins differentially expressed by ≥1.5 fold were used for Ingenuity Pathway Analysis (IPA). The response to milk removal was characterized by differential expression of 479 peptides, mapped to 38 proteins; 35 were eligible for IPA. The top ranked network comprised 17 proteins (Score = 42) and associated with post-translational modification, carbohydrate and lipid metabolism. A weak activation of prolactin signaling is predicted as an upstream regulator and associated with 6 of the differentially expressed proteins (activation score: 0.686; $P < 0.001$). The sustained response to 4X-milking was associated with differential expression of 1302 peptides, mapping to 97 proteins; 67 were used for IPA. The top network was associated with cellular assembly and organization, molecular transport and protein trafficking (Score = 46). Activation of leptin signaling is predicted as an upstream regulator and associated with 19 differentially expressed proteins (activation score: 2.200; $P = 0.003$). Data suggest that the response to milk removal involves proteins associated with mammary metabolism, and may be driven by prolactin signaling. The sustained response to 4X appears to modulate proteins involved in cellular organization and function, and may be regulated by leptin.

Key Words: proteomics, bovine mammary gland, lactation biology

Meat Science and Muscle Biology: Effects of Nutrients and Supplements on Animal Growth Performance and Meat Quality

88 Effect of dietary vitamin D_3 supplementation on meat quality of naked neck chickens. M. Mabelebele*[1,2], J. W. Ngambi[2], D. Norris[2], and O. J. Alabi[2], *[1]University of New England, New South Wales, Armidale, Australia, [2]University of Limpopo, Polokwane, South Africa,*

Consumers' interest in indigenous chicken meat is increasing. An experiment was conducted to determine the effect of vitamin D_3 supplementation on meat quality of indigenous male naked neck chickens. Two hundred 13-wk-old male naked neck chickens with a mean live weight of 1200 ± 3 g were supplemented with vitamin D_3 levels of 0, 2000, 4000, 6000 and 8000 IU per kg dry matter (DM) of feed for a period of 7 d before slaughter. A 2 (postmortem agings of 0 or 24 h) × 5 (vitamin D_3 levels) factorial arrangement in a complete randomized design was used for shear force and sensory evaluation of cooked chicken meat. Twenty chickens were used in each treatment. The meat samples were cooked and prepared according to an oven-broiling method using direct radiant heat. A quadratic equation was used to determine vitamin D_3 supplementation levels for optimum shear force value and sensory attributes. Vitamin D_3 supplementation and Vitamin D_3 and postmortem aging interaction did not improve ($P > 0.05$) shear force values of unaged or aged cooked naked neck chicken meat. Shear force values of unaged and aged cooked meat were optimized at different levels of 2512 ($r^2 = 0.669$) and 4249 ($r^2 = 0.873$) IU of vitamin D_3 per kg DM feed, respectively. Vitamin D_3 supplementation and its interaction had no effect ($P > 0.05$) on unaged meat tenderness, juiciness and flavor. However, vitamin D_3 supplementation improved ($P < 0.05$) aged meat tenderness and flavor. Postmortem aging did not improve ($P < 0.05$) sensory attributes of naked neck chicken meat. Tenderness, juiciness and flavor of aged naked neck chicken meat were optimized at supplementation level of 6830 ($r^2 = 0.839$), 6894 ($r^2 = 0.683$) and 9795 ($r^2 = 0.657$) IU of vitamin D_3 per kg DM. It was concluded that vitamin D_3 supplementation improved tenderness and flavor of aged naked neck chicken meat, however, shear force was not improved.

Key Words: shear force, postmortem aging, sensory attributes

89 Effects of supplemental lysine and methionine with zilpaterol hydrochloride on feedlot performance, carcass characteristics on finishing feedlot cattle. A. D. Hosford*[1], W. Rounds[2], J. E. Hergenreder[1], M. J. Anderson[2], M. A. Jennings[1], T. L. Harris[1], S. N. Aragon[1], and B. J. Johnson[1], *[1]Department of Animal and Food Science, Texas Tech University, Lubbock, [2]Kemin Industries Inc., North America, Des Moines, IA.*

Feeding zilpaterol hydrochloride (ZH) with encapsulated amino acids (AA) was evaluated in a feeding trial. Crossbred steers (n = 180; initial BW = 366 kg) were blocked by weight and then randomly assigned to treatments (45 pens; 9 pens/treatment). Treatment groups consisted of: no ZH and no AA (Cont−), ZH and no AA (Cont+), ZH and an encapsulated lysine supplement (Lys), ZH and an encapsulated methionine supplement (Met), and ZH and encapsulated lysine and methionine Lys+Met, (LysiPEARL, MetiPEARL). Zilpaterol hydrochloride (8.3 mg/kg DM basis) was fed for the last 20 d with a 3 d withdrawal. Lysine and Met were top dressed daily for the 134-d feeding trial to provide 12 and 4 $g \cdot hd^{-1} \cdot d^{-1}$, respectively, to the small intestine. Carcass characteristics were collected following harvest. Cattle treated with Met and Lys+Met had increased final BW of 15 and 14 kg ($P = 0.02$ and 0.03) as compared with Cont−. Average daily gain increased ($P < 0.05$) for Met and Lys+Met fed cattle as compared with Cont− and Cont+ for the entire 134 d feeding period. The supplementation of Lys, Met and Lys+Met improved G:F ($P < 0.05$) as compared with Cont− during the ZH feeding period (d 111 to 134) as well as the entire feeding period ($P < 0.05$). Zilpaterol hydrochloride increased carcass ADG ($P < 0.05$) when compared with non-ZH fed cattle. Lysine + methionine treated cattle tended to have increased carcass ADG ($P = 0.09$) as compared with Cont+. Methionine and Lys+Met treatments had heavier hot carcass weight (HCW, $P < 0.05$) as compared with Cont−. Yield grade was decreased ($P < 0.05$) for Cont+ cattle compared with Lys, Lys+Met, and Cont− treated cattle. There was a higher proportion of yield grade one carcasses ($P < 0.05$) with Cont+ treatment compared with any AA treatment. Supplementation of Met in conjunction with ZH feeding increased ADG and HCW. These findings indicated that cattle fed ZH may require additional AA absorbed from the small intestine to maximize performance, and supplementing encapsulated AA may actually increase the ZH response as compared with ZH alone.

Key Words: beef cattle, lysine/methionine, zilpaterol hydrochloride

90 Effects of supplemental lysine and methionine with zilpaterol hydrochloride administration on finishing feedlot cattle tenderness. A. D. Hosford*[1], W. Rounds[2], J. E. Hergenreder[1], M. J. Anderson[2], M. A. Jennings[1], T. L. Harris[1], S. N. Aragon[1], and B. J. Johnson[1], *[1]Department of Animal and Food Science, Texas Tech University, Lubbock, [2]Kemin Industries Inc., North America, Des Moines, IA.*

Steaks from beef steers that were fed encapsulated amino acids and zilpaterol hydrochloride were tested for tenderness using the Warner Bratzler shear force (WBSF) method. Crossbred steers (n = 180; initial BW = 366 kg) were blocked by weight and then randomly assigned to treatments (45 pens; 9 pens/treatment). Treatment groups consisted of: no ZH and no AA (Cont−), ZH and no AA (Cont+), ZH and an encapsulated lysine supplement (Lys), ZH and an encapsulated methionine supplement (Met), and ZH and encapsulated lysine and methionine Lys+Met, (LysiPEARL, MetiPEARL). Zilpaterol hydrochloride (8.3 mg/kg DM basis) was fed for the last 20 d with a 3 d withdrawal. Lysine and Met were top dressed daily for the 134 d feeding trial to provide 12 and 4 $g \cdot hd^{-1} \cdot d^{-1}$, respectively, to the small intestine. Cattle were slaughtered at a commercial facility and longissimus muscle samples were collected following fabrication. Four steaks (2.54 cm thick) from each strip loin were aged for 7, 14, 21 or 28 d, and WBSF was determined as an indicator of tenderness. Tenderness was reduced ($P < 0.05$) with ZH regardless of AA supplementation. Lysine, Met, Lys+Met, and Cont+ had less tender steaks ($P < 0.05$) throughout all aging groups as compared with Cont−. Steaks from Lys treated cattle were less tender ($P < 0.05$) than Cont+ during the 7 and 14 d aging periods. After 21 d of aging all steaks from AA's fed animal had similar WBS ($P > 0.05$) as Cont+. Control− also had the highest percentage of tender steaks after 21 d of aging ($P < 0.05$). Supplementation of encapsulated AA's in conjunction with ZH feeding resulted in decreased tenderness even after aging for 28 d when compared with steaks from Cont- cattle. Supplementation of encapsulated lysine and ZH resulted in less tender steaks up to 14 d of aging when compared with ZH alone. Further research is needed to determine if this decrease in tenderness can be detected by the consumers.

Key Words: lysine/methionine, tenderness, zilpaterol hydrochloride

91 Influence of multi exogenous enzymes on performance and carcass characteristics in growing rabbits. H. Gado*[1] and A. Z. M. Salem[2], *[1]Animal Production Department, Faculty of Agriculture, Ain Shams University, Qalubia, Egypt, [2]Facultad de Medicina Veterinaria y Zootecnia, Universidad Autonoma del Estado de Mexico, Mexico.*

This study was conducted to investigate productivity of growing rabbits fed different levels of multi exogenous enzymes of ZADO (EZ) in diets. One hundred twenty Hy-Plus 30-d-old weaned rabbits were used in the study. Animals were divided into 4 comparable experimental groups (30 growing rabbits in each group) in a completely random design. The first group was fed a commercial diet and kept without treatment as a control group. The 2nd; 3rd and 4th groups were fed the same diets but supplemented with 1(EZ1), 3 (EZ3) and 5 (EZ5) kg ZADO/ton of diet, respectively. The experimental period lasted for 30 d and was carried out during growing period (from weaning to marketing at 60 d). Daily body weight gain; feed efficiency, feed conversion and final body weight of growing rabbits increased ($P < 0.05$) with increasing the EZ levels in diets compared with control ones. Feed intake was not affected by EZ supplementation. Supplementation of rabbit diet with EZ increased ($P < 0.05$) dressing percentage, carcass weight and absolute and relative internal organs weight to carcass weight. Post-weaning mortality decreased ($P < 0.05$) compared with those unsupplemented rabbits. The improvement in rabbit performance and carcass characteristics was more in EZ3 or EZ5 than EZ1 group. It can be concluded that supplementation of ZADO to rabbit diets showed enhanced growth performance, carcass traits and decreasing mortality rate, during growing period. At the economic point 3 kg ZADO/ton diet is recommended for growing rabbits

Key Words: carcass, growth, productive

92 Influence of different forms of lipid supplements and frequencies of fed on physical characteristics of heifer meat. M. C. A. Santana*[1], R. A. Reis[2], A. V. Pires[3], T. T. Berchielli[2], V. C. Modesto[2], P. H. M. Dian[4], M. A. A. Balsalobre[5], and G. T. Pereira[2], *[1]EMATER, Goiânia, Goiás, Brazil, [2]São Paulo State University, Jaboticabal, Sao Paulo, Brazil, [3]Sao Paulo University, Piracicaba, São Paulo, Brazil, [4]Camilo Castelo Branco University, Descalvado, São Paulo, Brazil, [5]Bellman, Mirassol, São Paulo, Brazil.*

This research aimed to evaluate by physical quality of meat (color – a*, b*, L*; shear force–WBSF; water-holding capacity – WHC; pH and cooking loss percentage –CLoss) the effects of different fat sources on meat attributes of heifers finished in pasture. The experiment was designed as a completely randomized, using a 3x2 factorial arrangement of treatments, replicated 7 times, in which 17 mo-old crossbred heifers (1/4 Nellore x 1/4 Santa Gertrudis x 1/2 Braunvieh) were fed for 135 d according to the treatments: soybean grain (SG), soybean oil (SO), and rumen-protected fat, Megalac-E (MEG), and the 2 supplement feeding frequencies (Monday, Wednesday and Friday – MF; and daily –DL). At slaughter, LM muscle pH measurements were taken, and samples between 12th and 13th were harvested and frozen at −20°C for meat evaluation. Samples of LM were evaluated for color interface in the L*a*b* color space and LM steaks were thawed and roasted to evaluated WBSF. The WHC was obtained by determining the difference of the LM sample weights under 10 kg of pressure for 5 min. The CLoss value was determined according to the reduced percentage rate before and after the meat was cooked. All variables were not different ($P > 0.05$) among treatments. The results of this research suggest that the physical indicators of meat quality were not influenced by the supplements and its feeding frequencies.

Table 1. Means for shear force (WBSF), water-holding capacity (WHC), and percentage cooking loss (CLoss), the colors a, b and L, and meat pH of heifers fed with different lipid supplement (SG. SO, MEG) and supply frequencies [Monday, Wednesday and Friday (MF) or daily (DL)].

	Supplement and frequency					
Item	SG	SO	MEG	MF	DL	SD
WBSF (kgf/ cm3)	8.3	8.8	7.6	8.0	8.3	1.9ns
WHC (%)	72.0	72.3	72.9	73.2	71.8	3.1ns
CLoss (%)	33.9	33.7	32.6	33.2	33.6	2.1ns

93 Performance, carcass, economics of production, hematological status, and organoleptic evaluation of broilers fed with graded levels of cowpea testa-based diets. P. O. Fakolade*[1], B. O. Alabi[1], A. A. Amao[1], and A. H. Ekeocha[2], *[1]Osun State University, Osogbo, Osun, Nigeria, [2]University of Ibadan, Ibadan, Oyo, Nigeria.*

Nutritional challenge of today is to provide for the worlds' present inhabitants without degrading resources needed to meet the greater nutritional challenges of tomorrow. Now, livestock producers focus on agro- industrial by-products and wastes, which are not utilized by man in underdeveloped country; an example is cowpea testa meal (CTM). Cowpea testa meal has been reported to be a cheaper alternative (waste) to soybean meal in poultry nutrition, but contains some anti-nutritional factors, which could limit its usage. The objective of this study focus on digestibility status, carcass and organoleptical evaluation, economics of production and the hematological status, of 3 hundred and 60 broiler birds (Arbor acre) randomly allotted into 4 dietary groups with 3 replicates in a completely randomized design. Four diets were formulated with CTM replacing soybean meal at 0%, 15%, 30%, and 50% grade levels for 56 d. There were significant ($P < 0.05$) differences between diets in final weight gain, average daily feed intake, feed to gain ration. Birds on control (0%) and (15%) CTM diet had significant ($P < 0.05$) weight gained than those fed with 30% and 50% CTM inclusion level. Panelist rated T_1 and T_2 with highest values; for color, flavor, tenderness, juiciness, texture and overall acceptability, while color, tenderness and juiciness were seen to have no significance differences ($P > 0.05$) among all the treatments. For carcass evaluation, organs and primal cut, were seen to have significant differences for lungs, gizzard, proventriculus, and chicken back, while ($P > 0.05$) was not observed in others organs or cuts. Hematology studies had no significant differences ($P > 0.05$) but cost of production was lower in broiler fed 15% CTM compare with 0% and other inclusion levels. Therefore, cowpea testa can be used to substitute soybean at 15% in broilers diet at both starter and finisher phase for effective growth performance and good carcass quality at a reduced cost of production.

Key Words: cowpea testa, digestibility, organoleptic properties.

94 Effects of feeding flaxseed or sunflower-seed in high forage diets on biohydrogenation intermediates in adipose tissues of yearling steers. C. Mapiye*[1], T. D. Turner[1], D. C. Rolland[1], J. A. Basarab[2], V. S. Baron[1], T. A. McAllister[3], H. C. Block[4], and B. Uttaro[1], J.L. Aalhus[1], and M. E. R. Dugan[1], *[1]Agriculture and Agri-Food Canada, Lacombe Research Centre, Lacombe, AB, Canada, [2]Alberta Agriculture*

and Rural Development, Lacombe Research Centre, Lacombe, AB, Canada, [3]Agriculture and Agri-Food Canada, Lethbridge Research Centre, Lethbridge, AB, Canada, [4]Agriculture and Agri-Food Canada, Brandon Research Centre, Brandon, Manitoba, Canada.

Supplementing high forage diets with oilseeds can increase deposition of biohydrogenation intermediates in adipose tissues; however, the effects of forage type have not been widely studied. This study examined the effects of feeding 70:30 forage:concentrate diets to yearling steers for 205 d, with either grass hay (GH) or red clover silage (RC) as the forage source, and concentrates containing either sunflower-seed (SS) or flaxseed (FS), each providing 5.4% oil to diets. Two pens of 8 animals were fed per diet. At harvest, perirenal fat (PF) closest to the cranial-central part of the whole PF and subcutaneous fat (SF) adjacent to the 12th rib were collected, methylated with sodium methoxide, and analyzed using a combination of GC (100 m highly polar column) and Ag^{+}-HPLC. Data were analyzed using PROC MIXED procedure of SAS including oilseed, forage and their interaction as the main effects. Pen was the experimental unit. Overall, fatty acid (FA) profiles in PF and SF followed similar trends when feeding FS or SS in high forage diets but SF compared with PF had greater ($P < 0.05$) proportions of n-3 FA, conjugated linoleic acids, mainly rumenic acid (RA), atypical dienes (AD), and less ($P < 0.05$) proportions of n-6 FA and *trans*-18:1 isomers, mainly vaccenic acid (VA). Feeding diets containing SS versus FS elevated ($P < 0.05$) adipose tissues proportions of VA, RA and linoleic acid (LA). Steers fed diets containing GH versus RC or FS versus SS had greater ($P < 0.05$) adipose tissue proportions of total n-3 FA, mainly α-linolenic acid (ALA) and total AD. A forage × oilseed type interaction ($P < 0.05$) was found for total conjugated linolenic acid (CLNA), with their greatest adipose tissues proportions being produced when feeding the RC-FS diet. Overall, feeding SS containing diets was more effective in increasing adipose tissues proportions of VA, RA and LA while enrichment of ALA, CLNA and AD were achieved by feeding diets containing FS. Feeding forages also affected adipose tissue FA profiles, but their effects were generally of less magnitude compared with oilseed effects.

Key Words: adipose tissue, forage, oilseed

95 Growth, carcass traits and meat color stability in steers finished on a potato-based versus a corn-based ration. K. J. Thornton*, M. J. Colle, J. A. Macumber, M. E. Doumit, R. Richard, C. W. Hunt, and G. K. Murdoch, *University of Idaho, Moscow.*

Increasing feed prices and competition for available commodities has driven beef producers to consider alternate feedstuffs. However, it is imperative that these alternate feeds do not negatively affect growth, carcass traits, or end product quality. In the Northwestern US potato by-product is used as a corn substitute. We compared growth, carcass traits and color stability in steers fed either a conventional finishing ration containing corn and barley as the grains (CB, n = 20) or a ration with 10 percent potato by-product substituted for corn (PB), balanced for energy and nitrogen. No differences ($P > 0.05$) were observed in ADG, FCR, DMI, HCW, PYG, REA, KPH, FYG, quality grade or marbling score. Steers finished on a PB ration produced strip loin steaks with lower ($P = 0.04$) WBSF values. No significant differences were observed in the L*, a* or b* values in the longissimus dorsi (LD) measured at 0, 1, 3, 5, 7 and 9 d of simulated retail display . Gluteus medius (GM) steaks from steers finished on a PB ration had a higher a* value on d 5 ($P = 0.03$). No differences were observed in L* or b* values in the GM. American Meat Science Association (AMSA) evaluation guidelines were used to evaluate browning, discoloration, color uniformity and surface discoloration in the LD and GM muscles. The LD steaks from steers finished on a CB ration had numerically less; browning, discoloration, surface discoloration and more uniformity during simulated retail display. However, the amount of browning ($P = 0.01$) and the discoloration ($P = 0.05$) were significantly different on d 7. No visual color differences in color were observed in the GM. While steers finished on either a PB or CB finishing ration exhibited no difference in carcass quality, steers fed a PB ration had more tender strip steaks. In contrast, color stability may be increased in the LD of steers finished on a CB ration. Overall, subtle differences in meat quality exist between steers finished on either a CB or PB ration, but both rations result in high quality beef products.

Key Words: potato by-product, end-product quality, color stability

96 Influence of *Salix babylonica* extract and exogenous enzymes on meat quality in growing lambs. J. Cayetano[1], A. Z. M. Salem*[1], H. Gado[2], and R. Rojo[3], *[1]Facultad de Medicina Veterinaria, Universidad Autonoma del Estado de Mexico, Mexico, [2]Animal Production Department, Faculty of Agriculture, Ain Shams University, Qalubia, Egypt, [3]CU-UAEM Temascaltepec, Universidad Autonoma del Estado de Moxico, Mexico.*

The objective of the present study was to determine the effect of the addition of extract of *Salix babylonica* and exogenous enzymes in combination or individually on the quality of meat in lambs. Suffolk lambs of 6 to 8 mo-old were used in the study. Lambs were divided into 4 groups of 5 animals each in a completely randomized design and the treatments were (1) Control: fed a basal diet of concentrate (30%) and corn silage (70%); (2) EZ: fed the basal diet plus 10 g of enzyme; (3) SB: fed the basal diet plus 30 mL of *S. babylonica* extract, and (iv) EZSB: fed the basal diet plus 10 g enzyme and 30 mL of *S. babylonica* extract. Lambs were housed in individual cages for 60 d as experimental period. The SB was given orally while the EZ was mixed with a small amount of the concentrate, while the corn silage was offered ad libitum. At the end of experimental period, all lambs were slaughtered and samples of Longissimus dorsi muscle were taken. Samples were analyzed for crude protein, crude fat, ash and dry matter. Some parameters of meat quality were determined (color parameters, PH, carcass temperature and average daily gain). There were no significant differences between the 4 treatments ($P < 0.05$) in meat color coordinates (L*, a*, b*), temperature, average daily gain. Meat pH was lower ($P < 0.05$) in EZSB compared with other treatments. L* (lightness) was highest in EZSB ($P < 0.05$) compared with the other treatments. In conclusion, administration of EZSB in the diet improves measured meat quality parameters by reducing the pH and increase meat lightness compared with EZ and SB individually.

Key Words: exogenous enzyme, lamb, meat quality

97 Effects of alternative cattle finishing strategies on meat quality characteristics. K. J. Phelps*[1], K. A. Miller[1], C. L. Van Bibber-Krueger[1], A. K. Sexten[1], J. S. Jennings[2], J. S. Drouillard[1], and J. M. Gonzalez[1], *[1]Kansas State University, Manhattan, [2]Alltech Inc., Nicholasville, KY.*

Effects of alternative finishing strategies on fresh meat quality were examined in beef steers (64 pens; 8 steers/pen) using a randomized complete block design with a 2 × 2 factorial treatment arrangement. For factor 1, diets with inorganic trace mineral supplement, vitamins A and E, Rumensin, and Tylan (C) were compared with diets with PN Beef supplement (PN; Alltech, Inc.). The PN treatments were fed the basal diet with PN Beef Receiver from d 1–20, and PN Beef Finisher

from d 21 to harvest. Factor 2 consisted of the presence or absence of exogenous growth promotants (+GP vs. –GP). Steers in the +GP treatments were implanted initially with Component E-S, reimplanted with Component TE-S, and fed 400 mg/steer daily of ractopamine-HCl (Elanco Animal Health) for the final 28 d before harvest. The basal diet consisted of steam-flaked corn, wet corn gluten feed, wheat straw, and supplement. Steers were harvested on d 175, strip loins were removed from 2 carcasses selected at random from each pen, transported to Kansas State University, weighed, vacuum packaged, and aged for 14 d. On d 14, loins were reweighed to assess purge loss and fabricated into 2.54-cm-thick steaks for determination of Warner-Bratzler shear force and color stability during a 7-d retail display. There were no interactions ($P > 0.05$) between feeding strategy and exogenous growth promotants. Purge loss was less for PN compared with C loins ($P < 0.01$). Use of GP increased moisture loss during cooking ($P < 0.05$), while feeding PN decreased moisture loss during cooking ($P < 0.05$). Steaks from +GP were less tender ($P < 0.01$) than –GP steaks, but C and PN were not different ($P > 0.05$). Initial values for L* were less for C than for PN ($P < 0.05$), but changes in color, surface percentages of oxymyoglobin and metmyoglobin, and metmyoglobin reducing ability were unaffected by feeding strategy ($P > 0.05$). In conclusion, alternative feeding strategies can favorably affect meat tenderness and water-holding capacity without compromising retail display characteristics.

Key Words: implant, beta agonist, feed additive

98 Gene expression of lipogenic enzymes present in muscle of young bulls fed ground soybean or rumen-protected lipid with or without ionophore. M. M. Ladeira[1,2], D. M. Oliveira[1], A. Chalfun Junior[1], M. L. Chizzotti[1], H. G. Barreto[1], T. C. Coelho[1], P. D. Teixeira[1], C. C. Coelho[1], and D. R. Casagrande*[1], *[1]Federal University of Lavras, Lavras, MG, Brazil, [2]Purdue University, West Lafayette, IN.*

The objective of this study was to evaluate the gene expression of lipogenic enzymes in the muscle of young bulls fed soybean grain (SB) or rumen protected lipid (RPL), with or without the supplementation of monensin (M). Forty bulls were allotted in a completely randomized design using a 2 × 2 factorial arrangement. The diets had 6.6% EE and the corn silage was used as forage. Half of the bulls fed SB or RPL was supplemented with 230 mg/hd/d of monensin. The bulls were harvested with on average 497 kg. The genes evaluated were acetyl coA carboxylase (ACC), adipocyte-type fatty acid binding protein ($FABP_4$), stearoyl coA desaturase (SCD), lipoprotein lipase (LPL), glutathione peroxidase (GPX), peroxisome proliferator activator receptor (PPAR-α), and sterol regulatory element binding protein (SREBP-1c). The gene expression was analyzed using the qPCR technique and the evaluation of relative quantification was carried out by formula $2^{-\Delta\Delta C_T}$. The data were analyzed using PROC GLM of SAS 9.1. There was no difference ($P > 0.05$) in gene expression for ACC and SREBP-1c between diets. However, the LPL was 4 times more expressed ($P < 0.05$) in the muscle of bulls fed SB than RPL. The gene expression of $FABP_4$ also presented similar performance when SB was used, being around twice more expressed ($P < 0.05$). The largest difference in gene expression was observed for SCD. Muscle of bulls fed SBM, RPL, and SB, presented, respectively, 12, 6 and twice more SCD gene expression ($P < 0.05$) compared with the RPLM diet. The GPX was 2.5 times more expressed ($P < 0.05$) in the muscle of bulls fed SBM than the other 3 diets. Similar result occurred in the gene expression of PPAR-α. The gene expression of the enzymes FABP and LPL were influenced ($P < 0.05$) by the monensin only when RPL diet was used. For the first enzyme ionophores reduced the gene expression, and for the second, it increases the gene expression. The use of soybean grain or rumen protected lipid, with or without monensin, changed the gene expression of the lipogenic enzymes, and the main affected enzymes were LPL and SCD.

Key Words: nutrigenomics, monensin, soybean

99 Effect of enterotoxigenic *Escherichia coli* on Na^+-dependent glucose transporter-1 mRNA abundance in piglet jejunal segments infused with customized glycans. A. D. Woodward*, X. Chen, M. G. Gänzle, and R. T. Zijlstra, *University of Alberta, Edmonton, Alberta, Canada.*

Enterotoxigenic *Escherichia coli* (ETEC) induces diarrhea and reduces absorption of water and nutrients, yet effects of ETEC on glucose transport in pigs are poorly understood. Exopolysaccharides reuteran and levan from *Lactobacillus reuteri*, but not related glycans dextran and inulin, reduce the occurrence of ETEC-induced diarrhea, and may thus also influence the expression of glucose transporters. We hypothesized that ETEC infection reduces mRNA abundance of Na^+-dependent glucose transporter-1 (SGLT1) in ETEC-challenged piglets. Weanling gilts (5-wk-old; 10.2 ± 1.8 kg BW; n = 4) were prepared for small intestine segment perfusion with 10 jejunal segments. Five segments were infected with ETEC K88 (5×10^9 cfu/mL); remaining segments were treated with saline. Five pairs of segments, 1 ETEC and 1 non-ETEC infected each, were infused with 65 mL of 10 g/L of glucans (dextran, reuteran) or fructans (levan, inulin) or saline (control) for 8 h. After infusion, mRNA was extracted from mucosa, and cDNA was manufactured for quantitative reverse transcription-PCR. Gene expression was calculated as fold change, using the $2^{-\Delta\Delta C}{}_T$ method with β-actin and GAPDH as reference genes, and analyzed with PROC-MIXED in SAS. Overall, SGLT1 decreased (0.6 vs. 1.0 ± 0.2; $P < 0.05$) with ETEC infection but did not differ among glycan and saline treatments. Within treatments, ETEC-infection decreased SGLT1 expression in segments infused with saline (0.3 vs. 1.0 ± 0.4; $P < 0.05$), dextran (0.5 vs. 1.0 ± 0.4; $P < 0.05$), and reuteran (0.4 vs. 1.0 ± 0.4; $P < 0.05$) compared with non-ETEC-infection; however, SGLT1 did not differ between ETEC- and non-ETEC infection for inulin or levan. In conclusion, ETEC-infection decreased SGLT1 abundance. Reduction in SGLT1 abundance in response to ETEC-infection was eliminated with infusion of fructans inulin and levan, but not glucans reuteran and dextran. Thus, effects of ETEC pathogenesis on SGLT1 mRNA abundance in ETEC-infected pigs may depend on glycan composition or their degradation products rather than their effect on diarrhea.

Key Words: enterotoxigenic *Escherichia coli*, glucose transporter, pig

100 Effect of glycan infusion on cytokine expression in piglet jejunal segments challenged with enterotoxigenic *Escherichia coli*. A. D. Woodward*, X. Chen, M. G. Gänzle, and R. T. Zijlstra, *University of Alberta, Edmonton, Alberta, Canada.*

Adhesion of enterotoxigenic *Escherichia coli* (ETEC) to small intestine enterocytes causes release of toxins that stimulate cytokine release. The exopolysaccharides reuteran and levan produced by *Lactobacillus reuteri* may reduce inflammatory responses caused by ETEC-infection. We hypothesized that these exopolysaccharides also reduce mRNA abundance of cytokines interleukin-1β (IL1β), interleukin-6 (IL6), and tumor necrosis factor-α (TNFα) in ETEC-challenged piglets. Weanling gilts (5-wk-old; 10.2 ± 1.8 kg BW; n = 4) were surgically prepared for small intestine segment perfusion with 10 jejunal segments. Five segments were infected with ETEC F4 (K88) (5×10^9 cfu/mL); the rest were treated with saline. Five pairs of segments, 1 ETEC infected and 1 not, were infused with 65 mL of 10 g/L glucans (dextran, reuteran), fructans (inulin, levan), or saline (control) for 8 h. After infusion, mucosa was collected, mRNA extracted, and cDNA manufactured before quantitative reverse transcription-PCR. Contrasts between ETEC- and non-ETEC-infection were analyzed as fold change using the $2^{-\Delta\Delta C}{}_T$ method with β-actin and GAPDH as reference genes. The ETEC-infection increased IL1β (8.2 vs. 1.0 ± 0.2; $P < 0.01$) and IL6 (4.1 vs. 1.0 ± 0.6; $P < 0.01$), but did not affect TNFα, compared with control. Without ETEC, IL6 tended to increase for levan (6.3 vs. 1.0 ± 1.5; $P = 0.09$) and reuteran (7.1 vs. 1.0 ± 1.5; $P = 0.07$) compared with saline. With ETEC-infection, inulin decreased IL1β (0.4 vs. 1.0 ± 0.5; $P < 0.05$) and IL6 (0.1 vs. 1.0 ± 1.2; $P < 0.05$) compared with saline. With ETEC-infection within treatments, IL6 was increased (22.3 vs. 1.0 ± 1.3; $P < 0.01$) for dextran and tended to increase (5.6 vs. 1.0 ± 1.3; $P = 0.07$) for reuteran, but did not differ between inulin or levan, compared with non-ETEC-infection. In conclusion, ETEC-infection increased inflammatory responses based on tissue IL1β and IL6 expression. Luminal fructan infusion may reduce these inflammatory responses whereas luminal glucan infusion did not. Thus, effects of glycans on ETEC-induced cytokine release in pigs may depend on glycan composition.

Key Words: cytokine, enterotoxigenic *Escherichia coli*, pig

101 Dietary inclusion of low doses of microencapsulated zinc oxide affects inflammatory cytokine and tight junction protein expression in the ileum of piglets . E. Grilli*[1], B. Tugnoli[1], F. Vitari[2], and A. Piva[1], *[1]DIMEVET, University of Bologna, Ozzano Emilia, Italy, [2]Department of Health, Animal Science and Food Safety, University of Milan, Milan, Italy.*

Aim of this study was to investigate the expression of inflammation markers and tight junctions protein (TJ) in the ileum of piglets fed with low doses of microencapsulated zinc oxide (ZnO; Zincoret, Vetagro SpA, Italy) in comparison with either a pharmaceutical dose of free ZnO (positive control) or a negative control. Twenty-four pigs weaned at 28 d and divided in 4 groups, received either a basal diet (NC) or the basal diet added with zinc oxide at 2850 mg/kg (PC), or lipid encapsulated ZnO at 187 or 437 mg/kg (Zn200 and Zn400). After 15 d, 6 pigs per group were euthanized and ileal samples were collected for cytokines (IL-6, IL-10, TNF-a, and IFN-g), zonula occludens-1 (ZO-1), occludin (OCC) and claudin-1 at both mRNA and protein level. Data were analyzed with 1way ANOVA. Both groups receiving microencapsulated ZnO tended to have a reduced expression of IL-6 (−25%, $P = 0.1$), compared with both NC and PC. IFN-g expression was the lowest in Zn400 group ($P = 0.02$), and the protein tended to be lower in Zn400 than in PC ($P = 0.07$). Microencapsulated ZnO tended also to downregulate TNF-a expression compared with NC and PC ($P = 0.1$) and TNF content in ileal samples ($P = 0.07$). OCC gene expression was the lowest in Zn400 ($P = 0.04$), though the protein amount was 2–4 fold higher in Zn400 group compared with NC and PC, respectively ($P < 0.001$). ZO-1 expression was not affected by the treatments but ZO-1 amount in Zn400 group was 1.3–1.5 fold higher than in NC and PC, respectively ($P < 0.001$). Claudin-1 gene expression was 1.7–2.4 higher in Zn400 compared with NC and PC, respectively ($P = 0.01$). Overall, Zn200 group tended to have intermediate values between PC and Zn400. The results suggest that ZnO released from a lipid matrix is available in the ileum of piglets where it modulates the local immune response which, in turn, affects the intestinal permeability via the TJ proteins. In this respect, lipid encapsulated ZnO was effective at relatively low concentrations whereas free ZnO fed at 6–15 higher doses failed to be, probably because of a rapid metabolization in the upper gut.

Key Words: microencapsulation, piglet, zinc oxide

102 Effects of dietary clays on performance and barrier function of chicks challenged with *Salmonella enterica* serovar Typhimurium. J. A. S. Almeida*, J. J. Lee, P. Utterback, R. N. Dilger, and J. E. Pettigrew, *University of Illinois, Urbana.*

An experiment was conducted to test for beneficial effects of dietary clays on young chicks challenged with pathogenic *Salmonella* and to explore potential mechanisms through which clays may produce benefits, with emphasis on barrier function. Two hundred forty 1-d-old male commercial broiler chicks (initial BW: 41.6 ± 0.4 g; Ross × Ross) were allotted in a randomized complete block design with level on the battery as the block and pen as the experimental unit. Six replicates of 5 chicks/pen were assigned to each treatment. Pens were randomly assigned to 1 of 2 infection treatments (with or without *Salmonella* challenge at 2 wk of age) and 4 dietary treatments: basal, 0.3% smectite A (SMA), 0.3% smectite B (SMB) and 0.3% zeolite (ZEO). The *Salmonella* challenge reduced ($P < 0.05$) the growth rate of chicks fed the basal diet by 11% during d 3–7 post-inoculation (PI), but the clays prevented this reduction. The interaction between challenge and diet occurred ($P < 0.05$) for ADFI d7–10 PI and ADFI and ADG during the overall period (d0–14 PI), and the pattern was similar but not significant for other measures. Goblet cell number and size were increased ($P < 0.05$) by the *Salmonella* challenge in chicks fed the basal diet, and were reduced ($P < 0.05$) in *Salmonella*-challenged chicks by feeding SMA. Villus height was reduced by the *Salmonella* challenge in the chicks fed dietary clays ($P < 0.01$) but not in chicks fed basal diet (interaction $P < 0.05$). The mRNA expression of IFFN-γ, a canonical inflammatory marker, in cecal tissues remained low in all treatments. Clays did not alter the concentration of α-1 acid glycoprotein in the sham-challenged group but increased it in the *Salmonella*-challenged group. In conclusion, clays restored performance of *Salmonella*-challenged chicks, SMA had effects consistent with strengthening of the mucosal barrier, and the pattern of response suggests that different clays produce benefits through different mechanisms.

Key Words: goblet cell, chick, clay

103 *Bacillus licheniformis* and sodium butyrate protective effects on oxidative stress-induced inflammation in IPEC-J2 porcine intestinal epithelial cells. A. Ortiz*[1], P. Gálfi[2], E. Paszti-Gere[2], A. Jerzsele[2], M. Puyalto[1], and J. J. Mallo[1], *[1]Norel S.A., Madrid, Spain, [2]Szent István University, Budapest, Hungary.*

To determine whether sodium butyrate (SB) and *Bacillus licheniformis* (BL) spent culture supernatant (SCS) could exert protective effects under oxidative stimuli, IPEC-J2 porcine intestinal epithelial cells were treated simultaneously with hydrogen peroxide and the above mentioned active ingredients (AIs). Transepithelial electrical resistance (TER) measurement of monolayers was performed using epithelial tissue volt/ohmmeter (EVOM) to elucidate the effect of 0.5 m*M* peroxide and AIs on cell membrane integrity. Occurrence of cell death was monitored using 2 staining methods, Trypan blue exclusion assay (TB) and Neutral Red uptake test (NRU) by counting 300 cells per flask in 3 parallels. Administration of sodium butyrate at 2 m*M* significantly ($P < 0.05$) increased TER values compared with positive controls (84.09% vs. 67.55%), this barrier strengthening property remained elevated after an 24-h recovery period (174.41% vs. 143.16%). SCS of *Bacillus licheniformis* in 10% solution significantly ($P < 0.05$) elevated TER values compared with control (90.10% vs. 69.32%). Sodium butyrate at 2 m*M* significantly ($P < 0.05$) elevated the number of viable cells with NRU staining compared with H_2O_2 treated samples (68.71% vs. 58.37%). SCS of *Bacillus licheniformis* in 10% solution also increased cell viability significantly (79.60% vs. 58.37; $P < 0.05$) as a reduced number of dead cells was found. Sodium butyrate at 2 m*M* significantly ($P < 0.05$) elevated the number of viable cells compared with H_2O_2 treated samples (82.20% vs. 55.48%) with the TB assay. It is concluded that both SB at 2 m*M* and BL SCS in 10% solution have a protective effect on IPEC-J2 porcine intestinal epithelial cells.

Table 1.

		Mean TER (OHM·cm2)		
		Before treatment	After treatment	After 24 h
Trial 1	0.5 mM H2O2	7367	4976b	10535b
	0.5 mM H2O2 + 2mM SB	5688	4783a	9920a
Trial 2	0.5 mM H2O2	6254	4335b	—
	0.5 mM H2O2 + 10% BL	7224	6509a	—

Key Words: stress, butyrate, licheniformis

104 Effect of acute water and feed deprivation event on mucin, cytokine, and tight junction gene expression in weaned pigs. N. Horn*[1], G. Miller[3], K. M. Ajuwon[1], F. Ruch[2], and O. Adeola[1], *[1]Purdue University, West Lafayette, IN, [2]Enzyvia LLC., Sheridan, IN, [3]Biomatrix, Princeton, MN.*

The effect of acute water and feed deprivation events on mucin, cytokine, and tight junction gene expression in weaned nursery pigs were evaluated. Pigs (6.21 ± 0.29 kg) were allotted in a randomized complete block design to 4 post-weaning treatments on the basis of body weight at the time of weaning which consisted of a control, 24-h feed deprivation event, 24-h water deprivation event, and a 24-h feed and water deprivation event. There were 8 pigs per pen and 12 replicate mixed-sex pens per treatment. Following the deprivation events pigs were returned to normal management procedures. On d 2 and 7 post weaning one pig per pen was euthanized and ileal and jejunal mucosal samples were taken for gene expression analyses by RT-PCR for mucin (MUC2), cytokines interleukin 1 (IL-1β), interleukin 6 (IL-6), and tumor necrosis factor (TNF-α), and tight junction proteins claudin 4, occludin, and zonula occludens 1 (ZO-1). In the jejunum there was a decrease in TNF-α expression the day following the feed stress event ($P = 0.011$) and a significant feed x water interaction ($P = 0.017$). Furthermore, there was a decrease in occludin gene expression the day following the water stress event ($P = 0.019$). There were no differences in MUC2, tight junction, or cytokine gene expression in the jejunum 7 d post weaning. In the ileum there was a decrease in claudin 4 gene expression 7 d post weaning in water stressed pigs ($P = 0.008$). There was also a tendency for a decrease in ZO-1 gene expression with the water stress event ($P = 0.081$) and a tendency for a feed × water interaction ($P = 0.096$) was observed 7 d post weaning. There were no differences in MUC2, cytokine, or tight junction gene expression in the ileum 2 d post-weaning. The results from the current trial show a decrease in tight junction gene expression in the gastrointestinal tract of nursery pigs on d 2 and 7 post-weaning following a 24-h water deprivation event at weaning although expression of cytokines and MUC2 were largely unaffected by the stress events.

Key Words: tight junction gene expression, nursery pig, stressor

105 Effect of dietary fructo-oligosaccharide with different polymerization degree on the cellular immune response in weaned pigs. V. Halas*[1], I. Nochta[2], T. Tuboly[3], Cs. Szabó[1], and L. Babinszky[4], *[1]Kaposvár University, Kaposvár, Hungary, [2]Provimi, Zichyújfalu, Hungary, [3]Szent István University, Budapest, Hungary, [4]University of Debrecen, Debrecen, Hungary.*

Fructo-oligosaccharide (FOS) supports the beneficial microbiota that affects the immune status, particularly at weaning. However, it is not clear if degree of FOS polymerization can alter the animal response. Therefore the aim of the trial was to study the effect of different FOS supplementation on cellular immune response and growth performance of nursery pigs. A total of 464 piglets (7.9 kg BW) were assigned into 4 dietary treatments (6 flat deck pens/treatment) at weaning (28 d). The negative control (NC) diet was a commercial feed without growth promoter (basal diet), the basal diets was supplemented with 40 ppm avilamycin (treatment PC), 0.5 g/kg of FOS (3–5 degree of polymerization; Profeed, Allied Nutrition Ltd., South Africa; treatment FOS) or 0.5 g/kg of inulin (10 degree of polymerization; Fibrulin, Warcoing, S.A. Belgium; treatment IN). Pigs were immunized by inactivated Aujeszky's disease virus vaccine at d1 and 14 of the trial (28- and 43 d-age). Blood samples were taken at d1, 8, 15, 22 and 32 from 2 pigs/pen for lymphocyte stimulation tests (LST) with nonspecific mitogens (concanavalin A, pokeweed mitogen, phytohemagglutinin) and with specific mitogen (Aujeszky's virus). All piglets were individually weighed on d1, 15 and 32. Data were analyzed by ANOVA. Feed additives enhanced the nonspecific cellular immune response at d32 ($P < 0.05$), but no treatment effect was observed on specific LSTs at any time. At the first 2 weeks of the trial ADG was lower in FOS and IN groups (207 and 201 g/d, resp.) compared with the NC and PC groups (234 and 228g/d, resp; $P < 0.05$). However, there were no differences in growth rate among treatments ($P > 0.05$) either in the last 18 d (NC, PC, FOS, IN: 358, 361, 339, 346 g/d, resp) or in the whole nursery period (NC, PC, FOS, IN: 300, 299, 277, 278 g/d, resp). The ADFI and FCR values were similar in each period. In conclusion, fructo-oligosaccharide supplementation results in better non-specific cellular immune response regardless of degree of polymerization ranging from 3 to 10, even if no growth promoting effect is present.

Key Words: FOS polymerization, immune response, piglet

106 Astragalus polysaccharide reduces inflammatory response by decreasing permeability of LPS-stimulated Caco2 cells. X. Wang, Y. Li, X. Yang, and J. Yao*, *College of Animal Science and Technology, Northwest A&F University, Yangling, Shaanxi, China.*

As the major constituent of Radix Astragali, astragalus polysaccharide (APS) is known for its anti-inflammation and immunomodulatory functions. The objective of this study was to investigate the effect of APS on inflammatory response and structural changes in lipopolysaccharide (LPS)-stimulated Caco2 cells. Caco2 cells were cocultured with APS and LPS, with APS added after the addition of LPS (post-addition), before the addition of LPS (pre-addition), or simultaneously with the addition of LPS (simultaneous addition). The mRNA expression of inflammatory indicators (TNF-α, IL-1β and IL-8) and tight junctions (zonula occludens-1 (ZO-1) and occludin) was measured by RT-qPCR. Short circuit current (Isc) was recorded by an Ussing chamber system. Data were subjected to one-way ANOVA using the GLM procedure of SAS, version 8.02. Means were separated by Fisher's least significant difference multiple-range test. Addition of APS downregulated the expression of TNF-α, IL-1β and IL-8 ($P < 0.05$) and the Isc levels ($P < 0.05$) of LPS-stimulated Caco2 cells for all 3 administration treatments. The minimum anti-inflammatory concentration of APS was 50, 100, and 100 μg/mL for pre-, post-, and simultaneous additions of APS, respectively. The mRNA expression of ZO-1 and occludin was upregulated for post- and pre-additions of APS, respectively ($P < 0.05$). Results suggested that APS had context-dependent anti-inflammatory and tight junction protective properties for LPS-stimulated Caco2 cells, and may be used as a preventative treatment against LPS stimulation for intestine cells.

Key Words: astragalus polysaccharide, inflammatory response, tight junction

107 Oxygen consumption and respiratory control ratio (RCR) of broilers with and without growth enhancing levels of mineral supplementation challenged with *Eimeria maxima*. G. Acetoze*[1], R. Kurzbard[1], J. J. Ramsey[2], K. C. Klasing[1], and H. A. Rossow[3], *[1]Department of Animal Science, University of California, Davis, [2]School of Veterinary Medicine, University of California, Davis, [3]School of Veterinary Medicine, University of California, Tulare.*

Respiratory control ratio (RCR, State3/State4) provides an indication of mitochondrial coupling and efficiency of oxidative phosphorylation. However, the effect of dietary minerals fed at growth enhancing levels on mitochondrial function represented by RCR is unknown. Sixteen 7-d-old broilers were randomly assigned to 4 treatments: an infected control diet (Cu 15 ppm and Zn 60 ppm) + *Eimeria maxima* (Ei), 245 ppm Cu from tribasic copper chloride (TBCC) + Ei, negative control (Cu 15 ppm and Zn 60 ppm) - Ei and 2000 ppm Zn from ZnO + Ei. The diet was composed of 49% corn, 40% soybean meal, 6.2% vegetable oil (DM = 90.62%, CP = 21.37%, Fat = 7.7%, ME = 2.89Mcal/day) and were fed for 14 d. Mitochondria O_2 consumption was performed on isolated liver mitochondria (1g liver tissue) according to Ramsey et al. (2004). Statistical analysis was performed in R (version 2.15.1) using ANOVA. There was a trend of State 4 (leak-dependent O_2 consumption) being higher for infected birds fed 2000 ppm ZnO and infected birds fed Zn and Cu at the requirement levels ($P = 0.08$). However, State 3 (maximum ATP stimulated respiration) did not differ between treatments ($P = 0.51$). RCR values were 4.27, 2.40, 2.54 and 2.65 for the negative control group, the positive control group, 245ppm of Cu from TBCC group and 2000 ppm ZnO group, respectively and were different ($P = 0.02$). With the exception of birds not infected with Ei and not treated with high levels of minerals, birds that were fed levels of Cu from TBCC and Zn from ZnO above the requirement had higher RCR's compared with infected birds not treated with high minerals (2.54 and 2.65 versus 2.40, respectively). Levels of minerals (245ppm Cu as TBCC and 2000ppm Zn as ZnO) could possibly be decreasing the activity of Ei by acting as anticoccidials, protecting the cells from inflammation and therefore mitochondria uncoupling, loss of integrity and membrane disruption. Damage to the mitochondria membrane would interfere with proton leak kinetics which is highly related to H^+ gradient build up during electron transport chain and affects efficiency of H^+ use for ATP production.

Key Words: broilers, mitochondria, RCR

108 Retention and digestibility of Zn, Cu, Mn, and Fe in pigs fed diets containing inorganic or organic minerals. Y. Liu*[1], Y. L. Ma[2], J. M. Zhao[2], M. Vazquez-Añón[2], and H. H. Stein[1], *[1]University of Illinois, Urbana, [2]Novus International Inc., St. Charles, MO.*

The objective of this experiment was to measure the apparent total tract digestibility (ATTD) and retention rate of Zn, Cu, Mn, and Fe in pigs fed either inorganic micro minerals (IMM) or organic micro minerals (OMM). Thirty 2 barrows (BW: 38.4 ± 10.17 kg) were housed in metabolism cages and assigned to 4 treatments with a 2 × 2 factorial arrangement and 8 replicates per treatment. Semi-synthetic (SS) or corn-soybean meal (CS) diets were formulated with the inclusion of IMM ($ZnSO_4 \cdot 7H_2O$, $CuSO_4 \cdot 5H_2O$, $MnSO_4 \cdot H_2O$ and $FeSO_4 \cdot H_2O$), or OMM [$Zn(HMTBa)_2$, $Cu(HMTBa)_2$, $Mn(HMTBa)_2$ and FeGly] premix. The Zn, Cu, or $Mn(HMTBa)_2$ (MINTREX®, Novus International Inc., St. Charles, MO) is a chelate of 1 mineral with 2 2-hydroxy-4-methylthio butanoic acid and FeGly (MAAC®) is a chelate of 1 mineral with 1 glycine. Pigs were fed the SS diet without added micro mineral for 2 wk and then randomly assigned to 1 of 4 treatment diets. Fecal and urine samples were collected for 5 d following a 5-d adaptation period. The inclusion of OMM increased ($P < 0.05$) the ATTD and retention rate of Zn, Cu, Mn, and Fe in pigs. No difference was observed between SS and CS diets, except pigs fed CS diets had greater ($P < 0.05$) ATTD of Zn than pigs fed SS diets. Compared with IMM, adding OMM increased ($P < 0.05$) the ATTD and retention of Cu, Mn, and Fe to a lesser extent in SS diets than in CS diets (interaction, $P < 0.05$). This may be due to the greater concentration of phytate in CS diets than in SS diets. Results indicate that organic forms of micro minerals have better digestibility and retention rates compared with inorganic forms.

Table 1. Apparent total-tract digestibility (ATTD) of Zn, Cu, Mn, and Fe in pigs fed diets containing inorganic (IMM) or organic micro minerals (OMM)

	Semi-synthetic		Corn-soybean meal		
	IMM	OMM	IMM	OMM	SEM
Zn					
ATTD, %	49.11	57.63	44.04	53.60	1.75
Retention, %	40.65	48.44	38.61	49.55	1.37
Cu

Key Words: apparent total-tract digestibility, micro mineral, pig

109 Microencapsulated zinc oxide on piglets growth performance and intestinal architecture. E. Grilli*[1], B. Tugnoli[1], F. Vitari[2], A. Piva[1], and A. Prandini[3], *[1]DIMEVET, University of Bologna, Ozzano Emilia, Italy, [2]Department of Health, Animal Science and Food Safety, University of Milan, Milan, Italy, [3]ISAN, Università Cattolica Sacro Cuore, Piacenza, Italy.*

The aim was to compare low doses of microencapsulated zinc oxide (ZnO; Zincoret) in the diet of piglets with pharmacological level of ZnO on growth and ileal architecture. 144 weaned piglets, divided in 36 pens (n = 9), received a basal diet (NC; Zn at 45 mg/kg) or the basal diet with ZnO at 2850 mg/kg (PC), or with lipid microencapsulated ZnO at 187 or 437 mg/kg (Zn200 and Zn400). After 15 and 49 d, 6 pigs/group/time were euthanized to collect ileal mucosa for immunohistochemistry, histomorphology, and Na-dependent glucose transporter (SGLT-1) gene expression. Pigs BW and feed intake were recorded at 0, 14 and 42 d and ADG and FCR were calculated. Data were analyzed with 1 way ANOVA. At 14d the PC group had a 32% and 7% higher ADG and BW and a lower FCR compared with NC ($P < 0.05$), whereas Zn200 and Zn400 had intermediate values. At 42d both groups receiving microencapsulated ZnO had higher BW than NC and did not differ from PC ($P = 0.01$). ADG was on average 20% higher for PC and Zn400 than the NC ($P = 0.01$) and FCR was lower

in all treated groups compared with NC (−22%; $P < 0.01$). At 14 d, villi length in Zn400 pigs was 9% and 6% higher than in NC and PC, respectively ($P < 0.01$) and the villi:crypts ratio (V:C), as well as % of mitotic cells, were higher in all treated groups compared with NC ($P < 0.01$). SGLT-1 gene expression was the lowest in Zn400 pigs. At 49d villi length and V:C ratio were the highest for PC compared with all of the other groups (+10% than NC; $P = 0.01$). Mitotic cells were the highest in Zn400 group compared with other groups (+3% compared with NC and PC; $P < 0.01$), whereas SGLT-1 expression tended to be lower in Zn200 and Zn400 groups compared with NC and PC ($P = 0.06$). Pigs receiving low doses of microencapsulated ZnO had performance comparable to those receiving pharmacological level of ZnO overall the post-weaning phase. Moreover, in the first 2 weeks, microencapsulated ZnO improved the ileal architecture as reflected by the increased V:C ratio and the % of mitotic cells. The reduced SGLT-1 m-RNA abundance might suggest a reduced availability of glucose in the lumen of ileum, therefore suggesting a lower amount of undigested nutrients.

Key Words: microencapsulation, piglet, zinc oxide

110 Effect of dietary zinc and copper sources on wean-to-finish pig performance. J. Morales[1], C. Rapp*[2], and T. L. Ward[3], *[1]Pig Champ Pro Europa, Segovia, Spain, [2]Zinpro Animal Nutrition Inc., Boxmeer, the Netherlands, [3]Zinpro Corporation, Eden Prairie, MN.*

A total of 288 weanling pigs (7.5 kg BW; 28 d of age) were used to determine the effect of dietary Zn and Cu source on wean-to-finish growth performance by employing a 2 X 2 factorial arrangement of treatments and randomized complete block design. At weaning (d 1), pigs were blocked by BW and randomly assigned to 1 of 2 treatments for 35 d: (1) 2360 ppm Zn as ZnO + 150 ppm Cu as $CuSO_4$ [HZCS] or (2) 50 ppm Zn as zinc amino acid complex + 60 ppm Zn as ZnO + 150 ppm Cu as copper amino acid complex [COZC]. At the end of the nursery phase (d 35), one-half of the pigs from each treatment were assigned to 1 of 2 fattening treatments on which they were maintained until the end of the study (d 151): 1) 100 ppm Zn as ZnO [IZ] or 2) 50 ppm Zn as zinc amino acid complex + 50 ppm Zn as ZnO [CZ]. In the nursery, each treatment was replicated 24 times and in fattening, 9 times, with equal numbers of female and male pigs in each pen. Pigs were fed a phase 1 (d 1 to 14), phase 2 (d 15 to 35) and fattener diet (d 36 to 151). In phase 1, ADG and ADFI were increased (157, 130, 233, 202 g/d; $P < 0.05$) and proportion of pigs that needed therapeutic antibiotic treatment decreased (23, 48%; $P < 0.05$) in pigs fed HZCS compared with pigs fed COZC. In phase 2 and in the overall nursery period, ADFI and FCR were lower (646, 703, 467, 519 g/d; 1.47, 1.63, 1.49, 1.60; $P < 0.05$) in pigs fed COZC than pigs fed HZCS. Data were analyzed using the GLM procedure of SAS. No significant ($P > 0.13$) interactions between treatment in nursery and fattening period were observed. From d 131 to 151, ADG was increased (896, 829 g/d; $P < 0.05$) and FCR decreased (2.46, 2.70; $P < 0.05$) in animals consuming CZ compared with IZ. In the fattening period (d 36 to 151), FCR was lower (2.33, 2.41; $P < 0.06$) in pigs fed COZC than in pigs fed HZCS. Overall (d 1 to 151), FCR was decreased (2.22, 2.32; $P < 0.05$) in pigs fed COZC compared with HZCS. High levels of ZnO and $CuSO_4$ were more effective in mitigating negative effects of weaning immediately post-weaning than complexed Zn and Cu. However, supplementing complexed Zn and Cu in nursery improved feed conversion ratio over the entire nursery and fattening period.

Key Words: swine, growth, trace mineral

111 Effects of selenium-enriched exopolysaccharides produced by *Enterobacter cloacae* Z0206 on growth performance, antioxidant status, and immune functions in weaning piglets. Z. Q. Lu*, G. X. Wu, M. Huang, F. Q. Wang, and Y. Z. Wang, *Institute of Feed Science, Zhejiang University, Hangzhou, Zhejiang, China.*

This study was conducted to investigate the effects of Se-enriched exopolysaccharides (Se-Exo, 536 mg/kg Se) on growth performance, antioxidant status and immune functions in weaning piglets. A total of 150 piglets [(Landrace × Yorkshire) × Duroc] weaned at 28 d of age with an initial BW of 8.11 ± 0.12 kg were randomly allocated into 5 groups of 3 replicates each. The 5 treatments were: basal control diet (CON), Na_2SeO_3 diet (CON + 0.30 mg/kg Na_2SeO_3), Na_2SeO_3+ astragalus polysaccharide (APS) diet (CON + 0.30 mg/kg Na_2SeO_3 + 560 mg/kg APS), Na_2SeO_3+ EPS diet (CON + 0.30 mg/kg Na_2SeO_3 + 560 mg/kg EPS) and Se-Exo diet (CON + 560 mg/kg Se-Exo). On d 58, samples were taken for analysis: blood for total antioxidant content (T-AOC), glutathione peroxidase (GSH-Px), superoxide dismutase (SOD), tumor necrosis factor-α (TNF-α), interleukin-6 (IL-6), immunoglobulin G and M (IgG, IgM); liver, jejunum and ileum for gene expression of proline-arginine rich 39-amino acid peptide (PR-39), Hepcidin and porcine β-defensin-2 (pBD-2). Compared with CON group, ADG was enhanced in the Na_2SeO_3+APS, Na_2SeO_3+EPS and Se-Exo groups (+8.9%, +9.9% and + 12.3%, resp., $P < 0.05$) and F:G was decreased (−10.2%, - 8.4 and −10.2%, resp., $P < 0.01$). There were no differences in ADG between pigs fed the Na_2SeO_3+APS, Na_2SeO_3+EPS and Se-Exo diets. The Se-Exo group had higher serum T-AOC (+29.6%), GSH-Px (+25.6%) and SOD (+18.6%) activities than the CON group ($P < 0.05$), and the T-AOC activity in Se-Exo group was higher than the Na_2SeO_3 group ($P = 0.035$). Increases ($P < 0.05$) in serum IgG (+54.0%;), IgM (+56.1%), TNF-α (+61.6%) and IL-6 (+47.5%) were observed in the Se-Exo group compared with the CON. Pigs fed Se-Exo diet had higher PR-39 and Hepcidin gene expression levels in liver ($P < 0.001$) and pBD-2 gene expression levels in jejunum and ileum ($P < 0.05$) compared with the CON group. These results implicated that the combined effects of Se and exopolysaccharide are responsible for the bioactivity of Se-Exo which would be expected to be a new immunopotentiator in weaning piglets.

Key Words: exopolysaccharide, immunity, weaning piglet

112 Effects of chromium-loaded chitosan nanoparticles on growth, carcass characteristics, pork quality, and lipid metabolism in finishing pigs. M. Q. Wang*, Y. D. He, C. Wang, H. Li, S. Y. Chen, W. J. Tao, and S. S. Ye, *Animal Science College of Zhejiang University, Hangzhou, Zhejiang, China.*

Numbers of researches have been conducted to study the effects of Cr from different chemical forms. The study was conducted to evaluate the effects of chromium-loaded chitosan nanoparticles (Cr-CNP) on growth, carcass characteristics, pork quality and lipid metabolism in finishing pigs. A total of 160 barrows (66.1 ± 1.01 kg BW) were randomly divided into 4 groups, each group with 4 pens, 10 pigs per pen. Pigs were fed same basal diet(CP 17.98%, DE 13.2MJ/kg, Lys 1.05%, Met 0.45%)supplemented with 0, 100, 200, or 400 μg/kg Cr from Cr-CNP, respectively. All pigs were given free access to feed and water for 40 d. Average daily gain, feed intake and feed gain ratio were collected. Eight pigs from each treatment were slaughtered to measure carcass lean ratio, longissimus muscle area (LMA), backfat thickness, 45 min pH, Hunter L, a, b value, 24-h drip loss, and some serum parameters and enzymatic activities. The results showed that feed gain ratio of pigs fed supplemental Cr-CNP was decreased ($P < 0.05$). Dietary Cr-CNP increased the carcass lean ratio ($P < 0.01$) and LMA ($P < 0.01$), decreased carcass fat ratio ($P < 0.001$) and backfat thickness (P

< 0.001) with linear and quadratic manner. The 24 h drip loss was linear and quadratic decreased ($P < 0.01$), while 45 min pH value and Hunter L, a, b values in longissimus muscle were unaffected. Supplemental Cr-CNP linearly increased serum free fatty acids ($P < 0.001$), lipase activity ($P < 0.01$) and serum insulin-like growth factor I ($P < 0.01$), while linearly decreased serum insulin ($P < 0.001$). Dietary supplementation of Cr-CNP also linearly decreased activities of fatty acid synthase ($P < 0.01$) and malate dehydrogenase ($P < 0.01$), while increased the activity of hormone-sensitive lipase ($P < 0.05$) in subcutaneous adipose tissue with linear and quadratic manner. The present results suggested that dietary supplementation of Cr as Cr-CNP had beneficial effects on growth, carcass characteristics and pork quality, and positively affected on lipid catabolism in finishing pigs.

Key Words: chromium, carcass characteristics, lipid metabolism

Ruminant Nutrition Symposium: Advancements in Enhancing Cell Wall Digestibility and its Contribution to Improve Ruminant Production

113 Improving cell wall digestion and animal performance with fibrolytic enzymes. A. T. Adesogan*, J. J. Romero, and Z. X. Ma, *Department of Animal Sciences, IFAS, University of Florida, Gainesville.*

The objective of this paper is to summarize published responses to treatment of cattle diets with exogenous fibrolytic enzymes (EFE), to discuss reasons for variable EFE efficacy in animal trials and to recommend strategies for improving enzyme testing and enzyme efficacy in ruminant diets. A review of 24 dairy cow studies with 69 treatments revealed that dietary addition of exogenous fibrolytic enzymes (EFE) increased milk production and feed efficiency 20 and 23% of the time by 2.45 kg/d (7.6% increase) and 0.13 (9% increase) on average, respectively. This variability is attributable to several enzyme, feed, animal, and management factors that will be discussed in this paper. The variability reflects our limited understanding of the synergistic and sequential interactions between exogenous glycosyl hydrolases, autochthonous ruminal microbes and endogenous fibrolytic enzymes that are necessary to optimize ruminal fiber digestion. An added complication is that many of the standard methods of assaying EFE activities may over or underestimate their potential effects if they are based on pure substrate saccharification or if they do not simulate ruminal conditions. Our recent evaluation of 18 commercial EFE showed that 78 and 83% of them exhibited optimal endoglucanase and xylanase activities at 50°C and 77 and 61% had optimal activity at pH 4–5, respectively. Hence, most would not be optimally active under ruminal conditions. Of the many fibrolytic activities that act synergistically to degrade forage fiber, only a few are typically assayed, and of the latter endoglucanase and xylanase typically account for most the variability in fiber digestion. Yet, neither of these can hydrolyze the recalcitrant phenolic acid–lignin linkages that are the main constraints to ruminal fiber degradation. These factors highlight the futility of random addition of EFE to diets. This paper will discuss animal responses to fibrolytic enzymes, advance explanations for the variability in the response and suggest strategies to improve enzyme testing and enzyme efficacy in ruminant diets.

Key Words: fibrolytic enzyme, cow, digestion

114 Effects of neutral detergent fiber concentration and digestion characteristics on energy intake and partitioning of lactating cows. M. S. Allen*, *Michigan State University, East Lansing.*

Neutral detergent fiber (NDF) comprises from less than 28% to more than 40% of dietary dry matter for lactating cows. The concentration and digestion characteristics of NDF in diets affect dry matter intake, digestibility, and energy partitioning and can greatly affect productive performance of lactating cows. Ruminal turnover rate of NDF varies depending upon initial particle size, digestion kinetics and particle fragility. Longer retention time increases digestibility as well as digesta mass and volume. Increased digesta mass in the rumen can reduce risk of ruminal acidosis and abomasal displacement but can also limit feed intake. Signals to brain feeding centers from ruminal distension control feed intake when the drive to eat is high and metabolic control of feed intake is diminished (e.g., cows at peak lactation) while signals derived from metabolism of fuels dominate the control of feed intake when signals from distension decrease (e.g., cows in late lactation). Therefore, NDF turnover rate is an important consideration for diet formulation; a higher turnover rate is desirable when feed intake is limited by ruminal distention. Over half of the ruminal mass of NDF is in particles that are below the threshold size for passage. Ruminal retention of small particles is from entrapment by the pool of large particles in the rumen and passage rate is positively related to particle density. Forage family (e.g., legumes, grasses) and maturity at harvest affect digestion characteristics and ruminal retention time and therefore the filling effect of forages. Non-forage fiber sources (NFFS) contribute little to the filter bed of large particles but function to displace dietary starch. Substitution of fermentable fiber for starch can maintain milk yield while decreasing gain in body condition for cows with lower requirement for glucose. This presentation will discuss the effects of dietary NDF concentration and digestion characteristics on energy intake and partitioning of cows and how they change throughout the lactation cycle.

Key Words: physiological state, digestion kinetics, fiber fragility

115 Nutritional strategies to optimize feeding brown midrib corn silage to dairy and beef cattle. J.-S. Eun*, M. S. Holt, A. J. Young, and D. R. ZoBell, *Department of Animal, Dairy, and Veterinary Sciences, Utah State University, Logan.*

Digestibility of forage fiber affects many aspects of dairy and beef cattle production. In addition, providing adequate concentrations of digestible fiber in cattle ration is essential for animal health, as it is required to support an appropriate rumen function. Brown midrib corn silage (BMRCS) is characterized by its lower lignin concentration and higher fiber digestibility than conventional corn silage (CCS). Several, but not all experiments feeding BMRCS, have reported improved lactational performance of dairy cows. Inconsistent effects of BMRCS have been caused by various factors, including cows differing in physiological state and duration of experiment. Our recent study indicated that feeding BMRCS in high-forage diets can have beneficial effects to lessen body fat mobilization in fresh cows without limiting DMI around peak lactation, resulting in longer peak milk production. Similarly, another lactation study reported that feeding BMRCS during the transition period resulted in increased feed intake for the last 2 wk of gestation as well as the first 3 wk postpartum, leading to an increase in milk yield during the 3-wk postpartum period. When all cows were fed a CCS-based diet, a carryover effect occurred from the feeding of BMRCS during the transition period, resulting in increases in the yields of protein, lactose, and solids in these cows from wk 4 to 15 of lactation. Feeding BMRCS in growth-phase diets of beef steers resulted in increased DMI and improved digestibility of DM and fiber, whereas it did not result in improved ADG compared with those fed CCS. Feeding BMRCS at 24% of diet DM by replacing corn did not negatively affected growth rates in finishing beef cattle, implying that feeding BMRCS in a relatively higher dietary concentration can be a cost-effective alternative method to raising beef. Understanding interactive effects of dietary sources of fiber with BMRCS at various dietary proportions, physiological conditions of animals, and control of feed intake is needed to optimize potential benefits of feeding BMRCS in cattle diets.

Key Words: brown midrib corn silage, growth performance, lactational performance

116 The utility of lipid extracted algae as a protein source in forage or starch-based ruminant diets. S. L. Ivey* and L. N. Tracey, *New Mexico State University, Las Cruces.*

Microalgae are unicellular organisms that live and reproduce in many forms of water and use sunlight, CO_2 and added nutrients to produce carbohydrates, proteins and lipids. Algal biomass has shown many different advantages as a feedstock for the biofuel industry, including: (1) high biomass yield per unit cultivation; (2) minimal competition for land used for traditional agriculture; (3) uses various water sources such as waste, saline, and produced water; and (4) biomass from algae could potentially produce both fuel and valuable co-products. Co-products resulting from the algal biofuel industry may be a source of protein for ruminant livestock. It is widely recommended that the algal biofuel industry not trivialize co-product value but consider it an additional source of revenue in an effort to gain industry sustainability and food security in the US by using geographic areas and resources not used for traditional food production. The cattle industry consumes approximately 40 million tons of protein feeds annually; therefore, the potential exists for the ruminant feeding industry to be a consistent, large-volume outlet for high protein algal co-product. In addition to proteins and lipids microalgae utilize photosynthesis to produce carbohydrates. Carbohydrates are used for energy storage and structure by the algal cell and the types of carbohydrates present are species-dependent but may include cellulose, glycogen, starch and other monosaccharides. The algal biofuel industry will potentially use a variety of algal strains, growth conditions, and harvesting and oil extraction methods. All of these factors may influence the utility of the final co-product. This presentation will address ongoing research to evaluate LEA produced from various algal strains, cultivation methods, and harvesting and extraction protocols. Currently, oil extraction protocols coupled with multiple algal strains have yielded inconsistent coproduct that ranges in protein from 15 to 50%, 3 to 47% ash and an uncharacterized carbohydrate fraction.

Key Words: ruminant, algae, biofuel

117 Dietary protease increases amino acid digestibility of various proteinaceous feedstuffs in growing pigs. J. Escobar*, J. Lunnemann, J. Xue, K. Eckert, N. Odetallah, and M. Vazquez-Añón, *Novus International Inc., St. Charles, MO.*

Supplementing diets with an exogenous protease to increase amino acid (AA) digestibility may be used to reduce feed cost, decrease protein fermentation in the hindgut, or both. The objective of this study was to quantify apparent ileal AA digestibility (AID) in soybean meal (SBM), corn-derived distillers dried grain with solubles (DDGS), meat and bone meal (MBM), and poultry byproduct (PBP) without or with exogenous protease (Cibenza DP100 at 500 ppm, PROT). Eight growing barrows (initial BW: 56.1 ± 0.6 kg) were individually housed and surgically fitted with a simple T-cannula in the distal ileum. The test order of feedstuffs was randomized and they were the only source of AA in each diet, which included 0.4% of TiO_2 as an indigestible marker. For each feedstuff, pigs were randomly allotted to a 2-period crossover design to give n = 8 per diet. Each independent feedstuff trial consisted of 5 d of diet adaptation and 2 d of ileal digesta collection. Results indicate that supplementation with PROT increased AID of Arg, Cys, His, Ile, Leu, Lys, Met, Thr, Phe, and Val in PBP ($P < 0.04$) and SBM ($P < 0.006$). In DDGS, PROT increased ($P < 0.05$) AID of Cys, Leu, Met, Thr, Phe, and Val, as well as, Lys ($P = 0.06$) and Ile ($P = 0.08$). In MBM, PROT increased AID of Met ($P = 0.04$), Lys ($P = 0.06$), Leu and Thr ($P = 0.07$), and Arg ($P = 0.08$). Results from a meta-analysis of the 4 independent trials indicate that PROT supplementation increased ($P < 0.05$) AID of Ala, Arg, Cys, Glu, Ile, Leu, Lys, Met, Ser, Thr, Phe, and Val, as well as Asp ($P = 0.08$) and Gly ($P = 0.10$). The increase in percent AID points was 6.2 for Lys, 5.8 for Met, and 7.6 for Thr. Collectively from these results, it can be concluded that PROT is an effective protease that increases in vivo AA digestibility of animal- and plant-derived proteinaceous feedstuffs.

Key Words: enzyme, amino acid digestibility, swine

118 Protease and carbohydrase supplementation increased carcass weight and profit of finishing pigs. J. Escobar*, Y. Ma, N. Odetallah, and M. Vazquez-Añón, *Novus International Inc., St. Charles, MO.*

Inclusion of alternative ingredients and byproducts is a viable strategy to reduce the cost of diets. However, the combination of lower digestible ingredients and their higher content of anti-nutritional factors (e.g., fiber) compared with a corn-soy diet may contribute to reduce growth performance, carcass weight, and profit. The objective of this study was to evaluate the effect of enzyme supplementation of corn (TYP) and wheat (ALT) based diets with dietary protease and carbohydrases (Cibenza DP100 and Cibenza CSM, respectively, NZ) on growth performance, carcass weight, and profit. All diets contained 30% corn-derived DDGS and were formulated to contain equal content of ME and standardized ileal digestible amino acids. Barrows (TR-4 × C-22, PIC, Hendersonville, TN; 144 in total) were housed 2/pen and had free access to feed and water at all times. After a 7-d acclimation period, pigs were weighed (84.8 ± 2.9 kg BW) and randomly assigned to a 2 × 2 factorial arrangement of treatments in a complete randomized block design with n = 18 per treatment. Pigs were fed in 2 phases for 21 and 20 d each, and then transported to a commercial harvesting facility. Data were analyzed using the mixed procedure (SAS Institute, Cary, NC). Diet type or NZ inclusion had no effect ($P = 0.15$ to 0.71) on dressing percent, lean content percent, jowl iodine value, or last rib loin and backfat depths. No diet*NZ interactions were found ($P = 0.11$ to 0.92) for growth performance or carcass traits. A diet*NZ interaction ($P = 0.006$) was found for fecal DM content. Thus, NZ increased fecal DM in TYP but had not effect on ALT diets. Inclusion of NZ increased final body weight (+1.7%, $P = 0.001$), ADG (+6.3%, $P < 0.001$), ADFI (+1.9%, $P = 0.05$), GF (+2.7%, $P = 0.03$), hot carcass weight (HCW, +1.8%, $P = 0.009$), HCW-ADG (+5.6%, $P = 0.002$), HCW-GF (+4.3%, $P = 0.006$), carcass income (+5.6%, $P = 0.002$), and income-over-feed (+19%, $P = 0.03$) compared with CON. In conclusion, dietary enzyme supplementation can be a viable solution to increase growth performance, carcass weight, and profitability of swine enterprises.

Key Words: enzyme, growth performance, swine

119 Causes of in-transit losses of pigs. K. Zurbrigg*[1] and A. van Dreumel[2], [1]*Ontario Ministry of Agriculture, Food and Rural Affairs, Elora, ON, Canada,* [2]*Animal Health Laboratory, University of Guelph, Guelph, ON, Canada.*

The cause of death for hogs that die in transit to a packing plant is an economic and welfare concern to producers, transporters, abattoirs and consumers. The increase in shipping mortalities observed during the summer months in Canada and the United States is commonly attributed to heat exhaustion or heat stress. However few studies have identified the specific cause of death for these hogs. The objective of this study is to determine if there are underlying physiologic risk factors that predispose a market hog to death during transport to slaughter. Post-mortems on 62 hogs that died in transit were completed at the abattoir or at the Animal Health Laboratory, University of Guelph. Fifty hearts were collected from hogs that did not die in transit. Each heart was examined blindly by one veterinary pathologist (TVD) grossly and histologically. Heart weights for hogs that died in transit were compared with the controls. Heart failure was the cause of death for 68% (42/62) of the hogs that died during transport. Heart lesions were chronic in nature. In 21% of the hogs, the only findings on gross post-mortem examination were pulmonary congestion and edema of the lungs. In 11% of the hogs, lesions unrelated to heart failure were identified (e.g., respiratory or gastrointestinal disease, fractures). No lesions were found on the gross examination of the control hearts. Average total heart weight for hearts with lesions (451.50 g ± 63.33) was greater than hearts without lesions (380.75 g ± 40.27) ($P = 0.0001$). Final analysis of histologic results is pending. Compared with most other mammals, a pig's heart is small in relation to its body size (Friendship and Henry. 1998. Cardiovascular system, hematology and clinical chemistry. Pages 3–5 in Diseases of Swine. 7th ed.). As a result, hearts with compromised function have little reserve capacity to respond to challenges. The compensatory hypertrophy of defective hearts resulted in greater heart weights. In this study the majority of hogs that died in transit had a pre-existing cardiac abnormality resulting in hogs that were unable to survive standard transport practices.

Key Words: transportation, swine, death

120 Effect of pig insemination technique and semen preparation on profitability. D. Gonzalez-Pena*, N. V. L. Serão, J. Pettigrew, R. Knox, and S. L. Rodriguez-Zas, *University of Illinois at Urbana-Champaign, Urbana.*

Intrauterine (IUI) and deep intrauterine (DUI) artificial insemination (AI) require lower boar semen counts compared with conventional (CON) AI. Fresh (FRE) or frozen (FRO) semen preparation and AI technique affect boar utilization efficiency and selection pressure, genetic dissemination, and biosecurity. The combined effect of 3 AI techniques and 2 semen preparations on the net profit of a pig crossbreeding system was evaluated. A 3-tier system was simulated starting with the cross of nucleus breeds A and B (500 sows/breed) that generated 200,000 AB sows at the multiplier level. The AB sows were mated to breed C terminal boars (from 500 nucleus sows) at the commercial level resulting in 4,500,000 weaned pigs/year. The combinations of preparation and techniques were represented by distinct boar:sow ratios in the AB x C cross. To understand the effects of technique and preparation, the ZPAN simulation assumed 2.1 semen doses/estrus, 2.25 farrowings/year, 50 collection/boar/year, 3 sperm counts (CON = 3×10^9, IUI = 1×10^9 and DUI = 15×10^7). Sow stayability ranged from 1 year (nucleus) to 3 years (commercial) and involuntary culling was 32%. A range of farrowing rates (75–85%) and number of piglets alive/litter (9–12) was tested. A significant ($P < 0.0001$) improvement in the average net profit was observed in FRO (and FRE) from CON to IUI by 12.6% (4.0%) and to DUI by 17.8% (6%). There was a significant ($P < 0.0001$) reduction on the average cost in FRO (and FRE) from CON to IUI by 6.6% (3.3%) and to DUI by 9.4% (4.5%). Lower total costs in IUI and DUI were driven by lower fixed costs (60%) across preparations. The variable cost of boar maintenance decreased from CON to IUI and DUI by 66% and 95%, respectively across preparations. The variable cost of sow increased for FRE (and FRO) from CON to IUI by 8.56% (4%) and to DUI by 15% (7%). Synergistic effects of AI technique and semen preparation on the net profit of pig crossbreeding systems (−0.94 $/sow for CON, 0.24 $/sow for IUI, 0.70 $/sow for DUI, 0.95 $/sow for FRE, and −0.95 $/sow for FRO) were demonstrated.

Key Words: intrauterine insemination, deep uterine insemination, fresh semen

121 Use of exogenous hormones on estrus synchronization and the reproductive life of female pigs. L. J. Parazzi*[1], T. A. Del Santo[1], A. Arruda[2], S. M. M. K. Martins[1], A. F. C. Andrade[1], and A. S. Moretti[1], *[1]University of São Paulo (FMVZ-VNP), Pirassununga, São Paulo, Brasil, [2]University of Guelph, Guelph, Ontario, Canada.*

Estrus induction and synchronization in gilts using exogenous hormones can bring advantages to the productive life of the female. The objective of this study was to evaluate the use of exogenous gonadotropins before puberty and its effects on the reproductive life of the female until the seventh parity. Ninety-six hybrid gilts from a commercial herd were enrolled in this study. The mean age, weight and backfat thickness were 152.42 ± 4.46 d, 99.83 ± 8.12 kg and 11.90 ± 3.06 mm, respectively. The experimental design was a randomized trial with 2 treatments: use of an intramuscular injection of 600 IU of eCG (Novormon, Sintex S.A., Argentina) followed by an intramuscular injection of 2.5 mg of porcine LH (Lutropin Vetrepharm Canada Inc., Canada) 72 h later (Treatment H) and male stimuli only (Treatment M). Diet composition met NRC (1998) recommendations and was based on corn and soybean meal. Estrus was recorded for both groups until first artificial insemination. Data were collected through a computer program in place in the herd (Pig CHAMP software). A higher percentage of synchronization of estrus was observed on group H compared with group M ($P > 0.05$). There was no effect of treatment on litter size, number of piglets born alive, number of stillbirths or number of mummified fetuses ($P > 0.05$). There was a tendency effect for treatment H to farrowing interval ($P = 0.069$), with a lower value observed for this group. In conclusion, the use of exogenous hormones in gilts does not affect the productivity of the female regarding litter size; however it might bring advantages regarding number of non-productive days and facilitate female introduction in the sow herd.

Key Words: exogenous gonadotropin, longevity, productivity

122 Gestational heat stress alters postnatal thermoregulation. J. S. Johnson*[1], M. V. Sanz-Fernandez[1], S. K. Stoakes[1], M. Abuajamieh[1], J. W. Ross[1], M. C. Lucy[2], T. J. Safranski[2], R. P. Rhoads[3], and L. H. Baumgard[1], *[1]Department of Animal Science, Iowa State University, Ames, [2]Division of Animal Sciences, University of Missouri, Columbia, [3]Department of Animal and Poultry Sciences, Virginia Polytechnic Institute and State University, Blacksburg.*

Gestational heat stress (GHS) is a teratogen that negatively affects development in a variety of species, but how it alters postnatal thermoregulation is not well-understood. Study objectives were to characterize postnatal thermoregulation indices in pigs from differing in-utero thermal environments. First-parity gilts (n = 13) were exposed to 1 of 4 ambient temperature treatments [HS (cyclic 28 to 34°C) or TN (18 to 22°C)], applied for the entire gestation (HSHS; TNTN), the first half (HSTN), or second half (TNHS) of gestation. Of the resultant offspring, 24 barrows (30 ± 3 kg BW; n = 6 HSHS, n = 6 TNTN, n = 6 TNHS, n = 6 HSTN) were housed at the ISU Zumwalt Climactic Chambers in TN (21.7 ± 0.7°C) conditions and then exposed to 2 separate but identical HS periods (HS1 = 6 d; HS2 = 6 d; cycling 28 to 36°C). Core body temperature (T_{core}) was assessed hourly using Thermochron iButtons (Dallas Semiconductor), surgically implanted in the intraperitoneal cavity. Respiration rate (RR) was measured daily (0800, 1300, 1600, 2000 h). In TN conditions, all GHS pigs had elevated ($P < 0.01$; 0.35°C) T_{core} compared with TNTN pigs. Regardless of gestational treatment, both RR and T_{core} increased from TN to HS periods ($P < 0.01$; 61 bpm and 0.70°C, respectively). During HS1, HSHS and HSTN pigs had increased T_{core} ($P < 0.01$; 0.30 and 0.39°C, respectively) compared with TNTN pigs, and tended to have increased T_{core} compared with TNTN during HS2 ($P < 0.08$; 0.25°C). No gestational area under the T_{core} response curve differences were detected in either HS period ($P > 0.80$). No gestational differences were detected for either ADG or feed intake. In summary, pigs originating from in-utero heat stress (especially the first half of gestation) had increased T_{core} compared with controls, and this magnitude of differential was maintained in both TN and HS conditions. This suggests that in-utero HS increases (0.33°C) the thermoregulatory set-point, but how this influences whole body bioenergetics remains unknown.

Key Words: gestational heat stress, pig, thermal imprinting

123 Comparison of cathelicidin expression, cytokine and gut microbes between Jinhua and Landrace pigs experimentally challenged with *Escherichia coli* K88. Y. Gao*[1,2], X. Huang[1,2], H. Yi[1,2], Y. Rong[1,2], and Y. Wang[1,2], *[1]Institute of Feed Science/College of Animal Science, Zhejiang University, [2]Key laboratory of Animal Nutrition and Feed Science, Ministry of Agriculture, Hangzhou, China.*

This study was conducted to determine the possible role(s) of cathelicidins in the porcine immune system by comparing the cathelicidin expression, cytokine, gut microbes between Chinese Jinhua pigs and European landrace experimentally challenged with *Escherichia coli* K88. The *E. coli* challenge resulted in decreased growth rate and increased diarrhea rate in both breeds. Average daily gain (ADG) of Jinhua and Landrace pigs decreased by 25% and 28.6%, respectively. The ADG of Jinhua

pigs was significantly higher ($P < 0.05$) compared with Landrace pigs post-challenge. However challenged Jinhua pigs showed relatively lower rates of diarrhea compared with those in Landrace. Pigs challenged with *E. coli* showed different levels of expression for PR-39 and protegrin-1 between the 2 breeds examined. Jinhua pigs had a higher level of PR-39 in the bone marrow and spleen post-challenge compared with Landrace ($P < 0.05$). Additionally, pro-inflammatory cytokines were induced, while anti-inflammatory cytokines (IL-4 and IL-10) were attenuated in all challenged pigs. Jinhua pigs had significantly higher IFN-γ, IL-6 and IL-10 levels, but lower TNF-α and IL-4 levels compared with Landrace post-challenge. Moreover, *E. coli* challenge significantly increased the colonic quantity of *E. coli* in both breeds, and challenged Landrace had higher quantity of colonic *E. coli* compared with Jinhua pigs ($P < 0.05$). Our findings revealed that porcine cathelicidin expression could be upregulated by *E. coli* challenge, indicating that endogenous cathelicidin expression may relate to disease resistance in pigs. Jinhua pigs exhibited higher level of cathelicidins and were associated with higher growth rate, lower diarrhea rate and colonic *E. coli* number post-challenge compared with Landrace, which were probably due to Jinhua pigs had higher disease resistance and were less susceptible to *E. coli* challenge. These results, in concert with the antibacterial properties of cathelicidins, suggest that they may play a crucial role in porcine immune responses to bacterial infection.

Key Words: cathelicidin, *Escherichia coli* K88, Jinhua pigs

124 Whole-genome association analysis for feed efficiency traits in Duroc pigs. S. Jiao*[1], J. Cassady[1], C. Maltecca[1], K. Gray[2], and J. Holl[2], *[1]North Carolina State University, Raleigh, [2]Smithfield Premium Genetics, Roanoke Rapids, NC.*

Improvement of feed utilization is expected to significantly increase efficiency of production given that feed costs represent the largest variable cost in pork production. The objective of this study was to identify genomic regions associated with variation in feed efficiency and its component traits in a Duroc terminal sire population. Traits analyzed were ADFI (Average daily feed intake), ADG (Average daily gain), FCR (Feed conversion ratio) and RFI (Residual feed intake). Individual feed intake and serial pig body weights were recorded using the FIRE system on 1047 individuals. Feed intake data were edited by linear mixed model to adjust errors of individual visits to the feeders. Subsequent measures were estimated from both linear and robust regression. Genotyping was performed using Illumina PorcineSNP60K Bead Chip. After quality control 40,008 SNPs remained for analysis. Missing SNP genotypes were imputed for all available boars (n = 1022) with pedigree information. Single trait association analyses were performed using a Bayes-B model. The proportion of phenotypic variance explained by markers was 0.268 for ADFI, 0.175 for ADG, 0.187 for FCR and 0.076 for RFI. Significant regions were identified by using 3 different significance tests; posterior windows variance, Bayes factor and bootstrapping. Significance was declared for regions where tests significance overlapped. Regions associated with ADFI were mapped to chromosome 1 and 10. Similarly, regions associated with ADG mapped to chromosome 1, 4, 11, and 14. A significant region was found for FCR on chromosome 4 while no QTL were identified for RFI. In conclusion, we have identified several genomic regions associated with traits affecting nutrient utilization that could be considered for future genomic prediction to improve feed utilization.

Key Words: genomics, Duroc, feed efficiency

Teaching/Undergraduate and Graduate Education Symposium: Graduate Education in a Shifting Research Landscape

125 Mentoring graduate students for success in a shifting research landscape. R. Randel*, *Texas A&M AgriLife Research, Overton.*

The purpose of the educational process for graduate students is to develop scientists and educators who will be successful in their area of expertise. They must be capable of creating new knowledge and be able to impart this knowledge to appropriate end users. The research landscape is always shifting as economic change occurs and the technology of today will be replaced with new technology tomorrow. The scientific method will remain constant through technological and economic change. Scientists and educators grounded in the fundamental sciences as well as application to agriculture will remain in demand and will be successful in this shifting research landscape. Students require a blending of fundamental science with application to agriculture. Each student is a unique individual and will need a program designed to eliminate weaknesses and to amplify strengths. For animal agriculture each student must have a background in statistics and biochemistry. These 2 fundamental sciences should be included early in the educational process. It is never too early to involve a student in their own research. Early ownership of research data and with use of the scientific process is crucial for future success. Each graduate student should be involved in collaborative and interdisciplinary research. To be successful in a shifting research landscape requires having the ability to work and collaborate across disciplinary lines. With a well-designed program emphasizing fundamental science and use of the scientific method supported by understanding the application of science to agriculture, graduate students will have the tools needed to become successful in the shifting research landscape.

Key Words: mentoring, graduate student

126 Adjusting to the other side of the table: Experiences as a newer mentor. B. J. Bradford* and L. K. Mamedova, *Kansas State University, Manhattan.*

Effective graduate student mentoring is a crucial but under-recognized component of launching a research program. Advice for new faculty members is typically focused on research topics, teaching methodology, extension programming, and grant writing, and with the many tasks facing a new faculty member, mentoring can too easily be forgotten. However, effective mentoring is critical to student success, program visibility, and new student recruitment. Mentoring graduate students often requires a delicate balance between conflicting goals: providing guidance while fostering independence, offering broad experiences without loss of focus, and identifying weaknesses while building confidence. In our experience, striking the right balance is aided by some key practices, which we have learned through mistakes as much as success. First, the fit of a prospective student in the group must be considered, rather than selecting students based on academic merit alone; this can be a particular challenge for new faculty members who may not have lots of applicants. Second, expectations should be as clear as possible. Often students transitioning from BS to MS programs, or even from MS to PhD programs, fail to fully grasp the differences. Third, mentors must have adequate availability to provide constructive and timely feedback. This can be accomplished in a variety of ways, and we rely on both technology and team mentoring to help address this challenge. Finally, graduate training should develop "soft skills" in addition to technical knowledge. Research projects can offer excellent opportunities to develop abilities in personnel management, task/time management, communication skills, conflict resolution, and professional networking that will serve students well regardless of their career path. Key to all of these is a mindset that, while the graduate student is responsible for contributing to the research program, the mentor is also responsible for helping the student to grow personally and professionally. Despite its many challenges, mentoring is one of the most rewarding aspects of a professorial career if it is approached as a worthwhile endeavor.

Key Words: graduate education, mentorship, training

127 Making the transition from academia to industry researcher: Perspectives on similar and unique skill sets. A. E. Wertz-Lutz*, *ADM Alliance Nutrition, Quincy, IL.*

The objective of this presentation is to discuss skill sets that are similar and those that are unique to conducting research in an academic setting compared with an industry setting. Animal agriculture is dynamic, and with recent changes in the landscape of animal agriculture research, opportunities have arisen for suited individuals to transition from research in an academic to an industry environment. Making the transition from academic to industry research requires careful consideration. Evaluation of career goals, innate skills, and intended purpose are essential to making an informed decision and having a smooth transition. Additional factors such as opportunities for collaboration, expectation for research outcomes, and potential for research impact should all be considered when making a move from academic to industry research. The fundamental skills of written communication, sound experimental design, proper use of controls, ethical interpretation of the resulting data, and integrity are common to research in both an academic and industry setting. Beyond the commonality of these fundamentals, research within an industry setting has the added facet of interfacing with the business front. Issues such as product commercialization, compliance and regulatory, ethical use of science in marketing, and return on invested capital begin to emerge when taking a demonstrated biological response to marketable product. Strong interpersonal communication skills are needed to bridge the gap between business and research within an industry setting. Factors such as securing research funding, travel expectations, work pace, research focus, confidentiality, and student mentoring differ between research in the academic compared with industry setting. This presentation is intended to compare and contrast the role of academic and industry researcher, and to provide, based on personal experience, some guidance to current graduate students weighing the option of an academic or industry career with an advanced degree in animal science.

Key Words: Academic research, industry research, skill sets

128 An undergraduate research experience: Team dynamics and mentoring. B. J. Bequette*, *University of Maryland, College Park.*

The undergraduate research experience often exposes students to their first opportunity to see the scientific process up close. This first-time exposure can have a lasting impact on student's career options, and so the process should be designed carefully to instill a sense of research ownership and accomplishment by students, and the value of their

research to current and future societal issues. The Gemstone Program at the University of Maryland is a multidisciplinary 4-year research program for undergraduate honors students of all majors. Under guidance of faculty mentors and Gemstone staff, teams of students (6–15) design, direct and conduct research exploring the interdependence of science and technology with society. As freshman, students learn to explore current topics in science, technology and society, and the essentiality of team building to research success. During the year, students naturally migrate around a topic of mutual interest. In sophomore year, teams meet with their selected mentor when the process of teaching the scientific process begins in earnest for the mentor. As a mentor, patience is essential to guiding the team. Guiding the team toward a testable hypothesis and well-defined and achievable objectives must be step by step. To ensure team ownership, mentors should resist leading the team too far from their initial interests. As sophomores, students have yet to take courses that fill their heads with the basic knowledge required to write their proposal and initiate experimentation. Thus, the mentor should make use of the limited, yet valuable, time in team meetings to lecture, teach and discuss basic concepts and current literature. Take every opportunity to encourage and engage all team members; leave no student behind. Team and experimental challenges will arise, as they often do in research, and so mentors must use these instances as teaching moments of the essentiality of teamwork and the realities of conducting research. In the fourth year, teams present their research in the form of a thesis to experts selected by the students, and the students complete the program with a citation and a sense of accomplishment.

Key Words: undergraduate, research, mentoring

129 Effective personal development planning for scientists and graduate students. B. Rittgers*, *Elanco Animal Health, Greenfield, IN.*

Effective Development Planning is paramount in all aspects of business and academia as the workforce evolves and people are looking to grow professionally and personally. The saying "Help them Grow or Watch them Go" could not be more true. Effective Development Planning does not happen for a variety of reasons. These may include individuals not knowing what aspects of their scientific or transferable skill set to develop. (A lack of coaching and feedback); skill development and career planning are looked at separately or not at all. Personal development planning may be nothing more than a "check the box" exercise. No accountability on the part of students/scientists or supervision to prioritize development planning. Emphasis is put on class room training versus relationships and experiences to drive development; in other words, the 70–20–10 Principle of Effective Development is not followed. The 70–20–10 Principle was developed by the Center for Creative Leadership. The concept is based on findings that personal development occurs from 70% Experience: On the job experiences of in-place assignments that allow individuals to utilize and grow the aspects of performance or skills needed for success. These can happen on the job (55%) or through off-the-job experiences (15%) in the community, industry affiliations or faith based organizations; 20% Relationships: Relationships that provide individual feedback, coaching, personal insights and mentoring contribute to 20% of development; 10% Training: Although most prevalent when planning for development, training only contributes to 10% of actual development. To be sure, it is important but true development comes most frequently from experiences and relationships. Development Planning should be done around the congruence of personal interest and growth needs and the business or academic needs of the larger organization. By assessing and understanding the needs of both, individuals can develop a good balance of development that will help them develop their careers as well as further the goals of their organizations.

Key Words: development, coaching, training

Breeding and Genetics: Applications and Methods in Animal Breeding—Dairy I

130 The correlation analysis between Holstein body conformation traits and milk production traits in the Shanghai region. K. Zhu[1,2], G. L. Liu*[1,2], L. M. Huang[1], C. B. Zhang[2], and F. S. Fu[2], *[1]State Key Laboratory of Dairy Biotechnology, Shanghai Bright Holstan Co. Ltd., Shanghai, China, [2]Shanghai Dairy Breeding Center Co. Ltd., Shanghai, China.*

The objective of this study was to analyze the correlation between Holstein body conformation traits and milk production traits in the Shanghai region. In total, 871 Holstein cows were randomly chosen from 28 dairy farms in Shanghai at second stage of lactation as the object of our study. Five milk production traits, including 305-d milk yield, butter fat percentage, milk protein percentage, peak lactation days and peak milk production were obtained from dairy Herd Improvement (DHI) project of Shanghai Dairy Breeding Center. The quantitative values of 7 body conformation traits were recorded by 9-point methods and the model of multiple linear regressions was used here to analyze the correlation between the body conformation traits (as independent variable) and the milk production traits (as dependent variable). The results showed that the total score of body conformation were extremely significantly positively correlated with the 305-d milk yield, butterfat percentage, Peak milk production ($P < 0.01$), significantly positively correlated with the peak lactation days ($P < 0.05$), and weak correlation with the milk protein percentage (not significant). The body hindquarters capacity was significantly positively correlated with the milk yield. The cow hoofs character was extremely significantly positively correlated with the peak milk production, the butterfat percentage, and the milk protein percentage; and was significantly positively correlated with milk yield. The hip character was significantly positively correlated with the butterfat percentage. The lactation system and udder traits were significantly positively correlated with the peak lactation days. We concluded that the body hindquarters capacity, the hoofs character, the hip character, the lactation system and udder traits were the most important factors that influenced the milk production traits of Holstein cows. The identification and scoring of body conformation traits might provide significant guiding on screening high-yield, excellent producing Holstein cows as well as selection and assortative mating.

Key Words: Holstein cow, body conformation trait, milk production trait

131 Heterosis and effect of breed proportion for milk production traits in crosses between Danish Holstein, Danish Red, and Danish Jersey. E. Norberg*[1], K. Byskov[2], and M. Kargo[1,2], *[1]Centre for Quantitative Genetics and Genomics, Department of Molecular Biology and Genetics, Aarhus University, Tjele, Denmark, [2]Knowledge Centre for Agriculture, Agro Food Park 15, Aarhus N, Denmark.*

During the last decade the use of systematic crossbreeding in dairy cattle herds has been increasing in Denmark. The aim of this study was to estimate the effect of breed proportion and heterosis on milk production traits. The study was based on records on milk yield (MY), protein yield (PY) and fat yield (FY) from 52,165 first lactation cows born in 2004 or later from 104 herds using systematic crossbreeding. More than 50% of the cows were crosses between Danish Holstein (DH), Danish Red (DR) and /or Danish Jersey (DJ) and the remaining were pure DH, DR or DJ. Cows with less than 45 DIM and/or a calving age below 18 or above 40 mo were omitted. The statistical model included a fixed effect of herd-year and calving month, a regression on calving age, a regression on the proportion of DH, DR and DJ genes, a regression on the degree of heterozygosity between DH and DR, DH and DJ and DR and DJ, a random genetic effect of the cow and a residual. Data was analyzed using AI-REML in the DMU package. The effect of breed proportions was estimated relatively to a pure DH. For MY, a pure DR was estimated to give 259 kg less than a pure DH, while a pure DJ gave 1838 kg less than a pure DH. For PY there was no significant difference between DH and DR. Danish Jersey produced 40 kg less PY than DH and 35 kg less than DR. There was no significant effect of breed proportion for FY between the 3 breeds. Heterosis was significant in all combination of breeds for all 3 milk production traits. Heterosis for crosses between DH and DR was estimated to 177 kg, 5.8 kg and 8.4 kg for MY, PY and FY, respectively. Corresponding figures for crosses between DH and DJ was 320 kg, 13.4 kg and 17.5 kg, while crosses between DR and DJ gave heterosis estimates of 380 kg, 14.3 kg and 20.2 for MY, PY and FY, respectively. The results obtained in this study demonstrate the existence of heterosis on milk production traits in crosses between the 3 Danish dairy breeds.

Key Words: heterosis, breed effects, milk production

132 Genetic parameters for body condition score and body weight in Canadian Holsteins. A. Sewalem*[1], R. Cue[2], K. Wade[2], H. Delgado[2], D. Lefebvre[3], R. R. Lacroix[2], J. Dubuc[4], and E. Bouchard[4], *[1]Agriculture and Agri-Food Canada, Guelph, ON Canada, [2]Department of Animal Science, McGill University, Montreal, QC, Canada, [3]Department of Research and Development, Valacta, Centre d'Expertise en Production Laitière, Bellevue, Québec, Canada, [4]University of Montreal, St-Hyacinthe.*

The objective of this study was to characterize and determine the association between body weight (BW) and body condition score (BCS) in Canadian dairy Holsteins. Body weight was calculated from a heart girth circumference measurement and then converted to an estimated body weight (kg). A total of 75,443 BW and 22,899 BCS records were obtained from first lactation first records of Holstein cows that calved between 2002 to 2008. The average BW was 601.6 ± 34.1 kg. Body condition score was recorded by producers using a subjective scale of 1 to 5 (0.13, 16.51, 72.35, 10.79, and 0.23%, respectively). The data were analyzed using a multiple-trait animal model, including fixed effects for herd, calving year, calving season, age at first calving; linear and quadratic regressions of days in milk; and random effects for animal and residual. The data was analyzed using DMU software. Results yielded a heritability for BW and BCS of 0.19 ± 0.01 and 0.17 ± 0.16, respectively. The genetic and residual correlations between BW and BCS were low (0.195 ± 0.06 and 0.23 ± 0.01, respectively). A subsequent analysis of these data will be carried out using a random regression approach by including all available records.

Key Words: body weight, body condition score, genetic parameter

133 Lactation profile and genetic parameters of locomotion score and lameness in dairy cattle. A. Kougioumtzis[1], G. E. Valergakis[1], G. Oikonomou[1,2], G. Arsenos[1], and G. Banos*[1,3], *[1]Faculty of Veterinary Medicine, Aristotle University of Thessaloniki, Thessaloniki, Greece, [2]College of Veterinary Medicine, Cornell University, Ithaca, NY, [3]SRUC/Roslin Institute, Edinburgh, UK.*

Lameness greatly concerns the dairy cattle industry because of its high prevalence and associated costs. This study aims to investigate the profile and genetic parameters of lameness before and after calving and throughout lactation in primiparous Holstein cows. The study was carried out in a large commercial in Greece and included 237 cows that calved between 2008 and 2010. Cows were locomotion scored weekly on a 5-point scale, starting 6 weeks before calving and throughout lactation. Cows with a score greater than or equal to 2 were considered lame. These records were matched with weekly body condition score, liveweight and milk yield. Total number of repeated records amounted to 9,643. Traits were analyzed with bivariate random regression models that included the effects of year-season of calving, country of origin, calendar month, barn, calving age, a fixed regression on week from calving, and random regressions on week from calving associated with the additive genetic profile and the permanent environment of cow. Fixed curves for the 2 traits illustrated an increase in their relative levels up to mid-lactation. Weekly estimates of genetic variance were highest before calving and during the 4 weeks following calving and then decreased gradually; all estimates were statistically greater than zero ($P < 0.05$) demonstrating the presence of genetic factors that control the animal's capacity for uninhibited movement and resistance to lameness. Consistent with the genetic variance, heritability estimates were highest before calving and decreased with lactation stage; average estimates were 0.39 ± 0.06 and 0.26 ± 0.06 for locomotion score and lameness, respectively. Statistically significant ($P < 0.05$) genetic correlations were found of weekly locomotion score and lameness with body condition score ranging from -0.31 to -0.65 and from -0.44 to -0.76, respectively. It is concluded that locomotion score and lameness are amenable to improvement with genetic selection and body condition score can be used as an auxiliary trait for this purpose.

Key Words: genetics, locomotion, lameness

134 Multi-trait analysis of bovine leukosis incidence, somatic cell score, and milk yield in US Holstein cattle. E. A. Abdalla*[1], G. J. M. Rosa[1], K. A. Weigel[2], and T. Byrem[3], *[1]Department of Animal Sciences, University of Wisconsin-Madison, Madison, [2]Department of Dairy Science, University of Wisconsin-Madison, Madison, [3]Antel BioSystems Inc., Lansing, MI.*

Bovine leukosis (BL) can be defined as a retroviral disease caused by the bovine leukosis virus (BLV) which affects only cattle. Positive BL dairy cows produce less milk and have more days open compared with those that are negative. In addition, the virus also affects the immune system and causes a weak response to vaccines in infected animals. The objectives of this study were to estimate the heritability for BL incidence and its genetic correlations with BL, milk yield (MY) and somatic cell score (SCS). Results of a commercial ELISA assay used to detect BLV antibodies in milk samples were obtained from Antel BioSystems Inc. (Lansing, MI). The data included continuous milk ELISA scores and binary milk ELISA diagnosis as well as MY and SCS for 11,554 cows from 112 dairy herds across 16 US states. Continuous and binary ELISA results were analyzed jointly with MY and SCS using linear and threshold animal models, respectively. Estimates of heritability obtained with the 2 approaches were very similar and around 8%, indicating that there is a non-negligible genetic component underlying BL disease incidence. Estimated genetic correlations of BL incidence with MY were 0.14 and 0.17 using the threshold and linear model, respectively, whereas with SCS such correlations were 0.17 and 0.20. In summary, results of this study indicated that selection could be used to improve resistance to BL in Holstein cattle. In addition, selection for increased MY may also increase BLV susceptibility, such that higher infection rates may be expected in high-performing dairy herds. Nevertheless, selection for reduced SCS may increase the resistance to BLV. Hence, simultaneous selection for improved MY and BLV resistance using an appropriate index may lead to improvement of both traits.

Key Words: bovine leukosis, multi-trait analysis, heritability

135 Effect of genetic selection for Johne's disease resistance on the prevalence in dairy cattle using an epidemiological model. K. J. E. van Hulzen[1], A. P. Koets[1], M. Nielen[1], H. C. M. Heuven*[1,2], J. A. M. van Arendonk[2], and D. Klinkenberg[1], *[1]Faculty of Veterinary Medicine, Utrecht University, Utrecht, the Netherlands, [2]Animal Breeding and Genomics Centre, Wageningen University, Wageningen, the Netherlands.*

Johne's disease in dairy cattle is an important issue in the dairy industry. Genetic variation exists therefore genetic selection could be an additional approach to control this disease. The objective was to study the effect of different selection strategies on the prevalence of john's disease taking epidemiological aspects into account, using deterministic simulation. Three strategies were compared: (1) dam-selection, i.e., selection of cows only based on their ELISA test (current test and cull surveillance program); (2) sire-selection, i.e., using only the top 80% of the sires based on their EBV for resistance; (3) combining both strategies. Three parameters in the model were affected by genetic selection: length of latent period, susceptibility and length of susceptible period. The effect of selection on the parameter under selection was 'translated', using an epidemiological model, to an effect on prevalence to assess the effect of a selection strategy. For dam-selection, responses to selection for Johne's disease resistance were small, irrespective of the parameter that was varied in the model. For sire-selection, responses to selection were much larger for all 3 parameters that were varied. The largest effect was observed for length of susceptibility period, followed by susceptibility and then length of the latent period. Sensitivity analysis of the parameters showed that this ranking did not depend on the disease prevalence. The conclusion of this simulation study was that genetic selection for Johne's disease resistance on the sire level could contribute to the control of the disease.

Key Words: Johne's disease, genetic-epidemiological model, selection response

136 Genetic analysis of processed in-line mastitis indicator data. L. P. Sørensen* and P. Løvendahl, *Aarhus University, Department of Molecular Biology and Genetics, Center for Quantitative Genetics and Genomics, Tjele, Denmark.*

The aim of this study was to estimate heritability of elevated mastitis risk (EMR), a trait derived from in-line measurements of cell counts expressing risk of mastitis on a continuous scale, and its genetic correlation with in-line somatic cell counts. Log-transformed somatic cell counts (SCC; n = 855,181) based on in-line measurements (OCC, DeLaval, Sweden) in automatic milking systems were collected from 2007 to2013 in 7 herds from a total of 1986 first and second parity cows (5 to 305 d in milk). Only data from the lactation with most measurements was used from each cow. A bio-model based on exponential smoothing of the SCC values followed by factor analysis for estimation of the latent variable EMR was used. Finally, EMR was expressed as a continuum on the interval [0;1] using sigmoid transformation. Thus, an EMR value close to zero indicates low risk of mastitis and a value close to one indicates high risk of mastitis. The EMR values were summarized for each cow using the log-transformed median EMR. A second trait

was defined as the median of the log-transformed SCC values from 5 to 305 d in milk. A bivariate animal model was used for estimation of co-variance components for the 2 traits. The fixed part of the model included herd and parity. Estimates of heritability were 0.08 (SE = 0.04) and 0.14 (SE = 0.05) for EMR and SCC, respectively. The genetic correlation between the 2 traits was 0.97 (SE = 0.08). The high genetic correlation indicates that the 2 traits are influenced by common genes, as expected because EMR values are based on SCC measurements. The heritability of SCC is reduced when SCC measurements are processed into EMR values but with similar standard errors. The EMR values are useful in a management context for early mastitis detection and health surveillance; however the present results suggest that SCC values are preferable to EMR values for estimation of breeding values.

Key Words: mastitis, genetic parameter, dairy cow

137 Effects of mesenteric infusion of 0, 61, and 120 mmol/h of volatile fatty acids on hepatic metabolism in fasted pigs. U. Krogh*, A. C. Storm, and P. K. Theil, *Aarhus University, Department of Animal Science, Foulum, Tjele, Denmark.*

The aim of the study was to quantify hepatic metabolism of precursors potentially used as fuels in pigs in a post absorptive phase. Four fasted (18 h) pigs (BW 58 kg ± 2; Mean ± SD) were fitted with indwelling catheters in the portal vein, hepatic vein, mesenteric vein and -artery. VFA was infused into the mesenteric vein of anesthetized pigs to mimic effects of increased consumption of dietary fibers. Infusion 0 (INF0: 0 mmol/h VFA, 0.9% saline) was infused for 30 min followed by 45 min of infusion 61 (INF61: 61 mmol/h VFA) and 45 min of infusion 120 (INF120: 120 mmol/h VFA), with the consequence of a potential confounding effect of time. INF61 and INF120 contained 70, 20 and 5% of acetate, propionate and butyrate, respectively. Para-aminohippuric acid was infused to quantify blood flow and net hepatic flux of nutrients (NHF). Eight sets of blood samples were simultaneously drawn from the artery, portal-, and hepatic veins at 15 min intervals. Statistical analysis included fixed effects of infusion, sampling times (ST), random effect of pig, and interaction between infusion and ST, with ST included as repeated measure. Results of incremental change in NHF (ΔNHF) (i.e., INF61- INF0 and INF120-INF0) are shown in Table 1. Glucose ΔNHF tended to be higher at INF120 vs. INF61 ($P = 0.07$), while no effect was observed for lactate. Urea NHF increased ($P = 0.04$) from INF0 to INF61 and from INF0 to INF120, and ΔNHF of urea at INF120 vs. INF61 did not differ ($P = 0.74$). Oxygen ΔNHF tended to be higher at INF120 vs. INF61 ($P = 0.07$). The data indicate that VFA infusion levels influence hepatic glucose metabolism and oxidation pattern in the pig.

Table 1. Incremental change in net hepatic flux (ΔNHF) of glucose, lactate, urea, oxygen and carbon dioxide (mmol/h) in fasted mesenteric-infused pigs at 61 (INF61) and 120 (INF120) mmol/h of volatile fatty acids

Metabolite	INF611	INF1201	SEM	*P*-value
Glucose	5.1	28.2	16.5	0.07
Lactate	−3.8	−8.2	5.5	0.57
Urea	15.7	17.8	4.4	0.74
Oxygen	38.5	−66.9	67.7	0.07
Carbon dioxide	−97.9	−55.6	59.4	0.42

[1]INF61 = NHF61 − NHF0; INF120 = NHF120 – NHF0.

Key Words: gluconeogenesis, liver, VFA

138 Leucine pulse stimulates protein synthesis and suppresses protein degradation pathways in muscle of neonatal pigs fed continuously. C. Boutry*[1], S. El-Kadi[2], A. Suryawan[1], S. Wheatley[1], R. Orellana[1], H. Nguyen[1], and T. Davis[1], *[1]USDA/ARS Children's Nutrition Research Center, Houston, TX, [2]Virginia Tech, Blacksburg.*

Using neonatal pigs as a dual-model for animal agriculture and biomedicine, we have shown that muscle protein synthesis is enhanced with intermittent bolus feeding (BOL) to a greater extent than continuous feeding (CON). Leucine can act as a nutrient signal to stimulate muscle protein synthesis; limited evidence suggests leucine suppresses protein degradation. To determine if leucine can enhance protein anabolism during CON feeding, pigs (n = 20; 8-d-old) received formula by orogastric tube for 24h CON or by BOL (every 4 h for 15 min). For the CON+LEU group, leucine was pulsed parenterally (800 $\mu mol \cdot kg^{-1} \cdot h^{-1}$) every 4h. Plasma was collected at intervals during the last 4-h feeding cycle. At 25.25 h, muscle protein synthesis was measured by flooding dose methodology and intracellular signaling protein activation by Western blot. Data were analyzed by one-way ANOVA and mixed models for repeated-measures analysis. Plasma insulin increased 15min after a bolus meal and returned to baseline by 2h ($P < 0.001$); insulin was unchanged in CON and CON+LEU. In CON+LEU, plasma leucine was higher after the leucine pulse (+192% 1 h after pulse, $P < 0.0001$). LEU during CON feeding decreased plasma essential amino acid levels compared with CON ($P < 0.0001$). Muscle protein synthesis was greater in CON+LEU (+24%) and BOL (+56%) than CON ($P < 0.0001$). Muscle ribosomal protein S6 kinase 1 and 4E-binding protein 1 phosphorylation and eukaryotic initiation factor (eIF)4E•eIF4G formation were higher in CON+LEU and BOL than CON ($P < 0.05$). AMP-activated protein kinase-α, eIF2-α and eukaryotic elongation factor 2 phosphorylation was unaffected by treatment. Microtubule-associated protein 1 light chain 3 (LC3)-II to total LC3 ratio was lower in CON+LEU and BOL than CON ($P < 0.001$). There were no differences in Atrogin-1 and MURF-1 abundance and FoxO3 phosphorylation. These results suggest that administration of leucine pulses during continuous feeding increases skeletal muscle protein synthesis by stimulating translation initiation and suppressing autophagy-lysosome, but not the ubiquitin-proteasome, degradation pathways in neonatal pigs (NIH AR444474 and USDA/ARS 6250–51000–055).

Key Words: leucine pulse, protein synthesis, pig

139 Temporal proteomic analysis reveals defects in small intestinal development of porcine fetuses with intrauterine growth restriction during gestation. X. Wang[1], C. Liu[1], G. Lin[1], C. Feng[2], T. Wang[1], D. Li[1], G. Wu[1,3], and J. Wang*[1], *[1]State Key Laboratory of Animal Nutrition, China Agricultural University, Beijing, China, [2]Department of Obstetrics and Gynecology, China-Japan Friendship Hospital, Beijing, China, [3]Department of Animal Science, Texas A&M University, College Station.*

The fetus/neonate with intrauterine growth restriction (IUGR) has a high perinatal mortality and morbidity rate, as well as reduced efficiency for nutrients utilization, which predisposes the offspring to malfunction and jeopardize the postnatal development of small intestine. Our previous studies showed a significant alteration of small intestinal proteome in IUGR piglets at birth and continuous impairment during nursing periods. With the consideration of fetal programming for intestinal development during gestation and the dramatically increase in volume and nutrients concentration of amniotic fluid from d 60 of gestation in pigs, the analysis is extended to IUGR porcine fetuses from d 60 to d 110 of gestation (mid- to late-gestation in pig) with a purpose of disclosing the mechanisms responsible for developmental programming of fetal gut. In total, 59 differentially expressed small intestinal proteins that are related to gut growth, development and reprogramming were identified. Results reveal increased levels of proteins and enzymes associated with oxidative stress, apoptosis and protein degradation, as well as decreased levels of proteins required for maintenance of cell structure and motility, absorption and transport of nutrients, energy metabolism and protein synthesis in fetal small intestine during mid- and late-gestation. Moreover, IUGR interfere with expression of fetal small intestinal proteins associated with gene regulation and signal transduction starting from middle to late gestation. Collectively, these changes in the proteome profile indicate alterations in the expression of some of the proteins in

the small intestinal tissue of IUGR porcine fetuses, which may predispose the gut to metabolic defects during gestation as well as disruption of fetal gut developmental programming.

Key Words: intrauterine growth restriction, intestine, pig

140 Identification of porcine short-chain fatty acid receptors, GPR41 and GPR43, and their expression pattern in different development stages. G. Li*, H. Su, Z. Zhou, and W. Yao, *Laboratory of Gastrointestinal Microbiology, Nanjing Agricultural University, Nanjing, Jiangsu, China.*

In addition to supplying energy, short chain fatty acids also play a regulatory role in various physiological processes. Current researches revealed that SCFAs functioned as natural ligands for GPR41 and 43. To date, there is no systemic research about porcine GPR41 and 43. In this study, we tried to identify porcine GPR41 and 43 and determine their tissue distribution. Each 3 of Duroc × Landrace × Yorkshire pigs were slaughtered when 1, 25, 35, 70, 115 and 160 d old. Various tissues (liver, spleen, ileum, colon, heart, kidney, adipose tissue and skeletal muscle) were collected for RNA extraction. RT-PCR, Western blot and immunohistochemistry was used to detect GPR41 and 43 expressions in different tissues. The rapid amplification of cDNA ends was used to amplify the 3′ and 5′ end regions of porcine GPR41 and 43 mRNA. The qPCR was carried out to investigate expression pattern of GPR41 and 43 in different tissues and different development stages. A search of the pig genome database in GenBank revealed pig genome contains GPR41 and 43 genes, located on chromosome 6, highly similar to these genes in human and rodents. The RT-PCR, Western blot and immunohistochemistry analysis indicated that both GPR41 and 43 mRNA were detected in the tested tissues. A 2219bp and 1908bp nucleotide sequences representing the full-length cDNA sequence of procine GPR41 and GPR43 was obtained and encoded 335 and 329 amino acid sequence, respectively. The qPCR results showed that GPR43 was most highly expressed in spleen, while GPR41 was in ileum. The highest expression level of GPR41 in ileum and colon was on 70d and 1d, respectively. GPR43 expression in ileum and colon was on 25d and 70d, respectively. Furthermore, porcine GPR41 and 43 was expressed in adipose tissue with a significant time-dependent manner. Their expression level was upregulated after birth with a peak at 70d, and then decreased, suggesting that these 2 receptors may exert function mainly in early stage. However, further studies are essential to clarify their function in different development stages and different physiological processes.

Key Words: GPR41 and 43, short-chain fatty acids, pig

141 Effect of breed on the expression of sirtuins (Sirt1-7) and antioxidant capacity in porcine brain. Y. Ren*, T. Shan, L. Zhu, J. Huang, and Y. Wang, *Institute of Feed Science, Zhejiang University, Hangzhou, Zhejiang Province, China.*

Sirtuins, nicotinamide adenine dinucleotide (NAD)-dependent histone deacetylase (HDAC), play important roles in a variety of biological processes including metabolism, apoptosis, oxidative stress, cytokine responses and further influencing aging. In brain, aging increased the risk of psychiatric disorders and vascular diseases caused by age-related oxidative damage. Sirtuins are highly expressed in brain, indicating that they may play critical roles in cerebral development and nervous system. Sirt1 and Sirt3 have been proved to protect brain from oxidative stress. Furthermore, obesity may lead to oxidative stress and the plasma total antioxidative capacity (T-AOC) is different between obese and healthy people. Therefore, the aim of this study was to determine breed differences of porcine sirtuins expression and antioxidant capacity in brain between Jinhua pig (a fatty breed of China) and Landrace pig (a lean breed). The effect of age on sirtuins expression was also investigated. At the age of 180 d, the mRNA levels of Sirt1 ($P < 0.05$) as well as Sirt2 ($P < 0.01$) and Sirt4 ($P < 0.05$) were greater in Jinhua pig, but the mRNA levels of Sirt3, Sirt5, Sirt6 and Sirt7 were lower ($P < 0.01$) compared with Landrace pig. Likewise, the mRNA levels of sirtuins were significantly greater in Jinhua pig except for Sirt5 and Sirt7 at the same BW of 64 kg. Meanwhile, Jinhua pig had higher antioxidants activity than Landrace pig either at the same age ($P < 0.05$) or at the same BW ($P < 0.05$). In addition, mRNA levels of sirtuins were decreased with age in brain in both breeds from 30 d to 120 d. These results indicated that sirtuins expression was different between fatty and lean pigs in brain and may correlate to antioxidant capacity. Sirtuins expression could be also downregulated by age in porcine brain. These results may provide useful information for better understanding of the physiological roles of sirtuins and for further regulating metabolism and antioxidant stress in pig.

Key Words: antioxidant, brain, sirtuin

142 Goat milk: An alternative to cow milk. C. A. Becker*, N. D. Schock, and J. M. Bewley, *University of Kentucky, Lexington.*

Goat milk is still a niche market in the United States, but in many other countries, it is preferred over cow milk. Dairy goat products are not usually marketed in mainstream grocery stores. Rather, they are more often sold at specialty food stores and farmer's markets. As the consumer health craze continues to steadily increase, dairy goat milk and other dairy goat products are starting to see slow, steady growth trends. Goat milk is used to make many products including cheese, yogurt, and ice cream. Some dairy goat producers sell their products directly to retail stores or restaurants. Restaurants use goat cheese on menu items from pizza to dessert. Consuming goat milk can be very beneficial to a person's health. Goat's milk is a good source of protein, tryptophan, vitamin A, riboflavin and potassium, which all are associated with health benefits. The vitamin A in goat's milk is in pure form so that it can be readily absorbed by the body. Contrastingly, cow milk vitamin A is in the form of carotenoids that the body has to convert before it can be absorbed. Consumers who are unable to digest cow milk are often able to tolerate goat milk. Cow milk contains a protein, α_{S1}-casein, that is known to be a major allergen. However, goat milk contains much lower values of this protein, if any, allowing people with cow milk allergies to drink goa milk. The fat globules in goat milk are significantly smaller than the fat globules found in cow milk, making goat milk easier for intestinal enzymes to digest. Goat milk contains a high amount of short-chain and medium-chain triglycerides that aid in speeding up metabolism and help lower cholesterol levels, and make goat's milk easier to digest. Although goat milk is not the only alternative to cow milk, it may be considered the best alternative due to all the potential health and consumption benefits.

Key Words: goat milk, digestion

143 Dairy options for lactose intolerant consumers. A. R. Davis*, D. R. Winston, and B. A. Corl, *Virginia Tech, Blacksburg.*

Lactose intolerance is a condition in which the small intestine does not make adequate amounts of the enzyme lactase to break down the milk sugar lactose. It is characterized by bloating, diarrhea, flatulence, nausea, and cramps. Lactose intolerance must be diagnosed by a physician, but it is commonly misunderstood and many consumers self-diagnose. Between physician diagnosis and self diagnosis, an estimated 12% of consumers are lactose intolerant. Of that 12%, most avoid dairy products all together; however, exclusion of dairy from the diet is not necessary and has many health consequences, including higher incidence of osteoporosis and increased risk of developing diabetes and hypertension. According to a study led by the American Academy of Pediatrics, clarifying lactose intolerance misconceptions at a young age is essential. The best defense against osteoporosis is to establish peak bone mass before age 27, and dairy products have been shown to provide 77% of recommended dietary calcium. In a separate study, odds of developing diabetes or hypertension were significantly reduced by increased intake of calcium from dairy foods. The dairy industry should educate lactose intolerant consumers about what lactose intolerance actually is, the health consequences of a dairy-free diet, and how they can incorporate dairy foods into their diet for their overall health. This could lead to increased per capita consumption of milk by this group of consumers.

Key Words: lactose intolerance

144 Addition of Fiber to dairy foods. R. E. Brown* and C. C. Williams, *Louisiana State University, Baton Rouge.*

Many Americans do not meet the required amount of fiber needed in the diet, with women needing 25 g and men needing 38 g per day. According to the International Food Information Council Foundation's "2010 Food & Health Survey," only 5% of Americans meet the required intake of fiber with the average person consuming about 15 g of fiber. Fiber offers a variety of health benefits including, lowering body weight, preventing diverticulitis, and preventing type 2 diabetes. These statistics are important to the dairy foods industry, because processors have now found a way to incorporate fiber into dairy products to allow more consumers to meet their daily requirements. This is possible by adding isolated fibers such as inulin to ice cream, yogurt, and milk. Inulin is a low-caloric fructo-oligosaccharide that offers a blend of short-chained and longer-chained oligosaccharides that are soluble prebiotic fibers. The addition of fiber to dairy products has been met with some opposition. Some scientists believe that fortified fibers are not beneficial to the health of consumers, and can even cause harm if too much fiber is consumed. Although, most food consumed today has been processed research shows that isolated fibers can be added to dairy food products without changing the texture or taste. Therefore, giving consumers the fiber needed to meet their daily requirements without giving up the taste of dairy products would provide an additional health benefit to those already provided by milk and dairy foods.

Key Words: dairy food, fiber, diet

145 Pulsed electric field: A novel method of dairy product processing. C. Widener* and J. Fain, *Clemson University, Clemson, SC.*

Most Americans consume some type of heat-pasteurized dairy product daily. These traditional methods require a large energy input that is difficult to reclaim or recycle. With the movement toward sustainable agricultural production systems, food processing systems will need to follow suit. As consumers become more aware of the energy costs associated with dairy product processing, the industry needs to look toward alternatives that both lower energy costs and inputs. One of these alternatives is known as pulsed electric field (PEF). Traditionally, PEF works by using small bursts of electricity to inoculate microorganisms in liquid and semi-liquid foods. PEF has been applied commercially in fruit juices, and researchers across the country and internationally have begun to study its use in dairy products. Combination of this system with thermal methods allow processors to use lower temperatures and keep a shorter time frame, around 149°F for a total of 10 s, than traditional pasteurization, and thus a lower energy input. Additionally, PEF products have experienced a longer shelf life, in some cases as high as 24 additional days, with less of a "cooked milk" flavor associated with ultra-pasteurization methods. Raw milk processed through this method also maintained larger protein micelles and fat globules than milk processed with thermal methods while also successfully degenerating the enzymes that cause off flavors. Before this method could be implemented commercially, there would need to be a streamlining of parameters for both the temperature and the intensity of PEF. While there is still work and research to be done before commercial use, PEF

mixed with heat offers an energy efficient and nutritious option for the future of dairy processing.

Key Words: pasteurization, pulse electric, processing milk

146 Innovations in milk packaging. L. M. Kapanick* and D. R. Olver, *Pennsylvania State University, University Park.*

The first major development in fluid milk packaging was established at the end of the last century when the glass bottle became the most widely used container for distribution and storage. The glass bottle was the main method of milk packaging until 1933 when the first milk carton was introduced. This carton was made of wax paper and was widely used until the plastic bottle was developed in 1940. Together the plastic milk bottle and paper carton have created a wide range of containers suitable for milk packaging. Today consumers are offered more beverage alternatives, and fluid milk is being passed by in favor of other options such as bottled water. This can be seen in fluid milk consumption data. US fluid milk consumption declined 33% per capita from 1970 to 2011. New innovations in milk packaging are being developed to help reverse this trend. Factors such as convenience, environmental impact, and product quality are at the forefront of these new packages. Manufacturers have begun to rise to meet the challenge by producing smaller milk bottles in the shapes of animals for children and offering single-serve milk bottles for on-the-go adults. New designs have been launched in Israel that are capable of keeping milk fresh for 30 d. This packaging has a specific set of coatings that creates an electrical charge that kills bacteria. As the majority of consumer economic spending power shifts from "Baby Boomers" to "Millennials," it is crucial for the milk packaging industry to change and use methods that are appealing for the next generation. For example, a study commissioned by Tetra Pak concluded that 77% of their respondents would purchase one product over another because "the packaging would be better for the environment." As a result, manufacturers are constructing packages made of more easily recycled materials. Factors such as attractiveness, convenience, and increased shelf life are also important to these consumers, and milk packaging manufacturers are changing their products to meet these market needs.

Key Words: milk packaging, fluid milk

Undergraduate Student Competition: ADSA-SAD Undergraduate Competition: Dairy Production

147 Cow comfort: An important element of the 21st century dairy operation. A. Gibson* and L. Fox, *Washington State University, Pullman.*

Cow well-being is becoming an essential element of management in the modern dairy business. Cows that are given adequate and clean space to rest and eat appear more comfortable and will produce more milk. Cow well-being is also a societal concern. The public wants to be satisfied that their milk comes from healthy and well-treated animals. Producers can use cow well-being assessment tools such as the body condition score, locomotion score, and hygiene scores. Dairy managers can also observe cattle handling, and adjust the surroundings for heat stress to create the most ideal environment for the cow. Through careful observation of factors that can cause stress in the cow's life farmers can then locate the bottleneck that prevents optimum cow comfort and then alleviate that bottleneck. Inherently, cow well-being is an important aspect of the modern dairy. Uncomfortable cattle are less productive as they have decreased feed intake, and thus decreased production, and increased reproduction and disease problems. Minimizing stressful conditions for dairy cows is not only important economically but it is also good for public perception.

Key Words: cow comfort, welfare, cow well-being

148 Thermal variation effect on dairy calf rearing. A. C. Thompson*, D. M. Amaral-Phillips, and J. M. Bewley, *University of Kentucky, Lexington.*

Calves are the future productive units of a dairy herd. The herd's future performance, current and future earnings are based on their growth. Dairy calves are expected to double their birth weight from birth to 2 mo. Fluctuations in environmental temperatures and humidity affect how well a calf grows. One key to raising well-grown calves is a clean, draft-free, and well-ventilated environment. Temperature extremes outside of a calf's thermal neutral zone negatively affect growth and immune function. Calves begin to experience heat stress at temperatures exceeding 21°C. To reduce the effects of heat stress, ventilation, shade, and water need to be provided. According to Hill et al. (2011), ventilation with fans increased ADG ($P < 0.05$) and feed efficiency ($P < 0.05$). Shade allows the calf to grow while reducing the amount of energy expended to curtail heat effects (Spain and Spiers, 1996). Any energy that a calf uses to maintain their thermal neutral zone is energy diverted from growth. As ambient temperatures drop below 15°C, newborn calves begin to experience cold stress because they lack the fat stores necessary to stay warm. Calves older than 3 wk begin to experience cold stress at temperatures below 7°C because they develop fat stores as they age. During cold stress, the calf's energy requirement for maintenance increases. Additional dry bedding and draft-free ventilation alleviate the added stress. A calf provided deep bedding will nest creating a warmer microenvironment in contrast to bedding with sand or sawdust (Lago et al., 2006). This lowers the amount of energy the calf expends staying warm. According to Nonnecke et al. (2009), extra nutrients are needed for calves in cold environments to maintain growth similar to a warm environment. With colder temperatures, additional milk or milk replacer is needed to maintain growth. Minimization of environmental effects and additional nutrients from milk ensures that a calf doubles her birth weight by 2 mo.

Key Words: environmental temperature, stress, dairy calf

149 A survey on the challenges and opportunities regarding the transition from conventional to automatic milking systems in the northeastern United States. A. R. Ervin*, R. Peters, T. McCoy, and K. M. Moyes, *University of Maryland, College Park.*

As herd size increases, new technology that allows small-to-medium-sized dairy farmers to remain sustainable is greatly desired. Automatic milking systems are one way farmers can remain competitive and sustainable via improving management and production efficiency, as well as enhancing quality of life and business attractiveness to successors. The objective of this survey was to identify the interest and factors that are important to small-to-medium-sized dairy farmers when considering transitioning from conventional milking systems to AMS in the Northeast region. In January 2013, over 1330 questionnaires were sent to Maryland and Pennsylvania dairy producers having between 80 and 250 lactating dairy cows. The response rate was approximately 35%. Of the producers that completed the surveys, 33% expressed interest in transitioning to an AMS. Of the producers that expressed interest, 53% were between the ages of 50 and 64 and 45% possessed a high school diploma or graduate equivalency degree (GED). Return on investment/profitability, improving management of family time and improving herd management were the most important factors regarding their interest in AMS. Return on investment/profitability, financing/cash flow and barn design are the top 3 factors influencing dairy farmers' interest and concern when considering transitioning to AMS. Twenty-one percent of producers said they have access to information regarding changes in barn design, whereas 18.0% said they have access to information regarding changes in animal health/productivity and financing. Producers said more information on barn design, animal health/productivity and economic impact would be helpful when considering a transition to AMS. Results will serve as the basis for education programs designed to provide farmers with the decision-making tools required to estimate and quantify economic impacts, performance outcomes and lifestyle changes associated with AMS.

Key Words: dairy cow, survey, automatic milking system

150 Sexed semen, genomics, and crossbreeding as tools for increasing the value of dairy herd genetics and cull dairy animals. T. L. Boyd*, D. R. Winston, and B. G. Cassell, *Virginia Tech, Blacksburg.*

Sexed semen and genomic testing are recent developments in the dairy industry that have gained in popularity since their introduction, both in registered and commercial herds. As many farmers look for new ways to increase profitability in the face of increasing production costs, the cost-benefit ratio of these technologies is sometimes questioned. To maximize their value, crossbreeding has been suggested as a third tool to create a more valuable end product— cull dairy calves—while increasing the genetic value of those animals remaining in the milking herd. This is achieved by breeding genomically inferior heifers to beef semen, which creates a marketable product (half-beef, half-dairy bull and heifer calves) while keeping bad genetics from remaining in the herd. It can also reduce some semen costs, since good, expensive dairy bulls are not wasted on poor females, in addition to reduced health costs

due to fewer incidences of dystocia. The downside is that it requires expenditures in time and effort to implement, and it is a relatively new concept for commercial herds. The value of such a system was analyzed via meta-analysis by comparing traditional cull values with those produced by this system. The value of these culls was determined by comparing both the costs incurred by increased semen costs, genomic testing, and decreased fertility and the benefits of greater more valuable cull calves, more accurate culling, and superior replacement heifers. The analysis indicates a cost of approximately $20 per contemporary member of the breeding group, although management techniques can turn this into a net profit.

Key Words: sexed semen, genomics, crossbreeding

151 What lies within the rumen? S. M. Vignes* and C. C. Williams, *Louisiana State University, Baton Rouge.*

Subcute ruminal acidosis (SARA) is characterized by a sustained rumen fluid pH below the normal 5.8. Many factors can attribute to the pH dropping below this level including diet particle size, dietary carbohydrate concentration, limited saliva production, and water intake. Rumen microorganisms break down readily fermentable carbohydrates which lead to the production of volatile fatty acids (VFA) and lactic acid. In turn the ruminal fluid's pH is lowered. Acidosis can lead to the microorganisms in the rumen being harmed or becoming obsolete altogether as well as the absorptive papillae being damaged. SARA is of concern in mature dairy cattle but also in the growing calves. It is widely known that the first 24 to 36 h after a calf is born is the most crucial time to feed colostrum to ensure passive immunity. Once calves are transitioned onto their liquid feeding program, they should also be provided with high quality calf starter not only to provide nutrients but to promote rumen development. The starch and sugars provide the readily fermentable carbohydrates for production of VFA which help develop the rumen. With this practice though, subacute acidosis could occur as production of the VFA and lactic acid lead to the decrease in pH. This is a problem because the earlier weeks are the most vital time for initiating rumen development, and a fine line is being walked between beneficial and detrimental. The rumen must be provided for, but too much grain could result in SARA due to low rumen pH. Low rumen pH impairs fiber digestion by inhibiting the growth of cellulolytic microorganisms. Research has shown subacute rumen acidosis to be common among calves, but has it become a normal event?

Key Words: acidosis, calves

152 Rumination monitoring: A management tool for early detection of metabolic disorders. K. Carraway*, M. Brauneis, N. Engwall, and J. Fain, *Clemson University, Clemson, SC.*

Rumination monitoring is an important tool for dairy herd management as it is a direct reflection of cow health. Monitoring rumination rate has the potential to be utilized in an array of practices from heat detection to metabolic disorder diagnosis. Until recently, monitoring rumination has been achieved by visually monitoring cow activity, which is time consuming and lacks accuracy. Recently, SCR Engineers Ltd. of Israel released the HR-Tag, a rumination collar that has changed the way producers can manage their herds. The neck color is equipped with a built in motion sensor, microphone, and processor for recording rumination rates, chewing rhythm, and general movements. A scanner then transmits the recordings to a computer data system that keeps an activity report of the entire herd. By sensing a drop in rumination rates, the rumination collar is able to detect metabolic disorders such as ketosis, acidosis, displaced abomasums, as well as mastitis. This tool is especially useful in transition animals, a phase corresponding to a time when these disorders are most prevalent. Early detection allows producers to quickly begin remedial therapies that in turn reduce the costs associated with potential advanced treatment and production loss. Additional cost reduction may be realized through identification of a disorder's subclinical manifestations. There are some limitations that hold back the HR-Tag from its full potential. The cows must be near the transmitter to allow data to be sent to the computer, and any data not sent is lost in 24 h. Decreases in rumination are not always associated with illness or heat, and must be crossed checked with milk records for validation. Additionally, the cause of the drop in rumination is something that must be further investigated, for the exact disease or reason is not given. Proper placement of the tag is crucial for accurate readings, and that is difficult to achieve with some animals. Despite these minor setbacks, studies show that with proper training and experience, rumination monitoring is a highly effective and accurate way of detecting early illness, making it a valuable tool for herd management.

Key Words: rumination monitor, metabolic, management

153 The Fodder System. K. Supa* and B. Richards, *Delaware Valley College, Doylestown, PA.*

The Fodder System is a hydroponic system used to produce a fresh feed source for domestic animals. This new system was developed in Australia and introduced into the United Stated in 2009. The system will convert grain or legume seeds into a fresh feed source in 6 d. The end product or mats consist of the roots and the greens of the plants. The seeds are grown in a controlled and sterile environment which decreases the development of fungus or molds. A wide variety of seeds can be grown in the Fodder System to maximize the benefits of feeding the product. This unique management style using this system allows agricultural producers to deliver a feed source to their animals that is consistent and nutritious. Animals are fed a mat that includes the roots, which makes the feed source 70% digestible, according to the Fodder Systems website. This type of system is labor efficient and reasonably priced for the system. The cost of the system is affordable when compared with the high cost of equipment to make traditional forages. Less equipment also means less money for repairs on harvesting equipment. Another benefit to the fodder system would be the ability to farm on a smaller land base, thus allowing us to produce more quality feed with less foot print on the environment. The Fodder System provides a high quality feed product that can offer many benefits to agricultural producers in the United States.

Key Words: Fodder System, hydroponic, legume seeds

154 Effects of group housing and pairing calves before weaning. D. L. Grove* and D. R. Olver, *Pennsylvania State University, University Park.*

In the United States, the traditional way of raising calves has often been to house them individually until weaning and then group them together. This was thought to prevent the spread of disease and allow management of each individual calf. With the advent of automated feeders, group housing of calves before weaning has become more popular. Research from British Columbia showed that calves housed in pairs spent more time eating and had higher intakes of starter shortly after weaning. Pair-housed calves in the study vocalized 3 times less at weaning than individual calves, indicating that the pair-housed calves exhibited less stress. The individually-housed calves took on average 40 h longer

to start eating starter when mixed with other calves at weaning. They concluded pair-housing calves reduces behavioral responses to weaning and improves weaning performance. In another British Columbia study, calves housed in groups struggled less when handled than individually housed calves. These scientists also showed paired calves on a typical plane of nutrition spent more time playing than individually-housed calves with the same nutrition level. This is a positive sign of animal well-being. In a Spain study where calves were grouped either before weaning or else 6d after weaning, calves were 2 times less likely to have respiratory problems if they were grouped earlier. The early-grouped calves had higher starter intake at weaning in this study. The researchers believe that group housing allows more space for the calves, which reduces stress and leads to fewer health problems. A Canadian study agreed that more access to space may be beneficial to calf health and lead to reduced stress at weaning. All of these studies found a positive increase in animal well-being in group-housed calves.

Key Words: calf, housing

155 Effects of urea on uterine response to interferon-tau in presence of progesterone. J. Spencer*[1], K. Austin[2], K. Carnahan[1], and A. Ahmadzadeh[1], *[1]University of Idaho, Moscow, [2]University of Wyoming, Laramie.*

High blood and uterine urea concentrations, associated with high dietary protein, can reduce fertility in dairy cows. In an in vitro steroid free culture, urea did not affect bovine endometrial (BEND) cell expression of Mx1 and ISG15 in response to the ruminant maternal recognition protein (IFN-tau). However, uterine protein secretions are altered in response to IFN-tau in the presence of progesterone (P_4). Therefore, the objective of this study was to determine the direct effects of urea on protein expression of the endometrial cells of the bovine uteri in response to IFN-tau in the presence of P_4. Using BEND cells as a model, the effects of urea on the production of 2 IFN-tau stimulated proteins, ISG15 and Mx1, were examined. Bovine endometrial cells were grown to 80% confluency and further incubated for additional 24 h in culture media containing P_4 (10^{-7} *M*). Cells (90% confluent) were then treated with urea at final concentrations of 0, 5, 7.5, or 10 mM urea and subsequently, challenged with 0 or 10,000 antiviral units of recombinant IFN-tau and incubated for an additional 24 h. Once harvested, BEND cells were lysed and the cell supernatant was analyzed and quantified for Mx1 and ISG15, using SDS-PAGE, Western blot and immunoblotting protocols. Based on optical density, regardless of urea treatment, IFN-tau increased ($P < 0.01$) Mx1 and ISG15 by 11 and 4 fold, respectively. There was no effect of any urea treatment or urea by IFN-tau interaction on Mx1 and ISG15 production after 24 ($P = 0.9$) of culture. These results show that there is no disruption of IFN-tau stimulated Mx1 or ISG15 production, when BEND cells are exposed to varying concentrations of urea in the presence of P_4 in vitro.

Key Words: urea, interferon, bovine endometrial cells

156 Effect of bedding surface on the welfare of preweaned Jersey calves. C. A. Kurman* and P. D. Krawczel, *University of Tennessee, Knoxville.*

Previous research on the effect of the bedding surface on the welfare of dairy calves has produced mixed results with indication that calves prefer a soft, dry surface and others suggesting that bedding or flooring have no effect on behavior and performance. The objective of this study was to determine the effect on the behavior and performance of Jersey calves housed using individual hutches bedded with gravel, sand, or rubber mat. It was hypothesized that sand or rubber mat would increase lying time, decrease lying bouts, but not affect BW gain or feed intake in preweaned calves. Twenty-eight Jersey calves were blocked by birth date and randomly assigned to 1 of 3 bedding treatments (gravel, sand, or rubber mat). Lying time and lying bouts were assessed with dataloggers, recording at 1-min intervals for 3 consecutive days each week. Performance was determined by weight gain (calculated from birth weight and weekly BW) and grain intake (calculated as daily difference between grain offered and refused over 3-d). Data were collected for 8 wk following birth. Data were analyzed using a mixed model in SAS with repeated measures. Mean lying time (15.2 ± 0.3 h/d) was not affected by trt ($P = 0.51$), wk ($P = 0.16$), or trt × wk interactions ($P = 0.54$). Lying bouts were affected by trt ($P = 0.01$) and trt × wk interactions ($P = 0.05$) but not by wk ($P = 0.20$). Calves on mats engaged in more lying bouts/d (12.1 ± 0.7 n/d) than gravel (9.8 ± 1.0; $P = 0.01$) or sand (9.0 ± 0.7 n/d; $P < 0.001$). An effect of week was evident in BW gain (2.2 ± 0.2 kg/wk; $P = 0.002$), but trt ($P = 0.41$) or trt × wk interactions ($P = 0.19$) effects were not evident. Grain intake (gravel = 386.9 ± 59.8 g/d, mat = 413.3 ± 50.0 g/d, sand = 479.1 ± 52.7 g/d) increased from 0 g/d in wk 1 to 1095.8 g/d in wk 8 ($P < 0.001$) but there was no trt effect ($P = 0.48$) or trt × wk interaction ($P = 0.21$). There were no biological significant differences in behavior or performance among treatments. This suggests that, on a well-managed farm, any of these beddings may be used without compromising the welfare of preweaned Jersey calves.

Key Words: dairy calf, behavior, bedding

157 The effects of D-α-tocopherol and dietary energy on growth and health of dairy calves. L. A. Krueger*[1], K. Onda[1], M. Osman[1], M. R. O'Neil[1], R. L. Stuart[2], H. D. Tyler[1], B. Nonnecke[3,1], and D. C. Beitz[1], *[1]Department of Animal Science, Iowa State University, Ames, [2]Stuart Products Inc., Bedford, TX, [3]Ruminant Diseases and Immunology Research Unit, National Animal Disease Center, Agricultural Research Service, USDA, Ames, IA.*

To understand the effects of dietary vitamin E in relation to dietary energy on growth and immune status in dairy calves, 32 newborn Holstein bull calves were assigned to one of 4 treatments for 5 weeks in a 2 ×2 factorial randomized complete block, split plot design. Calves received one of 2 all-milk diets formulated to provide 70% or 100% of the dietary energy recommendation for milk-fed calves according to the NRC's Nutrient Requirements of Dairy Cattle. Calves in these 2 groups were either injected subcutaneously with 5 mL Vital E-A+D on d 1 and administered 200 IU vitamin E (Emcelle Tocopherol) orally via milk daily, or were not supplemented during the study period. Weight gain of calves receiving the 100% diet was greater than that of calves receiving the 70% diet. Calves receiving vitamin supplementation demonstrated elevated concentrations of plasma α-tocopherol, retinol, and 25-(OH)-vitamin D_3, but calves receiving the 100% diet demonstrated decreased concentration of plasma α-tocopherol. Serum haptoglobin, an acute phase protein, was higher at wk 2 for non-supplemented calves receiving the 100% diet. Serum amyloid A, also an acute phase protein, was not different among groups and was elevated from baseline during wk 1 through 3 before a return to baseline by wk 4. Plasma IgG_1 concentration was higher in vitamin-supplemented calves than in their non-supplemented dietary counterparts, while plasma IgG_2, IgA, and IgM concentrations were not different. In summary, dietary supplementation of vitamin E did not affect growth, but improved plasma α-tocopherol status, decreased serum haptoglobin associated with acute inflammation in calves fed the 100% diet, and slightly improved adaptive immune status. Consumption of the 100% diet increased weight gain in calves, but decreased plasma α-tocopherol and increased serum haptoglobin, indicating a role for vitamin E supplementation in prevention of inflammatory stimuli such as oxidative stress associated with accelerated growth and onset of infectious disease.

Key Words: tocopherol, haptoglobin, dairy calf

158 Metabolic and oxidant profiles of periparturient pastured dairy cows milked in an automatic milking system. M. F. Elischer*, J. M. Siegford, and E. L. Karcher, *Michigan State University, East Lansing.*

The periparturient period is a physiologically stressful time for dairy cows where an increase in energy expenditure paired with a decrease in feed intake leaves the cow highly susceptible to health issues, especially metabolic disorders and impaired immune function. Metabolic and oxidative status are related, though the precise linkage is unknown. Metabolic and oxidative stress profiles for cows in traditional milking and feeding are well documented, but little research has examined these health parameters in automatic milking systems (AMS) or with pasture-based diets. The objective of this study was to characterize metabolic and oxidative profiles for periparturient dairy cows milked in an AMS and consuming a pasture-based diet. Fourteen multiparous Friesian cows were sampled weekly from −21 to 21 d relative to calving. Eight primiparous cows were sampled weekly from calving to 21 d. Multiparous cows milked more frequently (2.60 milkings/d ± 0.24 vs. 1.93 ± 21; P kg/d ± 1.52 vs. 13.3 ± 1.37; P compared with primiparous cows. Blood was collected weekly and analyzed for nonesterified fatty acids (NEFA), β-hydroxybutyrate (BHBA), insulin, glucose, antioxidant potential (AOP), and reduced glutathione (GSH). NEFA concentrations declined from d 1 through 21 for both groups ($P < 0.05$). There was no significant effect of day or parity on BHBA concentrations. Insulin values did not differ significantly between the 2 groups. Glucose concentration was elevated on d 7 and 14 in primiparous compared with multiparous cows ($P < 0.05$). Primiparous cows had significantly higher AOP at 14 and 21 d postpartum, suggesting that primiparous cows had less oxidative stress as serum lipids were better protected. Lower concentrations of GSH, a major antioxidant, were exhibited in primiparous than multiparous cows, though this was not significant. Overall, blood analyses indicate primiparous cows experienced less metabolic and oxidative stress than multiparous cows, likely due to lower milk yield and frequency.

Key Words: oxidative stress, metabolism, robotic milking

159 Nutritional value and silage fermentation parameters of leaves and roots of yacón (*Smallanthus sonchifolius*) mixture as alternative supplementation of cattle in Colombia. L. Bernal*, *Universidad de La Salle, Bogotá, Colombia.*

In this study the nutritional value and fermentation parameters of silage leaves and roots of yacón (*Smallanthus sonchifolius*) was evaluated. Yacón is a native plant of the Andes. The leaves of yacón are not harvested for feeding ruminants. This forage does not compete with human food and has not been extensively studied in the country, in terms of animal nutrition. Samples were taken from the existing planting on the campus of La Salle University in Bogotá. Six treatments were evaluated with different inclusion rates of leaves and roots of yacón. T1: leaves 100%, T2: root 100%, T3: leaves 90: root 10; T4: leaves 80: root 20; T5: leaves 70: root 30 and T6: leaves 60: root 40. These mixtures were stored at ambient temperature in small plastic bags of around 1 kg fresh matter for a period of 56 d. At the end of the fermentation period, samples were taken for analysis of nutritional quality (dry matter DM, crude protein CP, neutral detergent fiber NDF, acid detergent fiber ADF and gross energy GE) and fermentation parameters (pH, ammonia nitrogen and its relation with total nitrogen). The experimental design was completely randomized, 6 treatments and 4 replicates. Variables were analyzed by the GLM procedure by SAS. There was a significant effect of the mixture ratio. The values of DM and CP were higher in leaves than in roots. The part of plant had a significant effect on values NDF, ADF and GE. The fermentation parameters were significantly different. The values of pH, ammonia nitrogen and the relationship between ammonia nitrogen/total nitrogen were better for mixed silages than for leaves and roots only. Finally, the result of nutritional value and silage fermentation parameter showed that it is better to use the mixture with up to 70% leaves, which is good option for feeding cattle.

Key Words: *Smallanthus sonchifolius*, roots, silage

160 Low cost on-farm predictors of individual cow risk for ketosis and fatty liver. Z. Sawall* and N. B. Litherland, *University of Minnesota, St. Paul.*

Early lactation data from 3 studies (n = 176 cows) were composited to determine on farm prediction tools for cows at risk for elevated serum BHBA and NEFA and liver triglycerides (TG). The objective of this retrospective analysis were to determine if low-cost, on-farm measures of colostrum yield (CY), colostrum specific gravity (CSG) and body condition score (BCS) at calving are good predictors of cow health and production in early lactation. Pearson correlation coefficients were calculated for CY, CSG, BCS, BHBA, NEFA and ME 305d milk production. CY is a significant predictor of serum BHBA on d 1 and d 7 postpartum. Serum NEFA can be predicted on d 1, 7 and 14 by CSG using Brix refractometer. Both CY and CSG are significantly correlated with liver TG on d 7 and CY and CSG help predict DMI during the first week postpartum. BCS is negatively correlated with serum calcium 24 h postpartum and can identify cows at risk for hypocalcaemia. BCS is positively correlated with serum BHBA at d 1 and d 14, serum NEFA at d 7 and d 14 and ME 305 d milk production. Low cost, on-farm measures of CY, CSG and BCS provides insight into rates of body reserve mobilization without blood or liver sample collection. The implementation of these tools together can allow dairy producers to quickly identify cows at risk for hypocalcaemia, ketosis, and low DMI shortly after parturition. Rapid, low cost identification of cows at high risk for these disorders allows for early treatment or implementation of tailored feeding and management strategies to minimize the incidence and severity of subclinical fresh cow disorders.

Table 1. Pearson correlations between colostrum yield (CY), colostrum specific gravity (CSG) and BCS on cow health parameters

	CY	CSG	BCS
Ca 12H	0.005	−0.14	−0.03

161 Mass loading of antibiotic resistance genes in feces of prophylactically treated dairy cattle. B. F. Willing*, L. R. Caudle, A. Pruden-Bagchi, and K. F. Knowlton, *Virginia Polytechnic Institute and State University, Blacksburg.*

Prophylactic antibiotic treatment has the potential to increase excretion of antibiotic resistance genes (ARGs) by dairy cattle through selection pressure on the gut microbiome. The objective of this study was to evaluate the effect of cephapirin on establishment and persistence of antibiotic resistance genes in dairy cattle during the dry period. To examine temporal variation in fecal excretion of ARGs, 32 end-of-lactation cows were used. Treatment cows (22) received cephapirin benzathine as an intramammary infusion before dry-off and control cows (10) received no antibiotics. Fecal grab samples were collected for each cow on d −2 or −3 (baseline, used as covariate), and d 1, 3, 5, 7, and once per week until d 56. Fecal samples were collected in sterile containers using a new glove for each cow, then freeze-dried. DNA was extracted from freeze-dried samples using a commercially available FastDNA SPIN KIT for Soil (MP Biomedical). The abundance of ARGs (Tet, Sul), integrase-specific gene (Int), and 16S rRNA were quantified using qPCR. Non-normal data were log-transformed and data were statistically analyzed using PROC GLIMMIX in SAS 9.2.There were significant interactions between treatment and day for all genes. In dry-treated cows, relative abundance (log gene copies/16S rRNA) of TetO, Sul1, and Int1 increased ($P < 0.0001$, $P < 0.001$, and $P < 0.0001$, respectively) from d 1 to d 56 following antibiotic treatment while relative abundance decreased ($P < 0.0001$, $P < 0.001$, and $P < 0.0001$, respectively) in untreated cows across the same time period. Relative abundance of TetW increased ($P < 0.0001$) during the dry period in both dry-treated and control cows. Administering long-acting antibiotics as intramammary dry therapy to dairy cows increases the selection pressure and subsequently increases the abundance and persistence of selected ARGs excreted during the dry period. Increased relative abundance of Int1 indicates increased potential of ARG dissemination by horizontal gene transfer.

Key Words: antibiotic resistance gene, cephapirin, prophylactic

162 Effect of oral administration of *Megasphaera elsdenii* on performance of Holstein cows during early lactation. K. D. Stevens*, M. L. Eastridge, S. K. Finney, and S. N. LeShure, *The Ohio State University, Columbus.*

Transition cows have a high risk for metabolic disease within the first 30 DIM. Administration of direct-fed microbials (DFM) may reduce the adverse effects that fresh cows experience during this transition period. *Megasphaera elsdenii* (*M. elsdenii*) is a lactic acid-utilizing bacterium that has shown promise as a potential DFM during the transition period. Primi- and multiparous Holstein cows (n = 162) at a commercial dairy herd in Ohio were assigned to 1 of 4 treatments: (1) control (no dose) (n = 44), (2) 200 mL Lactipro (*M. elsdenii*, 1×10^8 cfu/mL; MSBiotec, Littleton, CO) when cows entered (~−14 DIM) the close-up pen (n = 45), (3) 200 mL Lactipro at calving (n = 39), and 4) 200 mL Lactipro prepartum and 200 mL at calving (n = 34). Close-up cows were fed 71% forage (57:43 corn silage and wheat straw), and upon calving, cows entered the high group and were fed 41% forage (93:7 corn silage:wheat straw). All cows were body condition scored (BCS) prepartum and at 30, 60, and 90 DIM. Urine ketones (Ketostix; Bayer Corp., Leverkusen, Germany) were measured at 7 to 14 DIM. Cows were milked 3 times daily, and yield was recorded daily until 90 DIM using Afimilk (Kibbutz Afikim, Israel). Milk composition data were from monthly DHI (DHI Cooperative, Inc., Columbus, OH) samples taken from the first daily milking during the first 2 test dates postpartum. There was no difference in milk yield among treatments (39.8, 39.2, 39.7, and 40.3 ± 1.1 kg/d), and the test-day milk fat and protein percentages were similar among treatments. Test-day milk fat and protein were higher ($P < 0.001$) for the first (3.88%) versus second (3.38%) test-day, reflective of the low incidence of ketosis discussed below. Neither a difference in BCS by treatment nor a treatment by time interaction occurred. Based on urine ketones, only 2.5% of the cows in the study experienced clinical ketosis, but cows with ≥5 mg/dL were 31.8, 35.6, 25.6, and 17.6% for treatments, respectively. Concentrations of dietary starch and NDF fed both prepartum and postpartum may affect animal response to dosing with *M. elsdenii*.

Key Words: firect fed microbial, early lactation, *Megasphaera elsdenii*

163 Effect of heat stress in utero on calf performance and health through the first lactation. A. P. A. Monteiro*, S. Tao, I. M. Thompson, and G. E. Dahl, *University of Florida, Gainesville.*

Calves born to cows exposed to heat stress during the dry period have lower birth weight and weaning weight and compromised passive immune transfer compared with those born to dams that are cooled. However, it is unknown if heat stress in utero has carryover effects after weaning. The objective was to evaluate the effect of heat stress during late gestation on growth, fertility and milk production in the first lactation of the offspring. Data of animals obtained from previous experiments conducted during 5 consecutive summers were pooled and analyzed. Cows were dried off 46 d before expected calving and randomly assigned to either cooling (CL) or heat stress (HT). CL cows were housed under sprinklers, fans and shade, whereas only shade was provided to HT cows. Within 4 h after birth, 3.8 L of colostrum was fed to calves from both groups of cows. All calves were managed in the same manner and weaned at 49 d of age. Birth weight and survival of 147 calves (HT = 74; CL = 72) and body weight and growth rate from 72 heifers (HT = 34; CL = 38) were analyzed. Additionally, fertility and milk production in the first lactation from 38 heifers (HT = 17; CL = 21) were analyzed. As expected, HT calves were lighter (39.1 ± 0.7 vs. 44.8 ± 0.7 kg, $P < 0.01$) at birth than CL calves. CL heifers were heavier (200.2 ± 3.4 vs. 190.9 ± 3.7 kg, $P < 0.05$) up to one year old, but had similar weight gain (305.8 ± 5.9 vs. 299.1 ± 6.3 kg) compared with HT heifers. No differences in age at first AI or age at first parturition was observed, but HT heifers had a greater number of services per conception than CL heifers (2.6 ± 0.3 vs. 1.8 ± 0.3, $P = 0.03$). HT heifers tended to produce less milk up to 35 weeks of the first lactation compared with CL heifers (26.9 ± 1.9 vs. 29.3 ± 1.8 kg, $P = 0.11$), but no difference in body weight during lactation was observed (HT: 565.4 ± 12.0 kg; CL: 554.1 ± 11.0 kg). These data suggest that heat stress during the last 6 weeks of gestation negatively affects fertility and milk production up to and through the first lactation of offspring.

Key Words: calves, heat stress, postnatal performance

164 Association between dairy calf management practices and calf immune status. A. Bartier*, C. Windeyer, and L. Doepel, *University of Calgary, Calgary, Alberta, Canada.*

Dairy calves are at high risk of failure of passive transfer of immunity (FPT) if consumption of colostral IgG within hours of birth is inadequate. The objectives of this study were to determine (1) the incidence of FPT on Alberta dairy farms, (2) which neonatal calf management practices are used, and (3) the relationship between these practices and FPT. Fourteen commercial dairy farms were visited weekly from February to September, 2012. At each visit, blood samples were collected from

calves <7d old. Total serum protein (TSP) was determined with a refractometer and serum IgG was determined quantitatively by RID. Producers completed a survey for each calf outlining the management practices that were followed (e.g., amount of colostrum fed, time calf left with dam) in the first 7 d of life. A sample of first feeding colostrum was analyzed by RID for IgG content. A mixed linear models regression procedure was performed using TSP and serum IgG as response variables, management practices and colostrum IgG as predictor variables and 'farm' as a random effect. Data were obtained from 199 bull calves and 557 heifer calves. Minimum, maximum and mean ± SEM for TSP were 3.0, 10.0 and 5.39 ± 0.03 g/dL; for serum IgG, values were 0.35, 58.0 and 18.95 mg/ml. FPT was 44.7% based on TSP <5.2 g/dL and 27.7% based on IgG <10 mg/mL. Univariate analysis showed type of colostrum (e.g., pooled, dam) fed in the first 6 h and from 6 to 12 h of life, and amount of IgG consumed in the first 6 h of life to be significant predictors of serum IgG and TSP ($P < 0.0002$). Univariate analysis showed that type of milk (e.g., sale, waste) fed after colostrum, use of medications in the first week of life and if fresh or frozen colostrum was fed were significant only for serum IgG ($P < 0.03$); method of feeding in the first 6 h of life was significant only for TSP ($P < 0.003$). For the multivariate analysis all possible predictor variables were offered in the model and nonsignificant ($P > 0.05$) predictors were removed by backward elimination. IgG consumed in the first 6 h of life was the most important predictor variable ($P < 0.0001$) associated with both high serum IgG and TSP.

Key Words: IgG, calf management, FPT

165 Effects of acute feed restriction combined with targeted use of increasing LH in FSH preparations on superovulation and embryo quality in lactating dairy cows. R. W. Bender*, K. S. Hackbart, A. R. Dresch, P. D. Carvalho, L. M. Vieira, P. M. Crump, J. N. Guenther, R. D. Shaver, D. K. Combs, and M. C. Wiltbank, *University of Wisconsin-Madison, Madison.*

Superovulatory programs have multiple metabolic and hormonal factors that potentially affect success. This study evaluated the effect of acute feed restriction and increased luteinizing hormone (LH) content in the superovulatory preparation on superovulation response and embryo quality from lactating dairy cows. In each of 2 experiments, 16 lactating Holstein cows were superovulated in a Latin square design while exposed to a 2 × 2 factorial arrangement of treatments: feed restriction (FR; 25% reduction in DMI during 6 d before AI) vs. ad libitum (AL) feeding combined with high (H) vs. low (L) LH in the last 4 injections of the 8 injection superovulatory protocol. Embryos were flushed 7 d after AI. As expected, FR reduced circulating insulin concentrations ($P < 0.05$). Follicle numbers, ovulation rates, and corpora lutea on d 7 were not different. There was an interaction between FR and amount of LH on fertilization rates, percentage of structures that were Quality 1 and 2 embryos, and number of structures that were degenerate. In the first period analysis of experiments 1 and 2, fertilization rates were greater ($P < 0.01$) for the AL-L (89.4%) and FR-H (80.1%) treatments compared with the AL-H (47.9%) and FR-L (59.9%) treatments. Similarly, the proportion of total structures designated as Quality 1 and 2 embryos was greater ($P < 0.01$) for AL-L (76.7%) and FR-H (73.4%) treatments compared with AL-H (35.6%) and FR-L (47.3%) treatments. In addition, the number of degenerate embryos was lower ($P = 0.03$) for AL-L (1.3) and FR-H (0.4) treatments than AL-H (2.6) and FR-L (2.3) treatments. Thus, cows with either too low (FR-L) or too high (AL-H) of insulin and LH stimulation have lower embryo production following superovulation due to reduced fertilization rate and increased percentage of degenerate embryos. The interaction of the gonadotropin content of the superovulatory preparation with the nutritional program of the donor cow needs to be considered to optimize superovulatory success.

Key Words: superovulation, feed restriction, LH

166 Description of weighing errors and times during preparation of a ration. Y. Trillo*[1], A. Lago[2], and N. Silva-del-Rio[1], *[1]Veterinary Medicine Teaching and Research Center, University of California Davis, Tulare, [2]DairyExperts, Tulare, CA.*

The objectives of this study were to describe weighing errors, time intervals between loading ingredients, length of ration preparation, and dropping times for the high cow ration prepared in 4 California dairies (A, B, C, and D) ranging in size from 2,500 to 6,000 cows. Records from Jan to Dec 2012 were extracted from the feeding management software FeedWatch 7.0. The variables included were: date, drop number, recipe, ingredient, feeder, loading sequence, loading start-time, loading end-time, loading errors, dropping start-time, dropping end-time, and dropping sequence. Descriptive statistics were conducted with SAS 9.3. The high cow ration included 13 (A), 14 (B), 18 (C) and 12 (D) ingredients. All dairies had a main feeder and one (A), 2 (D) or 3 (B, C) relief feeders. The main feeder prepared 85% (n = 3,319), 64% (n = 2,547), 64% (n = 1,162) and, 83% (n = 1,949) of the high cow ration loads in dairy A, B, C and D respectively. The frequency in which ingredients were loaded with errors ≥ |2|% of the expected weight was 35.9% (A), 67.6% (B), 46.4% (C), and 44.0% (D) for the main feeders and 33% (A), 66% (B), 46% (C), and 48% (D) for the relief feeders. The frequency in which ingredients were loaded with errors ≤ |0.5|% of the expected weight was 22% (A), 8% (B), 13% (C), and 21% (D) for the main feeders and 22% (A), 9% (B), 15% (C), and 19% (D) for the relief feeders. Short intervals between loading of ingredients (<45 s) might indicate that the feeder was wrongly dropping leftovers from the previous ingredient in the next ingredient load. Intervals between loading of ingredients <45 s occurred in 12% (A), 14% (B), 1% (C) and 36% (D) of the loads done by the main feeder and in 7% (A), 16% (B), 1% (C) and 27% (D) of the loads done by the relief feeder(s). The first drop of the day had an interquartile range (Q0.25 – Q0.75) of 10 (C), 14 (A, B), and 20 (D) min whereas for the last drop of the day was 9 (D), 24 (C), 52 (A) and 54 (B) min. Feeding management software could be used to identify opportunities to improve the feeding process. Future research should define achievable goals on feeding management practices for dairies.

Key Words: dairy cow, feeding management, software

167 Evaluation of multiple ancillary therapies utilized in combination with an antimicrobial in newly received high-risk calves treated for bovine respiratory disease. B. K. Wilson*[1], C. L. Maxwell[1], D. L. Step[2], C. J. Richards[1], and C. R. Krehbiel[1], *[1]Department of Animal Science, Oklahoma State University, Stillwater, [2]Department of Veterinary Clinical Sciences, Oklahoma State University, Stillwater.*

This experiment evaluated 3 commonly used ancillary therapies in combination with an antimicrobial in high-risk calves treated for bovine respiratory disease (BRD). Crossbred steers (n = 516; initial BW = 217 ± 20 kg) were monitored daily for clinical signs of BRD. Calves that met treatment criteria (n = 320) were randomly assigned to 1 of 4 experimental treatment groups: intravenous flunixin meglumine injection (NSAID), intranasal viral vaccination (VACC), intramuscular vitamin C injection (VITC), or no ancillary therapy (NOAC). Mortality attributed to BRD was 13%. Data were analyzed using the GLIMMIX procedure (SAS 9.3) with pen (n = 16; 4 per experimental treatment) serving as the experimental unit. Steers receiving VACC tended (P = 0.10) to require a second BRD treatment less frequently than steers receiving NSAID or NOAC. Calves receiving NSAID or VITC tended (P = 0.09) to require a third BRD treatment less often than calves receiving NOAC. Of calves treated 3 times for BRD, those receiving NOAC had lower (P = 0.05) severity scores than those receiving VACC or VITC and heavier (P = 0.02) BW than those receiving NSAID, VACC, or VITC at the time of third treatment. Between the second and third BRD treatments, calves receiving NOAC also had greater (P = 0.03) ADG than those receiving VACC or VITC and tended (P = 0.06) to have greater ADG than those receiving NSAID. Calves receiving NOAC tended (P = 0.07) to have heavier BW on d 28 than NSAID, VACC, or VITC with mortalities and removals excluded. When contrasted with the average of NSAID, VACC, and VITC calves, NOAC calves tended (P < 0.10) to have heavier BW on d 56, greater ADG and DMI from first BRD treatment through d 28, greater DMI from d 28 through d 56, and had greater (P = 0.05) DMI from first BRD treatment through d 56 with mortalities and removals excluded. Responses to ancillary therapy were negligible in this experiment. The use of NSAID, VACC, and VITC appears to have minimal benefits and could potentially be detrimental to animal performance in severely challenged calves.

Key Words: ancillary therapy, bovine respiratory disease, high-risk calf

168 Interactions of rectal temperature status and vaccine type with sire on weight gain and feed intake in *Bos indicus* crossbred steers following Bovine Viral Diarrhea Virus challenge. C. A. Runyan*[1], X. Fang[1], E. D. Downey[1], T. B. Hairgrove[2], J. E. Sawyer[3], J. G. Moreno[1], J. F. Ridpath[4], and A. D. Herring[1], *[1]Texas A&M University, College Station, [2]Texas Agrilife Extension, College Station, [3]Texas Agrilife Research, College Station, [4]USDA-ARS, Ames, IA.*

Half-blood (F_2 and F_3), yearling Angus-Nelore steers (n = 106) were evaluated in 2012 for weight gain, feed intake, and rectal temperature after vaccination for Bovine Respiratory Disease (BRD) pathogens and subsequent intranasal challenge with Bovine Viral Diarrhea Virus (BVDV). Steers were confirmed free of BVD persistent infection and stratified by sire over 3 vaccine groups of killed (KV; n = 35), modified-live (MLV; n = 35), and non-vaccinated (NON; n = 36). KV steers received immunizations at d −49 and d −28, and MLV steers received a single immunization at d −28. On d 0 all steers were challenged via intranasal ingestion of BVDV Type 1b strain CA0401186a. Weights and rectal temperatures were collected on d 0, 3, 7, 10, 14, 28, 42. Steers were housed in 4 pens (balanced across vaccine groups) with daily feed intake (DFI) collected via a Growsafe system. A rectal temperature threshold over 40°C on evaluation days was used to classify steers for rectal temperature status (RTEMP). Mixed model procedures, with repeated measures were used to analyze DFI with a model that included fixed effects of vaccine group (VAC), pen, day, sire, RTEMP, and 2-factor interactions for VAC × RTEMP, sire × RTEMP, Sire × VAC and day × VAC; all were significant except VAC. ADG was calculated for the three 14-d periods as well as the 42-d period and was analyzed with a model containing similar fixed effects plus d-0 weight as a covariate; pen, Sire x VAC, and Sire × RTEMP were significant. For the Sire × RTEMP interaction (DFI, P < 0.01; ADG from d 0–42, P = 0.03), most sires had progeny rank higher for DFI and ADG when below RTEMP threshold, but some had higher DFI and ADG for progeny above RTEMP threshold. There was not a consistent trend across sires for the Sire × VAC interaction for DFI (P < 0.01) or ADG from d 0–42 (P = 0.05), implying that DFI and ADG may be affected quite differently across genetic backgrounds following BRD vaccination and subsequent pathogen exposure.

Key Words: BVDV, feed intake, ADG

169 Using DNA paternity testing to evaluate commercial bull performance. D. J. Drake[2], K. L. Weber[1], and A. L. Van Eenennaam*[1], *[1]Department of Animal Science, University of California, Davis, [2]University of California Cooperative Extension, Yreka.*

DNA markers for paternity identification were used to evaluate the breeding performance of bulls in multisire natural service breeding pastures on 3 large ranches in northern California for 3 consecutive years. All bulls passed breeding soundness examinations and were grouped with bulls of similar age. Two of the ranches had both fall- and spring-calving herds, while the third ranch had only a single fall calving herd. Breeding seasons ranged from ~90 d to 120 d depending upon the ranch. The cow:bull ratio was approximately 25 cows to 1 although the size of the group varied, giving bulls in larger groups access to a larger number of cycling females on any given day. Birthdate records and DNA samples were collected on 5,382 individually identified calves enrolled in the trial. Of these 5,272 (98%) were assigned to an individual sire. Bulls present per season (n = 296) produced 17.8 ± 13.1 progeny per calf crop, ranging from 0 to 63. Bulls with reduced breeding seasons due to injury or lack of condition produced fewer calves 9.1 ± 2.2 compared with full breeding season bulls 18.9 ± 0.78 progeny (P < 0.01). Bulls produced similar numbers of progeny across ranches (18.5 ± 1.2, 20.4 ± 1.8, 18.5 ± 1.4, P = 0.63), years (19.6 ± 0.4, 19.2 ± 1.4, 17.9 ± 1.4, P = 0.68), and season (20.3 ± 1.5, 18.3 ± 0.9, P = 0.27). The maximum number of calves sired by one bull in one day was 11 when placed with naturally cycling, unsynchronized females. The more prolific bulls sired more early calves (d 1–21 of the calving season) than low prolificacy bulls (P = 0.05). SC EPD was positively related to prolificacy (R^2 = 0.05, P < 0.01). There was a trend (R^2 = 0.01, P = 0.14) for older bulls to sire an increased number of progeny. Although most bulls in the study were Angus, the calves that were sired by South Devon (n = 217) and Hereford (n = 145) bulls were on average 20.4 kg and 16.4 kg heavier (P < 0.01) at weaning respectively, due to heterosis in these herds with high percent Angus commercial females. Prolificacy was the main driver of bull contribution to ranch income explaining 98.4% of the variation, whereas the individual calf value explained only another 0.88% of the variation.

170 Field assessment of progeny from sires with divergent residual feed intake genetic test results. K. L. Weber*[1], B. Welly[1], J. A. Rendon[2], C. Antwi[3], G. Acetoze[1], E. Kebreab[1], E. D. M. Mendes[4], and A. L. Van Eenennaam[1], *[1]University of California, Davis, Davis, [2]Universidad Autonoma de San Luis Potosi, San Luis Potosi, Mexico, [3]Kwame Nkrumah University of Science & Technology, Kumasi, Ghana, [4]Embrapa, Corumba, MS, Brazil.*

Due to the high cost of feed in beef production systems, there is interest in selecting cattle for feed efficiency, or ability to convert feed to marketable product. One measure of feed efficiency is residual feed intake (RFI), defined as the difference between observed feed intake and that predicted from metabolic body weight and rate of gain. The objective of this demonstration project was to assess the RFI in progeny derived from 2 Angus sires (HIGH, LOW) whose RFI breeding values differed by 0.32 kg/d based on the HD 50K MVP genetic test (Zoetis, Kalamazoo, MI). At 8 mo of age, 8 steer progeny from each sire, selected by live weight, were fed a growing ration (NEm 0.915 MJ/kg, NEg 0.525 MJ/kg). The steers' feeding intake and behavior were measured over 70 d using the GrowSafe System (Airdrie, AB Canada), and RFI calculated (RFI-GROW). The steers were finished in individual pens at the UC Davis feedlot, and finishing ration (NEm 1.76 MJ/kg, NEg 1.18 MJ/kg) feed intake was manually recorded. Body weights and ultrasound measures were taken every 2 weeks. Finishing RFI (RFI-FINISH) was calculated over an average of 91 d (70–105 d). Slaughter end point was determined based on ultrasound backfat thickness (11 mm), and a variety of carcass measurements were collected. Significance testing was performed using GLM procedures in R. Steers from the LOW RFI sire tended toward lower RFI-GROW (−0.64 kg/d, $P = 0.087$), with reduced visits to the bunk ($P < 0.05$) and increased visit duration ($P < 0.01$) when group-housed with GrowSafe. RFI-FINISH was significantly lower for LOW steers (−0.56 kg/d, $P < 0.05$). During the finishing period, LOW steers had heavier mid-test weights ($P < 0.05$), and a trend toward higher ADG ($P = 0.078$) and higher mid-test weight/hip height ($P = 0.083$). At slaughter, LOW steers had heavier empty body weights ($P < 0.01$) and increased carcass specific gravity ($P < 0.05$), suggesting LOW animals were leaner than HIGH animals for their carcass weight. These data showed a consistent trend of improved feed efficiency during both the growing and finishing phase in the steer progeny derived from the LOW RFI MBV Angus sire.

Key Words: beef, feed efficiency, genomic prediction

171 Relationships between residual feed intake EPD and metabolic variables of progeny from Red Angus sires divergent for maintenance energy EPD. C. M. Welch*[1], S. E. Speidel[2], W. J. Price[1], J. K. Ahola[2], J. B. Hall[1], G. K. Murdoch[1], D. H. Crews Jr.[2], C. S. Schneider[1], and R. A. Hill[1], *[1]University of Idaho, Moscow, [2]Colorado State University, Fort Collins.*

The Red Angus Association of America has developed the maintenance energy (ME_M) EPD as an estimator of maintenance requirements. Due to the associations among energy expenditure, performance, and feed intake, it has been proposed that ME_M EPD may be associated with residual feed intake (RFI). Postweaning RFI and other performance measures were recorded in 3 birth year contemporary groups from the progeny (n = 222) of sires (n = 12) divergent for ME_M EPD. The objectives of this study were to 1) identify relationships between sire RFI EPD and progeny serum IGF-I concentration and myogenic gene expression, and 2) identify the relationship between sire ME_M EPD and RFI EPD. Sires were partitioned into high (inefficient) and low (efficient) RFI groups based on their RFI EPD. For modeling purposes, RFI groups were considered as fixed effects while contemporary groups were random effects. Serum IGF-I concentration (collected at weaning) was higher ($P < 0.05$) in the high RFI group. In addition, serum IGF-I concentration was positively correlated (r = 0.34; $P < 0.0001$) with RFI EPD. Using biopsy samples collected from the biceps femoris, the relationship between key genes in various regulatory pathways and RFI EPD were evaluated, and no associations ($P > 0.05$) were detected for gene expression and RFI EPD. Furthermore, sire ME_M EPD was found to be negatively correlated (r = −0.26; $P < 0.003$) with sire RFI EPD. Therefore, our data analyses indicate (1) serum IGF-I concentration may be an underlying metabolic indicator of RFI due to its relationship with RFI EPD, (2) evaluation of myogenic gene expression offered no insight into the physiological mechanisms associated with the RFI phenotype, and (3) the negative correlation between RFI EPD and ME_M EPD may suggest that a properly weighted selection index tool could be developed to improve efficiency of feed utilization.

Key Words: EPD, IGF-I, residual feed intake

172 Factors influencing feed efficiency of beef cows of varying proportion of Brahman influence. S. W. Coleman* and J. P. S. Neel, *USDA ARS, El Reno, OK.*

Feed constitutes the greatest proportion of costs in cow-calf production. Therefore, genetic merit for feed efficiency has received interest from producers, but has generally been assessed in growing animals. The objectives of this study were to determine the main factors that contribute to variance in feed intake and determine whether proportion Brahman genetics (B) interacts with those factors. Ninety cows, varying in proportion Brahman influence (0, 1/4 and 1/2), were fed in groups of 30 over 3 seasons (S; 2 spring- and 1 fall-calving) in pens designed to determine individual feed intake. Within about 3 wk postpartum, cows and their calves were evaluated throughout lactation. Cow and calf weights and milk production and composition were determined at monthly intervals. Sorghum silage was the primary dietary component for cows, being supplemented with a grain and cottonseed mix to mimic forage from rangeland. Calves were offered whole oats in separate creep feeders. Diet samples were taken at weekly intervals and analyzed for CP and IVDMD while refusals were taken as needed. The diets averaged 8.2, 7.6, and 8.8% CP and 55.7, 50.3, and 48.9% IVDMD for each of the seasons, respectively. Digestible dry matter intake (DDMI) of cows was the variable of interest and analyzed using GLM of SAS. The model included class effects of S and B, continuous variables average daily milk energy produced, calf ADG, cow weight, and season-long weight change, and interactions of S and B with the continuous variables. Season ($P < 0.01$), milk energy ($P = 0.07$), calf ADG ($P < 0.01$), and the interaction of B with calf ADG ($P < 0.08$) and cow weight ($P = 0.06$) influenced DDMI ($R^2 = 0.9$). Each additional kg of calf ADG required 1.13 kg DDM, but cows with either 0 or 1/2 Brahman required less than those with 1/4 Brahman influence. A kg of milk energy required 1.32 kg additional DDM. Cows generally lost weight over the lactation on these diets, but the level of loss did not influence variation in intake. Dry matter intake of these cows was greater than that predicted by the NRC equation.

Key Words: feed efficiency, cow-calf, Brahman influence

173 The effect of heterosis of dam and crossbreeding on progeny's feed efficiency, performance and carcass characteristics. K. M. Retallick*[1], D. B. Faulkner[2], S. L. Rodriguez-Zas[1], J. D. Nkrumah[3], and D. W. Shike[1], *[1]University of Illinois, Urbana, [2]University of Arizona, Tucson, [3]Pfizer Animal Genetics, Kalamazoo, MI.*

Two experiments (1: n = 577) (2: n = 158) were conducted to analyze maternal effects and crossbreeding on subsequent steer performance,

carcass, and feed efficiency traits. Steers were early weaned at 78 ± 24 d of age and randomly pen allotted. Steers were managed similarly before weaning and fed a common finishing diet. In experiment 1, Angus (AN) and/or Simmental (SM) maternal dam breeds were represented: (1) 100% AN (AN), (2) 75% AN (75AN), (3) 50% AN (50AN), and (4) 25% AN (25AN). The remaining percentage was SM. Results from experiment 1 showed that DMI was 0.22 kg/d lower ($P < 0.05$) for progeny of 75AN and 50AN indicating a positive influence of maternal heterosis. Consequently, residual feed intake (RFI) had a tendency to improve ($P = 0.06$) for 75AN and 50AN compared with AN and 25AN dams. Residual BW gain of progeny tended to improve ($P = 0.07$) as percent of AN decreased in the dams. Steers whose dams had a decreased percentage of AN also had more desirable ($P < 0.05$) LM area, backfat, and yield grade. In conclusion, experiment 1 showed that dams of varying AN breed composition produce offspring that perform differently in the feedlot with progeny that were from 75AN dams excelling in the feedlot. In experiment 2, purebred AN and SM sires and dams were utilized. Experiment 2 resulted in progeny from SM dams having a more desirable RFI ($P < 0.05$). An improved HCW, backfat, LM area, and consequently yield grade was shown by progeny of SM dams ($P < 0.05$); however, marbling score was 80 units higher for progeny of AN dams ($P < 0.05$). When compared, sire breeds had no difference in HCW ($P = 0.82$), but SM-sired progeny had an advantage in LM area, backfat, and yield grade ($P < 0.05$). The only sire by dam breed interaction was for marbling score ($P = 0.05$). Experiment 2 showed both maternal and paternal effects on progeny in the feedlot with the maternal advantage in RFI given to progeny of SM dams. Overall, maternal breed effects on performance, feed efficiency measures, and carcass traits of resulting progeny appear to be important.

Key Words: feed efficiency, feedlot, maternal breed effect

174 Relationship among performance, carcass, and feed efficiency characteristics and their ability to predict economic value in the feedlot. K. M. Retallick*[1], D. B. Faulkner[2], S. L. Rodriguez-Zas[1], J. D. Nkrumah[3], and D. W. Shike[1], *[1]University of Illinois, Urbana, [2]University of Arizona, Tucson, [3]Pfizer Animal Genetics, Kalamazoo, MI.*

A 4-year study was conducted utilizing 736 steers of known Angus, Simmental, or Simmental × Angus genetics to determine performance, carcass, and feed efficiency factors explaining variations in economic performance. Steers were pen-fed and individual DMIs were recorded using the GrowSafe feeding system (GrowSafe Systems Ltd., Airdrie, Alberta, Canada). All steers received similar diet and management. Feed efficiency values investigated were: feed conversion ratio (FCR), residual feed intake (RFI), residual BW gain (RG), and residual BW gain and intake (RIG). Data were analyzed using stepwise option of PROC REG in SAS (SAS Inst., Inc., Cary NC) to determine regression intercept, slope, and model fit (R^2) explaining variation within each pricing scenario. Dependent variables were carcass value ($/steer), profit ($/steer), feed costs ($/steer*$d^{-1}$), and cost of gain ($/kg). Independent variables were year, DMI, ADG, HCW, LM area, marbling, yield grade, dam breed, and sire breed. A 10% improvement in RG ($P < 0.05$) yielded the most favorable cost of gain (−0.09 $/kg) and carcass value (17.92 $/steer). Carcass value increased ($P < 0.05$) as feed efficiency improved by 10% for FCR, RG, and RIG. Profit increased with a 10% improvement feed efficiency ($P < 0.05$) with FCR at 34.65 ($/steer), RG at 31.21 ($/steer), RIG at 21.66 ($/steer), and RFI at 11.47 ($/steer). The model for carcass value explained 96% of the variation among carcasses and included HCW, marbling score, and yield grade. Average daily gain, marbling score, yield grade, DMI, HCW, and year born constituted 81% of the variation for the prediction of profit. Variation in cost of gain was mainly explained by ADG and DMI ($R^2 = 0.78$). Prediction equations were developed that excluded ADG and DMI and included feed efficiency values. Cost of gain was explained primarily by FCR ($R^2 = 0.71$). Seventy-three percent of profitability was explained with RG and marbling accounting for 55% of this total explained variation. These models represent the relative importance of factors contributing to economic success in feedlot cattle based on current prices.

Key Words: feedlot economics, feed efficiency

175 Grass-finishing high-value beef: A pilot project in northern United States. P. Lammers*[1], M. Honeyman[2], R. Dewell[2], and S. Millman[2], *[1]Illinois State University, Normal, [2]Iowa State University, Ames.*

Grass-finished beef is a growing niche market but producer adoption of this feeding strategy has been limited. Consistently producing high-value beef on forage alone is challenging. Intramuscular fat (IMF) is a key factor in beef quality grading; both diet and genetics influence IMF. Ultrasound scanning of growing cattle can be used to identify cattle with high-IMF potential and predict carcass quality. This pilot study examined the potential for producing USDA Quality grade Choice beef by combining scanned IMF data with pasture management. Yearling Angus heifers (22 hd) were blocked by scanned IMF and body weight. Blocks of cattle were allotted to either pasture or feedlot on May 7, 2012 at the Armstrong Research Farm, Lewis, IA (41°N 95°W). The 10.5 ha pasture was a mix of alfalfa (*M. sativa*) and smooth brome (*B. inermis*). Initially, grazing cattle were moved to a fresh paddock every 3–4 d with surplus forage harvested to maintain pasture quality. In mid-July, overly dry conditions prevailed and cattle were given access to the entire pasture until marketing. Feedlot cattle were fed a mixed ration of 45% corn grain, 32% modified distillers grain, 20% ground hay, and 2% supplement that included monensin (DM basis). No cattle were implanted, fed hormones, or antibiotics. Cattle were weighed every 28-d until the average BW of the treatment group reached 453.5 kg. Cattle were weighed and scanned before harvest at a commercial abattoir where carcass data was collected. Initial BW and IMF and final BW were not different for the 2 treatments ($P > 0.5$). Feedlot cattle grew faster (1.78 vs. 0.94 kg/d, $P < 0.001$), had 0.41 cm more fat cover ($P = 0.02$), and produced a 7% larger carcass ($P = 0.05$). Yield grade, LMA, and scanned IMF at market were similar ($P \geq 0.08$) for both groups. All cattle increased IMF content during finishing and based on final scanned IMF, ≥90% of cattle in both treatments were expected to grade Choice. Ultimately 92% of feedlot heifers but only 60% of pasture heifers graded Choice or better. Fat cover of the pasture cattle was yellow which may explain why the scanned IMF did not predict the quality grade at the abattoir.

Key Words: beef quality, grass-finished, grazing

Bioethics Symposium II: Is Modern Animal Agriculture Ethically Defensible?

176 The food morality movement: The race to the moral high ground. K. Murphy*, *Food-Chain Communications LLC, Lees Summit, MO.*

Many critics of modern, intensive farming and food production have shifted their criticism to one based upon questions of religion, ethics and morality. We term this "the food morality movement" (FMM). The FMM often employs the language of science, food-safety, environmental impact and socio-economics to entice the general public into debate regarding ethical questions involving social justice, environmental justice, economic equality, animal rights, and others. Animal scientists and others who must respond to FMM-based criticism must adapt their response to incorporate several elements of a morality-focused defense, including reclaiming the farmer's moral heritage, relearning communication strategies based on morality, avoiding internecine strife caused by misunderstanding of FMM motives, and shedding lingering guilt based on moral uncertainty. The modern food system needs an agricultural apologia to answer the FMM in the race to the moral high ground.

Key Words: food morality movement, modern food system, animal science

177 Consumer perception of production process attributes for pork and lunchmeat products. M. G. S. McKendree*, N. J. O. Widmar, and C. C. Croney, *Purdue University, West Lafayette, IN.*

Livestock producers are facing a changing marketplace. Consumers are increasingly focused on the practices used to produce their food and are especially interested in the treatment of livestock. An online survey of 798 US consumers was conducted in June 2012. One objective of this study was to determine consumer purchasing patterns of meat and dairy products, and perceptions of hog rearing and livestock product attributes. Fourteen percent of respondents reported reduced overall pork consumption due to animal welfare/handling concerns in the past 3 years. Of those included in the survey, concern for pig rearing practices was highest for intensive housing practices; fewest respondents were concerned about castration and ear notching. Although concern for livestock animals is often discussed, consumers' actual shopping decisions focus on individual products. Lunchmeat purchasing and preferences for lunchmeat attributes were assessed. Inconsistencies were found between which lunchmeat attributes consumers associated with high quality and which attributes they actually considered during purchase. Over 73% of respondents agreed that "produced on farms with animal welfare and handling standards in place" and "produced by farmers certified in animal welfare techniques" were associated with higher quality lunchmeats. Of those purchasing lunchmeat, only 47% and 45% of respondents, respectively, reported considering these attributes during purchase. When asked about concern for animal welfare and food safety, the majority of products studied elicited concern from more respondents for food safety. Staple products (milk, eggs and ground beef) generated concern for the largest number of respondents. Numbers of respondents indicating concern varied across products, even when they were produced by the same animal species (i.e., steak versus roast beef lunchmeat). This work suggests that consumers' values and beliefs influence their perceptions of important product attributes (such as food safety and animal welfare/handling) and potentially their purchasing behavior. However, high variation exists in concerns as a function of the product type and attribute.

Key Words: consumer demand, animal welfare, pork

178 An analysis of perceived obligations by consumers across animal species: Livestock, pet, or neither? M. G. S. McKendree*, C. C. Croney, and N. J. O. Widmar, *Purdue University, West Lafayette, IN.*

Do perceived concerns about and obligations to animals vary based on their classification as a pet, livestock animal, or neither? An online survey (n = 798) was conducted with an objective of determining consumers' classification of animal species, the relationship between classification and opposition to eating those species, and the relationship between pet ownership/crating and their perceived obligations to animals. The survey collected information on household demographics, pet ownership and perceptions of pets, and perceptions of traditional and non-traditional livestock animals. One interesting species classification was the horse, with 55% selecting pet, 27% livestock and 18% neither. Respondent opposition to eating animals varied by animal species; 81 respondents opposed eating a beef cow while 151 opposed eating a dairy cow. Respondents opposed to eating certain animal species were less opposed to others eating them. Tying classification with opposition to eating animals, those classifying a beef cow as non-livestock more often reported opposition to eating animals than those classifying a beef cow as livestock. Sixty-six percent of respondents reported having at least one household pet. At the 95% confidence level, respondents with cats and/or dogs more frequently reported concern about livestock animal welfare than those without cats and dogs. Of those with cats and/or dogs, 20% reported using cages/crates. However, no statistical differences were found between those who used crates/cages and those who did not regarding their level of concern for pig housing and management practices (including gestation crates, farrowing crates, group housing, and indoor confinement). Dog and/or cat owners more frequently reported having a source for animal welfare information (51% of dog and cat owners vs. 32% without a cat/dog). Understanding consumers' views of different livestock species, their perceived obligations to animals and sources of relevant information is an important step in facilitating constructive discussions of agricultural animal care, welfare and ethics that incorporates layperson's beliefs and values.

Key Words: animal welfare, pet, livestock

179 Industry stakeholder views on dairy cattle welfare. B. A. Ventura*, M. A. G. von Keyserlingk, and D. M. Weary, *Animal Welfare Program, Faculty of Land and Food Systems, University of British Columbia, Vancouver, BC Canada.*

Increasing stakeholder engagement is important as the dairy industry seeks to address societal concerns about the welfare of farm animals. The aim of the current study was to facilitate engagement among stakeholders and to describe their perspectives on key issues affecting the welfare of dairy cattle. Five heterogeneous focus groups were conducted during a dairy cattle industry meeting in Guelph, Canada in October 2012. Each group contained between 7 and 10 participants and consisted of a mix of dairy producers, veterinarians, researchers, students, and industry specialists. The 1 h facilitator-led discussion focused on participants' perceptions of the key welfare issues and the role of different groups in addressing these concerns. Discussions were

audio-recorded and transcribed verbatim, and the resulting transcripts coded and the themes identified. Lameness was uniformly recognized as the most important welfare issue facing dairy cattle; cow comfort, painful procedures (such as dehorning) and other production diseases (such as mastitis) were also commonly discussed. Participants had mixed views on the roles of different stakeholders in formulating solutions; many felt that producers and others working within the dairy industry should be primarily responsible, but some believed that members of the general public also had an important role. Participants agreed that improved knowledge translation from researchers to producers and from dairy industry groups to the public was required to develop solutions to these concerns. These results illustrate the value of stakeholder engagement in developing solutions to dairy cattle welfare concerns.

Key Words: stakeholder attitudes, animal welfare, engagement

Breeding and Genetics: Applications and Methods in Animal Breeding—Pigs

180 Survival analysis of mice divergently selected for heat loss. A. S. Bhatnagar* and M. K. Nielsen, *University of Nebraska-Lincoln, Lincoln.*

Improvement in feed efficiency was achieved by reducing maintenance energy requirement without changing output in mice divergently selected for heat loss (MH = high, ML = low, MC = control). In 3 replicates of selection, feed intake at the same mature weight differs greatly (MH/ML~1.38). However, correlated decline in reproductive stayability may negate the benefit in reduced feed intake. For each line by replicate combination, 21 mating pairs were sampled at 7 wk of age (189 pairs). Pairs were culled due to death or illness of either member, no first parity by 42 d cohabitation, 2 consecutive litters with none born alive, 3 consecutive litters with none weaned, 42 d between parities, or average size of most recent 2 litters less than half the average of first 3 litters. All pairs were culled by 1 yr cohabitation. Survival curves were produced from Kaplan-Meier estimates and hazard ratios were produced using Cox proportional hazard model. Data were analyzed over the entire study and in 2 periods (P1: ≤ 5 parities, P2: > 5 parities). A competitive risk analysis was performed to explore risk of culling for each criterion. Log-rank tests of survival curves and hazard ratios showed similar trends. Overall, there was no difference in hazard rates between MH and ML mice. However, MH mice were 2.57 more likely to be culled than ML mice in P1 ($P < 0.04$) but 0.55 times less likely in P2 ($P < 0.04$). MH and ML mice had an increased hazard over MC mice ($P < 0.03$ and $P < 0.01$, respectively). MH mice carried an increased risk of 3.49 ($P < 0.02$) in P1, while ML mice carried an increased risk of 2.58 ($P < 0.01$) in P2 compared with MC mice. There were no differences found in the competitive risk analysis between MH and ML mice for any culling criteria. Results indicate that MH mice are more likely to be culled early and ML mice later, but MC mice have greater survival rates. For systems where smaller maximum parities are desirable, ML mice have less involuntary losses and thus enhanced efficiency in addition to their lower maintenance. But this advantage erodes in systems allowing larger numbers of parities.

Key Words: survival, feed efficiency, mice

181 Genome-wide association mapping including phenotypes from relatives without genotypes for three traits in broiler chickens. H. Wang*[1], I. Misztal[1], I. Aguilar[2], A. Legarra[3], W. Muir[4], R. Fernando[5], and R. Hawken[6], *[1]University of Georgia, Athens, [2]INIA, Las Brujas, Uruguay, [3]INRA, Toulouse, France, [4]Purdue University, West Lafayette, IN, [5]Iowa State University, Ames, [6]Cobb-Vantress Inc., Siloam Springs, AR.*

The purpose of this study is to extend genome-wide association studies using a single-step method (ssGBLUP) for a multi-trait model in broiler chickens. Data set consisted of 2 pure lines (L1 and L2) across 5 generations for 3 traits: body weight at 6 wk (BW6), ultrasound measurement of breast meat (BM), and leg score (LS) coded 1 = no and 2 = yes for leg defect. In total, there were 294,632 and 274,776 individuals in pedigree for L1 and L2, of which 4667 and 4553 were genotyped using a SNP 60k panel. After standard quality control, 40,615 SNP markers remained for analyses. For BM, there were ~74% missing phenotypes in both lines. Pedigree, phenotypic and genomic information were combined, and a multi-trait linear model was used through ssGBLUP. Genomic breeding values were calculated for all individuals in pedigree and converted to SNP effects. Variances of markers were calculated from SNP solutions and included as weights in a new genomic relationship matrix. The last step was repeated 5 times. Manhattan plots were constructed as proportion of genetic variance explained by each region consisting of 20 consecutive SNP markers. Several peaks explaining >1% of the genetic variation were found for BW6; however, peaks for L1 and L2 are on different chromosomes. No strong peaks have been observed for BM and LS, and each region for these traits explained <1% of total genetic variance. BM and LS seem to follow the infinitesimal model. Different peaks for the 2 lines for BW6 suggest different selection goals. The ssGBLUP approach allows for simple GWAS with complex models and easy accommodation of information from genotyped animals.

Key Words: chicken, genome-wide association, multi-trait model

182 Accuracy of estimation of genomic breeding values in pigs using low density genotypes and imputation. Y. M. Badke*[1], R. O. Bates[1], C. W. Ernst[1], J. Fix[3], and J. P. Steibel[1,2], *[1]Department of Animal Science, Michigan State University, East Lansing [2]Department of Fisheries & Wildlife, Michigan State University, East Lansing, [3]National Swine Registry, West Lafayette, IN.*

Genomic selection has the potential to increase genetic progress. Genotype imputation of high density SNP genotypes can improve cost efficiency of genomic breeding value (GEBV) prediction for pig breeding. Consequently, the objectives of this work were to (1) estimate accuracy of GEBV in a Yorkshire population and (2) quantify the loss in accuracy of GEBV prediction when genotypes were imputed (accuracy = 0.95) in selection candidates. Phenotypes (Table) and genotypes obtained with the PorcineSNP60 BeadChip were available for 965 Yorkshire boars. Genotypes of selection candidates were masked and imputed using tagSNP in the GeneSeek Genomic Profiler (10K). Imputation was performed with BEAGLE using 128 haplotypes as reference panel. SNP effects were estimated with ridge regression using de-regressed breeding values as response variables. Accuracy of GEBV was estimated as the squared correlation between estimated breeding values (EBV) and GEBV in a 10-fold cross validation design. Accuracy of GEBV prediction from observed genotypes (r^2_{obs}) ranged from 0.03 for LBW to 0.47 for BF (Table). Variation in accuracy between traits largely depended on the number of boars (N) with usable EBV. Using imputed genotypes for GEBV estimation caused a slight decrease in the accuracy of GEBV (r^2_{imp}) with the proportion of r^2_{imp} to r^2_{obs} ranging from 0.87 to 0.99. GEBV prediction from imputed genotypes is a cost efficient alternative for implementation of genomic selection in pigs. Furthermore, genotyping animals at lower cost and low density, followed by imputation, can result in increased accuracy by allowing more animals into the training panel.

Table 1. Accuracy of genomic prediction

	Backfat thickness	Days to 250 lb	Litter birth weight	Loin muscle area	Litter weaning weight	No. born alive	No. weaned	Wean to estrus
Boars with usable EBV (no.)	965	936	302	938	612	532	482	332
h^2	0.45	0.26	0.19	0.47	0.065	0.08	0.02	0.33
r^2obs	0.47	0.45	0.03	0.45	0.25	0.18	0.21	0.14
r^2imp	0.45	0.44	0.06	0.40	0.23	0.16	0.18	0.13
r^2imp/r^2obs	0.95	0.99	NA	0.89	0.91	0.93	0.87	0.90

Key Words: genomic prediction, pig, imputation

183 Estimation of US Yorkshire breed composition using genomic data. Y. Huang*[1], R. O. Bates[1], C. W. Ernst[1], J. S. Fix[2], and J. P. Steibel[1,3], *[1]Department of Animal Science, Michigan State University, East Lansing, [2]National Swine Registry, West Lafayette, IN, [3]Department of Fisheries and Wildlife, Michigan State University, East Lansing.*

White coat color, as an indication of breed purity has been a long-time selection requirement for the Yorkshire breed. Currently, color verification is completed using a test mating program, which creates an inefficient use of time and resources. In this study, genomic information from local chromosomal regions surrounding the positions where coat color genes are physically mapped, as well as the whole genome were applied to estimate breed composition of purebred Yorkshire animals. Genotypes for ~60,000 SNP from the Illumina PorcineSNP60 Beadchip (60K), including ~8,500 SNP from the GeneSeek Genomic Profiler for PorcineLD (GGP) (GeneSeek, Lincoln, NE) were available for reference animals, in which the genetic background was known, and study animals, that included Yorkshire sires (Tes_York, n = 889), and known crossbred animals that had Yorkshire heritage (Tes_U, n = 12). Haplotypes of 9 SNPs flanking the KIT gene (Dominant white) were developed for reference animals for the Duroc (n = 60), Hampshire (n = 52), Landrace (n = 56), Yorkshire (n = 64) and Pietrain (n = 15) breeds. Haplotypes observed in white reference breeds (Yorkshire and Landrace) were detected in 97% and 62% of haplotypes from Tes_York and Tes_U, respectively. Therefore, multi-SNP haplotypes flanking KIT can be used to classify animals that are not of Yorkshire or Landrace breed origin. In addition, whole genome SNP information was used in regression analyses to further differentiate breed composition. Using 60K SNP, regression coefficients for Yorkshire, indicating relative Yorkshire composition, ranged from 0.79 to 1.07 and 0.52 to 1.06 in Tes_York and Tes_U, respectively. Regression coefficients for Hampshire ranged from −0.029 to 0.052 and −0.005 to 0.38 in Tes_York and Tes_U, respectively. Animals in Tes_U were likely of Yorkshire and Hampshire breed origin. Correlation of regression coefficients for breed composition obtained by using the 60K and GGP SNP panel was 0.99. Genomic information can be used as a tool to describe an animal's breed composition and reduce the need for progeny testing for white coat color verification.

Key Words: haplotype, regression, SNP

184 Genome-wide association for human nose score of boar taint using single-SNP analysis. Y. G. Tesfayonas*[1,2], *[1]Wageningen University, Wageningen, the Netherlands, [2]Swedish University of Agriculture Sciences, Uppsala, Sweden.*

Human nose score (HNS) is one method used to reduce boar taint without castration. It involves the scoring of the level of boar taint in boars by sensory panel. The objective of this study was to identify SNPs that are associated with HNS and to determine the phenotype variation explained by the SNPs. Boar taint is the unpleasant odor released when cooking meat from entire male pigs. It is mainly caused by increased accumulation of androstenone and skatole in adipose tissue. Producers castrate male pigs to remove boar taint; however, this practice has raised animal welfare concerns from consumers. HNS of 1835 intact boars from 5 purebred (1,438) and 3 crossbred (397) lines genotyped with Porcine 60K SNP Bead chip, and 46,751 SNPs were used for the genome wide association study; boars that were part of the purebred and crossbred both contained sire and sow lines. The design of the study was population based. GRAMMAR approach in R package-GenABEL was employed for the genome wide association analysis. This study revealed genome wide SNP (FDR ≤0.05) on SSC5. The SNP had minor allele frequency of 0.04% and it explained 19% of the phenotype variation. In addition, Boars heterozygous for the SNP had a mean score (0.72) higher than the 2 homozygous genotypes (0.56 and 0.63) which suggests over dominance. Moreover, chromosome wide significant SNPs (FDR ≤0.05) were found on SSC2, SSC7 and SSC17. Some of the SNPs correspond to QTLs of androstenone and skatole. Therefore, HNS can be used to alleviate boar taint through breeding.

Key Words: human nose score, boar taint, SNP

185 Identification of a major QTL associated with N-specific IgG response in piglets experimentally infected with porcine reproductive and respiratory syndrome virus. A. S. Hess*[1], B. R. Trible[2], Y. Wang[2], N. J. Boddicker[1], R. R. R. Rowland[2], J. K. Lunney[3], and J. C. M. Dekkers[1], *[1]Iowa State University, Ames, [2]Kansas State University, Manhattan, [3]USDA, ARS, BARC, APDL, Beltsville, MD.*

Porcine reproductive and respiratory syndrome virus (PRRSv) costs the US pork industry $664 million annually; therefore, much emphasis has been placed on identification of genomic markers and pathways associated with host response. Serum level of immunoglobulin G (IgG) likely contributes to observed variability in health when infected with PRRSv. This study examined serum virus N protein-specific IgG levels, measured by fluorescent microsphere immunoassay. Serum and other data were collected on 462 Large White × Landrace piglets infected with PRRSv isolate NVSL 97-7895. 1:400 dilutions of sera, collected 42 post-infection, were added to virus N protein coupled beads. Antibody was detected by addition of biotin-conjugated goat anti-swine IgG, followed by addition of streptavidin-conjugated phycoerythrin. MAGPIX was used to obtain mean fluorescence intensity (MFI). Three standards were run on each plate: a negative control (no pig serum), a medium positive (serum with a median MFI), and a high positive (serum with a high MFI). Subtraction of the background and standardization using high positive resulted in a sample:positive ratio with the least between plate variation (4.6 ± 4.2% of total variance) and was used for analysis. Pedigree-based heritability was 13.5 ± 13.2%. In a genome-wide association study using 60k SNP data, the proportion of markers with no effect (π) was estimated to be 0.9999 using BayesCPi in GenSel. The 1-Mb region that explained the most genetic variation was on chromosome 7 in a region harboring the major histocompatibility (MHC) class I antigen genes, and was estimated to explain 54.2% of genetic variation. Analysis with Bayes B supported these results, indicating the presence of a major QTL associated with IgG levels. This is indicative of response to the N protein of PRRSv and is consistent with the presence of the MHC class I genes in the region, which play a direct role in immune response to viruses. Supported by NPB grant #12–120, Genome Canada, the National Pork Board and breeding companies of the PRRS Host Genetics Consortium.

Key Words: PRRSv, pig, antibody

186 eQTL analysis of blood RNA from pigs challenged with PRRSV reveal numerous differentially expressed transcripts associated with viral load QTL region. J. P. Steibel*[1], I. Choi[4], M. Arceo[1,3], C. W. Ernst[1], N. Raney[1], Z. Hu[2], C. K. Tuggle[2], N. Boddicker[2], J. Dekkers[2], R. R. R. Rowland[5], and J. K. Lunney[4], *[1]Michigan State University, East Lansing [2]Iowa State University, Ames, [3]North Carolina State University, Raleigh, [4]BARC-USDA, Belltsville, MD, [5]Kansas State University, Manhattan.*

This study's aim was to assess differentially expressed (DE) genes in pigs segregating for SNP WUR10000125 on SSC4, which has been reported as associated with porcine reproductive and respiratory syndrome virus (PRRSV) load post infection. Healthy pigs (n = 39) from a PRRS Host

Genetics Consortium (PHGC) trial were inoculated with PRRSV isolate NVSL 97–7985. RNA was prepared from blood Tempus tube samples collected at 0, 4, and 7 d post-infection. Pigs were assigned into 4 phenotypic groups according to the pigs' serum viral level and weight gain: (1) high viral level (Hv)-high growth (Hg), (2) Hv-low growth (Lg), (3) low viral level (Lv)-Hg and (4) LvLg. RNA was hybridized to the 20K 70-mer oligonucleotide Pigoligoarray in a blocked reference design with time 0 of each individual animal as the reference sample. Microarray data was analyzed using a linear mixed model with fixed effects of dye, time, phenotypic group (viral load × weight gain), WUR10000125 SNP genotype, interactions of SNP genotype × time and time × group, and random effects of array and pig. Nine oligonucleotides representing genes close to the WUR10000125 SNP were tested separately to assess cis-effects; a suggestive cis-acting association was detected for GBP4 ($P = 0.007$). A total of 107 oligonucleotides spanning 99 known genes across the genome were DE with respect to genotype within time effects (FDR <10%). Enrichment analyses for these 99 genes were performed with Ingenuity Pathways Analysis software. Top biological functions were Inflammatory Response, Cell-mediated Immune Response, and Lymphoid Tissue Structure And Development. Top canonical pathways included CCR5 Signaling in Macrophages, Cytotoxic T Lymphocyte-mediated Apoptosis of Target Cells, Calcium-induced T Lymphocyte Apoptosis and T Cell Receptor Signaling. Finally, TRAT1 and IL15 were identified as the top upstream regulators. These results provide insight into potential eQTL and mechanisms involved in the genetic control of gene expression in relation to PRRSV infection. A larger sample size is being processed to confirm these results in a broader eQTL scan.

Key Words: porcine reproductive and respiratory syndrome (PRRSV), eQTL, PRRS Host Genetics Consortium (PHGC)

187 Include birth weight in your breeding goal in the right way. R. Bergsma* and E. F. Knol, *TOPIGS Research Center IPG B.V., Beuningen, the Netherlands.*

The objective of our study was to examine optimal use individual birth weight (IBWT) observations to improve the genetic model for average daily gain (ADG). Data on ± 25,000 crossbred finishers were collected at TOPIGS Research farm in Beilen (NL). Pigs weighing 0.9 kg at birth had a grow-finish ADG of 828 g/d, while their 1.8-kg littermates gained 885 g/d, resulting in a reduction of 7 d to market. Pig breeding companies have been successful in selecting for increased litter size. As litter size increased, average birth weights tended to decline (b = −37 g/pig). When pig birth weight drops, the probability of preweaning death increases. Increasing birth weight by genetic selection seems, therefore, to be an attractive alternative. Several studies show that the heritability of IBWT is 0.30 or higher. A similar estimate was found in this data set. Birth weight, however, is not a characteristic of the piglet, but a characteristic of the sow. Analyzing IBWT with a direct–maternal genetic model reduced the heritability for the direct effect to 0.02 while the heritability for the maternal component was 0.15. The statistical properties of the latter model showed that this model is, by far, preferable to a direct genetic model. A bivariate model for IBWT and ADG showed that ADG and the direct effect of IBWT were uncorrelated and that ADG and the maternal component of IBWT had a moderate genetic correlation ($r_g = 0.34$). Since sows with a high genetic merit for ADG are heavier when giving birth (Bergsma et al., 2008), this genetic correlation showed that these sows give birth to heavier piglets because they are heavier themselves. As a bonus the genetic variance for ADG increased by 9%. The low heritability for the direct effect for IBWT also means that the sire of the litter hardly affects IBWT. This, together with the observation that IBWT and ADG are genetically uncorrelated, justifies the conclusion that selection for IBWT in sire lines is not relevant. Add IBWT as a direct–maternal effect to your genetic evaluation of ADG. This improves the perspective for selection for ADG and allows you to select for increased average birth weight (in dam lines) via increased litter weight.

Key Words: pig breeding, birth weight, daily gain

188 Genetic analysis of pig survival in a crossbred population. M. Dufrasne*[1,2], I. Misztal[3], S. Tsuruta[3], K. A. Gray[4], and N. Gengler[1], *[1]Gembloux Agro-Bio Tech, University of Liege, Gembloux, Belgium, [2]FRIA, Brussels, Belgium, [3]Department of Animal and Dairy Science, University of Georgia, Athens, [4]Smithfield Premium Genetics Group, Rose Hill, NC.*

The aim of this study was to estimate genetic parameters for survival traits at different steps of the fattening period and their relationships with final weight in a commercial crossbred population of pigs. The edited data set consisted of 24,376 crossbred pigs from 197 purebred Duroc sires and 1,671 non-pedigreed Large White x Landrace dams. Traits analyzed were preweaning mortality (PWM); farrow dock (FAD) defined as culling between farrowing and nursery site; nursery dock (NUD) defined as culling between nursery and finisher site; finisher dock (FID) defined as culling before packing plant; hot carcass weight (HCW). Genetic parameters were estimated with a threshold-linear sire model because of the combination of categorical (PWM, FAD, NUD, and FID) and continuous (HCW) traits. Fixed effects were sex and dam parity. Random effects were year × month of birth, sire, litter and residual. The PWM was 16.99%, FAD was 0.71%, NUD was 0.90%, and FID was 1.02%. The mean HCW was 93.4 kg. Estimates of heritability were low to moderate (0.04 for PWM, 0.02 for FAD, 0.14 for NUD, 0.07 for FID, 0.12 for HCW). The sire genetic effects, defined as the ratio between the estimated sire variance and the total variance, were even lower and followed the same pattern than heritability. Estimates of common litter effect were higher and decreased with time for survival traits (0.11 for PWM, 0.19 for FAD, 0.10 for NUD, 0.04 for FID). Estimate of genetic correlation was 0.10 between PWM and FAD. Estimates of genetic correlations were negatives between PWM and NUD (−0.51), between PWM and FID (−0.10), between FAD and NUD (−0.50), and between FAD and FID (−0.21); NUD was positively correlated with FID (0.41). Estimates of genetic correlation between survival traits and HCW were 0.08 for PWM, −0.11 for FAD, 0.03 for NUD, and −0.27 for FID. Survival at the beginning of the fattening period (PWM and FAD) is not a good predictor for survival until harvesting and high market weight. Docking at nursery and finisher stages are more similar traits than docking at farrowing stage. The influence of the sire line on the survival of crossbred pigs is small.

Key Words: genetic parameter, pig, survival

189 Survival from birth to weaning in gilts. A. J. Cross*[1], M. Knauer[1], A. DeDecker[3], K. Gray[2], J. Holl[5], S. Callahan[4], and JP Cassady[1], *[1]North Carolina State University, Raleigh, [2]Smithfield Premium Genetics, Rose Hill, NC, [3]Murphy-Brown LLC, Rose Hill, NC, [4]Virginia Polytechnic Institute and State University, Blacksburg, [5]PIC North America, Hendersonville, TN.*

The aim of this study was to evaluate the influence of birth weight on gilt survival. For the US pig industry to remain globally competitive production efficiencies must continue to be improved. Improved methods for producing pork that reduce inputs, minimize environmental impact, maximize pig well-being, and ensure a safe, nutritious pork supply are

needed. To improve reproductive efficiency, pigs have been genetically selected for increased litter size at birth. However as number born alive increases, individual piglet birth weight decreases. Low piglet birth weights can result in increased pre-weaning mortality and reduced wean-to-finish growth performance. Information on 12,968 gilts from 2 genetic multiplier farms in eastern North Carolina was recorded. Gilts were individually tagged and birth weights were recorded within 24 h of birth. Mortality was recorded based on date of death and reason. Average birth weight was 1250 g (±320). From the 12,968 gilts that were born, 10,742 (82.8%) survived to weaning. The average wean age of the gilts is 22.06 d (±2.74). Glimmix procedure was used to examine the effect of birth weight on survivability in gilts. A binomial distribution was used for death (1 = alive, 0 = dead). Birth week, parity, cross-foster, and farm were fixed effects. Number born, birth weight, and number nursed were covariates. All effects in the model were significant ($P <$ 0.05). Piglets with a 100g increase in birth weight are 1.16 times more likely to survive. When increasing number born and number nursed by one piglet, the odds of survival are 0.84 and a 0.95, respectively. Survival decreased 9.5% when piglets were cross-fostered. Producers should develop genetic and management strategies to select on birth weight and survivability. It was concluded that cross-fostering piglets decreased survivability.

Key Words: pig, survival, cross-fostering

190 Genetic parameters of maternal traits related to sow feed efficiency during lactation. D. M. Thekkoot*[1], R. A. Kemp[2], M. F. Rothschild[1], and J. C. M. Dekkers[1], *[1]Iowa State University, Ames, [2]Genesus Inc., Manitoba, Canada.*

Over the past few decades, the productivity of commercial sows has increased and this has resulted in higher energy requirements and greater mobilization of body reserves, which can negatively affect the longevity and later production performance of sows. One way to overcome this is to increase feed efficiency during lactation. The objective of this study was to estimate genetic parameters for traits related to feed intake and efficiency of sows during lactation. The data were provided by Genesus Inc. and included data on 1239 farrowings from 478 Yorkshires and 457 Landrace sows recorded between July 2011 and December 2012. Sow body weight and back fat were measured ~5 d before farrowing, and at weaning. Daily feed intake was recorded using the Gestal feed recording system. Heritabilities were estimated separately for each breed using a single trait linear mixed model analysis using ASReml. All models included fixed effects of parity (5 levels), contemporary group (farrowing year and season–7 levels), random animal and permanent environmental effects. Sow residual feed intake (RFI) and lactation energy balance (EB) were used to evaluate the overall efficiency of sows during lactation. Heritability estimates for RFI and EB were 0.21 and 0.12 for Landrace and 0.25 and 0.06 for Yorkshire sows. The major traits that contribute to the calculation of RFI and EB are total feed intake of sow (FI), Protein loss (PL), fat mass loss (FML), sow body weight loss (WL), litter birth weight (LBW) and litter weaning weight (LWW) and these traits exhibited moderate heritabilities (0.18, 0.36, 0.20, 0.32, 0.41 and 0.11 for Landrace and 0.33, 0.24, 0.12, 0.24, 0.32 and 0.10 for Yorkshire). Proportions of variance due to permanent environmental effects ranged from 0 to 0.10 for all traits except LWW, for which it was 0.24 and 0.18 for Landrace and Yorkshire sows respectively. These results suggest that for the population studied, selection based on these traits can result in reasonable genetic improvement for feed efficiency during lactation.

Key Words: sow lactation, feed efficiency, genetic parameter

191 Random regression models for daily feed intake in Danish Duroc pigs. A. B. Strathe*[1,2], T. Mark[1], J. Jensen[3], B. Nielsen[2], D. N. Do[1], and H. N. Kadarmideen[1], *[1]Department of Clinical Veterinary and Animal Sciences, Faculty of Health and Medical Sciences, University of Copenhagen, Frederiksberg C, Denmark, [2]Danish Agriculture & Food Council, Pig Research Centre, Copenhagen V, Denmark, [3]Department of Molecular Biology and Genetics, Aarhus University, Tjele, Denmark.*

The objective of this study was to develop random regression models and estimate covariance functions for daily feed intake (DFI) in Danish Duroc pigs. A total of 476201 DFI records were available on 6542 Duroc boars between 70 to 160 d of age. The data originated from the National test station and were recorded using ACEMO electronic feeders in the period of 2008 to 2011. The pedigree was traced back to 1995 and included 17222 animals. The phenotypic feed intake curve was decomposed into a fixed curve, being specific to the barn-year-season effect and curves associated with the random pen-year-season, permanent, and animal genetic effects. The functional form was based on Legendre polynomials (LP). A total of 64 models for random regressions were initially ranked by BIC to identify the approximate order for the LP using AI-REML. The parsimonious model included Legendre polynomials of 2nd order for genetic and permanent environmental curves and a heterogeneous residual variance, allowing the daily residual variance to change along the age trajectory due to scale effects. The parameters of the model were estimated in a Bayesian framework, using the RJMC module of the DMU package, where weakly informative priors were derived from preliminary AI-REML analysis. We used a burn-in of 10k followed by 90k rounds, interleaving every 10th sample. Posterior mean heritabilities were low for DFI, but increased from 0.07 to 0.12 at 100 d of age and then decreased fluctuating to around 0.08. The low heritabilities were due to a higher residual variance when using individual DFI records compared with average DFI records over the entire test period. The heritability of DFI for the entire test period was 0.28, corresponding closely to the estimate derived from analysis of average DFI records. Eigenvalues of the genetic covariance function showed that 33% of genetic variability was explained by the individual genetic curve of the pigs. This proportion was covered by linear (27%) and quadratic (6%) coefficients. Genetic eigenfunctions revealed that altering the shape of the feed intake curve by selection may be an option in Danish Duroc pigs.

Key Words: random regression model, Gibbs sampling, genetic parameter

192 Proteolysis and texture development in Prato cheese made with different coagulants. C. Merheb-Dini*[1], L. S. Alves[1], E. Gomes[2], R. da Silva[2], and M. L. Gigante[1], *[1]Faculty of Food Engineering, University of Campinas - UNICAMP, Campinas, SP, Brazil, [2]Instituto de Biociências, Letras e Ciências Exatas, UNESP - Univ Estadual Paulista, São José do Rio Preto, SP, Brazil.*

This work had the aim of comparing the effect of different coagulants on the ripening of a typical Brazilian cheese. Prato cheese was made using the following coagulants: laboratory obtained protease, from the fungus Thermomucor indicae-seudaticae N31, recently isolated in Brazil (Thermomucor cheese) and commercial coagulant from *Rhizomucor* sp. (Alternative, Bela Vista) (Control cheese). Fifty liters of milk were enzymatic coagulated in vats with heating-cooling jacket, stirrers and speed control. After cutting, the mass was cooked (42°C) and washed and, after whey drainage, chesses were pressed. For both chesses the amount of enzyme added was calculated to achieve milk clotting in ≈35 min. Cheese ripening was periodically monitored for 50 d. A 2 × 6 factorial design with 3 replications was performed and the results were evaluated by ANOVA and mean values were compared by Tukey's test ($P < 0.05$). Proteolysis (NS pH 4.6 (%NT)) and firmness were affected by coagulant type and by ripening time. Thermomucor cheese exhibited lower proteolysis and higher firmness and Control cheese exhibited higher proteolysis and lower firmness. For both cheeses, proteolysis increased and firmness decreased throughout ripening. However, the interaction between coagulant type × ripening time was not significant for the evaluated parameters. The capillary electropherograms showed that the protein hydrolysis profile of both cheeses was very similar exhibiting degradation of casein fractions α_{S1}-CN 8P, α_{S1}-CN 9P, β-CN A^1, β-CN A^2 and formation of hydrolysis products α_{S1}-I-CN 8P, α_{S1}-I-CN 9P and γ-CNs. This behavior was equivalent to the classic and expected profile of chymosin made cheeses: hydrolysis of α_{S1}-CN, by the residual coagulant during initial stages of ripening on the bond Phe23-Phe24, resulting in the formation of α_{S1}-I-CN and hydrolysis of β-CN by plasmin, resulting in the formation of γ-CNs. The data showed that ripening developed in the same way for both cheeses suggesting the potential of protease from Thermomucor indicae-seudaticae N31 as milk clotting agent for industrial scale cheese production. Acknowledgments: FAPESP, CNPq.

Key Words: ripening, capillary electrophoresis

193 Application of an improved powder X-ray diffraction method to evaluate cheese crystals. G. Tansman*[1], P. S. Kindstedt[1], and J. M. Hughes[2], *[1]Department of Nutrition and Food Sciences, University of Vermont, Burlington, [2]Department of Geology, University of Vermont, Burlington.*

Cheese crystals have been studied for over a century, often with the goal of eliminating visible crystals. With the resurgence of artisan cheese making in America and globally, the incidence and morphological diversity of visible crystals appear to be on the rise. During the 1930s through 1970s several investigators used powder x-ray diffraction (PXRD) to identify cheese crystals. However, attempts to optimize analyses using newer advanced PXRD instrumentation are limited. The objectives of this research were to develop an improved PXRD method for cheese crystal analysis and to demonstrate test capabilities by identifying major and minor components of crystal complexes in Cheddar, Gouda and Asiago cheeses. Cheese samples were obtained from commercial sources. Crystals were physically removed from the cheese surface or cheese interior using a dissecting needle, razor blade, and tweezers. Crystalline species were fractionated and purified through differential solubility in water and acetone, which enabled the identification of minor crystal components that might otherwise go undetected due to a lack of instrumental resolution and baseline noise. Purified crystals were dried in a desiccator for 12 h and ground into power using a mortar and pestle for analysis using a Rigaku MiniFlex II x-ray diffractometer. Surface crystals from aged Cheddar cheese contained crystalline calcium lactate pentahydrate, tyrosine, calcium phosphate and an unidentified crystalline component (UCC). Crystals from the interior of Cheddar contained only calcium lactate pentahydrate. In aged Gouda, interior crystals consisted mostly of tyrosine with lesser amounts of the same UCC found on Cheddar; crystals from the surface of interior eyes contained both tyrosine and the UCC. Interior crystals from Asiago were exclusively tyrosine. Powder x-ray diffractometry, combined with crystal separation though differential solubility, provides a rapid and sensitive means to identify crystalline species that comprise complex visible deposits in cheese. Such information may help to inform future studies aimed at elucidating mechanisms of co-crystallization in cheese.

Key Words: crystal, cheese, X-ray diffraction

194 The effect of the exopolysaccharide producing cultures and adjunct cultures isolated from the Egyptian dairy environment on the texture and sensory characteristics of fat-free Cheddar cheese. M. El Soda* and N. Ahmed, *Faculty of Agriculture, Alexandria University, Alexandria, Egypt.*

Low fat cheeses often suffer from undesirable texture and flavor properties, the exopolysaccharide producing cultures were used in the manufacture of low fat cheeses to increase yield and improve texture. The objective of this communication is to assess the effect of EPS producing cultures and adjunct cultures isolated from the Egyptian dairy environment on the texture and flavor characteristics of fat-free Cheddar cheese. Pilot-scale fat-free Cheddar cheeses were manufactured using commercial Cheddar starter in addition to selected EPS producing cultures and adjunct cultures obtained from our culture collection. Modifications to the cooking temperature, cheddaring conditions and pressing were also performed. The obtained results revealed that the best cheese was obtained using 2 mesophilic lactobacilli producing exopolysaccharides in addition to a 1:1 ratio of 2 strains of *Lactobacillus paracasei* exhibiting debittering activity. The obtained yield for the experimental fat free Cheddar was 8.3%, the values for moisture; fat and protein were 52% ± 0.5, 0.7% and 38% ± 0.8 respectively after 6 mo of ripening. The rheological parameters of full-fat Cheddar were compared with those of the experimental fat-free Cheddar. The obtained data reveal 80% similarity between the 2 cheeses for hardness, chewiness and gumminess, whereas fat-free cheeses showed more cohesiveness and springiness when compared with the full-fat cheese. The use of *Lactobacillus paracasei* strains led to a considerable reduction of bitterness and to the development of the characteristic Cheddar notes in the fat-free cheese. In conclusion, the use of EPS producing lactobacilli, *Lactobacillus paracasei* adjunct and the different modifications to the make procedure led to the production of a fat free Cheddar cheese exhibiting flavor and texture characteristics comparable to the full fat product.

Key Words: fat-free Cheddar, adjunct, exopolysaccharide

195 Effect of milk protein concentration on the microstructure and properties of full-fat Cheddar cheese during ripening. K. Soodam*[1,2], L. Ong[1,2], S. E. Kentish[1], and S. L. Gras[1,2], *[1]Department of Chemical and Biomolecular Engineering, The University of Melbourne, Melbourne, Victoria, Australia, [2]Bio21 Molecular Science and Biotechnology Institute, The University of Melbourne, Melbourne, Victoria, Australia.*

Ultrafiltered retentate (UF) can be used to standardize cheese milk and can potentially affect cheese yield but few studies have examined the effect of added UF on the microstructure of the cheese and linked these to the properties observed during ripening. This study investigated the effect of increasing the milk protein concentration on the microstructure, as well as the biochemical changes that occur during the ripening of Cheddar cheese. Advanced microscopy techniques, including confocal scanning laser microscopy and cryo-scanning electron microscopy (cryo-SEM) were coupled with textural, sensory and chemical analyses and applied during ripening. The milk protein level was found to significantly affect the hardness of the cheese. A possible link was also established between the protein level, stretchability and the microstructure of the cheese, as observed with cryo-SEM. Several changes were also observed during ripening for all protein treatments. The protein network within cheese contained fewer branches, as observed by the number of intersections (vertices), as a result of ripening. A significant correlation was also found between the microstructure of the cheese and level of proteolysis as well as the microstructure of the cheese and the cheese texture. Our findings provide new insights into the effect of processing conditions and the effect of the maturation process on the development of cheese microstructure and functional properties.

Key Words: cheese ripening, microstructure

196 Evaluation of an alternative method for the rapid and direct determination of sodium in cheese. J. A. Stankey*, C. Akbulut, J. Romero, and S. Govindasamy-Lucey, *Wisconsin Center for Dairy Research, Madison.*

Currently, Na in cheese is routinely determined via an indirect method using the Cl Analyzer. A direct and rapid method of Na detection is needed in the industry due to the increasing use of Na replacers. An x-ray fluorescence spectroscopy (XRF) method for the determination of Na in cheese was developed and compared with inductively coupled plasma-optical emission spectroscopy (ICP) and Cl Analyzer. Sodium quantification was performed by multi-point calibration with standard cheeses (n = 7) (Cheddar, Gouda, Mozzarella, pizza, nonfat and processed) over the range of 0–5% Na (wt/wt). Amount of Na in the each of cheese standard (cheese discs: 7 × 30 mm) was quantified with the XRF equipment. Method validation was performed and the results for linearity, precision, limit of detection and limit of quantification were determined. Linearity ($R^2 \geq 0.99$) was observed in calibration curves obtained for different cheese standards. Procedure was tested by quantifying the amount of Na in a wide range of commercial cheese samples. Na data obtained by XRF were in good agreement with those from ICP and Cl Analyzer for most commercial cheeses. Lowest concentration of Na (LOQ) that can be determined with an acceptable level of repeatability, precision, and trueness was about 245 mg/100g cheese. Calibration graph for Na quantification in the presence of increasing K levels was created using natural cheeses made with different ratios of Na:K and it was able to predict Na content in cheeses manufactured with K-based salt replacers. The Cl analyzer was less accurate than the XRF when Na-replacers may be present, due to the indirect quantification of Na (by the Cl Analyzer). If quantifying Na in the presence of K using XRF method, it was critical that the calibration plot should be created with standards in the presence of K. The XRF method enables the rapid and direct measurement of Na content in a variety of cheeses.

197 Proteolysis and microstructure of salt-reduced Cheddar cheese. A. Sheibani*, M. M. Ayyash, T. Vasiljevic, and V. Mishra, *Victoria University, Melbourne, Victoria, Australia,*

The effects of salt reduction on proteolysis and microstructure of Cheddar cheese was investigated. Four levels of dry salting including control (2.5%) and 3 treatments (1, 1.5 or 2% salt) were applied followed by storage for 8 weeks at 4°C. Samples were taken at fortnightly intervals and subjected to chemical composition, proteolysis rate and microstructure analysis. Except 12% trichloroacetic acid-soluble nitrogen (TCA-SN), water-soluble nitrogen (WSN) and 5% phosphotungstic-soluble nitrogen (PTA-SN) significantly ($P < 0.05$) differed among cheeses samples. There was no significant ($P > 0.05$) difference in the release of major peptides among samples during storage, whereas hydrophilic peptides differed substantially. Total free amino acids (TFAA) showed significant difference between experimental cheeses at the same storage time ($P < 0.05$). Significant differences in chemical composition except fat content were observed between cheese samples at every sampling point. There was a significant difference between pH of control cheese comparing with other experimental cheeses. pH values of all treatments increased significantly from about 4.8 to 5.1 after first 2 weeks of storage. In compare with control, microstructures of treatments 1, 2, and 3 were smooth, small voids and close structure. During storage, the structure of Cheddar cheeses became more close and homogenous. Salt reduction treatment significantly influenced cheddar cheese characteristics during storage period.

Key Words: salt reduction, proteolysis, microstructure

Companion Animals: Companion and Captive Exotic Animals

200 Ingredient composition of diets offered to black-and-white ruffed lemurs (*Varecia variegata*) from surveyed United States zoological institutions. B. C. Donadeo*[1], K. R. Kerr[1], C. L. Morris2,3, and K. S. Swanson[1], [1]*University of Illinois at Urbana-Champaign, Urbana,* [2]*Omaha's Henry Doorly Zoo & Aquarium, Omaha, NE,* [3]*Iowa State University, Ames.*

Fifty-eight US zoological institutions are registered with the International Species Information System (ISIS) as housing black-and-white ruffed lemurs (*Varecia variegata*), but little data are available on their captive diets. Our objective was to identify feed items and inclusion amounts of diets offered to captive *V. variegata* at US zoological institutions. Institutions were contacted via the Prosimian Taxon Advisory Group listserv and direct email contact to request participation in the study. Diet information (i.e., type and amount of diet items) was collected utilizing a survey (created on SurveyMonkey.com). Respondents were prompted to indicate inclusion level for items expected to be common, including fruits, vegetables, biscuits (and other commercial products), greens, and browse (i.e., twigs, shoots, leaves), and to provide information on items not specifically listed. Thirty-five institutions provided diet information utilizing the survey between July 27 and December 31, 2012, including 33 of the 58 ISIS listed institutions (57%). Data presented here are from 33 institutions which have provided complete information for analysis. The most commonly included items (30 of 33 zoos) were bananas (<5% to 30% of diet). Most institutions offer either Marion Zoological's Leaf Eater biscuit (10 zoos; <5% to 70% of the diet), Mazuri's Leaf-Eater biscuit (14 zoos; <5% to 50% of the diet), or Mazuri's Primate Browse biscuit (10 zoos; <5% to 25%). -seven institutions use browse (<5% to 10%); of these institutions, 10 indicated little to no consumption of browse offered. While *V. variegata* is a frugivorous species, research in our lab shows that Madagascan fruits available to wild *V. variegata* are higher in fiber and lower in carbohydrates than diets offered at US zoos. Therefore, high inclusion of fruit in captive lemur diets may be inappropriate. Further research is needed on the effects of different captive diet types and ingredient inclusions on lemur health.

201 Amino acid composition and standardized digestibility of whole prey diet items intended for captive exotic and domestic felids. K. R. Kerr*[1,2], P. L. Utterback[2], C. M. Parsons[2], and K. S. Swanson[1,2], [1]*Division of Nutritional Sciences, University of Illinois, Urbana,* [2]*Department of Animal Sciences, University of Illinois, Urbana.*

Whole prey diets are popular for captive exotic and domestic felids. However, research on whole prey has primarily focused on non-nutritive benefits. Our objective was to evaluate the amino acid (AA) composition and bioavailability of 20 whole prey sources: mice (1 to 2 d, 10 to 13 d, 21 to 25 d, 30 to 40 d, and 150 to 180 d of age); rats (1 to 4 d, 10 to 13 d, 21 to 25 d, 33 to 42 d, and >60 d of age); rabbits (still born, 30 to 45 d, > 65 d with skin, and >65 d of age with skin removed); chicken (1 to 3 d of age, ground adult); duck (ground adult); and quail (1 to 3 d, 21 to 40 d, and >60 d of age). We measured AA composition of each whole prey item and evaluated standardized AA digestibility utilizing the cecectomized rooster assay. We calculated the amino acid score (AAS) and protein digestibility corrected AAS (PDCAAS) utilizing the growth requirements for domestic cats as a reference value (AAFCO, 2012). For most the whole prey, AA concentrations were greater than the recommendations for domestic cats: AAS were greater than 88 for all species except rabbits (AAS: 6 to 56). The first limiting AAs were Cys + Met, Met, Tau, and Trp. In the 30 to 45 d-old rabbit, taurine concentration (0.01% DM) was lower than that recommended for domestic cats (0.10% DM). Standardized digestibility coefficients were quite high, but variable (Arg: 85 to 95%; His: 87 to 96%; Ile: 82 to 92%; Leu: 84 to 94%; Lys: 85 to 93%; Met: 89 to 97%; Phe: 83 to 94%; Thr: 80 to 95%; Trp: 84 to 94%; Val: 80 to 93%). The PDCAAS were 3 to 13 units lower than AAS. Given the AA digestibilities and high protein concentrations in whole prey, meeting the requirements likely would not be an issue for Cys + Met, Met, and Trp. However, some whole prey had Tau concentrations below the recommendations for domestic cats. If Tau concentrations are not measured before feeding, supplementation of whole prey may be beneficial. Standardized AA digestibility coefficients of 80 to 97% are expected.

Key Words: protein digestibility corrected amino acid score, cat

202 The effects of L-carnitine on energy expenditure and fuel selection in adult Miniature Dachshunds, Beagles, and Labrador Retrievers measured using indirect calorimetry. D. Minikhiem*, K. Shoveller, J. DiGennaro, and L. Fortener, *Procter and Gamble, Mason, OH.*

Despite the common incorporation of L-carnitine (LC) in dog food there is little research on the effects of LC on energy expenditure (EE) and fuel selection in healthy, lean dogs. In the present study indirect calorimetry was used to determine if dogs consuming 50 ppm LC (LC+) had lower RQ and greater EE compared with dogs fed control (CON). This study was a 2 × 2 Latin Square with baseline measurements before each period. A total of 16 dogs (6 Labrador Retrievers [Labs], 4 Miniature Dachshunds [Dachshunds], and 6 Beagles) were pseudo-randomly allocated to LC+ and CON diets and balanced for BW and food intake. Dogs were fed Iams ProActive Health MiniChunks with (LC+) and without (CON) 50 ppm added LC (as fed basis) to maintain BW. Indirect calorimetry was conducted during fasting and for 8 h post feeding at baseline, 3, and 6 wk. Area under the curve (AUC) for RQ and EE, and AUC for RQ and EE divided into 4 postprandial time periods (0–120 min, 120–240 min, 240–360 min, and 360–480 min) were analyzed using a random mixed model with breed and diet-by-breed interaction as covariates. There were no differences in RQ between treatments at baseline ($P > 0.05$). RQ tended to increase (contrary to expected results) from baseline at wk 3 and 6 for Dachshunds and Beagles fed LC+ ($P = 0.07$). There were no differences between treatments in EE at baseline for each breed. EE increased in Labs fed LC+ after 3 and 6 wk. Specifically, Labs fed LC+ had greater EE ($P < 0.05$) than Labs fed CON during the last 3 postprandial periods at wk 3 and 6. Fasted EE tended ($P = 0.08$) to be greater in Labs fed LC+ at 6 wk. There were no differences between treatments for Beagles or Dachshunds. In conclusion, effects of LC on dog metabolism are breed-specific. Dogs consuming a maintenance diet supplemented with 50 ppm LC exhibited an apparent increase in carbohydrate metabolism (Dachshunds and Beagles) and an increase in total energy expenditure (Labs).

Key Words: L-carnitine, dog, indirect calorimetry

203 Effect of photoperiod on feline adipose transcriptome profiles as assessed by RNA sequencing (RNA-seq). A. Mori*[1], K. L. Keppen[1], and K. S. Swanson[1,2], [1]*Department of Animal Sciences, University of Illinois, Urbana,* [2]*Division of Nutritional Sciences, University of Illinois, Urbana.*

Photoperiod is known to cause physiological changes in seasonal mammals, including body weight (BW), physical activity, and reproductive status. Because cats are seasonal breeders, we recently tested the effects of day length on resting metabolic rate (RMR), voluntary physical activity, and food intake. In that study, RMR, physical activity, and food intake to maintain BW were greater in cats exposed to long days (LD) vs. short days (SD). Because photoperiod has also been demonstrated to affect adipose tissue gene expression in several species, including dairy cows, sheep, and Siberian hamsters, the objective of this study was to determine the effects of day length on the adipose transcriptome profile of cats as assessed by RNA-seq. Ten healthy adult neutered male domestic shorthair cats were used in a randomized crossover design study. During two 12-wk periods, cats were exposed to either SD (8 h light:16 h dark) or LD (16 h light:8 h dark). Cats were fed a commercial diet to maintain baseline BW. Subcutaneous adipose biopsies were collected at wk 12 of each period for RNA isolation and sequencing. A total of 578 million sequences (28.9 million/sample) were generated by Illumina sequencing. Using a raw *P*-value of $P < 0.005$, 170 mRNA transcripts were differentially expressed between SD- and LD-housed cats. Of the 170 transcripts highlighted, 25 annotated transcripts were upregulated, while 116 annotated transcripts were downregulated by LD. Another 29 un-annotated transcripts (name and function not known) were also different between groups. In general, adipose tissue of LD-housed cats had greater expression of genes involved with cholesterol trafficking, fatty acid synthesis and immune function, and lower expression of genes involved with cell growth and differentiation, cell development and structure, and protein processing, when compared with SD-housed cats. This study has highlighted molecular mechanisms that may contribute to seasonal metabolic changes in cats. Although this area requires more research, these data may be used to develop strategies for feline obesity prevention or treatment.

Key Words: adipose tissue, cat, photoperiod

205 Potato pulp as a dietary fiber source in high quality dog foods. M. R. Panasevich*[1], R. N. Dilger[1,2], K. S. Swanson[1,2], L. Guérin-Deremaux[3], G. L. Lynch[4], and G. C. Fahey Jr.[1,2], *[1]University of Illinois Department of Animal Sciences, Urbana, [2]University of Illinois Division of Nutritional Sciences, Urbana, [3]Roquette Fréres, Biology and Nutrition Department, Lestrem, France, [4]Roquette America Inc., Geneva, IL.*

Dietary fiber is important in companion animal diets because of its positive effects on gut and systemic health. Potato pulp (PP), a co-product of potato starch processing (Roquette Frères, France), was evaluated as a potential novel fiber source in dog foods. The PP substrate was evaluated for chemical composition and in vivo responses. Ten female dogs with hound bloodlines (5.4 ± 0.0 yr; 22 ± 2.1 kg) were each provided 5 diets with graded levels (0, 1.5, 3, 4.5, or 6%; added in place of cellulose) of PP on an as-is basis in a replicated 5 × 5 Latin square design. Fresh fecal samples were collected to measure fecal pH and fermentation end products. Chemical composition results revealed that raw and cooked PP contained 55% total dietary fiber, with 32% insoluble fiber and 23% soluble fiber, as well as 4% crude protein and 2% acid-hydrolyzed fat. No differences were observed in total tract digestibility coefficients for dry matter (81.3 to 82.7%), organic matter (84.1 to 85.5%), crude protein (81.7 to 80.2%), acid-hydrolyzed fat (94.1 to 94.6%), or energy (84.9 to 85.7%). Total dietary fiber digestibility was greater ($P < 0.01$) for dogs fed the 3, 4.5, and 6% PP diets compared with dogs fed the 0% PP diet. Fecal pH was lower ($P < 0.01$) when dogs were fed the 4.5 and 6% PP diets compared with the 0% PP diet. Fecal acetate, propionate, and total SCFA were higher when dogs were fed the 3, 4.5, and 6% PP diets, and fecal butyrate was higher when dogs were fed 4.5 and 6% diets compared with the 0% PP diet ($P < 0.05$). Overall, with increasing PP inclusion, linear increases ($P < 0.01$) were observed for all SCFA, with a concomitant linear decrease ($P < 0.01$) in fecal pH. Fecal protein catabolites were physiologically low or undetectable, with the exception of spermidine, which was greater ($P < 0.05$) when dogs were fed the 6% PP diet compared with the 0% PP diet. These findings suggest that increased inclusion of PP elicited favorable fermentation characteristics without negatively affecting nutrient digestibility. Collectively, these data suggest that PP could be a functional dietary fiber in high quality dog foods.

Key Words: potato, fiber, dog

206 Mannoheptulose has acute effects on post-prandial energy expenditure, respiratory quotient and insulin response in adult Beagles fed diets with different macronutrient contents. L. L. McKnight*[1], E. A. Flickinger[2], J. France[1], G. Davenport[2], and A. K. Shoveller[2,1], *[1]University of Guelph, Guelph, ON, Canada, [2]Procter & Gamble Pet Care, Mason, OH.*

Overweight dogs are treated with nutritional management strategies that involve therapeutic diets and/or total calorie restriction (CR). As CR strains the human-animal bond, calorie restriction mimetics (CRM) [i.e., mannoheptulose (MH)] are being investigated. The objective of this study was 2-fold: (1) determine the effects of low carbohydrate CHO; high fat (32% CP; 30.6% CHO; 27.9% fat) and high CHO; low fat (27.0% CP; 53.6% CHO; 11.2% fat) diets on energy expenditure (EE), respiratory quotient (RQ) and glycemic response in adult beagles, and (2) determine whether these outcomes were affected by supplementing the diets with mannoheptulose (MH; 8 mg/kg). This study was designed as a 4 × 4 repeated Latin square with each dog (n = 8) randomly allotted to each dietary treatment (high CHO, HC; high CHO with MH, HC+; low CHO, LC; low CHO with MH, LC+). As indirect calorimetry methodology only allowed for 4 dogs to be measured per day, dogs were divided into 2 groups with each diet × MH combination represented on each day. Fasting and postprandial (24 h) EE and RQ were determined by indirect calorimetry (d 12 or 14). Glycemic and insulinemic responses (24 h) to the treatment meal were determined on the alternate day (d 12 or 14). Dietary CHO level did not affect fasting or postprandial EE, serum insulin or glucose:insulin as would be expected in lean dogs receiving these diets for 14 d. Dogs fed HC had higher postprandial RQ (indicating an increase in CHO oxidation) but lower serum glucose than dogs fed LC. MH acutely increased postprandial RQ (25 – 75 min, $P < 0.05$) and EE (5 – 7 h, $P < 0.05$) and decreased serum glucose:insulin (14 – 22 h, $P < 0.10$) (implying improved insulin sensitivity) irrespective of dietary CHO content. These findings suggest that MH elicits changes in pathways related to energy sensing and that these effects are at least partly mediated by changes in insulin signaling and not related to the macronutrient content of the diet. This study was funded by Procter & Gamble Pet Care.

Key Words: energy expenditure, macronutrient, mannoheptulose

207 In vitro fermentation characteristics of coconut endosperm and chicory pulp fibers using canine fecal inoculum. M. R. C. de Godoy*[1], Y. Mitsuhashi[2], L. Bauer[1], G. C. Fahey[1], P. R. Buff[2], and K. S. Swanson[1], *[1]Department of Animal Sciences, University of Illinois, Urbana, [2]The Nutro Company, Franklin, TN.*

The objective of this experiment was to determine the effects of in vitro fermentation of coconut endosperm fiber (CEF), chicory pulp (CHP),

and selective blends of these substrates on short chain fatty acid (SCFA) production and changes in microbiota using canine fecal inocula. A total of 6 individual substrates, including short-chain fructooligosaccharide (scFOS; a well-established prebiotic source), pectin (PEC; used as a positive control), pelletized cellulose (PC; used as a negative control), beet pulp (BP; considered the gold standard fiber source in pet foods), CEF, and CHP, and 3 CEF: CHP blends [75% CEF: 25% CHP (B1); 50% CEF: 50% CHP (B2); 25% CEF: 75% CHP (B3)] were tested. Triplicate samples of each substrate were fermented for 0, 8, and 16 h after inoculation. A significant substrate × time interaction ($P < 0.01$) was observed for pH change and acetate, propionate, butyrate, and total SCFA concentrations. After 8 and 16 h, pH change was greatest for scFOS (−2.0 and −3.0, respectively) and smallest for PC (0.0 and −0.1, respectively). After 16 h, CEF had the highest butyrate production among all the CEF: CHP blends, and it was not different than PEC. The substrate × time interaction was significant for bifidobacteria ($P = 0.013$) and lactobacilli ($P < 0.001$). After 8 h, bifidobacteria was highest for BP and lowest for PC; 12.7 and 10.0 $\log_{10}$ cfu/tube, respectively. After 16 h, PC had the lowest and scFOS had the highest bifidobacteria; 6.7 and 13.3 $\log_{10}$ cfu/tube, respectively. In general, CEF, CHP and their blends had similar bifidobacteria populations after 8 and 16 h of fermentation when compared with BP and scFOS. After 16 h, lactobacilli populations were highest for B1, B2, B3, BP, and scFOS, intermediate for PEC, and lowest for PC ($P < 0.05$). Overall, our data suggest that CEF had a butyrogenic effect and that CEF, CHP and their blends had similar bifidobacteria and lactobacilli populations as popular prebiotic and fiber substrates. Future research should investigate the effects of CEF, CHP, and their blends on gastrointestinal health and fecal quality in dogs.

Key Words: dog, fiber, in vitro

208 Pheromones and an interomone change the physiology and behavior of anxious dogs. W. G. Thompson* and J. J. McGlone, *Texas Tech University, Lubbock.*

Pheromones are species-specific odors used in communication and have been shown to have both behavioral and physiological effects. Interomones are pheromones in one species, but have diverse effects on other species. The objective of this study was to assess the efficacy of pheromones/interomones to modulate heart rate (HR) and behavior in adult anxious dogs (trembling, cowering, shy). The dogs (10.2 ± 4.2 kg; estimated 5–10 yr old, intact males) and were professionally diagnosed as anxious. Each dog was housed in a separately-ventilated room with a minimum of 12 m^2 of floor space. Heart rate was measured using a telemetry system (Data Science International, St. Paul, MN). Behavior was recorded and later processed by a trained individual (blind to treatment group) using a scan sample with a recording interval of 5 min over a 24 h baseline period. At the end of 24 h with a treatment or control pheromone collar, each dog was startled with a 110 db fog horn while behavior and HR were recorded. Each dog received each treatment in a Latin square design with repeated measures over time. This model allowed evaluation of effects of treatment, dog, treatment by dog, time, treatment by time and dog by time effects. Treatments were given in the form of a collar containing each pheromone/interomone and included Placebo, Sergeant's Formula H (SERG), 2-methylbut-2-enal–Rabbit Pheromone (RP), or Dog Appeasing Pheromone (DAP) collar. During baseline 24 h, DAP increased HR in 1 dog and decreased HR in 2 dogs; SERG increased HR in 2 dogs and decreased HR in 1 dog and RP increased HR in 2 dogs and decreased HR in 2 dogs (dog by trt, $P < 0.0001$). Dog lying behavior changed with SERG and RP but not DAP. After startle, each treatment changed dog HR in at least one dog (dog by trt, $P = 0.002$). Treatments caused one dog to increase while another decreased lying (dog by trt, $P < 0.001$) after startle. Individual dogs changed behavior and HR differentially in response to the pheromones/interomones evaluated. The pheromones/interomones tested clearly changed dog heart rate and behavior. However, anxious dogs did not respond uniformly to each pheromone/interomone tested.

Key Words: pheromone, interomone, behavior

Dairy Foods Symposium: New Approaches to Lower Sodium in Cheese and Techniques to Address Quality Challenges

209 Sodium reduction and public health—Why, how much, and current trends. J. Nicholls*, *National Dairy Council, Rosemont, IL*

To address sodium overconsumption, public health programs aimed at reducing sodium intakes of Americans have gained momentum in recent years. These include public education campaigns, regulatory approaches, standards for marketing and advertising to children, and voluntary industry programs for sodium reduction. The Dietary Guidelines for Americans recommends intakes of 2,300 mg sodium per day for most Americans and 1,500 mg per day for certain population groups. These recommendations are based on the links between high sodium intake, high blood pressure, and increased risk for cardiovascular disease. Sodium intakes of the majority of Americans exceed recommendations with average intakes of about 3,300 mg sodium per day. The Dietary Guidelines also recommend Americans consume 3 servings of dairy foods per day including milk, yogurt and cheese, and based on national survey data, cheese is among top sources of sodium in the diets of Americans. To understand what sodium reduction and public health efforts mean for cheese, dairy's role in the diet, key efforts underway to reduce sodium in the food supply, specific sodium reduction guidelines, and what to expect in coming years will be reviewed. Authoritative reports including the 2010 Institute of Medicine on Strategies to Reduce Sodium Intake in the United States and the Dietary Guidelines for Americans will be reviewed and put into context. Voluntary sodium reduction programs and regulations including USDA regulations for sodium reduction in school meals and proposed regulations for sodium content of "competitive" foods sold in schools will also be reviewed. Emphasis will be placed on policies and programs to reduce sodium intake by Americans and an understanding of the current environment relevant to dairy foods.

Key Words: sodium reduction, cheese, Dietary Guidelines for Americans

210 Lower sodium cheeses—Consumer acceptance and flavor differences. M. A. Drake*, *North Carolina State University, Raleigh.*

Sodium reduction is a key issue in the dairy industry as salt plays a crucial role in flavor and ripening of Cheddar cheese. This presentation will address the effect of sodium reduction on cheese flavor, studies to minimize these effects and consumer perception of sodium reduction in Cheddar cheese. Salt reduction as little as 30% alters cheese ripening and flavor development with increased development of sulfur, brothy and rosy flavors and bitter taste concurrent with volatile compound changes. Off-flavors are magnified in lower sodium reduced fat cheeses due to changes in volatile compound thresholds due to fat reduction. Sodium reduction effects vary with different starters suggesting that careful selection of starter culture strains can alleviate some of these effects. Sodium cation substitution with other cations such as potassium controls water activity similar to sodium chloride. Volatile compound effects were not evident up to 50% substitution although trained sensory panelists documented increased bitter taste and metallic mouthfeel with 25% substitution. Consumer interest in sodium reduction was lower than interest in fat reduction emphasizing the need for parity in sensory properties. Consumer liking scores were not different up to 50% substitution of potassium for sodium with either full fat or 50% reduced fat cheeses. These results suggest that a 25–30% sodium reduction in Cheddar cheese is readily achievable by substitution of potassium for sodium.

Key Words: cheese, sodium reduction, flavor

211 Lower sodium cheeses—Changes in the microbiology and safety. D. J. McMahon*, *Western Dairy Center, Utah State University, Logan.*

With the interest in reducing sodium content of foods for dietary reasons there has been a concern expressed about how reducing sodium content of cheese affects its microbiology and consequent safety. Lowering the level of salt addition to cheese changes the amount of whey expulsion after salting and so cheese manufacturing needs to be altered to maintain moisture targets. Cheddar cheese with 33% reduction in salt will lower the salt-in-moisture (S/M) content from ~4.7% to 3.2%, while a cheese with salt reduction to meet low sodium food regulations will have S/M <2.0%. This greatly reduces the use of salt content of cheese as a microbiology hurdle for controlling bacterial growth. This presentation will address the impact of sodium reduction on cheese microflora from the aspect of cheese ripening and survival of pathogens. When S/M is lowered in either full fat or low fat cheddar cheese, the lactococcal starter cultures survive for a longer time and the nonstarter lactic acid bacteria take longer to reach high levels and become the predominant culturable bacteria in cheese. Similarly, when potassium chloride was substituted for sodium chloride, there is a tendency for the lactococci to remain dominant for longer times, which is indicative of potassium ions subjecting the starter bacteria to less stress than high levels of sodium ions. There are also various metabolic pathways that can be expected to be upregulated or downregulated when potassium is substituted for sodium. When cheddar cheese was made with normal (1.8% salt) and low (0.7%) salt contents and then inoculated with *Listeria monocytogenes* and stored at 4, 10 and 21°C (for 3, 3 and 1 mo, respectively) the viable count decreased by about one log at regular salt levels and 0.5 log in low salt cheese at all temperatures, and at both high and low pH. When similar cheese was inoculated with *Salmonella* there was about 3 log reduction in *Salmonella* counts in all cheeses.

Key Words: cheese, salt, microbiology

212 Process cheese products—Approaches to manufacturing consumer acceptable process cheese products with less sodium. L. E. Metzger* and A. Kommineni, *South Dakota State University, Brookings.*

Process cheese products are an integral part of the American diet. However, these products contain a substantial amount of sodium (1265 to 1540 mg/100 g). The major sources of sodium in process cheese products are sodium based emulsifying salts, sodium chloride, and natural cheese. In a typical formulation emulsifying salts contribute 45% of the sodium whereas natural cheese and sodium chloride contribute 30 and 25% of the sodium, respectively. Consequently, various strategies that target one or more of the sodium sources in process cheese products can be used to decrease the level of sodium. The simplest and first strategy is to remove sodium chloride in the formulation. In a typical formulation if all of the sodium chloride is removed, the sodium content can be reduced from 1500 mg/100g to approximately 1100 mg/100 g. In addition to removing sodium chloride from the formulation, a variety of salt substitutes can be used to increase the perceived salty flavor of process cheese products with less than 1100 mg of sodium/100 g. Salt

substitutes utilize potassium chloride in combination with a masking agents or bitterness blockers. Masking agents and bitterness blockers are required when potassium chloride is used in a formulation because potassium chloride can result in bitter off-flavors. To produce process cheese with a sodium content below 1100 mg/100 g a portion of the sodium based emulsifying salts in the formulation must also be replaced with a potassium based emulsifying salt. Using a combination of removal of sodium chloride and addition of potassium based salt substitutes and potassium based emulsifying salts it possible to produce process cheese products with a sodium content below 1100 mg/100 g. However, process cheese products with this level of sodium have an extremely bland flavor and are perceived by consumers as having a flavor that is not typical of process cheese.

Key Words: process cheese, reduced sodium, salt substitutes

213 Unwanted gas formation in cheese—Newer information on causes and determining the composition of the cheese microbiota.
J. Steele*, *University of Wisconsin-Madison, Madison.*

Cheese contains microorganisms that are not intentionally added during manufacture. The organisms present in this adventitious microbiota can have significant, beneficial and detrimental effects on cheese quality. One detrimental impact this microbiota can have is the production of slits and cracks, which is related to gas production by the adventitious microbiota. A wide variety of microorganisms have been associated with this defect, including yeasts, *Clostridium tyrobutyricum*, obligately heterofermentative lactobacilli, *Leuconostoc* sp., *Propionibacteria* sp., and coliforms. However, recently cheeses with slits and cracks not containing detectable levels of these organisms have been sporadically observed. This research project evaluated the ability of *Lactobacillus curvatus* LFC1, a facultatively heterofermentative lactobacilli, to cause this defect. *L. curvatus* LCF1 when present at 4.5 log cfu/g in cheese on d 1 of ripening resulted in slits and cracks within 3 mo. Chemical analysis of the cheeses indicate that the addition of *L. curvatus* LCF1 resulted in higher levels of acetate and lactic acid and accelerated reductions in the levels of citrate and galactose. Culture independent analysis of the influence of *L. curvatus* LCF1 addition on the cheese microbiota was conducted by automated ribosomal intergenic spacer analysis and high throughput DNA sequencing. The results demonstrate that the addition of *L. curvatus* LCF1 resulted in a greater microbial diversity within the cheese matrix. Model fermentations conducted with added citrate and lactose demonstrated that these 2 substrates contribute to gas production by *L. curvatus* LCF1. Collectively, these results suggest that *L. curvatus* is capable of causing slits and cracks in cheese, when present at high levels and if the cheese contains sufficient levels of lactose and citrate.

Key Words: cheese defects, lactobacilli, cheese composition

Milk Protein and Enzymes Symposium: Role of Enzymes in Dairy Processing

214 Enzymes in milk—A dynamic system. D. E. Otter*, *AgResearch Ltd., Palmerston North, New Zealand.*

What are they? Where do they come from? Why are they there? How can we use them? The presence of over 70 enzymes encompassing a wide range of activities including lipases, proteinases and lysosomal enzymes have been described in milk. The most highly characterized enzymes include lactoperoxidase, lysozyme, plasmin, lipoprotein lipase and xanthine oxidoreductase. The levels of the different enzymes are species-specific and may relate to the immune maturity of the new-born offspring; for example, in human milk the levels are generally greater than in bovine milk. Milk and colostrum also contain several antimicrobial factors, which exert both specific and non-specific bacteriostatic and bactericidal activity. Enzymes may be present for several reasons, including happenstance, "spill over" from epithelial mammary cells or serum during milk secretion and/or during inflammation or infection of the mammary gland. With the evolution of the lactation process; for example, during cattle domestication and breeding for milk production, it is highly unlikely that their presence is random and indeed some enzymes have essential roles in lactogenesis regulation and are necessary elements of the innate immune system of milk. The enzymes are predominately associated with the MFGM (milk fat globule membrane) and vesicle membranes in milk and the activity of many enzymes can vary significantly due to the metabolic activity of cells, stage of lactation, uninfected or infected glands (mastitis), subclinical infection and inflammation and the hormonal, nutritional and metabolic status of the producing animal (e.g., diet, stress). Enzymes are active in the udder before milk let-down, during the refrigerated storage stage both on the farm and in the factory and may also be present in the final dairy product e.g., plasmin, lipases and phosphatases. They can be exploited in several ways during processing including as an index of the thermal treatment of milk and for consumer health and food safety, e.g., to combat bacterial invasion and growth. The effects of processing and the impact on product quality need to be explored further including the partitioning of enzymes into different milk fractions and the assay methods used to quantify them.

Key Words: enzyme, milk, review

215 Use of phospholipases to modify phospholipid functionality in dairy processing. R. Ipsen*, *Department of Food Science, University of Copenhagen, Frederiksberg C, Denmark.*

Phospholipids (PL), despite constituting only approximately 0.5% of the total lipid in bovine milk, have a critical role in stabilizing milk fat globules against coalescence. They also have different technologic roles in dairy products, e.g., by coating powder particles, providing higher foam volumes in aerated products and acting as co-emulsifiers. In addition, phospholipases can be used to modify phospholipid functionality in dairy processing by improving fat stability or increasing product yield. We have been shown that partial hydrolysis of PL increases cheese yield. In manufacture of part-skim Mozzarella cheese manufactured from milk hydrolyzed with fungal phospholipase A1 before renneting, reduced fat loss in whey and cooking water as well increased cheese yield was found as a result of improved fat and moisture retention. The mechanism of yield improvement due to phospholipases has been found to be complex and not only due to better O/W emulsification of lyso-PL, but also caused by the interaction of lyso-PL with protein and the increased water binding of lyso-PL. When extra phospholipid was added to cheese milk, increased yield also resulted, but the effect of phospholipase was more pronounced than the effect of adding PL. Phospholipase can also be used in the dairy industry to improve the foaming properties of whey protein as we have shown. In general the surface properties of milk and whey are dramatically changed by application of phospholipase and our results have also shown that the reaction between lyso-PL and whey proteins (β-lactoglobulin) increased the heat stability of the whey proteins and show promise for making more heat stable emulsions. It is known that PL influence milk fat crystallization and we have recently started investigating the effect of phospholipase treatment on water-in-oil emulsions of dairy origin. Our preliminary results indicate that the source of milk phospholipids (e.g., buttermilk, whey protein concentrate) has a major effect on the functional behavior.

Key Words: phospholipase, phospholipid, functionality

216 Oligosaccharides from lactose: Enzymatic synthesis and nutritional functionality. M. Gänzle*, *University of Alberta, Edmonton, Canada.*

Oligosaccharides produced from lactose are functional food ingredients to exploit specific biological functions, including low caloric value and prebiotic activity. Galacto-oligosaccharides are synthesized on a commercial scale from lactose by microbial β-galactosidases. Lactose acts as galactosyl-donor as well as galactosyl-acceptor to convert lactose to indigestible oligosaccharides. High lactose concentrations favor oligosaccharides synthesis by β-galactosidases over hydrolysis and high oligosaccharide yields are obtained at lactose concentrations of 30% or higher. Galacto-oligosaccharides are indigestible, stimulate colonic fermentation to short-chain fatty acids, and increase the abundance of intestinal bifidobacteria, and are thus recognized as prebiotic compounds. Transgalactosylation by β-galactosidases with acceptor carbohydrates other than lactose yields a large diversity of oligosaccharides. Lactulose and lactosucrose are produced with fructose and sucrose as acceptor carbohydrates, respectively; both compounds find commercial application as functional food ingredients to stimulate colonic fermentation and to alleviate constipation. *N*-Acetylglucosamine, mannose, fucose, or chitin-oligosaccharides also are galactosyl-acceptors for microbial β-galactosidases to produce novel galactosylated oligosaccharides. Experimental evidence obtained in vitro indicates that galacto-oligosaccharides and related compounds prevent the adhesion of enteric pathogens to mucosal surfaces. Their activity is likely mediated by specific interaction with bacterial glycan recognition proteins that are involved in early steps of pathogenesis. Oligosaccharide synthesis from lactose is an established process to produce galacto-oligosaccharides as functional food ingredients. Health benefits of galacto-oligosaccharides are mainly based on their colonic fermentation to short chain fatty acids. Emerging evidence indicates that lactose can also be used to produce novel oligosaccharides that benefit host health by complementary mechanisms, i.e., the prevention of pathogen adhesion.

Key Words: lactose, β-galactosidase, galacto-oligosaccharide

217 Utilization of enzymes to influence the functionality of milk proteins. U. Kulozik*, *Technische Universität München, Chair for Food Process Engineering and Dairy Technology, Freising-Weihenstephan, Bavaria, Germany.*

The objective of work presented in is paper was to develop new methods for the enhancement of structures in fermented dairy products, to make use of milk proteins in the production of microencapsulated sensitive microorganisms (probiotics) and to produce peptides from milk proteins with functionalities related to bioactivity and surface activity. The report will focus on the following subjects: (1) Strengthening gel firmness in stirred yogurt by Transglutaminase and investigation (avoidance) of structure changes along shelf life, using 3 approaches of enzymatic crosslinking of milk proteins in yogurt milk before fermentation, simultaneously with fermentation, only in supplementary milk used to increase dry matter and protein contents. (2) Microencapsulation of sensitive ingredients and probiotics in enzymatically crosslinked milk protein matrices using an emulsification method producing droplets of highly concentrated dairy proteins containing the core material with subsequently induced crosslinking reaction by Transglutaminase or Chymosin. (3) Selective enzymatic hydrolysis of whey proteins to eliminate individual components based on their individual sensitivity against action of various hydrolyzing enzymes. Targeted enzymatic hydrolysis of whey proteins or enzymatic crosslinking for the production of bioactive peptides, surface active peptides for the manufacture of foams and emulsions, caseinomacropeptide depleted cheese whey with upstream separation of precursor proteins and downstream fractionation of peptide mixtures using novel chromatographic methods

Key Words: transglutaminase, chymosin, trypsin

218 Use of digital infrared thermography to measure the skin temperature changes in estrus synchronized dairy cows. S. Talukder*[1], L. Ingenhoff[1], K. L. Kerrisk[1], S. C. Garcia[1], and P. Celi[1,2], *[1]The University of Sydney, Narellan, Australia, [2]The University of Melbourne, Parkville, Victoria, Australia.*

The primary aim of this study was to explore the potential use of digital infrared thermography for estrus detection in dairy cows. Twenty cows were synchronized using controlled internal drug release (CIDR, progesterone 1.9g) and prostaglandin $F_{2\alpha}$ ($PGF_{2\alpha,}$ cloprostenol sodium 500µg). Vulva and muzzle skin temperatures were measured every 12 h from CIDR insertion to 32 h post $PGF_{2\alpha}$ injection and then every 4 h until ovulation occurred. Thermal images obtained with a FLIR T620 series infrared camera were analyzed using ThermaCAM Researcher Professional 2.9 software. All the images of vulva and muzzle were averaged for the following 5 periods: 1) 24 h before PG injection (B-PG), 2) 32 h after PG injection (A-PG), 3) 36 h after PG injection to 1st sign of estrus (PG-E), 4) time from estrus to ovulation (E-OV) 5) 4 h interval in which ovulation occurred (OV). The relationship of vulva and muzzle temperature at different periods was analyzed by linear mixed model using Genstat version 14. Temperature humidity index and time of the day were included as covariates. Vulva and muzzle temperature changed significantly ($P < 0.01$) between time periods. Muzzle skin temperature increased from A-PG to E-OV after which temperature decreased. A positive ($P < 0.01$, r = 0.74) relationship was noted between muzzle and vulva skin temperature. The mean time of onset of estrus and ovulation were 54.7 ± 14.4 and 87.3 ± 19.1 h respectively after $PGF_{2\alpha}$ injection. Ovulation occurred 30.7 ± 9.8 h after onset of estrus. Muzzle and vulva temperature also changed significantly ($P < 0.01$) as ovulation approached. The most distinct increase in vulva and muzzle temperature was observed 22 and 16 h respectively before ovulation. Therefore, digital infrared thermography could be a promising tool for estrus detection or prediction of ovulation in dairy cows. Further biometrical analyses are required to build prediction models and to test the accuracy with hormonal assay.

Key Words: infrared thermography, estrus, dairy cow

219 Presynchronizing $PGF_{2\alpha}$ and GnRH injections before a fixed-time artificial insemination CO-Synch + CIDR program. S. L. Hill*[1], S. L. Pulley[1], KC Olson[1], J. R. Jaeger[1], R. M. Breiner[1], V. R. G. Mercadante[2], G. C. Lamb[2], and J. S. Stevenson[1], *[1]Kansas State University, [2]University of Florida.*

We hypothesized that pregnancy outcomes may be improved by inducing luteal regression and ovulation before a timed AI (TAI) program in suckled beef cows. This hypothesis was tested by presynchronizing estrous cycles before initiating a TAI program with the objective to increase the proportion of cows starting the program in a high (≥1 ng/mL) progesterone status and increase pregnancy per TAI (P/TAI). Cows were assigned randomly to 2 treatments after stratification by breed, parity, and days postpartum. Cows at 4 locations (n = 803) were assigned to either: (1) control (100 µg GnRH i.m. and insertion of a progesterone-releasing intravaginal controlled internal drug release (CIDR) insert on d –10, 25 mg $PGF_{2\alpha}$ i.m. and CIDR insert removal on d –3, and 100 µg GnRH i.m. plus TAI on d 0); or (2) PrePGG (same as control with a pre-$PGF_{2\alpha}$ injection at d –20 and a pre-GnRH injection at d –17). Blood was collected on d –20, –17, –10, –3, and 0 for progesterone assays. Ovarian structures in cows at 1 location were scanned. Binomial data were analyzed by procedure GLIMMIX. The PrePGG cows were more likely ($P < 0.05$) than controls to have luteolysis after the initial $PGF_{2\alpha}$ injection (42.2 vs. 14.4%) and had reduced ($P < 0.05$) concentrations of serum progesterone (0.37 vs. 0.71 ng/mL) at the time of the presynchronizing GnRH injection. On d –10 and –3 more ($P < 0.05$) PrePGG cows had at least 1 CL than controls (63.9 vs. 41.9% and 62.7 vs. 45.3%, respectively) indicating that ovulation had occurred in response to pre-GnRH. The P/TAI at d 35 did not differ between PrePGG and control (44.4 vs. 44.0%, respectively). Final pregnancy outcome (82.6 vs. 82.6%) and pregnancy loss (5.4 vs. 3.6%) did not differ between PrePGG and control, respectively. Cows having BCS >5.0 at d –20 were more ($P < 0.01$) likely to become pregnant than thinner cows (49.8 vs. 38.8%). Cows that were ≥70 d postpartum also had a greater ($P < 0.01$) P/TAI than cows with fewer days postpartum at TAI (52.6 vs. 36.1%). In summary, luteal regression and ovulation were enhanced by presynchronization before the 7 d CO-Synch program; however, P/TAI was not increased.

Key Words: timed AI, presynchronization, luteolysis

220 Influence of estrus at fixed-time AI on accessory sperm numbers and embryonic development. E. L. Larimore*[1], S. G. Kruse[2], B. J. Funnell[2], S. L. Bird[2], O. L. Swanson[1], G. A. Bridges[2], and G. A. Perry[1], *[1]Department of Animal Science, South Dakota State University, Brookings, [2]North Central Research and Outreach Center, University of Minnesota, Grand Rapids.*

Increased accessory sperm numbers have been correlated with increased embryo quality, and estrous expression before timed-AI (TAI) resulted in increased pregnancy success. Thus, the objective of this experiment was to determine if estrous expression before TAI affected accessory sperm numbers and embryonic development. Beef heifers at UMN (Rep 1; n = 44, Rep 2; n = 44) and SDSU (Rep 3; n = 50) were developed in a dry-lot and fed approximately 125% NRC requirements from weaning to AI. Ovulation was synchronized using the 5 d CO-Synch + CIDR with TAI on d 0. Estrous expression was assessed twice daily with the aid of EstroTect patches. Immediately following TAI, half the heifers continued on the pre-insemination diet and the remaining heifers were restricted fed. On d 6 embryos were collected and evaluated to determine quality (IETS standards; 1 = excellent, 5 = degenerate) and stage (1 = unfertilized, 9 = expanded hatched blastocyst). Embryos were stained and evaluated to determine the number of dead blastomeres (propidium iodide), total blastomeres, and number of accessory sperm (Hoechst 33342). Data was analyzed using the Mixed procedures of SAS. There were no treatment by replication or treatment by estrus interactions for any data evaluated, thus all data were pooled. Estrous expression before TAI did not affect the percent of embryos recovered ($P = 0.21$; n = 61 and 26 for heifers that did and did not exhibit estrus, respectively), number of dead cells ($P = 0.86$), or total cells ($P = 0.13$). However, embryos from heifers that exhibited estrus had improved embryo quality ($P = 0.03$; 2.2 ± 0.1) and advanced embryo stage ($P < 0.01$; 4.4 ± 0.1) compared with heifers that did not exhibit estrus (2.8 ± 0.3 and 3.7 ± 0.2, respectively). Heifers that exhibited estrus also tended to have increased numbers of accessory sperm ($P = 0.06$; 23.2 ± 3.6) and percentage of cells alive ($P = 0.08$; 81.1 ± 2.4%) compared with heifers that did not exhibit estrus (12.1 ± 2.8 and 69.7 ± 6.4%). In summary, initiation of standing estrus before TAI resulted in improved embryo stage and quality and tended to improve accessory sperm numbers and percentage of live cells.

Key Words: embryo, estrus, accessory sperm

221 Reducing handling in the 5-day timed AI program in dairy cows. J. S. Stevenson*, S. L. Pulley, and S. L. Hill, *Kansas State University, Manhattan.*

We hypothesized that 50 mg of prostaglandin $F_{2\alpha}$ (PG) on d 6 (not d 5 as previously tested) would induce luteolysis in a traditional 5-d Ovsynch-72 program (GnRH 5 d before [d 0] and 72 h after [d 8] 25-mg PG doses [d 5 and 6 after GnRH]; timed AI on d 8). Experiment 1 monitored luteal regression of original and GnRH-induced luteal tissue (CL) and blood progesterone (P4) after either of the 25-mg doses of PG (d 5 and 6; control; n = 31) or a single 50-mg dose of PG on d 6 (1 × 50 mg; n = 30). Estrous cycles were presynchronized (GnRH 7 d before 25 mg of PG) and 11 d later (62 to 71 d in milk) cows were enrolled in a 5-d Ovsynch-72 program and treatments were administered. Blood was sampled for P4 and luteal structures were measured by ultrasonography on d 0 (original CL) and d 5 through 9 to monitor new GnRH-induced CL. Data were analyzed as repeated measures using procedure MIXED. Control PG reduced ($P < 0.01$) luteal tissue area of original CL on d 6 and 7, but no difference was detected by d 9. In contrast, no differences were detected in luteal tissue area of the induced CL on d 5 through 9. Serum P4 on d 5 through 9 averaged: 5.6 vs. 6.0, 1.2 vs. 6.0 ($P < 0.01$), 0.29 vs. 0.65, 0.16 vs. 0.59, and 0.14 vs. 0.46 (±0.3 ng/mL), respectively, for control and 1 × 50 mg dose. Luteolysis occurred in all 31 controls, but luteolytic failure occurred in 2 of 30, 1 × 50 mg cows in which no CL were present on d 0 (1 or 3 new CL were present on d 5). Experiment 2 monitored luteolysis in non-pregnant repeat-service cows subsequently treated with the same 2 treatments as in Exp. 1. Serum P4 in 57 cows on d 5, 6, and 8 was: 5.4 vs. 6.6, 1.7 vs. 5.8 ($P < 0.01$), and 0.29 vs. 0.35 (±0.5 ng/mL), respectively, for control and 1 × 50 mg dose. Luteolysis occurred in 28/30 controls and in 26/26, 1 × 50 mg treated cows. Pregnancy outcome 32 d after AI for both experiments was 30/60 (50%) vs. 26/56 (46%) for control vs. 1 × 50 mg dose, respectively. We concluded that the single 50-mg dose was equivalent to the control based on actual luteal tissue regression, decreased P4, and pregnancy outcome.

Key Words: luteolysis, luteal, pregnancy

222 Effect of presynchronization using Ovsynch or a single GnRH injection 7 d before an Ovsynch56 protocol on fertility of lactating dairy cows at first service. P. D. Carvalho*, J. N. Guenther, M. J. Fuenzalida, M. C. Amundson, M. C. Wiltbank, and P. M. Fricke, *Department of Dairy Science, University of Wisconsin-Madison, Madison.*

Presynchronization strategies such as Presynch Ovsynch and Double Ovsynch increase fertility to timed artificial insemination (TAI); however, simpler presynchronization strategies could reduce costs and simplify reproductive management. Lactating Holstein cows (n = 400) were randomly assigned to one of 2 presynchronization treatments before beginning an Ovsynch56 protocol (GnRH (G1) at 70 ± 3 DIM; PGF 7 d later; GnRH 56 h after PGF; TAI 16 h later at 80 ± 3 DIM) for first TAI. Cows (n = 208) in the first treatment (Double Ovsynch; DO) were presynchronized using a modified Ovsynch protocol (GnRH at 53 ± 3 DIM, 7 d later PGF, 3 d later GnRH) ending 7 d before G1 of Ovsynch56. Cows (n = 192) in the second treatment (GGPG) were presynchronized using a single injection of GnRH 7 d before G1 of Ovsynch56 at 63 ± 3 DIM. Blood samples were collected at G1 and the PGF injection of the Ovsynch56 protocol to determine progesterone (P4) concentration and pregnancy diagnosis was performed by ultrasonography. Temperature humidity index (THI) was calculated based on data from a station located near the farm, and data were analyzed using PROC GLIMMIX of SAS. Overall, DO cows had greater ($P = 0.03$) pregnancies per AI (P/AI) compared with GGPG cows 32 d after TAI (50.2% vs. 40.8%). Treatment was not affected by parity (primiparous vs. multiparous), and pregnancy loss did not differ between treatments or parities. Interestingly, P/AI was similar for DO and GGPG cows during cool weather (THI < 72; 47.2% vs. 45.1%, respectively), whereas P/AI was greater ($P = 0.02$) for DO cows during heat stress (THI ≥ 72; 52.0% vs. 34.8%). Based on P4 at G1, more ($P < 0.001$) DO cows had P4 in a medium range (>0.5 to < 4 ng/mL) compared with GGPG cows (81.9% vs. 58.7%). In addition, more ($P < 0.001$) DO cows had high P4 (>4 ng/mL) at the PGF injection of Ovsynch56 compared with GGPG cows (69.0% vs. 36.8%). In conclusion, presynchronization with a modified Ovsynch protocol increased P/AI by increasing synchrony to the Ovsynch56 protocol particularly during heat stress compared with presynchronization with a single injection of GnRH.

Key Words: synchronization, timed AI, dairy cow

223 Relationship of follicle size and concentrations of estradiol among cows that do and do not exhibit estrus during a fixed-time AI protocol. O. L. Swanson*[1], E. L. Larimore[1], B. L. Perry[1], G. D. Djira[2], R. A. Cushman[3], and G. A. Perry[1], *[1]Department of Animal Science, South Dakota State University, Brookings, [2]Department of Mathematics and Statistics, South Dakota State University, Brookings, [3]USDA-ARS, U.S. Meat Animal Research Center, Clay Center, NE.*

Cows that exhibited estrus around the time of fixed-time AI had greater pregnancy success compared with cows that did not. The objective of this study was to determine the relationship between follicle size and peak estradiol concentration between cows that did or did not exhibit estrus during a fixed-time AI protocol. Beef cows were synchronized with the CO-Synch protocol [GnRH (100 µg) on d −7, $PGF_{2\alpha}$ (25 mg) on d 0, and a second injection of GnRH 48 h after $PGF_{2\alpha}$ (d 2)] in 3 replicates (n = 80, 22 and 24). Follicle size (d 2) and ovulation (d 4) was determined by ultrasonography. Blood samples were collected every 3 (replicates 1 and 2) or 4 (replicate 3) h from $PGF_{2\alpha}$ injection to h 56. Estrus was detected by visual observation with the aid of estrus detection patches, and cows that ovulated were classified as exhibited estrus (n = 46) or did not exhibit estrus (n = 63). Data were analyzed using the GLM procedure in SAS with replicate as a co-variate. Among all cows ($P < 0.01$) and among cows that exhibited estrus ($P < 0.01$), there was a significant positive relationship between follicle size and peak estradiol concentration, but there was no relationship ($P = 0.60$) between follicle size and peak estradiol concentration among cows that did not exhibit estrus. Cows that exhibited estrus had a larger ($P = 0.02$) follicle (13.4±0.25 mm) and greater ($P < 0.01$) peak estradiol concentration (12.4 ± 0.54 pg/mL) compared to cows that did not exhibit estrus (12.6 ± 0.22 mm and 7.8 ± 0.46 pg/mL). There was no relationship between follicle size and estradiol concentration at the second GnRH injection among all cows ($P = 0.27$), cows that exhibited estrus ($P = 0.34$), and cows that did not exhibit estrus ($P = 0.34$), but cows that exhibited estrus (8.9 ± 0.56 pg/mL) had greater ($P < 0.01$) concentrations of estradiol compared to cows that did not exhibit estrus (5.8 ± 0.45 pg/mL). In summary, follicle size had a positive relationship with peak concentrations of estradiol, but only among cows that exhibited standing estrus.

Key Words: follicle size, estradiol, estrus

224 Progesterone supplementation to dairy cows lacking a corpus luteum (CL) at the initiation of the Ovsynch protocol. R. S. Bisinotto*, N. Martinez, F. S. Lima, T. L. C. Pinto, R. S. Surjus, G. C. Gomes, E. S. Ribeiro, L. F. Greco, W. W. Thatcher, and J. E. P. Santos, *University of Florida, Gainesville.*

Objectives were to evaluate the effects of supplemental progesterone (P4) on fertility responses of Holstein cows lacking a CL at the initiation of the Ovsynch-56 program (d-10 GnRH, d-3 $PGF_{2\alpha}$, h-16 GnRH, d0 AI). Cows had their ovaries evaluated by ultrasonography on d-10 and those without CL were assigned randomly to receive 0 (Control; n = 270) or 2 controlled internal drug-release (CIDR) inserts containing P4 from d-10 to d-3 (2CIDR; n = 261). Cows with CL on d-10 were used as positive controls (Diestrus; n = 756). Cows had their ovaries scanned on d-3 to detect newly formed CL. Blood was sampled on d-10, −9, −7, −5, −3, and 0 and P4 concentrations determined by RIA. Estrus was detected based on removal of tail chalk. Pregnancy was evaluated 32 and 60 d after AI. The LOGISTIC and GLIMMIX procedures of SAS were used to analyze binomial and continuous responses. The use of 2 CIDR inserts increased ($P < 0.001$) P4 concentrations between d-9 and −3 compared with Control (2.57 vs. 0.75 ng/mL), but concentrations were less than those of Diestrus (4.45 ng/mL). Ovulation to the first GnRH was greater ($P < 0.001$) for Control and 2CIDR compared with Diestrus (61.9, 57.1, and 35.9%, respectively), which resulted in a greater ($P < 0.001$) proportion of cows bearing a new CL on d-3 (71.5, 65.9, and 39.0%, respectively). Nonetheless, a greater proportion of Diestrus cows had CL on d-3 compared with Control and 2CIDR (89.6, 71.5, and 65.9%, respectively). Pregnancy per AI was less for Control than for Diestrus and intermediate for 2CIDR cows (Table 1). However, this trend was observed only in cows that were not in estrus at AI.

Table 1. Fertility responses (%; no.) to treatment

	Treatment			
	Control	2CIDR	Diestrus	*P*-value
Estrus at AI	59.3 (270)	66.7 (261)	55.8 (756)	0.70
Pregnant d 32				
Overall	26.7 (270)^{b,B}	31.8 (261)^{A}	33.6 (756)^{a}	0.002
Estrus at AI	35.0 (160)	36.2 (174)	35.8 (422)	0.93
Not in estrus at AI	14.6 (110)^{b}	23.0 (87)^{a}	30.8 (334)^{a}	0.001
Pregnant d 60				
Overall	23.0 (270)^{b}	27.7 (260)^{b}	31.5 (752)^{a}	0.002
Estrus at AI	29.4 (160)	32.2 (174)	33.4 (419)	0.62
Not in estrus at AI	13.6 (110)^{b}	18.6 (86)^{B}	29.1 (333)^{a,A}	0.002
Pregnancy loss	13.9 (72)^{a}	12.2 (82)^{a}	5.2 (250)^{b}	0.03

Key Words: anestrus, progesterone, dairy cow

225 Resumption of postpartum ovarian cyclicity in dairy cows and its relationship with acute phase proteins, uterine health and lipolysis during the transition period. C. C. Brauner*[1], A. R. T. Krause[1], M. E. Lima[1], E. G. Xavier[2], A. Schneider[1], E. Schmitt[3], E. Schwegler[1], M. M. Weschenfelder[1], P. Montagner[1], F. A. B. Del Pino[1], M. N. Corrêa[1], and L. F. M. Pfeifer[3], *[1]Universidade Federal de Pelotas, NUPEEC, Pelotas, RS, Brazil, [2]Granjas 4 Irmãos S/A, Rio Grande, RS, Brazil, [3]Empresa Brasileira de Pesquisa Agropecuária EMBRAPA, Porto Velho, RO, Brazil.*

The aim of this study was to evaluate the resumption of postpartum cyclicity and its relationship with acute phase proteins, uterine health and lipolysis during the transition period of dairy cows. Twenty multiparous Holstein cows were enrolled in this study from a commercial dairy farm with annual rolling herd average of 7,891 ± 1.18 kg of milk. To assess the cyclicity resumption, blood samples were collected weekly from 16 to 44 d during the postpartum period to evaluate the concentration of progesterone. Cows were classified as either ovulatory (OC group), consisting of cows that ovulated up to 44 ± 2 d (n = 12) or anovulatory (AC group), those cows that did not ovulate in the same period (n = 8). Blood samples were collected weekly from day −21 relative to calving to 30 d postpartum aiming to evaluate the concentration of acute phase proteins (haptoglobin, paraoxonase and albumin), as well as, glucose and NEFA. Endometrial cytology was performed at 37 ± 2 postpartum days, to assess the uterus health considering the polymorphonuclear (PMN) cells count, using uterine low volume flushing. Data were analyzed by MIXED PROCEDURES of SAS. The OC had lower ($P = 0.05$) PMN percentage in endometrial cytology than AC with 26.3% vs. 53.4% PMN cells in the uterine flushing, respectively. The AC had lower ($P = 0.03$) concentrations of albumin during the prepartum (2.42 ± 0.07 vs. 2.64 ± 0.05 g/dL) and postpartum period (2.22 ± 0.09 vs. 2.52 ± 0.07 g/dL $P = 0.01$), and higher ($P = 0.04$) concentrations of haptoglobin during the prepartun (0.69 ± 0.16 vs. 0.23 ± 0.13 g/L) and tended ($P = 0.09$) to have lower activity of paraoxonase during the postpartum period (87.81 ± 9.11 U/L vs. 108.41 ± 7.45 U/L) than the OC group. No differences ($P > 0.05$) were observed of NEFA and glucose concentrations during the transition period. In conclusion, cows that return earlier to estrous cyclicity have reduced concentrations of haptoglobin and proportion of PMN in endometrium, and increased concentrations of albumin, but no differences in blood NEFA were observed between OC and AC.

Key Words: inflammation, ovulation, NEFA

226 A missense mutation in growth differentiation factor-9 (GDF9) increases ovulation rate in sheep. M. P. Mullen* and J. P. Hanrahan, *Animal and Grassland Research and Innovation Centre, Teagasc, Athenry, Co. Galway, Ireland.*

The Finnish Landrace is a well-known high prolificacy sheep breed and has been used in many countries to increase fecundity of local breeds. All of the evidence adduced to date suggests that mutations with a large effect on ovulation rate are not responsible for the exceptional prolificacy of Finnsheep. The objectives of this study were 1) to ascertain if any of the 10 established mutations with large effects on ovulation rate in sheep or 2) if any other DNA sequence variants within the candidate genes GDF9 and BMP15, are implicated in the high prolificacy of the Finnish Landrace breed using material from lines developed by divergent selection on ovulation rate. Genotyping results showed that none of 10 known mutations, $FecX^{G}$, $FecX^{B}$, $FecG^{H}$, $FecB^{B}$, $FecX^{I}$, $FecX^{H}$, $FecX^{L}$, $FecT^{T}$, $FecG^{E}$ or $FecX^{R}$, were present in the set of 108 Finnsheep tested and thus do not contribute to the exceptional prolificacy of Finnsheep. However, DNA sequence analysis of GDF9 identified a previously known mutation, V371M, segregating at significantly different frequencies between high and low ovulation rate lines. Subsequently analysis of Belclare sheep revealed a significant association V371M and ovulation rate ($P < 0.001$). Heterozygous carriers of V371M, a missense mutation in GDF9, exhibited increased ovulation rate (0.24 s.e. 0.084) relative to the wild type. This finding brings to 11 the number of mutations that exhibit large effects on ovulation rate in sheep and to 3, including $FecB^{B}$ and $FecG^{E}$, the number of known mutations within the TGFβ superfamily with a positive effect on prolificacy in the homozygous state without any associated sterile phenotype. These results further highlight the central role of members of the TGFβ superfamily in the control of fertility in mammals.

Key Words: fecundity, growth differentiation factor-9 (GDF9), control of fertility

227 Effect of exogenous FSH on endogenous FSH secretion and testicular development in prepubertal bulls. B. R. Harstine*[1], L. H. Cruppe[1], F. M. Abreu[1], M. D. Utt[1,3], R. S. Cipriano[1], C. Premanandan[2], J. M. DeJarnette[3], and M. L. Day[1], *[1]Department of Animal Sciences, The Ohio State University, Columbus, [2]Department of Veterinary Biosciences, The Ohio State University, Columbus, [3]Select Sires Inc., Plain City, OH.*

In prepubertal bulls, FSH facilitates testis maturation and a transient proliferation of Sertoli cells. Two experiments (Exp) examined the effects of exogenous FSH on hormone secretion and testis development of Angus-cross bulls. Exogenous FSH treatment consisted of IM injection of 30 mg NIH-FSH-P1 (Folltropin-V) in a 2% hyaluronan solution (pFSH). In Exp 1, bulls (50 ± 6.5 d age; d 0) received either pFSH (FSH, n = 5) or saline (control, n = 5) on d 0 and 3.5. Blood samples to assess FSH and testosterone (T) concentrations (CONC) were obtained every 6 h for 24 h after pFSH and every 12 h thereafter. Peripheral FSH CONC measured using a bovine FSH RIA were greater ($P < 0.05$) in the FSH than control treatment 6 h after pFSH and tended to be greater ($P \leq 0.08$) 12 h after pFSH. FSH CONC from 18 to 84 h after pFSH and T CONC throughout did not differ between treatments. In Exp 2, bulls were treated with pFSH (FSH, n = 11) or saline (control, n = 11) every 3.5 d from 35 ± 2 to 91 ± 2 d age. Blood samples were collected before each treatment to quantify T and FSH CONC. Body weight (BW) and scrotal circumference (SC) were measured weekly. Bulls were castrated at 93 ± 2 d age. Seminiferous tubule diameter, testis composition, and number of Sertoli cells per tubule cross section (GATA-4 positive staining) were determined from fixed and stained histological sections. FSH CONC did not differ between treatments from 35 to 67.5 d age, but increased ($P < 0.05$) in the FSH treatment at 70 d age and remained elevated and greater than control bulls through 91 d age. CONC of T, BW, SC, testis wt and volume, percent of parenchyma comprised of tubules, and tubule diameter did not differ between treatments. However, number of Sertoli cells per round tubule cross section was greater ($P < 0.05$) in the FSH than control (33.35 ± 0.9 vs. 28.27 ± 0.9 cells) treatment. In summary, exogenous pFSH treatment from 35 to 91 d of age increased endogenous FSH secretion and the number of Sertoli cells at 93 d of age. It is suggested that exogenous FSH altered endocrine mechanisms regulating endogenous FSH secretion and augmented Sertoli cell proliferation in young bulls.

Key Words: FSH, Sertoli cell, testes

228 Effect of estradiol benzoate on estrus intensity, estrus response and fertility in CIDR-treated crossbred heifers. M. U. Mehmood*[1], A. Y. Qamar[1], N. Ahmad[1], A. Sattar[1], and M. Abdullah[2], *[1]Department of Theriogenology, University of Veterinary and Animal Sciences, Lahore, Punjab, Pakistan, [2]Department of Livestock Production, University of Veterinary and Animal Sciences, Lahore, Punjab, Pakistan.*

Crossbred dairy animals are capable of sustaining higher levels of production than native buffalo, Sahiwal, Cholistani and Desi breeds, but also more environmentally adaptable to the harsh climates of Pakistan when compared with exotics (Friesian or Jersey). Unfortunately as replacement heifers are not lactating, they are often ignored by the owners in terms of feeding and evaluating the onset of puberty. Therefore, the objectives of the present study were to determine the effect of estradiol benzoate (EB) on estrus response, intensity and fertility in CIDR (Controlled Internal Drug Releasing Device; 1.38g Progesterone; Pfizer, USA) treated crossbred heifers. Crossbred (Sahiwal × Friesian) heifers with average body condition score of 2.5 ± 0.5 (1–5), were placed at 4 different farms near Lahore, Pakistan. All the heifers were treated with CIDR on d 0 and were injected $PGF_{2\alpha}$ (Dalmazine, FATRO, Italy; 0.075 mg/mL, im), on d 6 followed by removal of CIDR on d 7. Estradiol benzoate (100 µg/mL, im Sigma Aldrich Germany) was administered 24 h after the CIDR removal (n = 50) treated with EB (group-I) while the other group (n = 50) was without EB treatment (group-II). Estrus detection was carried out by visual observation; twice daily for at least 30 min. All heifers were artificially inseminated 48 and 60 h after CIDR removal. Pregnancy status was determined by ultrasonography (HS 1500V; Honda; Japan, with 7.5 MHz probe) between d 30 and 40 post-AI. Estrus response and pregnancy rate were analyzed using Chi-squared, while estrus intensity scored by Mann-Whitney test. Estrus response was 100% in both groups. Estrus intensity was scored at the time of AI as 1 = Low, 2 = Medium, 3 = High based upon the heat signs. Estrus intensity was highly significant ($P = 0.01$) in group I (2.9 ± 0.1) compared with group II (2.0 ± 0.7). Pregnancy rate was 54% (27/50) in group I and 36% (18/50) in group II heifers ($P = 0.07$). It is concluded that estradiol benzoate in CIDR protocol intensified signs of estrus and pregnancy rate. It is implied that CIDR could be a good tool to enhance fertile estrus.

Key Words: crossbred heifers, CIDR, estradiol benzoate

Physiology and Endocrinology Symposium: The Next Generation of Metabolic Endocrinology

229 Novel insights in to the biology of the emerging metabolic regulator FGF21. A. C. Adams* and A. Kharitonenkov, *Eli Lilly & Co., Indianapolis, IN.*

Fibroblast growth factor 21 (FGF21) is a multifaceted metabolic regulator which has potential applications in the treatment of diseases such as obesity, diabetes and fatty liver. When administered in vivo either peripherally or centrally FGF21 has a plethora of beneficial activities. To date the mechanism and site of action underlying these effects remains unknown with recent studies suggesting some of its effects may be mediated indirect and occur via modulation of other factors such as adiponectin and leptin. Using tissue specific knock out mouse models lacking either the FGF receptor (FGFR1) or the critical co factor β-Klotho (KLB) we sought to determine the tissue upon which FGF21 acts and receptor complex responsible for FGF21 its mediating in vivo efficacy. Importantly, when KLB is ablated from all tissues FGF21 action is completely abrogated. To determine the precise tissue of action we created 2 tissue specific lines harboring deletion of FGFR1 in neurons and in adipose tissue, respectively. Surprisingly, in animals with neuronal FGFR1 loss there was no change in the metabolic activity of FGF21 suggesting direct central FGF21 action is not required for its physiological endpoints. In contrast, when we examined the adipose FGFR1 mutants we found significant attenuation of metabolic efficacy. Importantly, the action of FGF21 via adipose tissue results in alterations in adipokine secretion and systemic sensitivity to these factors. Therefore, while FGF21 itself may not directly act on the CNS, leptin and other adipokines are likely be mediators of FGF21's secondary central effects downstream of direct adipose tissue engagement. Further studies are required to delineate the precise mechanistic basis underlying central FGF21 mediated physiology.

Key Words: FGF21, metabolism, diabetes

230 Biology of the novel hormone fibroblast growth factor-21 in the transition dairy cow. Y. R. Boisclair*, S. L. Giesy, and L. S. Caixeta, *Cornell University, Ithaca, NY.*

The modern dairy cow reaches near maximal productivity soon after parturition despite a substantial nutritional deficit. This ability is underpinned by coordinated adaptations that are most obvious in liver, adipose tissue and skeletal muscle and affect the metabolism of all major organic nutrients. Over the last 2–3 decades, most research in dairy cattle has focused on the roles played by growth hormone, insulin-like growth factor-I and insulin in driving these adaptations. The last 10–15 years, however, have witnessed the discovery of novel hormones with potent metabolic actions. Among those, the hormone fibroblast growth factor-21 (FGF21) appears relevant on the basis of its ability in laboratory animals to regulate mobilization of lipids from adipose tissue and their oxidation in liver, 2 processes that are crucial to the efficient utilization of lipid reserves in early lactating dairy cows. These observations led us to examine the regulation of the FGF21 system in high yielding dairy cows over the last 4 weeks of pregnancy (LP) and the first 8 weeks of lactation (EL). Plasma FGF21 was nearly undetectable in LP, peaked on the day of parturition and then stabilized at lower, chronically elevated concentrations during the energy deficit of EL. Gene expression studies showed that liver was the major source of plasma FGF21 in EL with little or no contribution by adipose tissue, skeletal muscle and mammary gland. Finally, we identified liver and adipose tissue as the only 2 major tissues with meaningful expression of β-Klotho, a co-receptor that is absolutely essential for FGF21 signaling. These results suggest that FGF21 may be a key metabolic hormone in early lactating dairy cows and provide impetus to identify factors triggering its production as well as FGF21-dependent liver and adipose tissue responses.

Key Words: periparturient period, liver, adipose tissue

231 Role of adiponectin and visfatin in chicken growth and reproduction. R. Ramachandran*, S. Krzysik-Walker, O. Ocon-Grove, R. Vasilatos-Younken, G. Hendricks III, and J. A. Hadley, *Department of Animal Science, Pennsylvania State University, University Park.*

Adiponectin and visfatin are 2 endocrine factors that affect metabolism in domestic animals. Adiponectin, a 30 kDa adipokine hormone, improves carbohydrate and lipid metabolism in humans and rodent animal models by activating 2 distinct transmembrane receptors (AdipoR1 and AdipoR2) that are widely expressed in various tissues in the chicken. We have cloned and characterized the chicken genes that encode for adiponectin, AdipoR1, and AdipoR2. While adipose tissue is the primary site of adiponectin expression in the chicken, we found that adiponectin and its receptors are ubiquitously expressed in other tissues. Adiponectin undergoes multimerization during biosynthesis in the adipose tissue and circulates as a unique heavy molecular weight isoform that is larger than 669 kDa mass. Plasma adiponectin levels were found to be significantly lower in 8-wk-old compared with 4-wk-old male chickens and inversely related to abdominal fat pad mass. In vitro studies using hepatocytes and ovarian follicular cells revealed that recombinant chicken adiponectin (rcADN) increased the abundance of phosphorylated adenosine monophosphate-activated protein kinase, phosphorylated acetyl coenzyme A carboxylase, and phosphorylated Erk 1/2, as well as increased glucose uptake. Future studies will focus on regulating the signal transduction pathways of adiponectin for improving growth and reproductive efficiency. Nicotinamide phosphoribosyltransferase (Nampt/visfatin/PBEF) has been identified as a rate-limiting NAD^+ biosynthetic enzyme and an adipokine/myokine found within the cells and circulation. Human and chicken skeletal muscles are reported to have the highest level of Nampt expression among various tissues. We found that plasma levels of visfatin dramatically increases 28-fold in pubertal broiler breeder chickens compared with pre-pubertal chickens. Furthermore, recombinant visfatin was found to alter the expression of key myogenic transcription factors in satellite cells suggesting that visfatin may influence postnatal myogenesis. Future studies will focus on elucidating the functional role of circulating visfatin in growth and reproduction of farm animals.

Key Words: adiponectin, visfatin, chicken

232 Characterization of serum adiponectin during lactation in dairy cows supplemented with conjugated linoleic acids. S. P. Singh*[1], S. Häussler[1], S. Dänicke[2], M. Mielenz[3,1], and H. Sauerwein[1], *[1]Institute of Animal Science, Physiology and Hygiene Group, University of Bonn, Bonn, Germany, [2]Institute of Animal Nutrition, Friedrich-Loeffler-Institute (FLI), Federal Research Institute for Animal Health, Braunschweig, Germany, [3]Leibniz Institute for Farm Animal Biology (FBN), Department of Nutritional Physiology, Dummerstorf, Germany.*

The adipokine adiponectin (Aq) is known for its insulin sensitizing effects. The metabolic profile of dairy cows may be affected by conjugated linoleic acids (CLA). The objectives of our study were to characterize serum Aq concentrations throughout lactation and to test whether dietary CLA supplementation affects this time course in multiparous (MP) and primiparous (PP) dairy cows. Thirty 3 pregnant German Holstein cows (22 MP and 11 PP) were included in the study from d 21 antepartum (ap) until d 252 postpartum (pp). From d 21 ap until calving, all animals received same diet. From d 1 to d 182 pp, animals received same lactation diet but were either fed CLA (100 g/d Lutrell Pure, BASF, Ludwigshafen, Germany; group CLA: 11 MP and 5 PP cows) or a control fat supplement (100 g/d Silafat; BASF; group CON: 11 MP and 6 PP cows). After d 182 pp, all animals were continuously fed with same lactation diet but without CLA or control fat supplement for further 12 wk. Blood samples were collected for determining serum Aq by ELISA (Mielenz et al., 2013, doi:10.1016/j.domaniend.2012.10.04). Data were analyzed by mixed model (SPSS). Treatment and parity were considered as fixed factors and sampling days as repeated effects. Serum Aq (μg/mL; means ± SEM) decreased from 21 d ap reaching a nadir at calving [18.5 ± 1.6 (mean for all groups together)] and increased gradually thereafter until d 21 pp in PP cows [35.9 ± 3.7 (CON), 25.8 ± 2.7 (CLA)] and until d 49 pp in MP cows [34.6 ± 2.2 (CON), 28.2 ± 2.1 (CLA)], respectively and remained unchanged thereafter. Serum Aq were lower ($P < 0.05$) in CLA than in CON cows; this difference emerged 4 wk earlier in PP cows than MP cows. Circulating Aq tended ($P = 0.09$) to be higher in MP cows of both CLA and CON groups compared with respective PP cows. Our results indicate that major changes in circulating Aq occur peripartum and that dietary CLA decreases serum Aq in both PP and MP dairy cows albeit at different times. In view of the insulin sensitizing actions of Aq described in monogastrics, the CLA effects observed herein point to a CLA-induced decrease in insulin sensitivity.

Key Words: adiponectin, conjugated linoleic acid, dairy cow

233 Daily injection of tumor necrosis factor alpha in the first week of lactation decreases milk production and promotes health disorders in Holstein dairy cows. J. K. Farney*, K. Yuan, L. K. Mamedova, and B. J. Bradford, *Kansas State University, Manhattan.*

Inflammation may contribute to transition disorders in dairy cattle. The objective of this study was to determine the production responses to administration of an inflammatory cytokine, tumor necrosis factor a (TNFα), in the first week of lactation. At calving, 33 Holstein cows (n = 9 primiparous, n = 24 multiparous) were blocked by parity and alternately assigned to either control (CON; 0 μg TNFα/kg BW), low dose (LOW; 1.5 μg TNFα/kg BW), or high dose (HIGH; 3.0 μg TNFα/kg BW) s.c. injections daily for 7 d. Daily DMI, water intake, and health disorder data were recorded; plasma samples were also collected daily for metabolite analyses. Data were analyzed using mixed models with repeated measures over time and significance was declared at $P < 0.05$ and tendencies at $P < 0.10$. Preplanned contrasts evaluating CON vs. TNFα treatments and LOW vs. HIGH were evaluated. Plasma TNFα concentrations tended to be increased in cows receiving TNFα injections ($P = 0.09$, 64% increase), but there were no differences observed between HIGH and LOW treatments. DMI was significantly reduced in cows receiving TNFα injections (18% decrease). Similarly, water intake was decreased 13% with TNFα. Milk production was reduced in TNFα treated cows as evidenced by 15 to 18% decreases in yields of milk, milk fat, milk protein, milk lactose, energy-corrected milk, and solids-corrected milk. Milk fat yield and SCM tended to be further depressed in HIGH cows, but no differences were observed between LOW and HIGH for any other milk variable. No treatment differences were observed for plasma glucose, β-hydroxybutyrate, nonesterified fatty acid, or triglyceride concentrations. Daily injection of TNFα increased total diagnosed health disorders in the first week of lactation, due in part to a tendency for an increased incidence of ketosis in cows injected with TNFα. The results of this study indicate that low grade inflammation induced by daily injection of TNFα negatively affects milk production and increases physiological stress on the transition dairy cow as evidenced by increased health disorders.

Key Words: inflammation, anorexia, metabolism

234 Inflammation and endoplasmic reticulum (ER) stress gene network expression in liver of peripartal Holstein cows fed two levels of dietary energy prepartum. M. J. Khan*[1], E. Trevisi[2], D. E. Graugnard[1], G. Bertoni[2], and J. J. Loor[1], *[1]University of Illinois, Urbana, [2]Universita Cattolica del Sacro Cuore, Piacenza, Italy.*

The peripartal period is characterized by marked changes in inflammatory status that are functionally related with impaired immune and metabolic responses in the cow. We examined blood metabolites and expression of genes related to inflammation and ER stress in cows assigned (6/diet) to a control (high-straw, CON; NEL = 1.34 Mcal/kg) or moderate-energy (OVE; NEL = 1.62 Mcal/kg) diet during the entire dry period. All cows were fed a common lactation diet (NEL = 1.69 Mcal/kg) postpartum. Blood was collected on d (±3) −14, −5, −2, −1, 0, 1, 2, 5, 7, 10, 14 and 21 d relative to parturition. A percutaneous liver tissue biopsy was harvested at −14, 7, 14, and 30 d relative to parturition for transcript profiling via quantitative PCR. Estimated prepartal energy balance (EBAL) OVE was greater ($P < 0.05$) and averaged 159% of requirements compared with 102% in CON. However, EBAL during the first week postpartum was lower in OVE (83% vs. 89% of requirements). After parturition the concentration of ceruloplasmin, creatinine, bilirubin and reactive oxygen metabolites (ROM) was greater (Diet × Time; $P < 0.05$) in OVE. Around calving the expression of ER and oxidative stress indicator genes XBP1, PERK, GRP94 and HSP40 was lower in OVE than CON but TRB3, HSPA1A, HSPA1B and CREB3L3 had greater (Diet × Time; $P < 0.05$) expression in OVE. Expression postpartum of the inflammatory genes NFKB1, RELA, CHUK, MYD88, TNF, SAA3, and PTX3 increased (Diet × Time; $P < 0.05$) in OVE. Genes associated with cell growth (mTOR, RPTOR, AKT3, TP53) also had greater (Diet × Time; $P < 0.05$) expression in OVE after parturition. Overall, results indicated that negative EBAL induced by prepartal OVE was associated with hepatic pro-inflammatory and pro-stress upregulation.

Key Words: transition cow, nutrition, transcriptomics

Production, Management and the Environment: Diet and Forage I

235 Effect of dried distillers grains with solubles on nitrogen emissions from soil-applied beef manure. J. Roth* and W. Powers, *Michigan State University, East Lansing.*

Dried distillers grains with solubles (DDGs) is an important feed in cattle diets but may affect emissions of ammonia (NH_3) and nitrous oxide (N_2O), an important greenhouse gas. The objective of this study was to determine the effect of feeding steers diets containing DDGs on NH_3 and N_2O emissions following manure application to soil. Angus steers (n = 4; initial BW = 414 kg) were fed diets containing 20% DDGs (12.2% crude protein) or 40% DDGs (16.6% crude protein) for 23 d. During the last 2 d, steers were housed in metabolism crates for a manure collection period. Steers were fed twice daily (0600 and 1800) during the collection period. Twice daily urine and feces were collected, separately, and mixed by treatment. Manure N content was determined (6.7% and 9.3% N for the 20% and 40% manures). Manure was stored frozen until the land application phase began. Thawed manure (570 g) was surface applied to 25 cm-deep soil over a sand base in 208-L tubs (6 replicates per treatment). Continuous NH_3 and N_2O headspace concentrations were measured for 26 d and daily emissions calculated. Data were analyzed using mixed model procedures. Average daily concentration of NH_3 (ppm) and average daily NH_3 emission (mg/d) were lower as a result of feeding the 20% treatment (6.4 versus 12.0 ppm ($P < 0.01$; SEM = 0.35); 52.4 versus 99.1 mg/d ($P < 0.01$; SEM = 3.14), for 20% and 40% tubs, respectively). Manure N-adjusted average daily NH_3 emission was less from tubs where the 20% manure was applied (13.4 versus 15.1 mg NH_3/g manure N; $P = 0.02$; SEM = 0.52). Average daily N_2O concentration (ppm) and average daily N_2O emission (mg/d) were lower from the 20% treatment (0.80 versus 0.92 ppm ($P < 0.01$; SEM = 0.02); 2.50 versus 5.25 mg/d ($P < 0.01$; SEM = 0.48) for 20% and 40% tubs, respectively). Manure N-adjusted average daily N_2O emission was not different between treatments (0.72 mg N_2O/g manure N; $P = 0.28$; SEM = 0.11) suggesting that differences in manure N content explained differences in N_2O emissions. Overall, feeding increased dietary protein resulting from high DDGs diets increases both NH_3 and N_2O emissions when manure is land applied.

Key Words: air emission, beef, dried distillers grains

236 Effects of PN Beef supplements and exogenous growth promotants on feedlot performance and carcass characteristics. K. J. Phelps*[1], K. A. Miller[1], C. L. Van Bibber-Krueger[1], C. A. Alvarado-Gilis[1], A. K. Sexten[1], J. S. Jennings[2], J. M. Gonzalez[1], and J. S. Drouillard[1], *[1]Kansas State University, Manhattan, [2]Alltech Inc., Nicholasville, KY.*

The experimental objective was to evaluate feedlot performance and carcass traits of beef steers fed alternative diets. Beef steers (initial BW 383 kg ± 30; 64 pens; 8 steers/pen) were used in a randomized complete block design with a 2 × 2 factorial treatment arrangement. For factor 1 (feed amendments), diets that combined inorganic trace mineral supplement, vitamins A and E, Rumensin, and Tylan (C) were compared with diets with PN Beef supplement (PN; Alltech, Inc.). PN treatments were fed a basal diet with PN Beef Receiver from d 1–20, and PN Beef Finisher from d 21 to harvest. Factor 2 consisted of the presence or absence of exogenous growth promotants (+GP vs. –GP). Steers in the +GP treatments were implanted with Component E–S, reimplanted with Component TE–S, and fed 400 mg/steer daily of ractopamine–HCl (Elanco Animal Health) for 28 d before harvest. The basal diet consisted of steam-flaked corn, wet corn gluten feed, wheat straw, and supplement. Steers were fed once daily ad libitum in partially covered, concrete-surfaced pens for 175 d then shipped to a commercial abattoir for harvest. Final BW, HCW, incidence of liver abscesses, marbling score, LM area, 12th rib fat thickness, and KPH were measured. There were no interactions between GP and feed amendments for performance or carcass traits ($P > 0.10$). Gain efficiency, DMI, ADG, HCW, and carcass traits were not different for C and PN ($P > 0.05$), but liver abscess incidence was greater for PN than for C (19.0 vs. 12.6%; $P < 0.05$). Gain, efficiency, and DMI were greater for +GP compared with –GP ($P < 0.05$). HCW were 432 and 376 kg for +GP and –GP, respectively ($P < 0.01$). Percentages of USDA Select were not affected by GP, but fewer carcasses were classified as premium Choice or Prime with +GP compared with –GP (42.8 vs. 58.4%; $P < 0.01$). Implants and β agonists increased carcass mass, but also decreased carcass quality grade. Inorganic trace elements, vitamins A and E, and in-feed antimicrobials were effectively replaced with PN Beef supplements, yielding comparable feedlot performance and carcass quality.

Key Words: growth promotant, antimicrobial, liver abscess

237 Effect of dietary nitrate supplementation on dairy cattle enteric methane and nitrous oxide emissions. Q. Wang[1], C. J. Neumeier*[1], G. Getachew[2], D. H. Putnam[2], A. R. Castillo[3], and F. M. Mitloehner[1], *[1]Department of Animal Science, University of California, Davis, Davis, [2]Department of Plant Science, University of California, Davis, Davis, [3]University of California Cooperative Extension, Merced.*

Nitrate acts as alternative hydrogen sink in the rumen to inhibit methanogenesis and therefore ruminal methane production. However, under anaerobic conditions, such as in the rumen, nitrate might be reduced to nitrous oxide, which may offset the greenhouse gas reduction benefit of nitrate feeding on methane mitigation. The present study investigated the effects of varying concentrations of nitrate supplementation (1, 2, and 3% nitrate ion on a dry matter basis) versus isonitrogenous concentrations of urea on enteric greenhouse gas emissions with an in vitro gas production system. Gas samples were collected from the in vitro systems at 2, 4, 6, 8, and 12 h incubation times and analyzed for carbon dioxide, methane, and nitrous oxide concentrations. Liquid samples were collected at 0, 3, 6, and 12 h incubation times and analyzed for nitrate, nitrite, and ammonium concentrations. All data was analyzed using the Proc Mixed Model in SAS. Nitrate vs. urea treatments at 2 and 3% decreased ($P < 0.001$) methane production during the early (0 to 8 h) and overall (0 to 12 h) incubation periods. Nitrous oxide production was observed only in the nitrate treatments. Nitrate feeding at 3% decreased ruminal methane by 3.2 mg/g dry matter feed and produced 0.018 mg nitrous oxide/g dry matter feed, respectively, equivalent to a decrease of 61.8 mg carbon dioxide equivalents/g dry matter feed. To maximize the inhibitory effect of nitrate on enteric methane production, nitrate would have to be supplemented at least 3 times daily. This study indicates that nitrate supplementation may be an effective strategy to mitigate enteric greenhouse gas emissions. Further research is necessary to evaluate methane and nitrous oxide emissions in vivo with nitrate supplementation.

Key Words: greenhouse gas, hydrogen sink, methanogenesis

238 Effect of dietary protein concentration on utilization of dairy manure nitrogen for plant growth, leachate nitrate-N losses, and ammonia emissions from lysimeters. C. Lee[1], G. W. Feyereisen[2], A. N. Hristov*[1], C. J. Dell[3], J. P. Kaye[4], and D. B. Beegle[4], *[1]Department of Animal Sciences, The Pennsylvania State University, University Park, [2]USDA-ARS-SWMRU, St. Paul, MN, [3]USDA-ARS-PSWMRU, University Park, PA, [4]Department of Crop and Soil Sciences, The Pennsylvania State University, University Park.*

Animal diet can have a significant effect on manure composition and nutrient losses during storage and following application to soil. This lysimeter experiment was designed to investigate the effects of dietary protein concentration on nitrate-N (NO_3-N) and ammonia (NH_3) losses from dairy manure applied to soil and manure N use for plant growth. Lactating dairy cows were fed diets with 16.7 (HighCP) or 14.8% (LowCP) crude protein content. Feces and urine were labeled with ^{15}N by ruminal pulse-doses of $^{15}NH_4Cl$. Unlabeled and ^{15}N-labeled feces and urine were used to produce manure for a study with 21 lysimeters (Hagerstown silt loam; fine, mixed, mesic Typic Hapludalf) in a greenhouse. Manure application rate was 277 kg N/ha. NH_3 emissions were measured at 3, 8, 23, 28, 54, and 100 h after manure application. Manure was incorporated into the soil and a leaching event was simulated. Spring barley was planted (387 plants/m^2) 7 d after the leaching event and harvested at senescence, 86 d after planting. There was no difference in whole-crop barley dry matter and N yields ($P = 0.11$ and 0.41, respectively) between LowCP and HighCP manures. The leachate NO_3-N concentration was also not different ($P = 0.08$) between manures, but urinary N had a greater ($P < 0.001$) contribution to NO_3-N than did fecal N. NH_3 emission rates were on average about 100% greater ($P < 0.001$) for HighCP vs. LowCP manures. Delta ^{15}N of NH_3-N was markedly greater ($P < 0.05$) for manures containing ^{15}N-labeled urine compared with manure with ^{15}N-labeled feces. In this study, similar plant yields and NO_3-N leaching losses were obtained by fertilizing with manures from cows fed low- vs. high-protein diets (deficient or adequate in metabolizable protein supply, respectively). Nitrogen from HighCP urine had the highest recovery rate in whole barley plants, barley kernels, and leachate NO_3-N. Applied at equal N soil application rates, HighCP manure resulted in markedly greater NH_3 emissions than LowCP manure with urine N being the primary source of the emitted NH_3.

Key Words: dietary protein, ammonia emission, nitrate leaching

239 Effect of abomasal ferrous lactate infusion on phosphorus digestion and absorption in lactating dairy cows. X. Feng*, K. F. Knowlton, A. D. Dietrich, and S. Duncan, *Virginia Polytechnic Institute and State University, Blacksburg.*

The objective of this study was to evaluate the effect of ferrous lactate infusion on phosphorus (P) digestion and absorption from the intestinal tract of lactating dairy cows. Four ruminally cannulated lactating cows were used in a 4 × 4 Latin square with 14 d in each period. Cows were fed a TMR diet containing 0.39% P, providing 100% of the cows' calculated P requirement. On d 8 to d 14 of each period, each cow was infused daily with 0, 200, 500, or 1250 mg Fe in the form of ferrous lactate solution (ferrous lactate in 1 L double distilled water) into the abomasum. Treatments were calculated to approximate 0, 2, 5, or 12.5 mg Fe/L in drinking water assuming cows drinking 100 L water per day. Total fecal collection was conducted in the last 4 d of each period and fecal samples were analyzed for total P and inorganic phosphorus (Pi) using the molybdovanadate yellow method and blue method, respectively. The phytate P content of feed and fecal samples was determined with high performance ion chromatography (HPIC). Milk samples were collected from d 11 to d 14 and coccygeal venous blood samples were collected in the last 2 d of each period. All data were analyzed using PROC GLIMMIX in SAS 9.2 and polynomial contrasts were used to evaluate linear and quadratic effects of treatment. Dry matter intake was not affected by treatment ($P > 0.05$) but the digestibility of dry matter, NDF, and nitrogen decreased linearly with increasing ferrous lactate infusion ($P < 0.01$; 68.5% to 67.0%, 38.3% to 36.2% and 66.4% to 64.1%). Milk yield, content of milk protein, lactose, and SNF, and SCC were unaffected by treatment ($P > 0.05$). A quadratic effect on milk fat percent was observed ($P = 0.04$) with the lowest milk fat at 500mg Fe/d infusion. Treatment effects on intake and digestibility of total P, Pi, and phytate P were not observed ($P > 0.05$). In the short-term, water iron up to 12.5 mg/L did not affect production or P status of lactating cows.

Key Words: dairy cow, ferrous lactate, phosphorus digestion and absorption

240 Effects of supplemented chromium propionate on milk performance and disease occurrence status in transition cows. C. Wang*[1,3], K. Wang[1], Z. Y. Duan[2], Y. Lao[2], D. M. Wang[1], and J. X. Liu[1], *[1]Institute of Dairy Science, Zhejiang University, Hangzhou, China, [2]Kemin Industries (Zhuhai) Co. Ltd., Zhuhai, China, [3]Zhejiang Agriculture & Forestry University, Lin'an, China.*

The objective of the study was to investigate the effects of supplemented chromium propionate on milk performance, blood parameters and disease occurrence status in transition cows. Seventy-five cows were blocked based on previous milk production, parity, estimated calving date and body weight, and were randomly assigned to one of 5 treatments and supplemented with 0, 25, 50, 100 and 150 g chromium propionate (KemTRACE Chromium Propionate 0.4% Dry containing 0.4% chromium) per ton of concentrate. The experiment lasted from one month before calving to 2 mo after calving. The Cr source was supplemented throughout the whole experiment. Milk yields were recorded and milk compositions were analyzed for 2 consecutive days every 10 d. Blood parameters and the content of chromium in milk, urine and feces were analyzed before trial, one week before calving, one week after calving, one month after calving and 2 mo after calving. All data except for disease occurrence status were analyzed by Mixed procedure of SAS. Disease occurrence status data were analyzed for treatment effects using the FREQ procedure of SAS. Milk yield increased as the dosage of supplemented chromium increased ($P = 0.02$) and then leveled off at a level higher than 50 g/ton. Supplementation of chromium decreased the disease rates and plasma NEFA of cows ($P = 0.05$) during the transition period. Chromium level in milk did not change in all treatments ($P > 0.05$), and the chromium in blood and urine did not increase ($P > 0.05$) at levels lower than 50 g/ton, indicating that chromium propionate can be safely fed to dairy cows at lower dosages. In conclusion, supplementation of chromium propionate at 50 g/ton can increase milk yield and is beneficial to dairy cow's health in transition period.

Key Words: chromium propionate, milk performance, health status

241 Transfer of dietary aflatoxin B1 to milk aflatoxin M1 and effect of adding absorbent on the transfer and lactation performance of dairy cows. J. L. Xiong*[1], Y. M. Wang[2], Y. Li[1,3], and J. X. Liu[1], *[1]Institute of Dairy Science, Zhejiang University, Hangzhou, China, [2]Novus International Trading (Shanghai) Co., Ltd., Shanghai, China, [3]Department of Animal Science, Zhoukou Vocational and Technical College, Zhoukou, China.*

The objectives of the study were to investigate the transfer rate of aflatoxin from feed to milk and to evaluate the efficacy of adsorbent in

reducing aflatoxin M1 (AFM1) in milk of dairy cows fed different doses of aflatoxin B1 (AFB1). Twenty-four Holstein cows in late lactation (271 ± 29 DIM, 21.6 ± 3.1 kg milk/d) were blocked by DIM, body weight, and milk yield in a 2 × 3 crossover design. Cows were added with aflatoxin B1 at 0, 20 or 40 μg/kg DM, with or without adsorbent (Solis Mos, Novus International Inc.), respectively. The experiment consisted of 2 consecutive periods with AFB1 challenging for 7 d and clearing for 5 d each period. In the second period cows were switched to different Solis Mos treatments without changing AFB1 level. Variables of data were analyzed using the mixed procedure of SAS. Dry matter intake, milk yield, contents of milk protein and milk fat, and somatic cell count were not affected by either AFB1 dosage or Solis Mos. Cows fed aflatoxin B1 at a level of 20 or 40 μg/kg excreted significantly higher AFM1 ($P < 0.01$) in milk than the 0 μg/kgDM, irrespective of Solis Mos, with significant difference between 20 and 40 μg/kg-added treatments ($P < 0.01$). Solis Mos numerically reduced the excretion of AFM1 ($P > 0.05$). Amount of AFB1 added to the diet and addition of Solis Mos did not have influence on the rate at which dietary AFB1 was transferred to AFM1 in milk. It is inferred that addition of Solis Mos and AFB1 in the diet has no effect on lactation performance of cows, while the milk AFM1 concentration linearly increased with the adding level of dietary AFB1 but was not influenced by the addition of Solis Mos.

Key Words: aflatoxin, adsorbent, transfer

242 Effect of stocking density in the prepartum period on health and productive parameters of Jersey cows. A. Dresch*[1], P. Silva[2], H. Hooper[1], C. Spies[1], P. Lau[1], K. Lobeck[2], K. Machado[1], M. Endres[2], and R. Chebel[1], *[1]Department of Veterinary Population Medicine, University of Minnesota, St Paul, [2]Department of Animal Science, University of Minnesota, St Paul.*

Objectives were to evaluate the effect of different stocking densities during the prepartum period on incidence of diseases and milk yield of Jersey cows. Within each replicate (n = 4), 2 pens were assigned to 80% stocking density (80D, n = 38) and 2 pens were assigned to 100% stocking density (100D, n = 48). Nulliparous and parous animals were housed separately pre and postpartum. Animals were scored for body condition and locomotion at enrollment, within 1 d postpartum (DIM), and at 35 and 56 DIM. Cows were examined within 1 DIM for retained placenta; 4, 7, 10, and 14 DIM for metritis; and, 35 DIM for endometritis. Data regarding displacement of abomasum, mastitis, and culling were recorded up to 60 DIM. Cows were milked thrice daily. Data regarding energy-corrected milk yield in the first month postpartum is reported. Pen was considered the experimental unit (n = 8/treatment). Dichotomous data were analyzed by logistic regression using the GLIMMIX procedure and continuous data were analyzed by ANOVA using the MIXED procedure for repeated measures. Pen was included as the random effect. Treatment was nested within pen and replicate and cows were nested within treatment. Stocking densities were 74.0 and 94.3% (±0.3) of headlocks and 80.7 and 102.8% (±0.4) of stalls for 80D and 100D, respectively. There was no effect of treatment on incidence of stillbirth (80D = 3.9 vs. 100D = 3.4%; $P = 0.50$), retained placenta (80D = 4.4 vs. 100D = 7.4%; $P = 0.13$), and endometritis (80D = 7.4 vs. 100D = 7.1%; $P = 0.65$). There was a tendency ($P = 0.10$) for incidence of metritis to be greater for 80D (21.5%) than 100D (13.9%). Treatment did not affect percentages of cows with locomotion score >2 at 35 ($P = 0.94$) and 56 ($P = 0.77$) DIM. Body condition score was not affected by treatment (80D = 2.97 ± 0.02 vs. 100D = 2.97 ± 0.01; $P = 0.91$). Percentage of cows removed from the herd within 60 DIM (80D = 4.4 vs. 100D = 3.0%; $P = 0.42$) and yield of energy corrected milk (80D = 27.56 ± 1.52 vs. 100D = 27.98 ± 1.50 kg/d; $P = 0.85$) were not affected by treatment. In conclusion, reducing stocking density did not improve health and productive parameters and unexpectedly tended to increase incidence of metritis.

Key Words: stocking density, prepartum, health

243 Supranutritional doses of selenium and vitamin E reduce the negative effects of heat stress in sheep by reducing systemic and respiratory oxidative stress. S. S. Chauhan*[1,2], P. Celi[3,2], B. J. Leury[2], F. Liu[2], and F. R. Dunshea[2], *[1]Department of Animal Husbandry, Himachal Pradesh, Shimla (HP), India, [2]Melbourne School of Land and Environment, The University of Melbourne, Parkville, VIC, Australia, [3]Faculty of Veterinary Science, University of Sydney, Narellan, NSW, Australia.*

The aim of the study was to elucidate the role of supranutritional dietary doses of selenium and vitamin E to ameliorate the effect of heat stress (HS) either individually or synergistically by reducing oxidative stress in sheep. Thirty-two Merino × Poll Dorset ewes were housed in one of 2 climatic chambers maintained at either thermoneutral (TN) (18- 21°C and 40–50% relative humidity (RH)) or HS (28–40°C and 30–40% RH) conditions. Sheep were allocated in 2 × 2 factorial design to different levels of selenium (0.24 (LS) and 1.20 (HS) mg Se (as SelPlex) kg^{-1} DM) and vitamin E (10 (LV) and 100 (HV) I.U. of vitamin E kg^{-1} DM). Respiration rate and rectal temperature were recorded at 0900, 1300 and 1700 h each day and blood samples were collected on d 1 and 7. Data were analyzed by multivariate linear mixed models using Genstat 14th edition. Average respiration rate (169 v. 78 breaths/min) and rectal temperature (40.10 v. 39.47°C) were increased ($P < 0.001$) during HS, particularly at 1700 h. Although there were no overall effects of vitamin E on physiological parameters, there were interactions ($P < 0.001$) between vitamin E and temperature such that vitamin E decreased respiration rate (157 vs. 182 breaths/min) and rectal temperature (40.26 vs. 40.54°C) during HS but not TN conditions. Se decreased respiration rate (165 vs. 174 breaths /min) during HS but not TN. Plasma reactive oxygen metabolites concentration were reduced by 20% ($P < 0.05$), while biological antioxidant potential was increased by 10% ($P < 0.05$) in sheep on the HSHV diet compared to those that received the LSLV diet. The ratio of daily water intake to feed intake was reduced by 22 % ($P < 0.05$) in sheep fed the HSHV diet compared to those fed the LSLV diet. Exhaled breath condensate hydrogen peroxide concentration was reduced by 40% ($P < 0.05$) in sheep fed the HSHV diet compared to sheep fed the LSLV diet. These data suggest that the negative effects of heat stress can be ameliorated by supranutritional doses of selenium and vitamin E through improved redox homeostasis

Key Words: heat stress, oxidative stress, sheep

244 Effect of rice bran and legume inclusion in a straw diet on intake, digestibility, nitrogen retention, digesta kinetics and methane production of beef cattle. M. Pen*, D. B. Savage, J. V. Nolan, and R. S. Hegarty, *School of Environmental and Rural Science, University of New England, Armidale, NSW, Australia.*

The effect on production of supplementing a straw diet with legume forage or rice bran was evaluated in beef steers. Twelve Brangus-cross, rumen-fistulated steers (671 ± 40 kg) were allocated randomly to 3 treatments (n = 4): straw only (S), 75% straw + 25% alfalfa (SA), 82% straw + 18% rice bran (SRB) on DM basis and were adapted to diets for 17 d, followed by 18 d of experimentation. Wheaten straw (DM 88.9%, CP 6%, crude fat < 1%), alfalfa (DM 86.2%, CP 15.8%, crude fat 1.3%) and rice bran pellet (DM 91%, CP 15.3%, crude fat 17.2%) were offered ad libitum each day at 10:00H and 17:00H. Fecal DM excretion and kinetics of particulate and liquid phases of digesta were determined from fecal marker patterns after dosing with Cr-mordanted-NDF and Co-EDTA. The purine derivatives:creatinine in 'spot' urine samples enabled prediction of daily microbial crude protein production (MCP). The data were analyzed by the General Linear Model procedure using SPSS 17.0. Inclusion of alfalfa or rice bran with straw increased DM intake by 19% and 15% ($P < 0.01$) and N intake by 83% and 67% ($P < 0.001$). DM digestibility did not differ between treatments (53.5%). The effective rumen degradation rate of straw in situ (rumen dilution rate 0.02/h) was lowest ($P < 0.001$) in SRB; i.e., 21.6%, cf. 32% (SA) and 29% (S). Rumen ammonia-N concentrations (mg/L) were 55 (SA), 36 (SRB) and19 (S) ($P < 0.05$). MCP (g/d) for SA (184) was higher ($P < 0.05$) than for SRB (90) and S (97). N retention for S (20 g/d) was increased ($P < 0.01$) by SA (122%) and SRB (149%). Methane yield (L/kg DMI) in respiration chambers, estimated over two 24-h periods, differed between treatments ($P < 0.05$), i.e., 23.1 (SA), 15.6 (SRB), 27.7 (S). The lowest yield (SRB-fed cattle) was associated with the highest crude fat intake ($P < 0.001$) and these cattle had the lowest total VFA concentration ($P < 0.01$), acetate:propionate ($P < 0.01$) and protozoa numbers ($P < 0.001$) in rumen fluid. The study indicates that inclusion of rice bran or alfalfa can markedly improve production in beef cattle given low-digestibility straw diets.

Key Words: rice bran, alfalfa, enteric methane emission

245 In vitro gas production and DM digestibility of two malt barley varieties sown with different seeding and N fertilization rates in seven sites across Canada. S. Ding*[1,2], M. Oba[2], M. L. Swift[3], W. Z. Yang[1], and T. A. McAllister[1], *[1]Lethbridge Research Centre, Lethbridge, AB, Canada, [2]Department of Agricultural, Food and Nutritional Science, University of Alberta, Edmonton, AB, Canada, [3]Alberta Agriculture and Rural Development, Lacombe, AB, Canada.*

Chemical composition of malt barley grain varies with seeding rate (SR), N fertilizer application rate (NR) and growing environment. However, few studies have documented the effects of these agronomic factors on the fermentability in the rumen. An in vitro study was conducted to examine the effects of SR and NR on gas production (GP) and DM disappearance (DMD) of malt barley grain using batch culture. Two malt barley varieties, Copeland (CL) and Metcalfe (MC), seeded at rates of 200 or 400 plants/m^2 with NR of 0, 30, 60, 90 and 120 kg/ha, respectively, were harvested and collected in 2007 from 7 sites across Canada. Total 560 samples (i.e., 7 sites × 2 varieties × 2 SR × 5 NR × 4 samples) were ground through a 6-mm screen and fermentability was assessed by measuring in vitro GP and DMD after 24 h of incubation. Across the 7 sites, the CP content (% DM) of malt barley linearly ($P < 0.01$) increased from 8.7 to 15%, whereas the starch content (% DM) linearly ($P < 0.01$) reduced from 66 to 57% with increasing NR. However, there were only 4 sites in which the effects of SR on the contents of CP and starch were significant ($P < 0.01$). Increasing NR linearly ($P < 0.01$) reduced DMD of CL from 2 sites and reduced DMD of MC from one site with no effects for other sites. There was only one site where SR decreased ($P < 0.01$) DMD of CL by 11%, but increased ($P < 0.01$) DMD of MC by 17%. At SR of 400, high NR (120 kg/ha) decreased ($P < 0.03$) GP of CL from 2 sites by 12 −17% compared with control, whist reduced ($P < 0.01$) GP of MC from one site by 38%. The results indicated that NR effectively changed CP, starch content of malt barley and ruminal degradation. Further, the differences in GP and DMD were site-dependent, suggesting a potential effect of growing environment on the nutritive value of malt barley.

Key Words: DM digestion, gas production, malt barley

246 Biomass yield and nutritive value assessment of *Chloris gayana* grown in a tropical region. S. Uwituze*[1], O. Twajamahoro[1], G. Uwimana[2], and M. Mutimura[2], *[1]National University of Rwanda, Butare, Rwanda, [2]Rwanda Agriculture Board, Kigali, Rwanda.*

The present study evaluated suitability of *Chloris gayana* (CG; also known as Rhodes grass) for pasture production in terms of biomass yield and nutritive value. The experiment was a complete randomized design with 3 treatments and 3 replicates. Treatments consisted of 3 cutting stages: at 80 d after planting (First cut), at 70 d after the first cut (Second cut), and at 150 d after planting (Late cut). There were 3 plots per treatment. The herbage was cut manually with a sickle to 5 cm above ground when CG achieved 50% flowering. Subsamples were used for proximate analysis. In vitro fermentation medium consisted of 1:2 ruminal fluid: McDougall's buffer and each sample (0.2 g, DM basis) was put in a gas syringe. There were 3 replicates per treatment. Syringes containing samples with 30 mL of fermentation medium and 2 blanks were incubated in a water bath at 39°C for 72 h. Readings of gas volumes were recorded every 2 h. Gas accumulated within 24 h of incubation was used to compute kinetic coefficients of fermentation using PROC Nonlinear Model of SAS. Biomass yield for the late cut (1.88 ton DM/ha) was greater ($P < 0.01$) than that obtained during the first (0.79 ton DM/ha) or second (0.71 ton DM/ha) cuts. The first cut of CG yielded biomass similar ($P = 0.68$) to that obtained during the second cut. Concentrations (DM basis) of ash (10.1%), CP (8.7%), P (0.4%), N (1.4%) decreased as CG matured from 80 d to 150 d (9.0, 6.9, 0.3, 1.1) % for ash, CP, P and N, respectively. There was an interaction between incubation time and cutting stage ($P < 0.01$). The first cut of CG yielded more gas throughout the 72-h incubation period than the second and late cuts, but the second and late cuts produced similar gas over time ($P > 0.05$). First cut had the greatest ($P < 0.05$) degradation rate but the shortest ($P < 0.05$) in vitro retention time compared with the second and late cuts, respectively. The current study recommends CG for farmers of tropical region due to its good biomass yield and nutritional quality. It is also recommended to harvest CG for the first time at 80 d after planting to benefit from its best nutritive value.

Key Words: biomass yield, *Chloris gayana*

247 Dietary exposure to ergot alkaloids decreases contractility of bovine mesenteric vasculature. A. M. Egert*[1], D. H. Kim[1], D. L. Harmon[1], and J. L. Klotz[2], *[1]University of Kentucky, Lexington, [2]USDA-ARS, FAPRU, Lexington, KY.*

Ergot alkaloids are hypothesized to cause vasoconstriction in the midgut, and prior exposure may affect vasoactivity of these compounds. Objectives were to profile vasoactivity of ergot alkaloids in mesenteric artery and vein and determine if previous exposure to endophyte-infected tall fescue affected vasoactivity of ergonovine (ERN), ergocryptine (ERP), ergotamine (ERT), ergocristine (ERS), ergocornine (ERO), ergovaline (EXT), lysergic acid (LSA), and 5-hydroxytryptamine (5HT). Ruminally cannulated Angus steers (n = 12; BW = 547 ± 31 kg) were paired by weight and randomly assigned to 6 blocks. Steers were ruminally dosed daily with 1 kg of either endophyte-infected (E+; 4.45 ppm ergovaline) or endophyte-free (E-) tall fescue seed for 21 d before slaughter. Branches of mesenteric artery (MA) and vein (MV) supporting the distal jejunum were collected after slaughter, placed in a modified Krebs-Henseleit buffer on ice, cleaned of fat and connective tissue, and sectioned into 2-mm segments. Vessels were equilibrated to 1.0 g tension for 90 min in a multi-myograph chamber with 5 mL of Krebs-Henseleit buffer and constant oxygenation (95% O_2/5% CO_2; pH = 7.4; 37°C). Final working concentrations of alkaloids ranged from 5×10^{-10} to 1×10^{-6} M for EXT and 5×10^{-9} to 1×10^{-4} M for all other agonists. Contractile response was normalized to a maximum KCl response. Data were analyzed using PROC MIXED of SAS for effects of seed treatment, agonist concentration, and the interaction. There were seed × concentration interactions ($P < 0.01$) for ERP, ERT, ERS, ERO, EXT, ERN, and 5HT in MA indicating that E- steers had a greater contractile response than E+ steers. Steers receiving E- had a greater MV contractile response to ERP, ERN, and 5HT ($P < 0.01$) and tended to for EXT ($P = 0.09$). No response was evident for ERN, ERP, ERS, LSA, and 5HT in MA and ERN, LSA, and 5HT in MV of E+ steers. These data show that steers exposed to E+ had diminished contractility in small intestinal vasculature and suggests initial exposure to ergot alkaloids has potential to alter nutrient absorption from the midgut, but the response may be transient.

Key Words: ergot alkaloid, mesenteric artery and vein, tall fescue

248 Steam-explored rice straw produced in an industrial-scale reactor as a feed ingredient for lactating dairy cow. Y. J. Su[1], G. L. Liu*[1,2], X. K. Zhang[1], C. G. Zhang[1], and G. Yang[1], *[1]State Key Laboratory of Dairy Biotechnology, Shanghai Bright Holstan Co. Ltd., Shanghai, China, [2]Shanghai Dairy Breeding Center Co. Ltd., Shanghai, China.*

Rice straw is an important roughage resource for ruminants in many rice-producing countries. In this study, Steam-explored rice straw (SERS) was produced by the proprietary process in an industrial-scale reactor. To evaluate the value of SERS as a feed ingredient for lactating dairy cow, production parameters and milk composition were determined in a feeding trial with 50 Chinese Holstein cows (DIM = 82 ± 10.0 d; BW = 538 ± 54.9 kg) in a completely randomized design involving 2 diets and 60-d periods. One diet was a conventional dairy ration that contained corn silage, alfalfa hay, Chinese leymus and commercial concentrate. The other diet contained these same feed ingredients and added SERS at 2% of ration dry matter. These 2 diets were formula to be similar net energy of lactation (1.7 Mcal/kg), neutral detergent fiber (32.4%) and crude protein (17.2%) levels. There were no difference in average DMI (23.5 versus 23.6 kg/d, $P = 0.832$) and milk yield (38.6 versus 38.8 kg/d, $P = 0.899$) for cows fed the 2 diets. Compared with the conventional ration, the diet that contained SERS did not affect ($P > 0.05$) the percentage of milk protein, fat and lactose. These results indicated that SERS produced in an industrial-scale reactor may be useful as a feed ingredient for lactating dairy cows in China.

Key Words: dairy cow, rice straw, steam

249 Volatile fatty acids accumulated in rumen contributed to the low dietary physically effective NDF induced subacute ruminal acidosis. F. Li, J. Yao*, Z. Li, S. Li, and K. Liu, *College of Animal Science and Technology, Northwest A&F University, Yangling, Shaanxi, China.*

The objective of this experiment was to characterize the relationship among rumen fermentation variables, microorganisms and dietary peNDF content that eliminating the confounding effects of dissimilar DMI. Ten multiparous Xinong Sannen dairy goats with 4 fitted with ruminal cannula were divided into 2 groups. Goats in each group were assigned into 1 of the 2 dietary treatments (Long alfalfa, LA or Short alfalfa, SA) according to a paired 2 × 2 crossover design with 2 periods. The $peNDF_{8.0mm}$ content of alfalfa hay was 42.1 and 14.5% for LA or SA group, respectively. Each period, goats in LA group were fed 1 d ahead of SA group and orts alfalfa of each goat was recorded before the morning feeding. The amount of alfalfa supplied to the goats in SA group was equal to the corresponding LA goats. Each period consisted of a 21-d adaptation period, followed by a 9-d sample period. Three species cellulolytic microorganisms relative abundance were measured by RT-qPCR. Rumen pH and chewing time were continuous monitored for 24 h. Milk production, composition and DMI have no different between LA and SA group. Duration time that pH below 5.80 in SA group was longer than LA group (5.08 vs. 1.65 h). Reducing dietary peNDF increased rumen total VFA (114.6 vs. 95.1 mM) and decreased chewing time (511 vs. 723 min/d), but did not affect the ratios of acetate, propionate and butyrate. Relative abundance of *Fibrobacter succinogenes* and *Ruminococcus flavefaciens* were increased with reducing dietary peNDF, but did not changed the *Ruminococcus albus*. In summary, reduced dietary peNDF induced subacute ruminal acidosis and the low rumen pH was contributed to the high rumen VFA concentration which was correlated with the amount of cellulolytic microorganisms.

Key Words: peNDF, rumen fermentation, subacute ruminal acidosis

250 Visceral chemical composition and cellularity of beef cows grazing different herbage allowances of native pastures. A. Casal, A. L. Astessiano*, A. I. Trujillo, and M. Carriquiry, *Facultad de Agronomia, UdelaR, Montevideo, Uruguay.*

Associations between food intake and mass and composition of various organs of the gastrointestinal tract (GIT) and liver in the short term were reported previously in ruminants. To study the long-term of 2 forage allowances of native pastures on mass and composition on GIT organs and liver in beef cows of different genetic groups, adult cows (n = 32) in a factorial arrangement of herbage allowances throughout the year (2.5 vs. 4 kg DM/kg BW; LO vs. HI) and cow genotype (purebred: Angus and Hereford vs. F1 crossbred; PB vs. CR) were used in a complete randomized block design. Cows were maintained in the herbage allowance treatment since May 2007 and gestated and lactated one calf every year from 2007 to 2009. At the end of the third year, cows were slaughter at 190 ± 15 d postpartum and GIT viscera and liver samples were collected to measure concentration of protein, lipid, DNA and RNA. Data were analyzed using a mixed model and means were considered to differ when $P < 0.05$. Expressed on an empty body weigh basis, PB cows tended ($P = 0.07$) to present a greater relative mass of the

stomach complex than CR cows. Protein content of the abomasum and omasum was greater in HI-PB than LO-PB and intermediate in CR (HI and LO) cows. The lipid content of the reticulum-rumen and abomasum tended to be less ($P < 0.09$) in HI than LO cows. Large intestine DNA tended ($P = 0.07$) to be lower in HI than LO cows. The protein:DNA ratio of the large intestine was greater in HI-CR than LO-CR cows but did not differ between HI-PB and LO-PB cows. Although hepatic DNA concentration did not differ among cow groups, the protein:DNA ratio was lower in HI-CR than LO-CR cows but did not differ between HI-PB and LO-PB cows that presented intermediate values. Small intestine RNA concentration and RNA:protein ratios were greater in LO-CR than other 3 cow groups. Hepatic RNA and RNA:protein was greater in HI-CR than HI-PB, being intermediate in LO (CR and PB) cows. These results suggested that CR cows showed greater plasticity to adapt their visceral mass and composition to sparse environments.

Key Words: cattle, rangeland, viscera

251 Substitution of polymer coated urea for soybean meal on growth performance and blood parameters in feedlot lambs fed corn stalks. A. Chegeni*[1,2], Y. L. Li[1], C. G. Jiang[1], and Q. Y. Diao[1], *[1]Feed Research Institute, Chinese Academy of Agricultural Sciences, Beijing, China, [2]Lorestan Agricultural and Natural Resources Research Center, Khorramabad, Lorestan, Iran.*

The objective of this experiment was to evaluate the effects of replacing different levels of soybean meal by Optigen II (Alltech Inc. Nicholasville, KY) as polymer coated urea (PCU) on feed intake, growth performance and blood parameters of feedlot lambs. Sixty 4 thin-tailed Han × Dorper crossbreed lambs were blocked by BW (27 ± 3.3 kg) and allocated in a randomized complete block design to 4 treatments. Each treatment had 4 pens with 4 lambs per pen. The treatments were control (PCU0), PCU33, PCU66, and PCU100 with 0, 33%, 66%, and 100% substitution rate of soybean meal nitrogen by Optigen II (DM basis), respectively. Four isonitrogenous(CP = 13.5%) and isocaloric (ME = 1.95 Mcal/kg) dietary treatments contained 60% concentrate and 40% corn stalk (DM basis) and were offered ad libitum as TMR to ensure approximately 5% ort. Lambs were fed 56 d after 14 d adaptations twice daily in 2 equal portions at 0700 and 1900 h. Data were analyzed as a RCBD using the GLM procedure of SAS (pen was as the experimental unit). Substitution of Optigen for 33% and 66% soybean meal nitrogen had no effect on DMI, but PCU100 significantly ($P = 0.04$) decreased DMI. There was no difference for ADG between PCU33 and CON, however, by increasing percent of Optigen II in the diet, ADG significantly decreased ($P < 0.01$). As a result, gain to feed ratio (G/F) was not influenced when 33% soybean meal nitrogen was replaced by Optigen, but G/F decreased ($P = 0.02$) in PCU66 and PCU100 compared with CON. Blood urea nitrogen tended to linearly increase ($P = 0.09$) with increasing Optigen percent in the diet. Substitution of Optigen for 33% and 66% soybean meal nitrogen had no effect on plasma total protein, but it was lowest ($P = 0.02$) in PCU100. The results showed that soybean meal could be partly replaced by Optigen in the diet of feedlot lambs. Substitution of Optigen for 33% soybean meal nitrogen had no negative effect on growth performance or blood parameters in feedlot lambs fed 40% corn stalk.

Key Words: feedlot lambs, growth performance, polymer-coated urea

252 Effect of conservation and maturity of primary growth grass/clover on chewing activity and fecal particle size in heifers. A. S. Koch*[1], P. Nørgaard[1], and M. R. Weisbjerg[2], *[1]Dept. of Veterinary Clinical and Animal Science, University of Copenhagen, Copenhagen, Denmark, [2]Dept. of Animal Science, Aarhus University, Foulum, Denmark.*

The study evaluated structural effectiveness of NDF from of spring harvest grass/clover forages of primary growth by assessing chewing activity and feces particles > 1.0 mm in heifers. Two batches of mixed ryegrass, red and white clover harvested in 2009 on May 9 and 25 were conserved as either silage or hay. The forages early silage (ES) and hay (EH), and late silage (LS) and hay (LH) had DM contents of 45, 84, 25 and 83%, and NDF contents of 32, 44, 42 and 50% of DM, respectively. Forages were fed as sole feed to 4 Jersey heifers of 435 ± 30 kg BW in a 4 × 4 Latin square experiment. Feeding level was 90% of individual ad libitum intake, divided in 2 daily meals at 0800 and 1530 h. Jaw movements oscillations (JMO) were recorded for 96 h continuously using Hall sensor fitted chewing halters. Jaw movements (JM) were identified from JMO, clustered into cycles and periods of rumination and eating and summarized into min per day. Feces were sampled 3 times daily and machine washed in nylon bags of 0.01 mm pore size. Feces particulate matter was freeze-dried and divided into small (0–1.0 mm) and large (>1.0 mm) particle fractions by dry sieving. Data was analyzed by the MIXED procedure in SAS with period, conservation, harvest time, and conservation × harvest time as fixed effects and heifer as random. Daily intake of ES, EH, LS, and LH was 8.7, 9.4, 7.2, and 7.2 kg DM and 2.7, 4.1, 3.0, and 3.6 kg NDF respectively. Early compared with late harvest caused similar NDF intake and time spent eating, but smaller mean rumination per kg NDF intake ($P = 0.002$). Hay compared with silage caused greater NDF intake ($P < 0.001$), and less mean time spent eating ($P = 0.02$) and ruminating ($P = 0.004$) in min/kg NDF intake. Feeding silage compared with hay resulted in a greater proportion of washed fecal particle DM < 1.0 mm, while harvest time hardly affected fecal particle size. Results indicate that NDF from late cut forages and silage stimulated rumination more effectively, and that heifers retain large forage particles in the rumen better with silage compared with hay.

Key Words: chewing activity, fecal particle size, grass/clover

253 Effect of weaning age and milk feeding level on pre and post weaning growth performance of Sahiwal calves. S. A. Bhatti*[1], A. T. Cheema[1], G. Akbar[2], P. C. Wynn[3], M. Sarwar[1], and H. M. Warriach[3], *[1]Institute of Animal Nutrition and Feed Technology, University of Agriculture, Faisalabad, Pakistan, [2]Livestock Production Research Institute, Bahadurnagar, Okara, Pakistan, [3]EH Graham Centre (NSW Industry and Investment and Charles Sturt University), Wagga Wagga, Australia.*

Our objective was to evaluate pre and post weaning growth of Sahiwal calves weaned either at 8 or 12 weeks (WK) and offered milk at 10 or 15% of body weight (BW) to weaning. Forty-eight Sahiwal day-old calves born within 45 d were randomly allocated to 4 groups of 12 equalized for sex. Calves in 2 groups were offered milk either at 10 (M10) or 15% (M15) of BW up to d 28 adjusted weekly. The calculated milk intake at d35 was reduced to zero by d 56 (WK8). Calves in the other 2 groups were offered milk as for groups 1 and 2 but were weaned at d 84 (WK12) by reducing the milk for BW at d 70 to zero. Calves were offered a concentrate ration (21% CP and 80% TDN) from d 28 to 112 (16 weeks of age; WK16). Fed and fasted (12h) blood was taken fortnightly from wk 3. Data were analyzed using mixed procedures (SAS) in a 2 × 2 factorial design with weaning age and milk feeding level as the 2 factors. The weaning combination of WK8/M10 produced a significantly smaller calf at the least cost per kg live weight. By contrast the WK12/M15 calves were heavier, but more costly. The significant differences in fed and fasted blood glucose at WK9 showed that the calves weaned at WK12 remained in the pre-ruminant state longer

than those weaned at WK8. By WK13 both groups showed a similar glucoregulatory response. Thus early-weaning or restricted milk feeding are likely to accelerate rumen development. Offering milk at 15% of BW and weaning at 8 weeks provided the best compromise to minimize feeding cost, but maintain a growth performance commensurate with early puberty.

Table 1. Live weights, growth rates, production cost and blood glucose (mg/dL) of calves offered milk 10% or 15% (M10 or M15) of BW and weaned at WK8 or WK12

	WK8		WK12		
Parameter	M10	M15	M10	M15	SE
Live weight WK16 (kg)	60.2[a]	70.7[b]	72.0[b]	88.3[c]	20
Daily live weight gain (g/d)	350[a]	432[b]	450[b]	544[c]	2.2
Cost/kg live weight (PKR[1])	188[a]	232[b]	249[b]	313[c]	11
Fed blood glucose WK9	86.7[c]	87.3[c]	120.7[b]	135.2[a]	6.0
Fasted blood glucose WK9	80.1[c]	79.2[c]	98.2[b]	108.8[a]	4.2
Fed blood glucose WK13	77.7	79.1	74.8	75.8	6.0
Fasted blood glucose WK13	86.9	89.6	90.1	88.9	4.2

254 Investigating the nutritive value of Mexican sunflower leaves for ruminant animals. A. H. Ekeocha*[1] and A. O. Akinsoyinu[2], *[1]Ondo State University of Science and Technology, Okitipupa, Ondo, Nigeria, [2]University of Ibadan, Ibadan, Oyo, Nigeria.*

An experiment was conducted to determine the proximate composition of Mexican sunflower leaves (MSL). Proximate composition of MSL was determined according to AOAC (1990). The MSL (g/100g DM) contained CP 16.3; CF 21.8; EE 2.8, ash 14.7; and GE 1.9 kcal/g. The CP content was 16.3% and this was high when compared with tropical grass species, which seldom exceed a CP level of 15% and whose protein content is satisfactory for animal production for only about 4 mo of the year. It compares favorably with that of cassava leaf meal (16.67%), and far exceeds the minimum protein requirement (10–12%) for ruminants. The CF level of 21.8% for MSL is low compared with that of tropical grass species which may be as high as 45–50% at more matured stages of growth. It is comparable to the CF level of *Amaranthus* spp. (17.01%), Siam leaf meal (16.0%), Cassava leaf meal (15.63%), deep litter manure (16.60%) and guava leaf (16.10%). %). The ether extract content was low (2.81%). This value was lower than the values of 5.61% reported for *Vernonia amygdalina* leaf and far lower than the value of 8.14% reported for Siam weed. The total ash content 14.68% was high and this was comparable to the ash content of *Vernonia amygdalina* leaf (13.86%) but higher than the value of 8.28% reported for *Acacia albida* used as a browse plant for sheep in the semi-arid region of Nigeria and higher than the value of 11.00% reported for Leucaena to feed Yankassa sheep and 11.54% reported for Siam weed leaf meal but commensurable with the value reported for cassava leaves which has an ash content of 16.07%. The gross energy (GE) value was 1900kcal/kg. This is lower than the GE value of Groundnut cake (2600kcal/kg) and *Vernonia amygdalina* leaf (2720 kcal/kg). The Nitrogen Free Extract level of 44.38% for MSL was comparable to that of Siam leaf meal (44.40%) used to feed West African Dwarf Sheep but lower than the value of 33.85% reported for *Vernonia amygdalina* leaf. On the whole, gross chemical analysis indicates that MSL contained appreciable level of nutrients that could be utilized in the diets of ruminants.

Key Words: Mexican sunflower leaves, nutritive value, sheep

812 Evaluation of a high forage total mixed ration in mid- to late-lactation dairy cows D. Gadeken*, C. Hulstein, D. P. Casper, K. Kalscheur, and J. Anderson. *Dairy Science Department, South Dakota State University, Brookings.*

Dairy producers have been asking how much forage could be included in the ration so that a lactating dairy cow can consume sufficient nutrients to support similar milk production. The production of high quality forages having high DM and NDF digestibility are needed to evaluate this feeding scenario. Twenty mid- to late-lactation lactating Holstein dairy cows were blocked on parity (10 primiparous and 10 multiparous), milk production (range 33.9 to 56.6; mean = 41.5 kg/d), and DIM (range 140 to 287; mean = 225 d) and randomly assigned within blocks to 1 of 2 rations based on ration forage concentration. Forages were 60% 2012 first-cutting alfalfa haylage and 40% 2012 corn silage blended on a DM basis and then fed at either 60% (Low Forage, LF) or 80% (High Forage, HF) of the ration DM. Experimental design was a randomized completed block design with 4 continuous weeks for data collection preceded by a 1 week covariate data collection period in which all cows were fed the LF ration. Cows were milked 3x/d and milk weights recorded at each milking and milk samples were collected at each milking once weekly for analysis of milk composition. Rations were similar in CP (16.4%), starch (20.1%), ADF (21.8%), and NDF (34.1%) concentrations. The use of a covariate was highly significant ($P < 0.01$). Milk production was reduced ($P < 0.01$) by feeding the HF diet compared to cows fed the LF (28.1 and 24.1 kg/d for LF and HF, respectively), while milk fat (3.98 and 3.96%), milk protein (3.17 and 3.11%), milk lactose (4.81 and 4.77%), and milk solids-not-fat (8.87 and 8.77%) percentages were similar ($P > 0.10$) for cows fed both rations. The forage quality and digestibility in this study was not adequate to support the milk production of mid- to late-lactation dairy cows. The digestibility of DM (DMD = 75.7%) and NDF (NDFd = 55.7%) for the alfalfa haylage was above average but, the corn silage quality was average (DMD = 72.9, NDFd = 52.3%, and starch = 32.1%) in this study. In this study, the forage quality and digestibility when fed at high rates did not support similar milk production in mid- to late-lactation dairy cows.

Key Words: forage, lactation, dairy cow

816 Use of pelleted sericea lespedeza (*Lespedeza cuneata*) for natural control of coccidiosis in weaned goats. T. H. Terrill*[1], D. S. Kommuru[1], S. Desai[1], J. E. Miller[2], J. M. Burke[3], and J. A. Mosjidis[4], *[1]Fort Valley State University, Fort Valley, GA, [2]Louisiana State University, Baton Rouge, [3]USDA/ARS, Booneville, AR, [4]Auburn University, Auburn, AL.*

Coccidiosis can be a devastating disease in goats, particularly for young, recently-weaned animals, causing diarrhea and even death. Feeding dried sericea lespedeza (SL; *Lespedeza cuneata*) to young goats has been reported to reduce the effects of internal parasites, but there have been no reports of the effects of feeding this forage on *Eimeria* spp. in goats. A confinement feeding study was completed on 24 recently weaned intact Kiko-cross bucks to determine effects of SL pellets on an established *Eimeria* infection. The bucks were assigned to 1 of 2 treatment groups based upon *Eimeria* oocysts per gram (OPG) of feces (n = 12/treatment group, 2 animals/pen), and then fed 1 of 2 pelleted rations ad libitum; 90% SL leaf meal pellet or a 14% crude protein commercial pellet. Fecal samples were taken from individual animals every 7 d for 28 d to determine OPG and gastrointestinal nematode eggs per gram (EPG), and blood samples to determine packed cell volume (PCV). After 7 d, the SL pellet diet reduced ($P < 0.05$) OPG and EPG in goats by 96.9 and 78.7%, respectively, compared with animals fed the control diet. The OPG and EPG remained lower ($P < 0.05$) in treatment than control animals until the end of the trial. There was no effect of diet on PCV values throughout the experiment. Dried, pelleted SL has excellent potential as a natural anticoccidial feed for weaned goats.

Key Words: coccidiosis, goats, sericea lespedeza

817 Sericea lespedeza as an aid in the control of *Eimeria* spp. in lambs. M. Acharya*[1], J. Burke[1], J. Miller[1], T. Terrill[1], and J. Mosjidis[1], *[1]University of Arkansas, Fayetteville, [2]USDA, Agricultural Research Service, Booneville, AR, [3]Louisiana State University, Baton Rouge, [4]Fort Valley State University, Fort Valley, GA, [5]Auburn University, Auburn, AL.*

Coccidia, a diarrhea causing protozoan parasite, is a significant health and production challenge for sheep during times of stress. Typical treatment involves the administration of sulfa drugs and amprolium, a thiamine antagonist. This research examines the effect of sericea lespedeza (SL) for control of coccidiosis in lambs. In Exp. 1, naturally infected lambs (n = 76; 23 ± 1 kg) weaned at 102.7 ± 1.4 d of age were randomly assigned to groups receiving 2% BW/d of either alfalfa pellets (n = 38, control) or SL (n = 38, treatment) with or without amprolium added to drinking water. Fecal oocyst count (FOC), fecal egg count (FEC), and fecal score (FS; 1 = solid pellets; 5 = slurry) were determined from the day of weaning to 21 d post-weaning in 7 d intervals. In Exp. 2, naturally infected lambs (n = 72; 20 ± 1 kg) were randomly assigned to groups. They were fed either control creep feed (n = 40, 16% CP) or SL pellets (n = 32, 14% CP) 30 d before weaning. Intake of SL was increased from 100 g/lamb/d (before weaning) to 454 g/lamb/d (after weaning). Lambs were weaned at 103.6 ± 0.9 d of age and moved to semi-confinement. The FEC, FOC, packed cell volume (PCV), FS, and dag score (soiling around rear of lamb; DS; 1 = no soiling; 5 = heavy soiling) were determined 14 d before weaning and in 7 d intervals from weaning until 21 d post weaning. A mixed model was used for data analysis. To determine treatment differences, chi-squared analysis was used. In Exp. 1, dietary group showed similar FOC, but in amprolium treated lambs FOC decreased ($P < 0.001$). Higher fecal score in control compared with SL lambs ($P = 0.05$) indicated signs of coccidiosis. In Exp 2, pre-weaning FOC was similar but decreased in post-weaning SL lambs and remained lower ($P = 0.004$). Post-weaning coccidiosis treatment was required for 33% of control ($P < 0.001$) but not in SL lambs. Dag ($P = 0.01$) and FS ($P = 0.001$) were similar pre-weaning, but lower at weaning and thereafter in SL-fed lambs. The use of SL was effective in prevention and control of coccidiosis in lambs.

Key Words: coccidia, lambs, sericea lespedeza

818 The relationship of OPP infection to performance and TMEM154 genotype in a Midwestern sheep flock. T. W. Murphy*[1] and T. A. Taylor[1], and D. L. Thomas[1], *[1]Department of Animal Sciences, University of Wisconsin-Madison, Madison, [2]Research Animal Resources Center, University of Wisconsin-Madison, Madison.*

Ovine progressive pneumonia (OPP) is an incurable, degenerative, viral disease of sheep affecting the respiratory and nervous systems in an escalating fashion over an animal's lifetime. Objectives of the study were to determine (1) effect of OPP status (POS or NEG) on the performance of Hampshire (H; n = 72) and Polypay (P; n = 58) ewes and their lambs, and (2) relationship between TMEM154 genotype and OPP status of the ewes. Data were from the UW-Madison flock at the Arlington Ag Research Station and consisted of 314 ewe and 425 lamb records. The flock is intensively managed with most ewes lambing in winter and a few ewes lambing in fall. Incidence of POS ewes was 58.3% and 43.1% among H and P ewes, respectively. The statistical model for analysis of ewe fertility, litter size, and weight of lamb weaned per ewe exposed included year, breed, OPP status, and age at lambing nested within year as fixed effects, and service sire and ewe as random effects. 70-d lamb weaning weight was analyzed similarly but with the addition of fixed effects of lamb birth type, sex, and the breed x birth type interaction. There were no differences ($P \geq 0.24$) between POS and NEG ewes for any of the traits. The ewes were enrolled in the National Sheep Improvement Program (NSIP), and EBV's for traits and indexes were available for each ewe. Within breed analyses considering only OPP status revealed no significant differences ($P > 0.14$) between POS and NEG ewes for the NSIP values. Frequencies of TMEM154 haplotypes across both breeds were 0.77, 0.13, 0.04, and 0.06 for haplotypes 1, 2, 3, and 4, respectively. Within and across breeds, ewes with 1 or 2 copies of haplotype 2 or 3 had a higher ($P \leq 0.024$) incidence of OPP than ewes of diplotype 1,1. Our results agree with some previous studies that have shown no effect of OPP infection on ewe performance, which suggests that intensive management from lambing to weaning may minimize negative effects of OPP infection. In agreement with very recent studies on genetic susceptibility to OPP, producers wishing to decrease genetic susceptibility to OPP infection should select 1,1 TMEM154 diplotype animals.

Key Words: sheep, ovine progressive pneumonia, TMEM154

819 Effect of feeding a pelletized diet containing 21% ground pumpkin seeds on BW, fecal egg count, and blood hematocrit in Katahdin cross lambs. E. N. Escobar, J. Rodriguez*, A. N. Gideon, V. Purnell-Cropper, and H. Taylor, *University of Maryland Eastern Shore, Princess Anne, MD.*

This investigation was conducted to evaluate the effect of a diet containing ground pumpkin (*Cucurbita* sp.) seeds (PS) on *Haemonchus contortus* infection in lambs. Katahdin cross female and wether lambs (n = 20, 4 to 6-mo old), with average BW = 22.6 ± 0.91 kg, were used. Following a 2-wk adjustment period, the lambs were randomly allocated to individual pens (1.9 × 2.3 m) with slotted floors and unrestricted access to fresh water. Individual feed intake was adjusted up to 4% BW to minimize orts and recorded daily. The lambs were dewormed with albendazole (Valbazen, 10 mg/kg) and moxidectin (Cydectin, 0.2 mg/kg). After a 21-d dewormer withdrawal period, all lambs were orally inoculated 3 times, every other day, with a larval inoculum containing 1,450 L3 *H. contortus*. After the experimental inoculation, a pelletized commercial 15% crude protein diet was fed as the control (CTRL, n = 10). The treatment (TRT) feed was formulated with similar ingredients as the CTRL diet plus 21% ground PS, and it was calculated to be similar in protein and energy content and fed to 10 lambs. To minimize feedstuff selection ground PS were incorporated into the pelletized mixture. The experimental diets were fed for 9 consecutive week. Weekly the lambs were weighed, and fecal (rectal) and blood (jugular venipuncture) samples were collected. A modified McMaster technique was used to determine fecal egg count (FEC, eggs per gram, epg), and hematocrit (% PCV) was determined in whole blood. The data were analyzed as repeated measures using the SAS statistical package. FEC+100 was natural log-transformed to stabilize variance. After 9 wk, overall BW of the Katahdin lambs was similar ($P > 0.05$) in CTRL lambs (25.85 kg) and the TRT lambs (24.11 kg). The only significant difference ($P < 0.05$) in BW was between weeks, as expected. After 9 wk, there was no significant difference ($P > 0.05$) between the CTRL and TRT groups on % PCV or FEC (31.02 vs. 31.58 and 380.8 epg vs. 502.3 epg, respectively). Ground PS incorporated into pelletized feed at a rate of 21% failed to affect *H. contortus* burden in lambs as expressed in FEC and PCV.

Key Words: ground pumpkin seed, *Haemonchus contortus*, lamb

820 Effect of ground pumpkin seeds (*Cucurbita* sp.) fed in a pelletized diet on BW, fecal egg counts, and blood hematocrit in experimentally *Haemonchus contortus* infected meat goat kids. E. N. Escobar*, J. Rodriguez, A. N. Gideon, V. Purnell-Cropper, and H. Taylor, *University of Maryland Eastern Shore, Princess Anne, MD.*

This investigation was conducted to evaluate the effect of ground pumpkin (*Cucurbita* sp.) seeds (PS) on *Haemonchus contortus* infections in meat goat kids. Sixteen 6- to 8-mo-old females and castrated male goat kids, average BW 20.8 ± 1.4 kg, were used. After a 2-wk adjustment period, the kids were randomly allocated to individual pens (1.9 × 2.3 m) with slotted floors and ad libitum access to water. Individual feed intake was adjusted up to 4% BW to minimize orts and recorded daily. The kids were dewormed with albendazole Valbazen (10mg/kg) and Cydectin (0.2mg/kg). After a 21-d dewormer withdrawal period, all goat kids were orally inoculated 3×, every other day, with a larval inoculum containing 1,450 L3 *H. contortus*. Then, a pelletized commercial 15% CP diet was fed as the control (CTRL) feed to 8 kids. The treatment feed (TRT) was formulated with similar ingredients as the CTRL diet plus 21% PS, calculated to be similar in protein and energy content and it was fed to 8 kids. To minimize kid feedstuff selection PS were ground and incorporated into the pelletized mixture. The experimental diets were fed for 8 consecutive weeks. Weekly, the kids were weighed (BW), and fecal (rectal) and blood (jugular venipuncture) samples were collected. A modified McMaster Technique was used to determine fecal egg count (FEC, eggs per gram, epg), and hematocrit (% PCV) was determined in whole blood. The SAS statistical package was used for data analysis. FEC+100 was natural log-transformed to stabilize variance and the data analyzed. After feeding 8 wk, overall BW was similar in CTRL (20.53 kg) and TRT (20.74 kg) fed kids ($P > 0.05$). The only significant difference ($P < 0.05$) in BW was between wk, as expected. The mean FEC was similar ($P > 0.05$) between CTRL (473.2 epg) and TRT (478.5 epg) groups of kids. The values for % PCV were 26.07% and 27.30% for the CTRL and TRT kids, respectively ($P > 0.05$). Ground PS fed at a level of 21% incorporated into a pelletized diet failed to affect *H. contortus* burdens in goat kids expressed as FEC and %PCV.

Key Words: goat kids, *Haemonchus contortus*, pumpkin seeds

821 Safety and efficacy of low-dose, subacute exposure of mature ewes to sodium chlorate. J. B. Taylor*[1], R. S. Dungan[2], and D. J. Smith[3], *[1]USDA, ARS, US Sheep Experiment Station, Dubois, ID, [2]USDA, ARS, Northwest Irrigation and Soils Research Laboratory, Kimberly, ID, [3]USDA, ARS, Biosciences Research Laboratory, Fargo, ND.*

The objective was to determine the safety and efficacy of low-dose, subacute exposure of mature ewes to $NaClO_3$ in the drinking water. Twenty-five ewes (BW = 62.5 ± 7.3 kg) were placed indoors in individual pens with ad libitum access to water and feed. After 7 d of adaptation, ewes were assigned randomly to 1 of 5 treatments: 0 (control), 30, 60, 90, or 120 mg $NaClO_3 \cdot kg\ BW^{-1} \cdot d^{-1}$. Treatments were delivered in the drinking water for 5 d (i.e., 120 h). Endpoints of subclinical toxicity were daily water intake, whole-blood methemoglobin percentage, and packed-cell-volume (PCV). Efficacy of treatments was based on fecal *Escherichia coli* concentrations. Based on water intakes and BW, actual daily $NaClO_3$ exposures were 0 and 28, 56, 80, and 110 ± 2 mg $kg\ BW^{-1}$ for control and 30-, 60-, 90-, and 120-mg treatments, respectively. Such doses neither induced methemoglobin formation (0.310, 0.304, 0.382, 0.334, and 0.300 ± 0.053%, respectively) nor altered PCV (42.5, 44.2, 43.8, 41.4, and 42.9 ± 1.9%, respectively). Ewes that consumed ≈110 mg $NaClO_3 \cdot kg\ BW^{-1} \cdot d^{-1}$ drank ≈14% less ($P < 0.05$) total water on d 2 than did other treatment groups. By d 5, the comparative reduction in voluntary water intake was nearly 30% less, which was accompanied with a reduction in feed intake. This response indicated that subacute exposure to ≥110 mg $NaClO_3 \cdot kg\ BW^{-1} \cdot d^{-1}$ may not be safe for mature ewes. Consumption of $NaClO_3$ for 5 d reduced fecal *E. coli* in a dose-dependent fashion ($P < 0.08$). Using unlike letters (a, b, and c) to indicate differences ($P < 0.10$) in fecal *E. coli* concentrations, the result of treatment contrasts for ewes consuming 0, 28, 56, 80, and 110 mg $NaClO_3 \cdot kg\ BW^{-1} \cdot d^{-1}$ were a, a, b, bc, c, respectively. These data suggested that subacute exposure to ≤28 mg $NaClO_3 \cdot kg\ BW^{-1} \cdot d^{-1}$ was not efficacious, with respect to fecal *E. coli*. At 22 d after treatments stopped, fecal *E. coli* in all $NaClO_3$-treated ewes were similar to control ewes, which indicated that the effect of $NaClO_3$ is rapidly reversible following subacute exposure. In summary, daily consumption of 56 to 80 mg $NaClO_3 \cdot kg\ BW^{-1}$ for 5 d was safe for targeted, short-term reduction of fecal *E. coli* in mature ewes.

Key Words: chlorate, diarrhea, *E. coli*

822 Cyclical and mild heat stress does not reduce dry matter intake but decreases average daily gain in Afshari lambs. E. Mahjoubi*[1], L. H. Baumgard[2], H. Amanlou[1], H. R. Mirzaei[1], N. Aghaziarati[1], M. H. Yazdi[1], G. R. Noori[1], and M. G. Khan[1], *[1]Zanjan University, Zanjan, Iran, [2]Iowa State University, Ames.*

Decreased DMI during heat stress (HS) does not fully account for decreased performance in dairy cows but does appear to completely

explain reduced growth in calves and pigs. To investigate the effect of heat stress on DMI and growth of Afshari lambs, 32 male lambs (38.1 ± 5.1 kg) were used in a completely randomized design in 2 periods (16 lambs per treatment). In period 1 (P1) all 32 lambs were housed in thermoneutral (TN) conditions [25.6 ± 2.6°C and a temperature-humidity index (THI) of 72 ± 2.6] and fed at libitum for 8 d. In P2, which lasted 9 d, 16 lambs were subjected to HS (29 to 43°C and a THI of more than 83 at least 14 h/d), the other 16 lambs were maintained in TN, but they consumed the same amount of feed (pair-fed, PFTN) as the HS lambs. During each period DMI and water intake were measured daily. Respiration rate, rectal temperature and skin temperature at the shoulder, rump, and front and rear leg were recorded at 0700 and 1400 h daily. All data were statistically analyzed using the PROC MIXED procedure of SAS to test differences between environments and periods. Water intake increased ($P < 0.05$) during P2 in both HS and TN lambs (88 and 35%, respectively). HS increased the 0700 and 1400 h temperature at the shoulder (3 and 10.6%), rump (2.7 and 12.7%), rear (3 and 13%), and front leg (3 and 13%) and respiratory rates (72 and 124%; $P < 0.001$, 0700 and 1400 h, respectfully) but only the 1400 h rectal temperature increased ($P < 0.01$; 0.62°C) in HS lambs. Interestingly, HS did not decrease DMI but average daily gain was reduced (36%; $P < 0.01$) compared with the PFTN lambs. These results imply that the direct effects of heat (not mediated by reduced DMI) are responsible for a portion of reduced sheep growth.

Key Words: Afshari lamb, heat stress, growth rate

823 The relationship between metatarsal and metacarpal condyle length and claw size in sheep—A postmortem study. S. Azarpajouh*[1], M. Mehdizadeh[2], and A. Mohamadnia[3], *[1]University of Missouri-Columbia, Columbia, [2]Shahrekord University, Shahrekord, Iran, [3]Ferdowsi University, Mashad, Iran.*

Understanding the hoof growth pattern in sheep could provide valuable information for proper hoof trimming to create appropriate weight bearing surfaces. The objective of this study was to determine whether differences in hoof growth result from the anatomic condition of distal condyles of the metacarpal and metatarsal bones in sheep. Fore and hind limbs of twenty 2-yr-old (average wt 27 kg) untrimmed pastured Afshari ewes were collected after slaughter. The following distances of the metacarpal and metatarsal bones were measured in mm: L1 = lateral end of the bone to the lateral border of the physis; L2 = lateral end of the bone to the abaxial border of the lateral condyle; X1 = lateral border of the physis to the abaxial end of the lateral condyle; X2 = the physis to the distal end of the condylar ridge; X3 = the axial aspect of physis to the axial end of the lateral condyle; D1 = lateral end of the bone to the medial border of the physis; D2 = lateral end of the bone to the abaxial border of the medial condyle. Analogous measurements were taken on the medial surfaces. Toe length, toe height, heel height, and sole length were also measured on the claws. Similar measurements between right and left legs were averaged and medial and lateral surfaces of each bone and medial and lateral claws on each limb were compared using a paired *t*-test. All the measurements in metacarpal bone were greater on the medial surface and the differences were significant ($P < 0.05$), except for X2 and X3. In metatarsal bone L1, X1 and X3 were greater on the medial surface but L2, X2, D1 and D2 were greater in the lateral surface and the differences were significant in X2 and D2. In forelimbs, toe length and toe height were greater in the lateral claws, but heel height and sole length were greater in the medial claws. In hind limbs, all the measurements except toe height were greater in the lateral claws. In conclusion, there is no relationship between metacarpal and metatarsal condyle length and the size of the corresponding claws, and there is no significant difference between claws in sheep. Therefore, beginning hoof trimming from a special claw is not necessary.

Key Words: hoof anatomy, hoof trimming, sheep

824 Doe fitness traits among four meat goat breeds in a reconstituted herd on humid, subtropical pasture. R. Browning Jr.*[1], J. Groves[1], M. L. Leite-Browning[2], L. Moore[1], and M. Byars Jr.[1], *[1]Tennessee State University, Nashville, [2]Alabama A&M University, Huntsville.*

This 2-yr study evaluated does brought together to rebuild the TSU research herd after natural disaster. Straightbred does (n = 253) were of the Boer (B), Kiko (K), Myotonic (M), and Spanish (S) breeds. The average doe age was about 4 yr for each breed. Does were mated each fall to produce purebred and F_1 kids. Herd management follows a low-input model to assess doe fitness. Does grazed on mixed-species pastures year-round at 9.5 head/ha supplemented with orchardgrass hay. Does had ad libitum access to 16% CP molasses tubs during winter. Does were dewormed once per year as a group at kidding and as individuals upon signs of endoparasitism. Does were sampled for fecal egg counts and pack cell volumes several times over the 2-yr study period to further assess internal parasitism. The proportional rates of does showing signs of endoparasitism once or multiple times annually were affected by breed ($P < 0.01$). Boer had higher ($P < 0.01$) annual treatment rates (78 ± 6%) than K, M, and S (41, 38, and 32 ± 8%, respectively); the other 3 breeds did not differ. Boer had higher ($P \leq 0.02$) multiple treatment rates per year (37 ± 15%) than K, M, and S (10, 15, and 6 ± 6%, respectively); the other 3 breeds did not differ. Fecal egg counts and packed cell volume were affected ($P < 0.01$) by breed, lactational status, and sample month. Boer had higher ($P \leq 0.03$) egg counts (1547 eggs/g feces) than K, M, and S (996, 723, and 890 eggs/g, respectively); the other 3 breeds not differing. Boer had lower ($P < 0.01$) hematocrits (14.5 ± 1.2%) than K, M, and S (19.5, 20.3, and 21.5 ± 1%, respectively); K and S also differed ($P = 0.01$). The proportion of does weaning kids per doe exposed and doe exit rates were affected by breed ($P < 0.01$). Weaning rates were higher ($P < 0.01$) for K (53 ± 13%) and S (54 ± 13%) than for B (7 ± 4%) and M (19 ± 9%). Annual doe exits due to illness or reproductive failure differed ($P \leq 0.03$) among all the breeds (B = 71 ± 6%; K = 18 ± 4%; M = 46 ± 7%; S = 17 ± 4%), except between Kiko and Spanish. Significant genetic variability was observed among doe breeds for fitness under the prevailing management conditions.

Key Words: breed, fitness, goat

825 Modeling the body composition of growing Santa Inês ewe lambs. L. F. L. Cavalcanti*[2,1], I. Borges[2], V. L. Silva[2], and L. O. Tedeschi[1], *[1]Texas A&M University, College Station, [2]Universidade Federal de Minas Gerais, Belo Horizonte, Minas Gerais, Brazil.*

The most common breed of sheep in Brazil is the Sanat Inês. It is characterized by animals of small frame score and high capacity for storing energy in the form of fat deposits, mainly into the abdominal cavity. Therefore, the use of empirical equations based on body condition score to predict body composition (i.e., fat) may not be accurate. The objective of this study was to evaluate the Von Bertalanffy nonlinear equation [$Y = A \times (1\text{-}B \times e^{-k \times EBW})^3$; in which Y is the measured variable (kg), A is the asymptote (kg), B is a constant related to the intercept (kg), and k is the growth rate (1/kg)] to predict body composition of Santa Inês ewe lambs. Fifty 5 female lambs with initial live BW of 14 to 23 kg were confined and fed *Cynodon* spp. hay, corn meal, soybean meal, and mineral diet formulated to contain 2.3 Mcal/kg of ME, 22.5% CP, and

34.6% of NDF. The animals were divided into 2 groups in pairs and the first animal was fed at ad libitum regimen while the second animal received about 70% of the ad libitum animal DMI. Both animals were slaughtered when the ad libitum animal reached 20, 30, or 40 kg of BW (6 per BW). The body components were analyzed for ether extract (EE) and CP. The Von Bertalanffy nonlinear function was fitted using the CP% and EE% on the empty BW (EBW, kg, DM basis). The coefficients obtained to estimate CP were: A = 22.82 ± 4.6%, B = - 0.63 ± 0.07%, k = 0.07 ± 0.03 1/kg with a residual standard error (RSE) of 3.83%. For the EE, the coefficients were: A = 64.76 ± 3.7%, B = 1.36 ± 0.53%, k = 0.14 ± 0.03 1/kg with a RSE = 6.46%. When the predicted values of each model was linearly regressed on the respective observations, both had intercept = 0 and slope = 1 ($P < 0.001$). The mean bias (MB), Pearson correlation coefficient (r), and bias correction (Cb) for the CP% were, −0.0002, 0.8637, and 0.9893, respectively; and for the EE% these statistics were 0.0071, 0.8827, 0.9927. The observed increase in EE percentage and decrease in CP relative to BW as the EBW increased was in agreement with the literature for growth of mammals. The Von Bertalanffy nonlinear equation can satisfactorily predict the body composition of Santa Inês ewe lambs.

Key Words: evaluation, growth, Von Bertalanffy

826 Time limits of postmortem cell survival in goat ear skin stored at room temperature. M. Singh*, X. Ma, G. Kannan, and E. Amoah, *Fort Valley State University, Fort Valley, GA.*

Cloning of animals from somatic cells has been achieved in almost all livestock species in recent years. This technology has great potential for reviving endangered species, preserving lost genetics due to accidental death, and/or expanding use of superior quality animals. For a successful cloning experiment, integrity of nuclear DNA of the somatic donor cells is a pre-requirement. Any damage to DNA will lead to developmental defects in cloned offspring. In many instances, animals may be dead for days, leading to decomposition of cellular structures and ultimately damage to nuclear DNA. One way of ensuring nuclear integrity is by in vitro culture of cells to be used as nuclear donors. The goal of this study, therefore, was to determine the maximum time limit within which live cells can be obtained from animal tissues after their death. To achieve this goal, whole ears of 3 healthy Spanish goats of 2–3 yr old were collected from a slaughter facility and stored in the laboratory at 25–26°C. After 0, 2, 4, 6, 8, 10, 12, 14, 16, 18 and 20 d of storage, 2- to 3-mm^2 skin pieces (n = 30) were excised from ear skin for each time interval and cultured in DMEM media supplemented with 10% FBS, 50 units/mL of penicillin, and 50 μg/mL of streptomycin in 6 (60 mm) dishes. The outgrowth of fibroblast-like cells around the explants (>50 cells) was recorded after 10–12 d of culture. All explants exhibited growth of cells up to 8 d postmortem (dpm), 66.6% exhibited growth in 10-dpm, but none of the explants exhibited growth beyond 10 dpm. Secondary cultures were established from primary outgrowth of 0- and 10-dpm cultures from one of the goats and a growth-curve was generated using a 24-well microtiter plate format at passage 3 level. Although the primary cells from 10-dpm cultures took a longer time to reach the comparative confluence level of 0-dpm, the growth-curves generated from passage 3 cell populations of these cultures were not significantly different, and showed similar cell morphology. These results suggest that live cells can be cultured from dead animals up to 10 d after their death, with comparable growth profile to that of fresh tissues.

Key Words: cell survival, goat skin, postmortem

827 Validation of the role of chromium in reducing body fat by determining the expression of multiple transcripts involved in fatty acid biosynthesis in domestic goat. M. Sadeghi and M. J. Najafpanah*, *University of Tehran, Tehran, Iran.*

Understanding relationships between metabolic health and diet is one of the main goals of biochemistry researchers. Chromium is required for the normal role of insulin in the use of carbohydrate, protein and fat. In this study, we examined the expression of 7 genes related to lipid metabolism in 4 tissues (liver, visceral fat, subcutaneous fat and longissimus lumborum muscle) in Mahabadi kids after feeding. Twenty-four, 4–5 mo old male kids were individually penned for 90 d feeding period. Treatments included levels of 0.5, 1, and 1.5 mg/d of Cr^{3+} plus standard control diet and a standard control diet lacking Cr^{3+}. On d 90, the kids were slaughtered and tissue samples were collected. Total RNA was extracted and real-time PCR was performed using HSP-90 as a housekeeping gene. In the following table, the status of gene expression is shown. The results showed that except for SCD gene, lipid biosynthesis has increased significantly in all lipogenic tissues ($P < 0.05$). The beneficial role of SCD gene is to convert saturated into unsaturated fatty acids. In agreement with a previous study, this experiment suggests that the decrease in body fat synthesis can be explained by the decrease in gene expression.

Table 1.

Gene name	Liver	Visceral fat	Subcutaneous fat	LL muscle
Stearoyl CoA desaturase (SCD)	↑	↑	↑	↑
Fatty-acid-binding protein (FABP)	↓	↓	↓	↓
Lipoprotein lipase (LPL)	↓	↓	↓	NS
Fatty acid synthase (FASN)	↓	↓	↓	NS
Leptin (LEP)	NS	↓	↓	↓
Hormone-sensitive lipase (HSL)	NS	↓	↓	↓
Diacylglycerol acyltransferase (DGAT1)	↓	↓	↓	↓

255 Leptospirosis and erythrocyte patterns: An exploration through nonlinear dynamics. C. A. Comyn*[1], S. P. Washburn[1], and V. Cortese[2], [1]*North Carolina State University Department of Animal Science, Raleigh,* [2]*Zoetis, Cattle-Equine Immunology and Biologics, Simpsonville, KY.*

Leptospirosis, a bacterial disease of worldwide distribution and significance, hays long had a correlation to erythrocytes, platelet counts, and hemoglobin levels in various mammalian species. However, documentation of these phenomena has been rare in cattle. Using the principles of physiological nonlinear dynamics, the study objective was to compare erythrocyte fluctuation patterns in healthy cattle versus patterns in cattle testing positive for *Leptospira* spp. with the expectation that cows testing positive for *Leptospira* spp. would have fewer fluctuations from the linear trend. Experimental and control groups were established by testing cattle for *Leptospira* spp. using urine samples followed by real-time PCR to identify bacterial isolates in the urine. Nine visibly healthy Holstein cows from one dairy herd in Virginia were used in this study; 4 tested positive for *Leptospira* spp., and 5 tested negative for *Leptospira* spp. Blood samples were collected at 24-h intervals for 12 d. The blood samples were submitted for complete blood counts at the Antech Diagnostic Laboratory in Manakin, VA. Mean red blood cell (RBC) counts were similar for the 2 groups of cows across the 12-d period. A linear trend line for RBC counts was calculated for each cow and then average fluctuation from the linear trend was calculated using the mathematical technique of detrended fluctuation analysis (DFA). Cattle testing positive for *Leptospira* spp. had numerically lower fluctuation in RBC counts compared with cattle testing negative for *Leptospira* spp., but the difference was not significant (0.29 ± 0.045 vs. 0.45 ± 0.115; $P = 0.26$). It should be noted that the group observed was relatively small; with a larger study group, results may have been more significant. Further, because animals observed in this study were asymptomatic, it may be possible that cattle experiencing an acute infection would maintain a lower DFA value for RBC counts. However, more research will need to be done to corroborate this.

Key Words: leptospirosis, nonlinear dynamics

256 Effect of milk feeding frequency and weaning age on growth and intake of dairy calves. S. A. McCullough*[1], T. S. Dennis[1], S. E. Fraley[1], B. Houin[2], and T. D. Nennich[1], [1]*Purdue University, West Lafayette, IN,* [2]*Homestead Dairy, Plymouth, IN.*

The objective of this study was to determine the effects of milk feeding frequency and weaning age on growth, intake, and feed efficiency of dairy calves on a commercial dairy. In this randomized complete block design with a 3 × 2 factorial arrangement of treatments, 162 Holstein heifers (BW = 40.5 ± 5.18 kg) were blocked in groups of 6 by birth date and hutch type. Heifers were assigned to either 2 (2×), 3 (3×), or 4 (4×) times per day milk feeding and either 7 (7WK) or 9 wk (9WK) weaning times. Calves were fed whole milk and allowed ad libitum access to starter. Calves received the same amount of milk per treatment at 3.8 L/d of milk for 14 d, 6.7 L/d from d 15 to 21, and 7.6 L/d from d 22 to 1 wk before weaning when calves were reduced to 3.8 L of milk once per day. Calves were weighed at birth and measured every 2 wk for weight, hip and withers height, heart girth circumference (HGC), and hip width. Data were analyzed as repeated measures using the Proc Mixed procedure of SAS. There were no interactions between feeding frequency and weaning age. Body weight at wk 10 was the greatest for 4× with calves weighing 95.6, 93.5, and 91.4 kg for 4×, 3×, and 2×, respectively ($P < 0.001$). Average daily gain (ADG) was greater ($P < 0.01$) for 4× calves than 2× calves with 3× being intermediate (0.79, 0.73, and 0.76 kg/d, respectively). At wk 10, calves fed 4× were taller at the hip ($P < 0.008$) and withers ($P < 0.01$) than 2×. The HGC was greater ($P < 0.01$) for 4× and 3× calves than for 2× (93.2, 92.8, and 91.9 cm, respectively). Starter intakes were similar for milk treatment, but calves weaned at 7WK had greater starter intake ($P < 0.01$) from 6 to 8 wk of age than 9WK. Calves weaned at 9WK were heavier at the end of the study than those weaned at 7WK (95.0 and 92.0 kg, respectively; $P < 0.001$), and overall ADG was greater for 9WK calves at 0.78 kg/d as compared with 0.74 kg/d for 7WK ($P < 0.02$). Calves weaned at 9WK had greater HGC ($P < 0.05$) and hip widths ($P < 0.001$), and were taller at the hip ($P < 0.001$) at the end of the study. Feeding calves milk 4 times per day improved calf growth as compared with feeding milk 2 times per day.

Key Words: dairy calf, milk, weaning

257 Characterization of quarter milking pulsation and take-off in a conventional milking parlor. S. M. Smith*, J. M. Bewley, K. J. McQuerry, and C. L. Wood, *University of Kentucky, Lexington.*

Overmilking may increase teat end hyperkeratosis and contribute to mastitis incidence. The objectives of this study were (1) to characterize the frequency of individual quarter milking using the Milpro P4C (Milkline, Gariga di Podenzano, Italy) and to describe the anatomical features that contribute to uneven milkout. The Milpro P4C system stops milking individual quarters using an individual quarter pulsation milking system with 4 independent pulsation channels per cluster instead of 2. The study was conducted at the University of Kentucky Coldstream Dairy during January 2013. The exact times when the partial take-off feature was employed were collected recorded by the milking system. Udder and teat characteristics were scored subjectively 3 times to create composite scores. Teat length and udder tilt were scored using the Holstein Association Linear Scoring System. Teat shape was scored according to the system described by Hickman (1985). Teat end shape was scored using the system described by Seykora and McDaniel (1985). Teat end callosity was scored according to Mein (2001). Milk weights were collected from the Milkline System. Cow demographic data (DIM and parity) were collected from PCDart. The partial takeoff procedure was not recorded for 5 of the 8 milking units due to equipment error or failure. For the 3 milking units functioning properly, the partial takeoff feature of the milking system was employed in 55% of 1263 valid milkings. The LOGISTIC procedure of SAS (Cary, NC) was used to develop a model to predict the likelihood of uneven milkout. Udder tilt, teat shape, teat end shape, and teat callosity were significant predictors of uneven milkout ($P < 0.05$) while milk yield (kg) was not ($P = 0.14$). These results demonstrate that a quarter based pulsation system may be beneficial for cows with varying udder and teat shapes. The partial takeoff feature was employed in over half of valid milkings indicating potential improved milkout and reduced risk of overmilking with this type of milking system.

Key Words: quarter milking, udder trait, pulsation

258 Variation in milk production within dairy herds. S. K. Finney*, M. L. Eastridge, W. P. Weiss, and N. R. St-Pierre, *The Ohio State University, Columbus.*

Understanding the variation of milk yield on dairy farms may assist dairy farmers in improving profitability. This study was conducted to determine the variation among farms with different levels of rolling herd average (RHA) for annual milk yield. Data from Dairy Herd Improvement were collected yearly from 2003 through 2011. The data included yearly RHA for milk, fat, and protein for each herd in Ohio and the annual production of milk, fat, and protein by individual cows having completed a lactation within the respective year for each herd. Dairy farms having at least 50 cows of either Holstein or Jersey were used, and individual cows must have completed a lactation of over 290 d in milk. Cows either above or below 3 standard deviations from the average milk yield for a herd were eliminated. The individual cow data were analyzed with SAS to calculate the herd average and standard deviation (SD) for yields of milk, fat, and protein. These data were then merged with the RHA data by herd. Quartiles within each year were determined using PROC Univariate within SAS and were then used to classify herds into categories for yields of milk, fat, and protein. For Holstein herds, the SD within each quartile RHA class was (low to high RHA milk) 1515, 1594, 1676, and 1801 kg and coefficients of variation (CV) were 17.5, 16.6, 16.1, and 15.0%, respectively. The SD for Jersey herds was 1060, 1239, 1262, and 1378 kg and CV of 17.4, 17.5, 16.6, and 16.7%, respectively. Variation within herds increased ($P < 0.01$) as the RHA increased, but the CV decreased ($P < 0.01$). Variation in milk yield within herds also was affected by year. Further analysis of this variation may provide evidence for recommendations to minimize the variation of milk yield on dairy farms.

Key Words: RHA milk, milk yield variation, yield variation within herd

259 Choosing appropriate temperature-humidity indices to predict the incidence of heat stress in lactating dairy cattle by analyzing local weather data for central Iowa. E. Hodges*, P. J. Berger, and G. Takle, *Iowa State University, Ames.*

Heat stress is known to cause a depression in milk yield and reduce reproductive success in dairy cattle. Few areas in the United States have been evaluated to compare temperature-humidity index (THI) values to milk yield and reproductive success. The objective of this research was to determine if weather conditions in central Iowa could be expected to cause heat stress in dairy cattle. Hourly weather data was obtained over a period of 5 years (2008–2011) from 2 local weather stations. The data were used to calculate hourly, daily, and monthly values for 7 temperature-humidity indices (THI) previously applied in dairy cattle. Each THI was a different weighted function of temperature and humidity. Six additional indices were calculated to incorporate wind speed and solar radiation. These indices had previously been applied in beef cattle feedlot settings. THI values from other states were matched against those in central Iowa, with the incorporation of wind speed and solar radiation. The former have been ignored in comparison of indices with regard to dairy cattle. The incorporation of wind speed and solar radiation relationships from beef feedlot trials in Nebraska matched an existing THI formula established from Georgia work. The onset of heat stress in beef cattle was established by visual observation. The onset of heat stress in dairy cattle was established by analysis of reproduction and lactation data. This research confirmed the existence of heat waves in the summer months with sufficient magnitude to facilitate the discovery of depressed milk yield and reproductive success.

Key Words: temperature-humidity indices, solar radiation, wind speed

260 Correlations among nutritional status of the dairy cow during early gestation and subsequent growth and cardiac measurements of her offspring. D. K. Hardin*, B. E. Voelz, H. M. Kerr, K. A. Barton, C. O. Lemley, and J. E. Larson, *Mississippi State University, Mississippi State.*

The potential of calves to become productive cows may be related to characteristics of growth and cardiac function early in life. The objective of this experiment was to determine whether nutritional status of the dam, as determined by concentrations of glucose and β-hydroxybutyrate (BHBA) and milk production during early gestation, was correlated with measurements of the calf at birth and at 1 mo of age. From parturition until 90 d pregnant, blood samples were collected every 14 d in Holstein cows. Plasma was later assayed for concentrations of glucose and BHBA. Calves (n = 26) born from these cows were measured for blood pressure, heart girth, hip and wither height as well as carotid artery hemodynamics measured via Doppler ultrasonography (pulsitility index (PI), resistance index (RI), and vessel diameter). Mean arterial pressure (MAP), pulse pressure (PP), and blood flow (BF) were then calculated. The CORR procedures of SAS were used to analyze data; means (±SD) are presented. In calves at birth, mean milk production of dams during early gestation (89.2 ± 18.3 kg) was positively correlated ($P < 0.05$) with heart girth (77.0 ± 4.3 cm). As expected, length of gestation was also positively correlated with heart girth of calves at birth ($P < 0.05$) and at 1 mo of age ($P < 0.01$). There tended to be a positive correlation between mean concentration of glucose in dams ($P = 0.07$; 3.48 ± 0.6 mmol/L) and MAP in calves at birth (80.1 ± 8.8 mmHg) and a negative correlation between mean concentration of BHBA in dams ($P = 0.06$; 905.3 ± 505.2 μmol/L) and PP in calves at birth (42.8 ± 7.0 mmHg). Mean concentration of glucose in dams was positively ($P < 0.05$) correlated with wither height in calves at 1 mo of age. Length of gestation was negatively ($P < 0.01$) correlated with RI in calves at 1 mo of age. Milk production in the dam was positively correlated ($P < 0.10$) with hip and wither height, and PI but negatively correlated with MAP in 1 mo old calves. These correlations lead to speculation that early gestational environment may affect growth and hemodynamic parameters in young calves.

Key Words: cattle, dairy, Doppler

261 High moisture corn increased hepatic gene expression for anapleurotic and gluconeogenic enzymes compared with dry corn for Holstein cows in the postpartum period. C. M. Ylioja*, R. J. Rockwell, and M. S. Allen, *Michigan State University, East Lansing.*

Holstein cows (n = 48) were used in a randomized block design experiment to determine hepatic gene expression responses to dietary starch source in the postpartum period (PP). Treatments were dry corn (DC) or high moisture corn (HMC) fed from parturition until 28 ± 3 d PP. HMC increased milk yield 3.4 kg/d compared with DC (42.6 vs. 39.2 kg/d, $P = 0.02$), but did not affect 3.5% fat-corrected milk (FCM, $P = 0.11$) or dry matter intake (DMI, $P = 0.52$) during the treatment period. Sustained effects of treatment were detected when cows were offered a common diet from 29 ± 3 d to 84 ± 3 d PP; HMC increased DMI and FCM compared with DC but effects diminished over time (interaction $P < 0.03$). HMC increased plasma glucagon concentration over time during the treatment period compared with DC both before ($P = 0.001$) and after ($P = 0.04$) feeding. Liver tissue obtained by biopsy at 7 ± 3d prepartum and 14 ± 3d PP was analyzed by qRT-PCR for relative mRNA abundance of genes related to metabolism. HMC allowed increased anapleurosis compared with DC by increasing gene expression for pyruvate carboxylase (1.44 fold, $P = 0.01$), propionyl CoA synthetase (1.19 fold, $P = 0.05$), propionyl-CoA carboxylase α (1.16 fold, P

= 0.05), and increasing expression for methylmalonyl CoA epimerase more over time (pre- vs. postpartum) for HMC than DC (1.30 vs. 1.03 fold, $P = 0.03$). Gene expression for carnitine palmitoyl transferase 1α tended ($P = 0.11$) to decrease more over time for HMC (0.77 fold) than DC, which was relatively unchanged (0.97 fold). HMC also increased expression for citrate synthase compared with DC (1.15 fold, $P = 0.07$). Expression for phosphoenolpyruvate carboxykinase (PCK1) was not affected by treatment ($P > 0.15$) but HMC increased glyceraldehyde 3-phosphate dehydrogenase (1.13 fold, $P = 0.02$), and tended to increase glucose 6-phosphatase (1.17 fold, $P = 0.10$), consistent with increased gluconeogenesis. Effects of treatment on plasma glucagon concentration and hepatic gene expression are consistent with increased milk yield for HMC compared with DC.

Key Words: starch fermentability, glucagon, gene expression

262 The association of telomere length and body weight in lactating Holsteins. I. W. Haagen*, C. D. Dechow, and D. E. Brown, *Penn State University, University Park.*

Telomeres are a repetitive TTAGGG DNA sequence on the end of chromosomes that protect the integrity of the chromosome and are reported to become shorter following cell division. The objective of this study was to evaluate the association between telomere length and body weight (BW) in lactating Holstein dairy cows. A total of 132 cows with 273 BW observations from 11 commercial herds and 88 cows with 46,020 observations from the Penn State Dairy Research Center herd were used in this study. BW in commercial herds was estimated using heart girth circumference measurements taken up to 4 times per lactation from 2008 to 2009. BW is electronically recorded daily at the Penn State Dairy Research Center as cows exit the milking parlor and BW from lactations 1 to 3 were considered. DNA was extracted from whole blood and telomere length estimated with quantitative PCR by comparing relative expression of a 79 base pair telomere product to a 144 base pair reference gene product. Cows ranged in age from 22 mo to 121 mo at the time of blood collection. Cows were stratified into high (TH) and low telomere (TL) length groups of equal size. BW was evaluated separately for commercial herd cows and PSU cows with a model that included effects of telomere group, lactation, stage of lactation, contemporary group, and the random effect of cow. Telomere group had a significant association with BW ($P < 0.05$) in both the commercial and PSU populations. The least-squares-means (LSM) estimate of BW in commercial herd TH was 737.5 kg compared with 685.9 kg in TL. The TH at PSU had a LSM estimate of 661.6 kg, whereas cows in TL had a LSM estimate of 639.6 kg. The results of this study suggest that a positive association may exist between telomere length and BW. However, telomere length was available at different ages. A controlled study with telomere length determined at the same age for all cows is required to more fully describe the relationship between telomere length and BW.

Key Words: telomere, body weight

263 The effects of corn silage inclusion in pre-weaned calf diets. S. Retz*[1], S. I. Kehoe[1], K. McFarland[2], and G. Suen[2], *[1]University of Wisconsin-River Falls, River Falls, [2]University of Wisconsin-Madison, Madison.*

Dairy calves should receive feed that will stimulate rumen development and allow for healthy growth. However, calf grain starters can be expensive and some farmers feed corn silage instead. Corn silage may not provide enough rumen stimulation and energy substrate for healthy papillae development. The objective of this trial was to assess the effects of starter feed on calves over the course of their developmental cycle by quantifying rumen morphology. Thirty 6 heifer calves and 9 bull calves were reared in blocks of 15 at the US Dairy Forage Research farm where they were individually housed in hutches. All treatments were fed pasteurized milk with either all calf starter (C; 18% crude protein), 40% corn silage and 60% calf starter (CC), or all corn silage (CS). Nine bull calves, one from each treatment during each block, were slaughtered at 8 wk of age. Rumens were collected and 3 samples from 4 areas within the rumen were taken; left side caudal dorsal sac (LB), right side caudal dorsal sac (RB), right side cranial ventral sac (RD) and left side cranial ventral sac (LD). Twelve papillae per sample were randomly measured for length and width. The Mixed procedure of SAS (2010) was used with block as a random effect to analyze for treatment differences. No significant differences were found for papillae length for region LB (8.1 ± 1.5, 3.9 ± 1.9, and 6.4 ± 1.5 for treatments C, CC, and CS, respectively) and RB (10.2 ± 3.2, 4.4 ± 2.4, and 7.9 ± 2.4 for treatments C, CC, and CS, respectively). There were significant differences between treatments for regions LD (11.7 ± 1.2, 5.3 ± 1.2, and 10.1 ± 1.2 for treatments C, CC, and CS, respectively) and RB (8.7 ± 1.1, 2.8 ± 1.1, and 5.7 ± 1.1 for treatments C, CC, and CS, respectively). There were no significant differences between treatments for papillae width. This data indicates that corn silage added to calf starter may not result in as much rumen development for some areas of the rumen as calf starter or only corn silage. Data collected for calf health and growth parameters is currently being analyzed.

Key Words: calf, corn silage, rumen development

Teaching/Undergraduate and Graduate Education: Learning Styles and Student Success

264 Developing critical academic and social connections for incoming students prior to the first day of classes using a combination of innovative programs . H. D. Tyler* and J. A. Sterle, *Iowa State University, Ames.*

At-risk college students are most successful if they develop early connections to the faculty and other students in their major. Accordingly, 3 strategies were developed to create meaningful connections to our program. First, a computer program was developed to survey students during Freshman Orientation on their interests and career goals and assign faculty academic advisers based on common interests. These students were able to connect with their adviser before coming to campus for classes; an added benefit is that these matched advisors are more able to provide appropriate career mentoring, having more contacts with the industry of interest for that particular student for finding relevant internships and jobs. Although students can re-enter the program and switch advisors at any time in their program, less than 5% actually do so. Second, the peer mentor program in our department was greatly expanded to allow selected, trained upperclassmen to mentor small groups of 6–10 new students during their first semester of college. All new students within a peer mentor group have the same faculty advisor; often, the peer mentor also shares the same advisor. Mentor groups meet at least once a week during their first semester in addition to taking relevant industry trips together. Lastly, Facebook groups were created for each cohort of potential incoming students 6 mo before their college entry date. This allowed them to establish relationships with other students and create a social network before the first day of school. Over 200 students were members of the group formed for incoming students in 2012. The types of posts evolved from the time the group was formed; initially, students shared information about themselves. After they signed up for classes, they sought information about our program, and finally after they arrived at Iowa State, they used the site to plan social activities and coordinate classes with their peers. Investing time and resources into the new student experience is crucial for developing successful relationships that are vital to student success.

265 Learning style preferences of animal science undergraduates. C. Mortensen* and A. Thoron, *University of Florida, Gainesville.*

Studies have linked higher student achievement when instructed in learning environments that match their learning styles. We administered 2 learning style instruments to investigate the learning style preferences of undergraduate students in the Department of Animal Sciences at the University of Florida. The Group Embedded Figures Test (GEFT) segregates students into either field-dependent or field-independent learning styles. The Gregorc Style Delineator (GSD) measures student's natural predispositions for learning along 4 bipolar continuous mind qualities: Concrete-Sequential (CS), Abstract-Sequential (AS), Abstract-Random (AR), and Concrete-Random (AR). Student scores were evaluated based on sex and their specific degree option: Food Animal Industry, Equine Industry, and Animal Biology (pre-veterinary medicine). Results of the GEFT indicated Animal Biology students had a higher preference for a field-independent learning style (mean score 14.0 ± 0.36) compared with Equine Industry (13.0 ± 0.79; $P = 0.10$) and Food Animal Industry (12.5 ± 1.04; $P \leq 0.05$) students. Male students (14.8 ± 0.64; n = 26) had a higher preference ($P = 0.06$) for a field-independent learning style compared with female students (13.4 ± 0.36; n = 129). Overall, 63% of animal science students preferred a field-independent compared with 19% field dependent learning style, 18% remained neutral. Students with a field-independent learning style are described as being more analytical, find it easier solving problems, likely to favor learning activities that require individual effort, and are less receptive to social reinforcement. Field-dependent learners perceive globally, have a more difficult time solving problems, are more attuned to their social environment and tend to favor a spectator approach to learning. No differences were found among degree options or sex in GSD scoring. Overall, students scored higher in CS (48%) compared with AS (15%), AR (15%) or CR (21%) learning styles. The CS learner is described as relating to the concrete world with hands-on experiences, prefer structure and wants explicit and clear directions. Activities that accommodate CS learners are checklists, worksheets, demonstrations, outlines and diagrams.

Key Words: learning style

266 Motivation for undergraduate students to participate in an equine study abroad course. C. Brady*[1], J. Peters[2], M. Voigt[1], and M. Russell[2], *[1]Department of Youth Development and Agricultural Education, Purdue University, West Lafayette, IN, [2]Department of Animal Sciences, Purdue University, West Lafayette, IN.*

The purpose of this study was to assess what motivated students to participate in a short-term equine study abroad course. The survey instrument was adapted from an instrument validated for assessing motivation to participate in voluntary career development events. The adapted instrument was reviewed by an expert panel for content validity, and a post-hoc Cronbach's α coefficient of 0.943 demonstrated an excellent level of internal validity. The survey was administered following the Dillman Tailored Design Method to 22 students in fall 2012, after their participation in the study abroad course in spring 2012. Twenty-two 5-point Likert scale questions were used to measure self-efficacy and 4 motivation factors; attainment (significance of doing task well), cost (negative aspects of task), intrinsic (individual satisfaction in task) and utility (relationship of task to future goals). Sixteen students completed the survey, 15 females and 1 male. Cost motivation (4.43 ± 0.61) had the highest mean score, followed by self-efficacy (4.33 ± 0.53), intrinsic (3.99 ± 0.53), utility (3.94 ± 0.36) and attainment (3.45 ± 1.08). Means were compared using a paired sample *t*-test. Using a value of ($P < 0.05$) cost motivation was greater than all other factors. Self-efficacy was greater than either attainment or utility. Intrinsic motivation was only different from cost motivation, and there was not difference between attainment and utility motivation. There has been a perception that intrinsic motivation, was a primary motivator, but in this set of students, that supposition was not supported. It is important to note that cost motivation were time and effort costs and did not include any items about material cost to participate. This study indicates that time cost is a primary student motivator, and short-term study abroad courses may be a path to involvement of more students in a study abroad experience.

Key Words: study abroad, student motivation

267 Student perceptions of sustainable and organic agriculture. L. Unruh Snyder*[1], T. Durham[2], A. Davis[4], and T. Irani[3], *[1]North Carolina State University, Raleigh, [2]Florida Gulf Coast, Fort Myers, [3]University of Florida, Gainesville, [4]Purdue University, West Lafayette, IN.*

Eighty-four students at 3 different universities were recruited for a survey that assessed their knowledge, attitudes, and opinions on the prospects of incorporating more curriculum on organic and sustainable agriculture. Respondents were enrolled in 1 of 4 agricultural courses or one biology class among the 3 universities. Subjects were asked to self-report basic demographic information and address a series of open-ended short answer questions developed by the investigators, including questions centered on the concepts of organic and sustainable agriculture. Students provided a range of words for the themes to define organic and sustainable agriculture. Overall, student responses demonstrated many different variations of organics. However, definitions of sustainable agriculture were more ambiguous. A prevailing view did not emerge from the data, with 13% reporting "do not know." Within the cohort, students' qualitative responses speculated that organic agriculture will increase in the future (40%), and 11% of students felt that it would decrease. With the remaining students perspectives speculating that organic agriculture will not change (4%) or will remain a minority in agriculture (11%). Nine percent of the students were unsure about whether organic agriculture would change at all and the remaining 25% not responding to the question at all. If a university was to implement a teaching plan that incorporates organic agriculture to a greater extent, students indicate they would prefer "hands-on" techniques (51%) and field work situations as the primary methods of learning. Traditional methods of discussion and lecturing were cited 4% and 7%, respectively. When asked about the utility of field trips as learning modality, 15% of the student responses agreed with this prompt. However, 68 students responded "no," 14 said "yes," and 3 did not respond. Those who volunteered a reason overwhelmingly cited "lack of time." Although the results indicated a lack of direct participatory interest, the results of this survey denoted a role for organic and sustainable agriculture in the curriculum.

Key Words: perceptions, organic, sustainable

268 Student engagement in learning anytime/anywhere: Enhancing learning with technology in the animal sciences. J. M. Osborne*, B. A. Wenner, T. A. Evans, M. C. Chakerian, R. W. Flood, M. R. Hendrick, and H. N. Zerby, *The Ohio State University, Columbus.*

Many courses in the OSU Department of Animal Sciences occur in a traditional setting with students attending lecture in person at scheduled times. Conversion from quarters to semesters and an institutional directive to align educational experiences with student needs prompted consideration of alternative forms of instruction. Instructors of the large enrollment (100+) writing course "Animals in Society" chose the Hybrid-Flexible (Hy-Flex) Instructional Model, which allowed students to attend twice-weekly lectures in-person or synchronously online. Lecture content was integrated in learning activities during weekly in-person recitation sections (25–30 students). Technologies to implement the Hy-Flex model for lectures were selected to permit students to vary mode of attendance on a daily basis and review lectures anytime-anywhere. The technologies were expected to support a robust learning community and provide student-instructor interaction. Adobe Connect was the internet platform for lecture delivery and recording. Students responded to questions using Poll Everywhere software, which also provided a back-channel for student questions regardless of attendance mode. Small online discussion groups used the OSU course management system. In autumn 2012, 94 students consented to participate in a research study. Online attendance increased from 20 to 40% to 60–70% by the end of the term, with 49% of students attending more than 75% of lectures online. Eighty-four percent of students agreed that technology helped them actively participate in the course; 17% thought that technology hindered their interaction with the instructor. A slight majority (56%) agreed that instructional technology helped create a sense of community among students. There was no correlation between mode of attendance and overall grade or grade on writing assignments that required knowledge of lecture content. Results suggest that online attendance did not cause reduced understanding of course concepts and that technology can be used to support student engagement with course content and develop a learning community within a large enrollment course.

Key Words: technology, online, anytime/anywhere learning

269 Predicting the quality of an undergraduate animal science course using the IDEA survey. M. J. Anderson, K. J. Stutts, M. M. Beverly, and S. F. Kelley*, *Sam Houston State University, Huntsville, TX.*

The Individual Development and Educational Assessment (IDEA) survey is a mechanism that uses student feedback to assess and improve teaching, learning, and the higher education process. The IDEA survey contains questions pertaining to course objectives, teaching methods and styles, and a description of the course with the goal of determining the quality of the instructor and overall course. The objective of this study was to determine which of the survey questions were most important when predicting the quality of the course in undergraduate animal science courses. A step-wise regression analysis was performed on data from 238 courses spanning a 6-year period. Thirty-five of the 43 questions on the survey were included in the analysis. Eight questions were not included in the analysis because they involved students' preconceptions that could not be affected by the instructor during the course. This analysis indicated that only 6 of the 35 questions entered into the model were significant. These 6 questions had an r^2 of 0.7056 compared with an r^2 of 0.7443 for all 35 questions. The analysis indicated that these questions account for the majority of variation within the model. The top 3 questions with positive relationships toward predicting the quality of the course were: 1) the instructor demonstrated the importance and significance of the subject matter, 2) students made progress on gaining factual knowledge, 3) the instructor explained course material clearly and concisely. Conversely, a question pertaining to the instructor encouraging students to use multiple resources for research purposes had a negative relationship toward predicting the quality of the course. This indicated that students believed this area was not a valuable skill in animal science courses. In conclusion, an animal science instructor can improve the quality of their course by displaying the importance the subject matter and clearly presenting the course material to expand the students' knowledge of that subject.

Key Words: IDEA, undergraduate teaching, animal science

270 The role of trace minerals in feed stability and swine production. M. D. Lindemann*, *University of Kentucky, Lexington.*

Trace minerals (Cu, Fe, Mn, Zn, I, and Se) must be supplemented to diets of swine of all ages to meet their physiologic need for a variety of body purposes such as energy metabolism, connective tissue growth, bone formation, inflammatory response, immune function, and structural or catalytic involvement with a host of enzymes. The collective effect of these metabolic and physiologic impacts can result in changes in the rate and efficiency of whole animal growth and production. While minimum concentrations of these nutrients are established for growth, relatively less research is available that would establish supplementation needs to optimize the metabolic responses. Additionally, while there is some research that helps to establish the whole animal toxicity levels for the nutrients, there is relatively less research related to the effect of supplementation rates between those of the supposed requirement for growth and the presumed toxicity level on factors related to metabolic efficiency. In addition to the direct effect of absorbed minerals on metabolism, because of the prooxidant nature of Cu, Fe, Mn, and Zn, the supplementation level has the potential to interact with time, temperature, and moisture to affect the stability of various constituents of the feed. The constituents that are potentially affected most by prooxidants are vitamins, fats, and exogenous enzymes. Historic research has demonstrated that all of these can be affected by the level of supplemental trace minerals. The trace mineral affecting stability the most has varied among studies. Additionally, because oxidation is a chemical phenomenon, it would be assumed that the reactivity of the individual minerals should be a function of its chemical properties (e.g., rate and extent of dissociation) and that assumption has been demonstrated to be valid in comparisons of the forms of the minerals that are available to the feed industry (various inorganic forms as well as organic forms). Decisions about trace mineral supplementation should, in many situations then, also involve consideration of the source of minerals and their effect on feed stability relative to its consequent effect on animal wellbeing.

Key Words: trace mineral, feed stability

271 Exploring cellular trace mineral metabolism in bovine and porcine tissues. R. S. Fry*[1], J. W. Spears[2], M. S. Ashwell[2], and S. L. Hansen[3], *[1]Provimi North America, Brookville, OH, [2]North Carolina State University, Raleigh, [3]Iowa State University, Ames.*

The objective of this presentation is to provide an overview of the metabolic pathways responsible for copper (Cu), iron (Fe), and zinc (Zn) metabolism in mammalian tissues. Rodents and cell lines have been utilized for more than a decade to determine the role and necessity of these cellular mechanisms. These data have provided a foundation for scientists to build upon, and we have conducted numerous trials characterizing gene products responsible for Cu and Fe metabolism in bovine and porcine tissues. Copper transporter 1 is essential for Cu uptake. Mice with intestinal deleted Ctr1 are characterized by high mortality rates and reduced survivability, and liver Cu and cuproenzyme synthesis is markedly reduced in mice with hepatic Ctr1 deletion. Antioxidant 1 (ATOX1) is one of several vital Cu chaperones that prevent Cu deficiency and toxicity. Copper is delivered to Cu-dependent ATPases via ATOX1. While both are present in the intestine and liver, ATP7A is essential for Cu utilization from the enterocyte for synthesis of cuproenzymes, and ATP7B is required for biliary Cu excretion and incorporation of Cu into ceruloplasmin, a Cu-dependent ferroxidase. Divalent metal transporter 1 is responsible for Fe acquisition in the small intestine and liver. Manganese can also be transported via DMT1 and possibly a small portion of Cu. Ferroportin (FPN) is responsible for Fe export from the enterocyte and is regulated by hepcidin, a small peptide hormone that is produced by the liver and secreted into plasma to promote internalization and degradation of FPN in response to increases in body Fe stores. Proteins responsible for Zn absorption are categorized into 2 families. The family of ZnT transporters is responsible for Zn utilization and these transporters may also play a role in sequestering Zn in intracellular compartments. The ZIP family of transporters is responsible for Zn acquisition, especially ZIP4, which is essential for intestinal Zn uptake. Further characterization of these molecular mechanisms will broaden our knowledge of trace mineral metabolism in animal nutrition.

Key Words: copper, iron, zinc

272 Relative bioavailability, immune function, and antimicrobial effects of trace minerals. K. C. Klasing* and V. J. Iseri, *University of California, Davis.*

There are many nutritional and non-nutritional effects of nutrients that are added to feeds to optimize animal performance and health. A subset of nutritionally required lipids, vitamins and trace minerals possess bioactivities that function across a range of mechanisms including substrates or co-factors for key metabolic processes (nutritional effects), regulators of pathways and cellular decisions, and direct activities on the viability of potential pathogens along the mucosa of the GI track (pharmacological or non-nutritional effects). Among trace minerals, iron, zinc, and copper have been shown to possess this range of activities. Investigations of bioactive nutrients must consider each of these mechanisms to understand their net impact on the health and productivity of animals. For example, copper is required at relatively low levels as a co-factor for a variety of enzymes; each of which has a different priority for this cofactor. Studies examining the ability of dietary copper to fulfill its role as a cofactor should focus on those enzymes that have a low priority, such as lysyl oxidase in tendons, and not on enzymes that have a higher priority or can switch to other divalent cations, such as superoxide dismutase in immune cells. Copper also has direct anti-microbial effects on intestinal microflora and these actions occur at levels that are an order of magnitude higher than needed as a cofactor for lysyl oxidase. Studies on the anti-microbial actions of copper should focus on the dietary fraction that remains in the lumen of the distal intestines and is available to influence the microbial milieu rather than the fraction that is absorbed and used as a cofactor for enzymes. At intermediate concentrations, copper influences regulatory decision made by T-helper lymphocytes and macrophages. Thus, bioavailability/bioefficacy is context dependent and the specific function (nutritional versus regulatory versus anti-microbial) needs to be considered when comparing nutrient sources.

Key Words: copper, requirement, immunity

273 Practical applications of trace minerals in dairy cattle. T. R. Overton* and T. Yasui, *Cornell University, Ithaca, NY.*

Trace minerals have critical roles in immune function, oxidative metabolism, and energy metabolism in ruminants. To date, the primary trace elements of interest in diets for dairy cattle have included zinc (Zn), copper (Cu), manganese (Mn), and selenium (Se), although

data also support potentially important roles of chromium (Cr), cobalt (Co), and iron (Fe) in diets. Trace minerals such as Zn, Cu, Mn, and Se have classically and essentially defined roles as components of key antioxidant enzymes and proteins. Available evidence suggests that these trace minerals can modulate aspects of oxidative metabolism and immune function through these roles; recent work has demonstrated that source of Zn, Cu, and Mn fed to dairy cattle during the transition period and early lactation can modulate both aspects of oxidative metabolism and production. Chromium has been shown to have roles in both immune function and energy metabolism of cattle; dairy cows fed Cr during the transition period and early lactation have evidence of improved immune function, increased milk production, and decreased subclinical endometritis. Limited research has been conducted with focus on Co and Fe nutrition; some data do support roles of Co in cow productivity during early lactation. At the farm level, one factor that complicates trace mineral nutrition is the existence of a large number of antagonisms affecting bioavailability of individual trace minerals, thus determining the optimum level and source of trace minerals at the farm level continues to be a challenge. Collectively, increasing evidence supports a role for trace mineral nutrition in modulating production, health, and reproduction in cattle. Furthermore, opportunities for specific modulation of aspects of health, milk production, and reproduction through supplementation strategies for diets of transition dairy cows are attractive because of the known dynamics of energy metabolism, immune function, and oxidative metabolism during this timeframe.

Key Words: trace mineral, oxidative metabolism, immune function

Dairy Foods: Chemistry and Processing II

W1 Microfiltration and ultrafiltration process to produce micellar casein concentrate and milk protein concentrates with 80% protein content. P. Salunke, C. Marella*, and L. E. Metzger, *Dairy Science Department, Midwest Dairy Foods Research Center, South Dakota State University, Brookings.*

Milk protein concentrates (MPC) are used in applications that require dairy ingredients with higher level of protein relative to total solids (TS). MPC is essentially skim milk (SM) powder with reduced level of lactose. MPC has same ratio of casein to serum protein (SP) as found in SM. In some applications, protein ingredients with a reduced level of SP content may be preferred. The objective of the present research was to compare microfiltration (MF) and ultrafiltration (UF) processes for production of MCC and MPC with 80% protein relative to TS. 227 L of pasteurized SM was subjected to MF using 0.5-μm spiral-wound polyvinylede fluoride membrane. During the process, diafiltration (DF) water was added at 6 intervals, totaling to 100% of feed volume. In another process, 227 L of pasteurized SM from the same lot was subjected to UF using 10 kDa polyethersulfone membranes. During the process, DF water was added at 4 different intervals, totaling to a final addition of 40%. Both the processes used a volume reduction of 5. There were significant ($P <$ 0.05) differences in all of the compositional parameters except fat and casein for the MF retentate (MFR) and UF retentate (UFR). UFR had a higher total nitrogen (TN), TS, lactose, ash and calcium content as compared with MFR. This affected the TN/TS ratio found in both the retentates, MFR had a ratio of 81.7 and UFR had a ratio of 77.18. The differences in membrane pore sizes, operating pressures and level of DF used all contributed to the differences in final TN/TS ratio obtained. Capillary gel electrophoresis analysis of individual protein fractions present in the UFR and MFR showed that UFR has β-lactaglobulin to α-lactalbumin (α-LA) ratio of 2.57, which is close to the ratio found in SM. The MFR has a ratio of 3.57 indicating preferential transmission for α-LA by the MF membrane. The results from this study show that MF and UF processes could be used for production of MCC and MPC with similar TN/TS ratio with careful selection of operating parameters.

Key Words: MPC or MCC, micro- and ultrafiltration, capillary gel electrophoresis

W2 Understanding shear-induced aggregation in partially crystalline oil-in-water emulsions. G. Fuller*[1,2], T. Considine[1], M. Golding[2], L. Matia-Merino[2], and A. MacGibbon[1], *[1]Fonterra Co-operative Group Limited, Palmerston North, New Zealand, [2]Massey University, Palmerston North, New Zealand.*

Fat globules in food products such as cream are prone to irreversible aggregation due to the presence of both solid and liquid fat in the dispersed phase and weak interfacial films. This can lead to undesirable changes in both texture and functionality. Despite the need to understand and control this process, many questions still remain because the factors affecting aggregation are numerous and often interdependent. To study the aggregation process, 35% fat emulsions with different solid fat content (SFC) stabilized by 2% sodium caseinate were studied under shear (cone-and-plate geometry) at 5°C over 6 d. SFC was varied by combining hydrogenated palm kernel oil and canola oil. To study the effect of different interfacial film compositions, Tween 20 (0.5. 1.5 and 2.5% by wt) was added after homogenization. The results showed that emulsions containing 0.5% Tween 20 had distinctly different aggregation behavior compared with those with ≥ 1.5% Tween 20 regardless of solid fat content and the applied shear rate. At 0.5% Tween 20, aggregation time increased with increasing SFC whereas at ≥ 1.5% Tween 20, aggregation time decreased with increasing SFC. This behavior was likely due to a transition from a mixed protein-surfactant interface at 0.5% Tween 20 to a surfactant dominated interface at ≥ 1.5% Tween 20. By revealing how small changes in surfactant concentration significantly influence shear-induced aggregation behavior in oil-in-water emulsions with different SFC, these results will aid in the development of food products with improved shelf-life and stability.

Key Words: emulsion, shear-induced aggregation, partial coalescence

W3 Effect of Maillard-induced glycosylation on the molecular configuration of whey protein and its solubility and thermal stability for beverage applications. Q. Wang* and B. Ismail, *University of Minnesota, St Paul.*

Whey proteins are reasonably soluble in acidic beverages; however, thermal processing and prolonged storage can result in protein aggregation and subsequent deterioration of quality. Consequently, whey protein acidic beverages available on the market have a short shelf life and contain at most 4% protein, which is below the minimum percentage (4.2%) required by the FDA to claim a "high protein beverage." The objective was to determine the solubility, thermal stability, nutritional quality, and structural changes of partially glycosylated whey protein (PGWP). Maillard-induced glycosylation conditions were optimized to promote glycosylation of whey protein, while minimizing browning and maintaining nutritional quality. Solubility and thermal stability of PGWP and WPI were compared over a wide range of pH, protein concentrations, and heating temperatures and times. Differential scanning calorimetry and SDS-PAGE were employed to monitor onset of denaturation and polymerization, respectively. Samples were analyzed by surface-enhanced Raman spectroscopy and by matrix-assisted laser desorption ionization-time of flight mass spectrometry to determine secondary and tertiary structural changes and glycosylation sites, respectively. Compared with WPI, PGWP maintained higher solubility and thermal stability at protein concentrations greater than 4.2%, over a wide range of pH, including the pH around the isoelectric point (pI) of whey protein. The enhanced solubility and thermal stability was attributed to structural rigidity, unique glycosylation sites and resistance to denaturation. The nutritional quality was maintained and advanced stages of Maillard reaction were not detected. Our findings demonstrated the possibility of using PGWP in the production of high protein acidic beverages (>4.2% protein) and provided information that is essential to understand the structure/function relationship upon Maillard-induced glycosylation of whey proteins.

Key Words: whey protein, glycosylation, solubility

W4 Development of a multiclass method for determination of 38 veterinary drugs in milk by ultra-high-performance liquid chromatography-tandem mass spectrometry. R. W. Han[1,3], N. Zheng[1,2], J. Q. Wang*[1,2], Z. N. Yu[3], X. M. Xu[1,2], Y. P. Zhen[1,2], X. Y. Qu[1,2], and L. C. Huang[1,2], *[1]State Key Laboratory of Animal Nutrition, Institute of Animal Science, Chinese Academy of Agricultural Sciences, Beijing, China, [2]Ministry of Agriculture–Milk and Dairy Product Inspection Center (Beijing), Beijing, China, [3]College of Food Science and Engineering, Qingdao Agricultural University, Qingdao, Shandong, China.*

A simple, selective and rapid multi-residue method was developed to determine 38 veterinary drugs simultaneously in milk by ultra-high-performance liquid chromatography-tandem mass spectrometry (UPLC-MS/MS). The selected veterinary drugs include 14 β-lactams, 8 quinolones, 8 sulfonamides, 5 tetracyclines, and 3 macrolides. The analytes were extracted by water-acetonitrile (1:3), and then purified using Oasis HLB cartridge. The elution with water-acetonitrile (8:1) was injected into the UPLC-MS/MS system on a Waters UPLC C_{18} column in gradient mode. Multiple reaction monitoring (MRM) experiments in the positive ionization mode were performed to achieve data acquisition under MS/MS. Results showed good accuracy and repeatability. Average recoveries for different veterinary drugs in milk were 67.9–117.5% for β-lactams, 79.3–117.7% for quinolones, 71.3–106.1% for sulfonamides, 76–115.5% for tetracyclines and 78.2~106.1% for macrolides. The coefficients of variation (C.V.) of the recoveries were less than 15% for intraday and interday precisions. The limits of quantification (LOQs) for β-lactams, quinolones, sulfonamides, tetracyclines and macrolides were 0.3–10 ng/mL, 0.03–0.6 ng/mL, 0.03–0.3 ng/mL, 0.6 ng/mL and 0.03–0.6 ng/mL, respectively. Finally, the method was applied to 25 raw milk samples and traces of some veterinary drugs under allowable levels were detected, such as flumequine, sulfapyridine, sulfamethoxazole and lincomycin.

Key Words: veterinary drugs, milk, UPLC-MS/MS

W5 A UPLC-MS/MS method to simultaneous determine aflatoxin M1, ochratoxin A, zearalenone and α-zearalenol in milk. L. C. Huang[1,3], N. Zheng[1,2], J. Q. Wang*[1,2], J. B. Cheng[1,3], R. W. Han[1,2], X. M. Xu[1,2], and S. L. Li[1,2], *[1]State Key Laboratory of Animal Nutrition, Institute of Animal Science, Chinese Academy of Agricultural Sciences, Beijing, China, [2]Ministry of Agriculture–Milk and Dairy Product Inspection Center (Beijing), Beijing, China, [3]College of Animal Science and Technology, Anhui Agricultural University, Hefei, China.*

Our objective was to develop an ultra-high-performance liquid chromatography triple-quadrupole spectrometry (UPLC-MS/MS, TQ-S, waters, USA) method to simultaneously determine aflatoxin M1, ochratoxin A, zearalenone and α-zearalenol in milk. The analytes were extracted by acetonitrile, and purified by solid phase extraction (SPE) using Oasis HLB cartridge, and then injected into the UPLC-MS/MS system. The mycotoxins were separated by UPLC BEH C_{18} column in gradient mode and determined in multiple reaction monitoring mode under positive- and negative-mode electrospray ionization. The optimized conditions of purification were SPE pH 5.0, eluting solution of 100% methanol, SPE flow rate of 1.5 mL/min and washing water of 2 mL. The matrix effects of 3 milk matrices, including raw milk, liquid milk and milk powder, were evaluated by the signal suppression-enhancement and compensated by external matrix-matched calibration. Correlation coefficients (r^2) of external matrix-matched calibration curves were higher than 0.996 in their respective linear ranges (0.01–1.00 μg/kg). The LOD and LOQ ranges of 4 mycotoxins selected were 0.001–0.005 μg/kg and 0.003–0.015 μg/kg, respectively. The method validation in 3 matrices at low (0.025 μg/kg) and high (0.5 μg/kg) spiked levels obtained reasonable recoveries (87.0–109%) and repeatability (CV < 10%). Intra- and inter-day tests at levels of 0.025 μg/kg also got satisfactory recoveries (23.1–25.4 μg/kg) and RSDs (7.4–9.9%). Finally, the method was successfully applied to milk samples, and traces of 4 mycotoxins were detected. The results demonstrated that the proposed method was sensitive, reliable and robust. Therefore, the developed method was suitable for the simultaneous determination of 4 mycotoxins in milk and could be performed for their routine analysis in mycotoxin study and survey.

Key Words: mycotoxin, milk, UPLC-MS/MS

W6 Comparison of amino acid composition of milk from different species. J. X. Zhang[2,3], J. Q. Wang*[1,2], D. P. Bu[2], J. H. Yang[2], L. Ma[2], and J. T. Chen[2], *[1]Agronomy College of Heilongjiang August First Land Reclamation University, Heilongjiang, China, [2]Institute of Animal Science, Chinese Academy of Agricultural Sciences, Beijing, China, [3]Xinjiang Agricultural University, Urumqi, China.*

The objective of this study was to investigate variation of milk amino acids composition of different dairy animals. Milk samples from cows, goats, yaks and buffalos (n = 20 for each species) were obtained from different farms, and transported to the laboratory as packed for analysis. Amino acids were extracted by hydrolyzed with 7.8 mol/L HCl for 24 h, and concentrations of amino acids were determined by Hitachi L-8900 high speed amino acid analyzer. Data was processed by Excel and analyzed by SAS 9.0 and PCA with The Unscrambler 9.8 procedure. Results showed that concentrations of all tested amino acids were different among the cow, yak, buffalo and goat ($P < 0.01$). Concentration of total AA was found to be yak > buffalo > goat > cow (11024.49, 8271.16, 6325.35, 5688.38). According to Ser (118.60, 171.55, 234.44), Thr (119.39, 181.45, 230.47), Val (203.83, 287.27, 376.91) and Tyr (107.62, 132.26, 172.70) profiles base of the PCA scores and loading plots, cow, buffalo, and yak milk were grouped together, whereas goat milk (the 4 amino acids were 170.45, 176.08, 254.19, 128.09) was in a second group. Buffalo and yak milk showed higher Pro (483.01, 613.23) and Ile (263.96, 321.50) concentrations compared with the cow (Pro 132.50, Ile 230.16) samples, whereas yak (518.21) milk was characterized by a higher concentration of Lys compared with the milk from buffalo (368.53). It was concluded that the 4 specials showed distinct amino acids profiles.

Key Words: milk, species, amino acid

W7 Determination of milk composition using near-infrared transflectance spectrum. L. Ma[1,2], J. Q. Wang*[1], D. P. Bu[1], J. H. Yang[1], J. X. Zhang[1], and J. T. Chen[1], *[1]Institute of Animal Science, Chinese Academy of Agricultural Sciences, Beijing, China, [2]Inner Mongolia Agricultural University, Huhhot, Inner Mongolia, China.*

Near-infrared transmission/reflection spectrum has been used in food and agricultural products test extensively. The objective of this study was to investigate main components in milk using near-infrared transflectance spectrum. Milk samples (n = 150) were collected from one dairy farm, and protein (3.70 ± 0.24%), fat (4.56 ± 0.69%), lactose (5.02 ± 0.14%), total solids (14.09 ± 0.79%) and non-fat solids (9.74 ± 0.27%) in milk were measured by MilkoScan FT 120. Milk transflective spectra ranged from 400 to 2500 nm were collected using NIRS DS2500, with sample 2 mm thick. Data was exported to the Unscrambler 9.8 (CAMO, Oslo, Norway) for multivariable analysis. The same samples were employed for calibration and full cross validation. Regression model of spectroscopy was constructed via partial least squares. The loading plots showed that middle and long wavelength (1300–2500 nm) spectroscopy contributed much to milk components model. Satisfied results of calibration and prediction were obtained in this study, for high determination coefficients (R^2) of calibration and validation for protein, fat, lactose, total solids and non-fat solids above 0.90. Root mean square error (RMSE) of validation suggested better prediction accuracy for milk protein, lactose, and nonfat solids, which were less

than that of fat and total solids. Excellent ratio of prediction to deviation (RPD) value was observed for protein, while RPD for fat, lactose, total solids and non-fat solids were acceptable. It was concluded that near infrared transflectance spectrum would be capable of in milk composition determination.

Table 1. Parameters of milk composition model

			Calibration			Validation			
Milk composition	Pre-treatment	PC	Predicted Y vs. measured X	RMSE	R^2	Predicted Y vs. measured X	RMSE	R^2	RPD
Protein	No	9	Y =0.969x +0.114	0.036	0.98	Y=0.960x +0.148	0.045	0.97	4.97
Fat	No	6	Y =0.916x +0.383	0.177	0.93	Y=0.910x +0.410	0.197	0.92	3.06
Lactose	MSC	12	Y =0.928x +0.362	0.029	0.96	Y=0.911x +0.448	0.042	0.91	3.15
Total solids	SNV	5	Y =0.922x +1.093	0.219	0.92	Y=0.915x +1.188	0.234	0.91	3.41
Nonfat solids	SNV	11	Y =0.940x +0.569	0.067	0.94	Y=0.927x +0.695	0.077	0.92	3.54

Key Words: near-infrared transflectance spectrum, milk composition

W8 Evolution of milk calcium content during the year. C. Hurtaud*[1], M. Johan[1], S. Leurent[2], Y. Gallard[2], and L. Delaby[1], *[1]INRA-Agrocampus Ouest UMR 1348 PEGASE, Saint-Gilles, France, [2]INRA Domaine du Pin-au-Haras, Exmes, France.*

Calcium content is regarded as being relatively stable in cows' milk during lactation. However, results from commercial herds, have suggested that changes in milk calcium (Ca) content can occur. The objective of this experiment was to compare the characteristics of milk (especially milk Ca content) based on low input grass based systems compared with corn silage based systems, across 2 breeds of dairy cows (Holstein, HO vs. Normande, NO).The experiment took place on the INRA experimental farm of Le Pin-au-Haras. Sixty dairy cows were observed from calving to drying off. Two feeding systems were compared. The Intensive system (IS) was designed to maximize individual performance, with a high energy diet (in winter, corn silage with 30% concentrate; in spring, summer and autumn periods, pasture with 4 kg/d of concentrate supplemented with corn silage from July). The Grass system (GS) was designed to decrease inputs (in winter, conserved grass with no concentrate; in spring, summer and autumn, pasture with no concentrate). The experimental design was a continuous design. No significant interaction was detected between feeding system and breed for milk yield and composition. During the whole year, GS treatment reduced milk yield (−5 kg/d), with no significant effect on protein and total Ca contents. The NO cows produced less milk, but with higher protein and total Ca contents. During winter, GS treatment reduced milk yield, protein and total Ca contents. Milk Ca content decreased from January to June and rapidly increased after July irrespective of breed. During May and June, HO milk had a Ca concentration below the French limit of 1.2 g/L of the European health allegation of milk for consumption. There was a significant effect of stage of lactation and month on Ca content. Month included numerous significant factors such as maximum daily temperature, day length and radiance duration. This study clearly showed that both cow genotype and lactation stage affects milk Ca content. However, the lactation stage did not explain all the seasonal variations of milk calcium content observed in this trial.

Key Words: milk, dairy cow, calcium

W9 Quantitative analysis of supercritical carbon dioxide (sc-CO_2) treated β-lactoglobulin tryptic peptides. C. Kembel* and R. Jimenez-Flores, *California Polytechnic State University, San Luis Obispo.*

Whey protein is an abundant source of biologically active peptides that have a diverse set of functional properties. One limitation in the production of novel peptides is the native folding of the proteins secondary and tertiary structure. β-Lactoglobulin is a barreled protein with a hydrophobic core capable of binding other proteins. Due to its abundance in whey, it represents an important source of bioactive peptides. We present a method with the potential for the production of novel bioactive peptides from whey. Supercritical CO_2 is known to change protein conformation due to its hydrophobic properties, high diffusion coefficient, low viscosity, and low surface tension. Because β-Lactoglobulin contains a large hydrophobic core where binding sites are present, sc-CO_2 treatment is likely to expose these hydrophobic sequences. These sequences are normally confined to the interior of the protein away from enzymatic attack under normal conditions. Therefore upon exposure to sc-CO_2, these sequences were shown to be more susceptible to trypsin hydrolysis. This method increases the potential for the production of novel peptides. Minor changes in the temperature of the sc-CO_2 treatment induced subsequent conformational changes resulting in different peptides. Variable conditions (pH, temperature, and pressure) sc-CO_2 was shown to yield unique fingerprints by SDS-PAGE. Capillary electrophoresis was then used to discern the peptide profiles of the sc-CO_2 treated peptides as well as native peptides. Distinct differences in peptide profiles were noted. Subsequent analyses will include HPLC-MS to determine peptide sequences and quantity differences in peptide treatments.

Key Words: supercritical CO_2, whey protein, bioactive peptide

W10 AFM imaging and analysis of phospholipid monolayers. J. Cuthbert*[1], S. Gallier[2], D. Gragson[1], and R. Jimenez-Flores[1], *[1]California Polytechnic State University, San Luis Obispo, [2]Massey University, Palmerston North, New Zealand.*

Membrane structure analysis in biological systems is fundamental for understanding its relationship with function. Membrane analyses still relies on observations of the physical phenomena of its components in model systems. Dairy foods are complex systems that incorporate parts of colloidal properties with emulsions. The emulsion in a dairy system is unique due to the presence of the milk fat globule membrane (MFGM). This membrane is composed of phospholipids and proteins, and it has an important biological function in the initial stages of mammals' lives, and in humans it has an important nutritional role throughout their life. In our work to elucidate the structure/function relationship of the MFGM, we are exploring some structural aspects of its phospholipids. Therefore, in this work we present how the properties of the phospholipid/protein monolayers found in milk fat globules were investigated using atomic force microscopy (AFM) in a model system with phospholipids extracted from raw milk and either β-casein or β-lactoglobulin. Slides of the phospholipid and phospholipid-casein monolayer films were prepared as models from a Langmuir trough. The aim was to determine if the monolayers would form liquid-ordered domains or alternatives. Our observations indicate that this technique distinguishes liquid ordered domains in AC contact mode. In this mode, the cantilever oscillates above the surface. It is gentle enough to image phospholipid monolayers without damage. When the tip approaches the surface, the sample's intermolecular and electrostatic forces change the cantilever's amplitude and phase angle. As the cantilever is affected by surface forces, a piezoelectric scanner adjusts its height. The monolayer

domains were best observed in the height and phase traces where the ridges were salient. Because the monolayer domains were more elastic than the surrounding surface, they can be observed in the phase trace. A typical monolayer region was approximately 2 nm high and showed a change of 4° in the phase trace. We conclude that the AFM is a good technique to measure changes in monolayers that could happen during digestion of lipids.

Key Words: atomic force microscopy, milk fat globule membrane, monolayer

W11 Correlation between solubility and solubility index of high protein milk protein concentrates. H. Patel*[1], P. Salunke[1], and J. Amamcharla[2], *[1]Dairy Science Department, South Dakota State University, Brookings, [2]Animal Sciences and Industry, Kansas State University, Manhattan.*

Solubility of high protein ingredients such as milk protein concentrate (MPC) is an important primary property. Measuring the solubility of MPC is a lengthy and tedious process. Developing a simple, quick, and reliable procedure can save time and efforts. Solubility Index (SI) is a well-established method for the determination of solubility of milk powders. The SI is a good indicator of insoluble constituents of milk powders. However, no reports are available in the literature indicating the use of SI for predicting solubility of MPC. The objective of present study was to find out whether correlations exist between SI and percent solubility of MPC80 under a wide range of reconstitution conditions. Five representative samples of MPC80 with a similar protein (81–82%), lactose and mineral contents were obtained from different countries. Solutions (5% w/w) were prepared by reconstituting MPC at 4 different temperatures (20, 40, 50 and 60°C). During reconstitution, aliquots from each of this solution were withdrawn at different time intervals (2, 10, 20, 30, 45 and 60 min). A total of 120 samples were analyzed in this way. The SI of these samples was determined using a centrifugation method at 700g for 10 min). Percent solubility was determined by the standard gravimetric method. The data were analyzed using PROC REG available in SAS and the correlation coefficient (r^2) between percent solubility and SI was obtained. The results of the present study indicated that there was a strong correlation between the solubility and SI measured at different time and temperature of reconstitution. As the temperature and time of reconstitution increased, there was a significant ($P < 0.05$) increase in the solubility. Consequently, there was a significant ($P < 0.05$) decrease in SI. The r^2 value of 0.94 for different reconstitution temperatures and that of 0.81 for different reconstitution time indicated that SI can be used as a quick and routine method in place of the traditional solubility method for characterizing the solubility of MPCs as it is simple, fast, reliable, and easy to perform.

Key Words: milk protein concentrate (MPC), solubility, solubility index (SI)

W12 Phospholipids from milk help cancer prevention in skin cell culture. L.-A. Nguyen*[1], L. H. Laiho[1], and R. Jiménez-Flores[2], *[1]California Polytechnic State University, Biomedical Engineering Department, San Luis Obispo, [2]Dairy Products Technology Center, San Luis Obispo.*

Milk phospholipids (MPL) have a unique composition due to their biological role of engulfing the milk fat globules as milk is synthesized. This unique combination of MPL has been studied and found to have diverse biological activities or functions. In this study we focused on measuring the protective effect of milk phospholipids on skin cell culture after exposure to UV light. This model system has been used as means to identify skin cancer preventing agents. Our study focused on evaluating the expression of a UV-induced DNA damage marker, cyclin-dependent kinase inhibitor, p21WAF1/CIP1. Our previous work had shown some preliminary histology and MTT tissue viability results, which suggested that MPL act upon skin cells in a protective manner against UV (UV) radiation. Western Blots were used to quantify p21 expression in human keratinocytes in 4 categories of samples: No-UV, UV, UV+MPL, MPL and in HeLa (p21 positive control). In the No-UV samples, cells were not irradiated by UV light. Treatment consisted on exposure to a UV dosage of 10 mJ/cm^2. After UV treatment, the same amount of protein from each sample (determined by BCA assay) was loaded into a 4–12% Bis-Tris SDS-PAGE gel, run under denaturing, non-reducing conditions then blotted and treated with antibodies for the quantitative detection of p21 proteins. Finally, intensities of p21 protein bands were analyzed. Under non-reducing conditions, 3 p21 proteins covalently bonded with each other showed up as 63 KDa molecules on the PVDF membrane. The UV and HeLa samples showed a 2.28 fold, and 1.23 fold increase in p21 expression, respectively, compared with the No-UV samples control. The MPL samples showed a 0.948 fold decrease in p21 compared with the No-UV samples, and the UV+MPL samples showed only a 1.13 fold increase in p21. Less p21 expression in the UV+MPL samples compared with the UV samples suggested that less DNA damage occurred in the samples that were treated with MPL. Conclusion: Milk Phospholipids reduced UV-induced DNA damage in human keratinocytes through incorporation in cell media and could potentially be incorporated as a chemopreventive agent.

Key Words: milk phospholipid, cancer, UV

W13 Reduction of aflatoxin M_1 content during manufacture and storage of Egyptian Domiati cheese. M. Motawee*, *National Organization for Drug Control and Research, Cairo, Egypt.*

Elevated levels of aflatoxin M_1 (AFM_1) in milk and milk products is considered to pose certain hygienic risks for human health. The maximum level of AFM_1 allowable in Egyptian milk is 50 ng/L and while a previous study found the majority of milk was below this level, some milk contained up to 250 ng/L. Domiati cheese is the most popular soft white pickled cheese in Egypt and accounts for 75% of the cheese produced and consumed in Egypt. During manufacture of Domiati cheese from 5% to 14% of salt is added to the milk depending on the season and cheese ripening temperature. The aim was to determine what proportion of initial AFM_1 in milk is retained after manufacture into Domiati cheese and remains during 90 d storage. Milk was inoculated with 1µg/kg AFM_1 then pasteurized at 63°C for 30 min and made into Domiati cheese using salt additions of 6%, 8% and 10% (wt/wt). Cheese making was performed on 3 separate occasions. The AFM_1 levels in milk, cheese and whey were determined using an ELISA test kit. Pasteurization of milk caused ≤ 10% loss of AFM_1. About 60%, 58%, and 56% of total AFM_1 remained in cheese curd made using 6%, 8% and 10% salt respectively, with the residual being lost in the whey. After 2 wk storage at 20°C, all of the cheeses had a 17% reduction in AFM_1 compared with their levels after manufacture. With continued storage through 90 d the losses of AFM_1 were significantly different ($P < 0.05$) with reduction in AFM_1 or 20.5%, 21.4%, 22.0% for cheeses made using 6%, 8% and 10% salt respectively. Thus, including pasteurization of milk, conversion of milk into Domiati cheese and its subsequent storage period for 3 mo produced an overall 32% reduction of AFM_1. In conclusion, as well as avoiding contamination of milk with AFM_1 there is a lower health risk to the population from the presence of AFM_1 in

milk when the milk is pasteurized and converted into Domiati cheese that is then stored for the customary 3 mo.

Key Words: aflatoxin, Domiati cheese, storage

W14 Limited glycerolysis and transesterification reactions to change the fatty acid composition and crystallization properties of butterfat. D. Sanchez-Macias[2,1], A. Laubscher*[1], and R. Jimenez-Flores[1], *[1]California Polytechnic State University, San Luis Obispo, [2]Agroindustrial Engineering Department, Universidad Nacional del Chimborazo. Riobamba, Ecuador.*

Saturated fatty acids in butterfat have been regarded as a nutritional disadvantage in some dairy products. Several different strategies have been tried and tested for the modification of the fatty acid composition of bovine milk. The nature of the rumen forces the cow to produce saturated fatty acids, and bypass techniques have limited results. Enzymatic modification of milk fat has also limits in efficiency since enzymes work only in an aqueous media and therefore only in the interface of emulsions. Fractionation of butterfat based on differential crystallization had in the past some limited success, but no clear difference was obtained by removing crystals formed at relative high temperatures, where saturated fatty acids were assumed to be present in higher concentration. We approached this strategy, by attempting a chemical rearrangement of fatty acids in the triglycerides of milk fat by a limited glycerolysis and transesterification, in which glycerol was used as an intermediary for rearrangement of fatty acids, and limited amounts of oleic acid were added. Glycerolysis and transesterification took place in the same vessels with minimal amount of alcoholic KOH as catalyzer and a temperature of 200°C for 2 h. Resulting combinations of triglycerides from this reaction showed significantly different fatty acid distribution; Control butterfat heated without any catalyzer served as control and reference. The major differences were observed when comparing the crystals separately from the remaining oil fraction. Even in the group without oleic acid, the crystals showed fatty acids increase in 16:0 and 18:0 of 17 and 45% respectively; changes of fatty acid composition on the other tested fractions was even more pronounced. The crystal fractions were drastically different in morphology and color in the treated samples compared with controls. We conclude that there is some technological potential in partial chemical glycerolysis and transesterification to modify the composition of butterfat fractions

Key Words: fatty acid, butterfat, glycerolysis transesterification

W15 The effects of microfluidization on the particle size distribution of liposomal aggregates between whey buttermilk and commercial sweet buttermilk. T. Nguyen* and R. Jimenez-Flores, *California Polytechnic State University, San Luis Obispo.*

Milk-derived ingredients from the production of cheese and butter can be used as vehicles for nutrients. One of the advantages of ingredients from milk that contain milk fat globule components such as phospholipids is that they form emulsions with fat, or liposomes when treated with high shear. Our objective in this work was to measure the effect of shear on regular buttermilk and whey buttermilk. The effects of microfluidization at 2000 psi on the particle size distribution of liposomal aggregates between whey buttermilk and commercial sweet buttermilk at pH 4.6 and 6.8 were compared with whey protein isolate. At pH 4.6, the average aggregate size increased in sweet buttermilk after every one of 3 passes total through the microfluidizer. There was a slight decrease in the average aggregate size of whey buttermilk after the first pass and an increase in the average size for the second and third passes. Similarly, a slight decrease was seen in the average particle size of whey protein isolate after the first 2 passes and an increase in the average size after the third pass. The aggregate size distribution of whey buttermilk resembled that of whey protein isolate at pH 6.8. There was an alternate decrease and increase in the average aggregate size after each pass. In contrast, a slight decrease in average particle size was seen in sweet buttermilk after the first 2 passes and an increase in size after the final pass at pH 6.8. At pH 4.6, whey protein isolate and both buttermilks had a greater number of small particles after microfluidization. In contrast, at pH 6.8, each dairy product had a greater number of larger particles. This could be due to hydrophobic interactions between the aggregates. This study suggests that microfluidization at various pH affects the size distribution of whey buttermilk aggregates or liposome particles so that size can be manipulated and therefore can be utilized as a novel ingredient and in the processing of dairy foods to deliver nutrition.

Key Words: phospholipid, microfluidization, nutrition delivery

W16 Fast and easy screening of whey protein types using a novel portable infrared spectroscopy. T. Wang* and L. Rodriguez-Saona, *The Ohio State University, Columbus.*

Whey proteins are attractive ingredients to the food industry because of their high nutritional value and wide functionality. Whey protein powders are available from different suppliers using various processing methods and conditions, resulting in variability in their macromolecular structure, components levels and thus having an effect on their functionality. There are 3 major types of whey protein including whey protein isolates (WPI), whey protein concentrates (WPC) and whey protein hydrolysates (WPH) providing diverse functionality to food applications. Our objective was to develop a simple and rapid method to differentiate whey protein types by combining a portable infrared spectrometer and pattern recognition analysis. Whey protein powders including WPI (n = 23), WPC (n = 8) and WPH (n = 14) from different suppliers were evaluated. A portable infrared spectroscopy (Cary 630, Agilent Technologies) was used for spectra collection by pressing the whey protein onto an ATR-IR diamond crystal with a pressure clamp. Spectra were analyzed by soft independent modeling of class analogy (SIMCA) for powder classification. SIMCA model showed a strong ability to differentiate whey protein types by forming tight clusters far from each other (interclass distances > 3). Major band responsible for separation was associated with carboxylic acid side chain in amino acids present in whey proteins. Portable IR units enable to quickly assess the quality of the incoming raw material allowing for timely corrective measures during manufacture. Portable systems are simple to use and require minimal or no sample preparation, thus reducing assay time and helping to streamline the analytical procedure so that it is more applicable for field-based screening and higher sample throughput.

Key Words: whey protein, infrared spectroscopy, pattern recognition analysis

W17 Effect of transglutaminase treatment on the functionality of MPC and MCC: Functional properties. P. Salunke*, C. Marella, and L. E. Metzger, *Dairy Science Department, Midwest Dairy Foods Research Center, South Dakota State University, Brookings.*

Milk protein concentrate (MPC) and micellar casein concentrate (MCC) are products manufactured using ultra- and micro-filtration

respectively. Functional properties such as alcohol stability (AS), heat stability (HS), solubility and solubility index (SI) are affected by presence or absence of constituents in MPC and MCC particularly, casein, whey proteins, lactose, and minerals. However, MPC and MCC alone are unable to deliver critical functional properties required in certain products such as high heat stable products, emulsions, and processed cheese products. The use of cross-linking enzymes such as transglutaminase (TGase) has the potential to modify the physical properties of MPC or MCC and may improve their functional properties. The objective of this study was to determine the effect of TGase treatment of MPC and MCC retentates on the functionality of MPC and MCC. Three lots of MCC and MPC retentate were produced using 3 different lots of pasteurized skim milk. Each replicate of retentate was divided into 3 equal portions. One portion of the retentate was treated with TGase at 0.3 units/g of protein, one portion was treated with TGase at 3.0 units/g of protein and one had no TGase addition. All the retentates were incubated for 25 min at 50°C, heat treated at 72°C for 10 min, cooled to 4°C and then spray dried. Various functional properties including AS, HS, solubility and SI at room temperature (RT) and hot water were tested using 5% protein solution of MCC and MPC. MPC samples had significantly ($P \leq 0.05$) higher AS, HS, solubility and significantly ($P \leq 0.05$) lower SI as compared with respective MCC treatments. TGase treatment significantly ($P \leq 0.05$) increased the AS, HS, SI, and significantly ($P \leq 0.05$) decreased the solubility. The study demonstrates that TGase treatment was found to significantly ($P \leq 0.05$) affect and modifythe functionality of MCC and MPC. These TGase treated ingredients can be used in products where whey protein have detrimental effect including high heat stable products, emulsions or processed cheese products.

Key Words: transglutaminase, MPC or MCC, functional properties

W18 Effect of transglutaminase treatment on the functionality of MPC and MCC: Yogurt formulation. P. Salunke*, C. Marella, and L. E. Metzger, *Dairy Science Department, Midwest Dairy Foods Research Center, South Dakota State University, Brookings.*

Milk protein concentrate (MPC) can be used in yogurt formulations to increase the protein content of yogurt. In contrast micellar casein concentrate (MCC) produced using microfiltration has a reduced level of whey protein and has not been utilized in yogurt. The use of transglutaminase (TGase) has the potential to modify the physical properties of MPC or MCC and may improve its functionality in yogurt. The objective of this study was to determine the effect of TGase treatment of MPC and MCC retentates on the functionality of MPC and MCC when they are used in yogurt formulation. Three lots of MCC and MPC retentate were produced using 3 different lots of pasteurized skim milk. Each replicate of retentate was divided into 3 equal portions. One portion of the retentate was treated with TGase at 0.3 units/g of protein, one portion was treated with TGase at 3.0 units/g of protein and one had no TGase addition. All the retentates were incubated for 25 min at 50°C, heat treated at 72°C for 10 min, cooled to 4°C and then spray dried. Each MCC and MPC was then used in a yogurt formulation that was standardized to 8.5% MSNF and 5.75% protein using deproteinized whey powder and distilled water. In each formulation, the MPC or MCC utilized contributed 5% protein. All the ingredients were mixed and were subjected to heat treatment in the rapid visco analyzer (RVA) at constant speed of 150 rpm using a profile where it was heated from 45°C to 93°C over a period of 10 min, held for 6 min at 93°C, and cooled to 45°C in 10 min. After cooling to 45°C, the sample was acidified using glucono-δ-Lactone and mixed thoroughly at 500 rpm for 1 min, incubated at 45°C in water bath for 2.5 h and subsequently stored at 4°C overnight. The yogurt manufactured using MPC had significantly ($P \leq 0.05$) higher RVA-viscosity, water holding capacity (WHC) and syneresis as compared with the MCC samples. In the MCC yogurt samples there was significant ($P \leq 0.05$) decrease in RVA-viscosity, WHC and syneresis as enzyme level increased. TGase treatment was found to significantly ($P \leq 0.05$) affect the functionality of MCC and MPC in yogurt formulations.

Key Words: transglutaminase, MPC or MCC, yogurt functionality

W19 Adiponectin concentrations in cow milk during induced negative energy balance. S. P. Singh*[1], S. Häussler[1], J. J. Gross[2], R. M. Bruckmaier[2], and H. Sauerwein[1], *[1]Institute of Animal Science, Physiology and Hygiene Group, University of Bonn, [2]Veterinary Physiology, Vetsuisse Faculty University of Bern.*

Induced negative energy balance (NEB) in dairy cows decreased milk protein concentration. Fat mobilization during NEB may affect the concentrations of the adipokine adiponectin (Aq) in blood but also in milk. We therefore aimed to investigate the effect of a deliberately induced NEB on Aq concentrations in these body fluids. Multiparous Holstein cows (n = 21) were allocated to either a control (C, n = 10) or restriction (R, n = 11) group after 12 wk of lactation. Feeding in the preceding period and in the C group was according to the recommendations of Society of Nutrition Physiology. In R, an energy deficit was induced of at least 30% of the calculated requirements. Skim milk samples from 2 consecutive milkings each in wk 2, 12 and 17 of lactation (wk 17 = 2nd wk of R or C feeding) and plasma samples from these times were used. Milk protein content was assessed by infrared analyzer and Aq was measured by ELISA (Mielenz et al., 2013, Domest. Anim. Endocrinol.). The intra- and interassay variations were 4.5% and 11.9%. The limit of detection was 0.03 ng/mL. Assay accuracy was determined by linearity of serial samples dilutions. Milk Aq (μg/mL and ng/mg milk protein) were calculated and data (means ± SEM) were analyzed by Mixed Model (SPSS). Milk Aq concentrations (μg/mL) were higher in wk 2 than in wk 12 of lactation (0.88 ± 0.05 vs. 0.47 ± 0.03; $P < 0.001$). Numerically less Aq was observed in milk of R compared with C cows (0.43 ± 0.03 vs. 0.56 ± 0.06; $P > 0.05$); plasma Aq was not different between R and C. Across all animals in wk 12 and 17, milk Aq was correlated with plasma Aq (r = 0.342; $P = 0.026$). Blood Aq during this period was about 70 fold higher than in milk (35.02 ± 1.15 vs. 0.48 ± 0.02). When expressed as per mg of milk protein, Aq concentrations in wk 2 were also higher (1.7 fold) than in wk 12 ($P < 0.001$), and R animals had slightly lower concentrations (−15%, $P > 0.05$) than C cows. Our results indicate a significant decline in milk Aq both per volume and per mg milk protein as lactation advances. The lack of differences between the R and C group indicates that an induced NEB at this stage of lactation does neither affect Aq secretion nor transfer from blood to milk.

Key Words: adiponectin, milk, feed restriction

W20 Effect of transglutaminase treatment on the functionality of MPC and MCC: Imitation mozzarella cheese manufactured in twin screw cooker. P. Salunke*, C. Marella, and L. E. Metzger, *Dairy Science Department, Midwest Dairy Research Center, South Dakota State University, Brookings.*

A critical parameter in dairy based imitation mozzarella cheese (IMC) is the amount of intact casein provided by dairy ingredients in the formulation. From a functionality perspective, rennet casein is the preferred ingredient to provide intact casein in a formulation. However, the use of transglutaminase (TGase) has the potential to modify the physical properties of MPC or MCC and may improve its functionality in IMCs. The objective of this study was to determine the effect of TGase treatment of MPC and MCC retentates on the functionality of MPC and MCC when they are used in IMCs. Three lots of MCC and MPC retentate were produced using 3 different lots of pasteurized skim milk. Each replicate of retentate was divided into 3 equal portions. One portion of the retentate was treated with TGase at 0.3 units/g of protein, one portion was treated with TGase at 3.0 units/g of protein and one had no TGase addition. All the retentates were incubated for 25 min at 50°C, heat treated at 72°C for 10 min, cooled to 10°C and then spray dried. Each MCC and MPC was then used in IMC formulation that was standardized to 21% fat, 1% salt, 48% moisture, and 20% protein. In each formulation, the MPC or MCC utilized contributed all the protein. A preblend of all the ingredients (except lactic acid) was prepared (4.0 kg) in the Blentech twin-screw cooker by mixing at 50 rpm for 20 min at 20°C. The temperature of the preblend was then increased to 74°C over 5 min and held for an additional 4 min maintaining the auger speed of 120 rpm. The IMC formulation using either MCC or MPC treated with the highest TGase level did not form an emulsion. The IMC made from MCC treatments had significantly ($P \leq 0.05$) higher TPA-hardness and stretchability on pizza as compared with their respective MPC treatments. The IMC made from TGase treated MCC and MPC had significantly ($P \leq 0.05$) lower melt area, and significantly ($P \leq 0.05$) higher transition temperature and stretchability as compared with their respective controls. The study demonstrates that TGase treatment modifies the functionality of MCC and MPC in IMC applications.

Key Words: transglutaminase, MPC or MCC, IMC functionality

Fats, Fatty Acids, Oils, and Glycerin Supplementation I

W21 Investigation of microbial diversity in the feces of cattle fed different diets. M. Kim*[1], J. Kim[2], L. Kuehn[1], J. Bono[1], E. Berry[1], N. Kalchayanand[1], H. Freetly[1], A. Benson[2], and J. Wells[1], *[1]USDA, ARS, U.S. Meat Animal Research Center, Clay Center, NE, [2]University of Nebraska, Lincoln.*

Understanding of the bovine fecal microbiome could contribute to solving issues regarding animal production, cattle health and food safety. The objective of this study was to examine the influence of diet on the fecal microbiome in feedlot cattle. The next-generation pyrosequencing technology was used to investigate fecal microbiomes of 426 cattle fed one of 3 diets: finishing diet (83% dry-rolled corn, 13% corn silage, 4% supplement), late growing diet (66% dry-rolled corn, 26% corn silage, 8% supplement), and early growing diet (70% corn silage and 30% alfalfa haylage). A total of 2,149,008 16S rRNA gene sequences were obtained from 333 cattle with at least 2,000 sequence reads and classified into taxa using the RDP classifier. One-way ANOVA followed by Tukey's test was used to compare the mean abundance of a taxon among the 3 diet groups. *Firmicutes* was the first predominant phylum and accounted for more than 50% of total sequences in all 3 diet groups. *Bacteroidetes* was the second predominant phylum in the finishing and the late growing diet groups, while TM7 was the second predominant phylum in the early growing diet group. The genera *Fecalibacterium*, *Anaerovibrio*, *Prevotella*, *Parabacteroides* and *Pantoea* were significantly more abundant ($P < 0.0001$) in the late growing diet group than in other 2 groups, while the genera *Oscillibacter*, *Turicibacter*, *Coprococcus*, *Clostridium*, *Blautia*, *Lactobacillus* and *Subdoligranulum* were significantly more abundant ($P < 0.0001$) in the finishing diet group than other 2 groups. The abundance of the genera *Sporacetigenium*, *Anaerovorax*, *Propionibacterium* and *Akkermansia* was significantly higher ($P < 0.0001$) in the early growing diet than other 2 diet groups. A principal coordinates analysis of the unweighted UniFrac showed that bovine fecal microbiomes were separated based on diets. The present study indicates that diet has an effect on the fecal microbiome of cattle, particularly between cattle fed forage-rich and grain-rich diets. USDA is an equal opportunity provider and employer.

Key Words: 16S rRNA, microbiome, pyrosequencing

W22 Reproductive performance of beef heifers supplemented with saturated or unsaturated rumen bypass fat. N. M. Long*[1], T. A. Burns[1], S. K. Duckett[1], and D. W. Schafer[2], *[1]Department of Animal and Veterinary Science, Clemson University, Clemson, SC, [2]Department of Animal Science, University of Arizona, Tucson.*

Research on fat feeding to influence reproduction has shifted to feeding fat before and after breeding. Heifers (n = 118) were blocked by age, breed, and BW and pen fed alfalfa hay (4.5 kg/head/d). Heifers were individually fed an isocaloric supplement that contained 90% beet pulp and 10% molasses at 1.0 kg (C) or either 0.5 kg of the C with 0.2 kg of StratG (SG) or EnerGII (EG) fed 5 d/wk. Heifers received treatments for 3 wk before 7 d controlled intravaginal drug release (CIDR) synchronization followed by visual estrus detection. Blood samples were collected 3 times 4 d apart before CIDR insertion. Heifers were AI 12 h after estrus was detected and remained on treatment supplementation regimen for 28 d after CIDR removal. A blood sample was collected at the end of treatment. Pregnancy was determined d 30 post AI via transrectal ultrasonography. Serum progesterone (P4) and leptin were measured by RIA and serum triglycerides and cholesterol was measured by colorimetric procedures. Serum fatty acid (FA) profiles were measured by GLC. Serum lipids and hormones were analyzed using the MIXED model of SAS and binary reproductive data was analyzed using the GLIMMIX procedure. Heifers BW gain during supplementation was similar ($P = 0.35$) between treatment groups (32 ± 2 kg). Percent of heifers cycling (P4 > 0.75 ng/mg in any samples) tended to be less ($P = 0.08$) for SG heifers compared with the other treatments (36 vs 55 and 56%, SG, C and EG). Rates of estrus after PGF2α were similar ($P = 0.19$) between treatments (53, 69, and 77%, C, SG and EQ). AI pregnancy rates of heifers detected in estrus were similar ($P = 0.35$) between treatments (81, 77, and 63%, C, SG and EQ). Serum total and specific FA, cholesterol and triglycerides were different ($P < 0.05$) between treatments at d 21 and 56. Serum leptin was increased ($P < 0.05$) in both SG and EG at d 21 compared with C heifers. At d 56 of treatment, SG had greater ($P < 0.05$) plasma leptin compared with EG with C heifers having further reduced serum leptin concentration. Feeding rumen protected FA led to no changes in reproduction, but changed circulating lipid composition and leptin with differences between fat types.

Key Words: fats, heifer, serum fatty acid

W23 Effect of crude glycerin on carcass and meat characteristics of Nellore bulls. E. H. C. B. van Cleef[1], J. M. B. Ezequiel[2], A. P. D`Aurea[2], J. B. D. Sancanari[2], D. A. V. Silva[2], F. B. O. Scarpino[2], and R. M. P. Pardo*[3], *[1]Kansas State University, Manhattan, [2]São Paulo State University, Jaboticabal, São Paulo, Brazil, [3]Sucre University, Sincelejo, Colombia.*

A study was conducted to determine the effect of crude glycerin on carcass and meat characteristics of Nellore bulls. Thirty animals (277.7 ± 23.8 kg BW) were fed experimental diets for 82 d. Treatments consisted of a control diet containing 30% corn silage, 35% corn grain, 19.2% soybean hulls, 14.6% sunflower meal, and 1.2% supplement, and diets containing 7.5, 15, 22.5 or 30% glycerin (dry matter basis). Crude glycerin replaced corn grain and soybean hulls. Bulls were stratified in a randomized block design, by initial BW, and assigned randomly to 30 individual pens. Over a period of 21 d, bulls were transitioned from diets containing 20% concentrate to their respective 70% concentrate diets, using 4 step-up diets. Cattle were harvested on d 103, carcass data was collected 24 h post chill, and meat was sampled from the 12th rib. Data were analyzed using the MIXED procedure of SAS, with the animal considered as the experimental unit. Contrasts were used to determine the linear and quadratic effects of glycerin, and 0% glycerin × glycerin treatments. HCW (223.6 ± 7.6 kg), DP (53.4 ± 0.6%) LM (64.3 ± 3.3 cm^2), BF (3.8 ± 0.8 mm), carcass pH (6.1 ± 0.1), and commercial cuts weights were not affected ($P > 0.05$) by the addition of crude glycerin to the diets. The estimated body fat was 2.85% greater ($P \leq 0.05$) for treatments with glycerin. There were no difference on meat color (L* = 32.6 ± 2.2; a* = 12.3 ± 0.8; b* = 3.2 ± 0.6), shear force (4.4 ± 0.5 kgf/cm^2), cooking loss (32.4 ± 2.2%), and water-holding capacity (74.4 ± 2.1%), however, the cholesterol content of meat was decreased ($P \leq 0.05$) from 36.8 mg/g (control) to 27.0 mg/g (30% glycerin). Feeding up to 30% crude glycerin to Nellore bulls can increase meat quality, decreasing cholesterol content without depreciating carcass characteristics.

Key Words: biodiesel, carcass, feedlot cattle

W24 Effect of essential oils, monensin, and tylosin on performance and carcass characteristics of finishing heifers. J. S. Schutz*[1], M. L. Hubbert[1], C. J. Redding[1], J. D. Caballero[2], P. J. Guiroy[3], and C. A. Loest[2], *[1]Clayton Livestock Research Center, New Mexico State University, Clayton, [2]Animal and Range Sciences, New Mexico State University, Las Cruces, [3]Cargill Incorporated, Minneapolis, MN.*

Public perception regarding antimicrobial drug use in animal diets has increased investigations of alternative natural plant extracts to modify ruminal fermentation and potentially improve efficiency of feed utilization. This study evaluated the effects of plant extract products containing essential oils (EO) on performance and carcass traits of feedlot heifers fed diets with or without monensin and tylosin. Crossbred yearling heifers (n = 662; initial BW = 324 ± 3 kg) were assigned to 36 pens (18 or 19 heifers/pen) in a randomized complete block design (blocked by BW). Six treatments, in a 2 × 3 factorial arrangement, were finishing diets with (MED) or without (NON-MED) added monensin (300 mg/d) plus tylosin (90 mg/d), and top-dressed with a pellet (230 g/d) containing either plant extract-A (EOA; 300 mg/d active product), plant extract-B (EOB; 250 mg/d active product), or no EO (CON). Statistical analysis used the mixed procedure of SAS and orthogonal contrasts. Antimicrobial drug × EO interactions were not significant ($P > 0.15$). Heifers fed MED diets had similar ($P = 0.21$) ADG (1.48 vs. 1.46 ± 0.02 kg/d), lower ($P < 0.01$) DMI (8.11 vs. 8.29 ± 0.11 kg/d), and greater ($P < 0.01$) G:F ratio (0.183 vs. 0.176 ± 0.001) than heifers fed NON-MED diets during 134 (3 blocks) and 135 (3 blocks) DOF. Carcasses of heifers fed MED diets had lower ($P = 0.04$) marbling scores, and tended to have greater ($P = 0.14$) LM area than those fed NON-MED diets. Heifers receiving EOA and EOB had a tendency for lower ($P = 0.11$) carcass-adjusted ADG, a tendency for greater ($P = 0.12$) DMI from d 0 to 84 (and numerically greater DMI overall), and lower ($P = 0.07$) G:F ratio than those receiving CON. Heifers given EOA had a tendency for more ($P = 0.11$) carcasses to grade choice or better than those receiving CON (51.6% vs. 43.6%). Results indicated that the essential oils evaluated in this study were not as effective as monensin and tylosin for improving feed efficiency. Supplementing feedlot finishing diets with EOA could possibly improve quality grade.

Key Words: essential oil, antimicrobial, beef cattle

W25 Traditional and novel feed additives for beef cattle. F. G. Ribeiro*[1,2], C. C. Coutinho[1,2], D. C. Rivaroli[1,3], A. Cominotte[1,4], E. Rodrigues[1], A. M. Jorge[1], E. A. Filgueiras[5,2], and R. D. Sainz[6,7], *[1]Universidade Estadual de São Paulo, Botucatu, SP, Brazil, [2]CAPES - Coordenação de Aperfeiçoamento de Pessoal de Nível Superior, Brasília, DF, Brazil, [3]CNPq - Conselho Nacional de Desenvolvimento Científico e Tecnológico, Brasília, DF, Brazil, [4]FAPESP - Fundação de Amparo à Pesquisa do Estado de São Paulo, São Paulo, SP, Brazil, [5]Universidade Federal de Goiás, Goiânia, GO, Brazil, [6]Embrapa, Goiânia, GO, Brazil, [7]University of California, Davis.*

Four diets were fed to 64 crossbred heifers (predominantly Angus and Red Angus) for 28 d (adaptation) plus 95 d (experimental). Treatments consisted of: C, Control diet; B, Control diet plus a probiotic + prebiotic premix (Bioformula, 2 g/day); M, Control diet plus Rumensin (120 mg monensin/day);BM, Control diet plus a combination of these 2 additives (Biofórmula + Rumensin). The concentrate:forage of the diet was 25:75 on a dry matter basis. Animals were weighed individually every 28 d after 12 h feed withdrawal. Feed offered was monitored daily, and feed refusals collected and weighed every 2 d. All animal care procedures were conducted according to the regulations of the Brazilian National Council on Control of Animal Experimentation (CONCEA). Performance variables were analyzed using the GLM procedure of Minitab (Minitab, Inc., State College, PA, USA). Body weight data were analyzed by analysis of covariance, with treatment as a main effect, and days on feed as a covariate, with animal nested within treatment included as a random effect to correct for auto-correlation of repeated measures in the same animal. Individual feed intakes were estimated using the methodology of Perry and Fox (1997; J. Anim. Sci. 75:300–307). Estimated feed intakes were similar among treatments (9.91, 9.90, 9.83 and 9.81 kg/day for C, B, M and BM, respectively; $P > 0.10$). However, ADG were greater in animals fed diets containing feed additives relative to controls (1.280, 1.322, 1.319 and 1.397 kg/day for C, B, M and BM, respectively; $P = 0.054$. Likewise, these feed additives improved feed efficiency relative to controls (0.129, 0.134, 0.139 and 0.143 for C, B, M and BM, respectively; $P < 0.001$). We conclude that supplementation with probiotics and prebiotics has potential to improve the performance of beef cattle, and that these effects are additive with those obtained using ionophores.

Key Words: probiotic, ionophore, feedlot

W26 Effect of essential oils (Next Enhance 300) on fermentation characteristics of rumen microbiota in continuous culture. N. F. Johnson*[1], M.C. Westerhold[1], M. S. Kerley[1], W. J. Sexten[1], and T. J. Wistuba[2], *[1]University of Missouri, Columbia, [2]Novus International Inc., St. Charles, MO.*

Antibiotics and ionophores are used to improve feed efficiency by modifying rumen fermentation. Public concern with antibiotic use has increased interest in alternative modifiers. Essential oils are naturally occurring volatile plant compounds reported to improve ruminant N and/or energy utilization via rumen modification. Next Enhance 300 (NE, Novus International Inc.) is a combination of garlic (diallyl disulfide) and cinnamon (cinnamaldehyde) extracts which have demonstrated the ability to modify rumen fermentation. The objective of this experiment was to evaluate fermentation characteristics of rumen microbiota in continuous culture as NE inclusion increased. Treatment levels of 0, 15, 30, 60, 120, and 240 mg/kg DM were added to a corn (60.3%) and DDG (24.3%) diet. Two continuous culture fermentation runs were conducted using dairy cow rumen fluid inoculum. Fermenters were acclimated for 4 d followed by 3 d collections. Fermenter pH was measured and sampled at 0, 4, 8, and 12 h post feeding with daily effluent collection. Run was treated as a block with the experiment analyzed statistically as a randomized complete block. NE did not affect ($P > 0.59$) microbial efficiency, ammonia, pH, or VFA concentrations. Increasing NE inclusion quadratically increased ($P < 0.05$) OM and CP digestibility. Microbial nitrogen flow responded quadratically, but was not significant ($P = 0.29$). Inclusion of NE at 30 and 60 mg/kg DM resulted in maximal OM and CP digestibility. Based on these results, it was concluded that Next Enhance 300 could affect ruminal fermentation of low fiber corn based diets by increasing digestibility and microbial protein flow from the rumen. The next step will be to determine the mechanism by which NE results in greater fermentation activity.

Key Words: essential oil, feed efficiency, rumen fermentation

W27 Supplementation of rumen-protected PUFA in corn-fed beef steers. C. M. Warner*, S. L. Archibeque, T. E. Engle, J. J. Wagner, D. R. Woerner, I. N. Roman-Muniz, and H. Han, *Colorado State University, Fort Collins.*

Rumen bypass fat is commonly added to increase energy intake in dairy cattle. The objective of this study is to examine the addition of rumen bypass fat during finishing period on performance and carcass charac-

teristics in grain fed steers. This study was conducted as a completely randomized block design with 126 cross-bred steer calves (initial BW 529.5kg ± 10.7) randomly assigned to pens with 9 steers/pen (n = 7 pens / treatment). Each pen was randomly assigned to one of 2 treatment groups; the rumen bypass fat treatment (BF) and the control diet (CON). The diets were formulated to be isonitrogenous and isocaloric. Animals were fed twice daily at 110% of the previous daily ad libitum intake. Feed bunks were cleaned and orts were collected weekly. DM content was analyzed and diet samples were collected weekly for proximate analysis. Feedlot performance and carcass characteristics were assessed. Steers fed the CON diet had a greater level of performance for most of the parameters measured. The CON treatment had greater DMI (10.14 kg vs. 8.77 kg; $P < 0.02$) and tended to have greater ADG (1.699 kg vs. 1.469 kg; $P < 0.09$). Hot carcass weight was not significantly different between treatments ($P < 0.19$). Marbling score ($P < 0.04$) and quality grade ($P < 0.02$) were greater for steers fed the CON diet than those fed BF. The L. dorsi area tended to be greater ($P < 0.10$) in steers fed CON (87.60 cm^2) than those fed BF (84.88 cm^2). Gain:feed was slightly increased for the BF treatment group, but was not significant ($P < 0.74$). These data suggest that rumen bypass fat can be added to finishing diets without significant reduction in final body weight, although there may be modest reductions in marbling and quality scores. More research is needed to elucidate the potential mechanism for these reductions.

Key Words: bypass fat, fatty acid composition, PUFA

W28 Effects of extracts of cashew nut shell and castor oil on in vitro ruminal fermentation, gas production kinetics, and methane production. C. T. Marino[2], M. J. Ruiz-Moreno[1], T. M. Schulmeister[1], F. M. Ciriaco*[1], D. D. Henry[1], V. R. G. Mercadante[1], G. C. Lamb[1], and N. DiLorenzo[1], *[1]North Florida Research and Education Center, University of Florida, Marianna, [2]Universidade de São Paulo, FMVZ, Pirassununga, Brazil.*

Extracts of cashew nut shell oil contain anacardic acid, cardol and cardanol, which have been reported to have antimicrobial and antioxidant activity. Ricinoleic acid, one of the fatty acids from castor oil has been reported to have antimicrobial activity similar to that of ionophores. The objective with this study was to evaluate the effects of a mixture of extracts (EX) of cashew nut shell oil and castor oil on in vitro ruminal fermentation parameters, gas production kinetics and methane production. Two incubation substrates (80% concentrate and 100% forage) and 4 doses of EX (0, 40, 80 and 120 mg/L of fermentation fluid) were tested in a randomized complete block design with a 2 × 4 factorial arrangement of treatments. Incubations were conducted for 24 h in 3 d (replicates) with duplicate bottles each day and a 2:1 ratio of buffer:ruminal fluid. Total gas produced was collected in gas sampling bags and analyzed for methane and H_2S concentration. No effect ($P > 0.10$) of EX dose or diet x EX dose interaction was observed for any of the variables. Total gas production and fractional rate of gas production was greater ($P < 0.01$) for concentrate vs. forage substrate. Concentrate substrate had greater ($P < 0.01$) IVDMD (62.0 vs. 56.8%) and methane production (1.91 vs. 1.30 mmol) than forage. Concentration of NH_3-N in the incubation fluid was greater (7.0 vs. 5.2 m*M*; $P < 0.01$) in forage vs. concentrate substrate, likely as a result of N concentration in the incubation substrate. In conclusion, adding up to 120 mg/L of a mixture of extracts from cashew nut shell and castor oil did not affect in vitro ruminal fermentation or methane production in forage- or concentrate-based incubation substrates.

Key Words: fermentation, cashew nut, castor oil

W29 Production performance parameters of early lactation dairy cows fed a diet supplemented with Megalac or a fatty acid prill containing high levels of palmitic acid. E. Block*[1], L. Kung[2], and C. Merrill[2], *[1]Arm & Hammer Animal Nutrition, Princeton, NJ, [2]University of Delaware, Newark.*

Megalac (Church & Dwight Co. Inc., Princeton, NJ) calcium salts of fatty acids (palmitate 45%; oleate 37%; linoleate 6%; stearate < 3%; other fatty acids < 10%) was compared with a high palmitic acid fatty acid prill (Guarantee-palmitate (min) 80%; stearate 4–7%; oleate 8–12%; other fatty acids <5.5%), in an early lactation feeding trial for 10 wk. Thirty multiparous cows (average of 45 DIM) were randomly assigned to 1 of 2 rations identical except for supplemental fat. Fat sources were supplemented on an equal fatty acid basis and were 1.2% of total DM added fatty acids. Daily milk weights and DMI were averaged by week. Milk components were assessed twice weekly, and these were averaged by week. All cows were placed on a common diet for one week before initiation of the trial. All data except body weight was analyzed using a GLM, with treatments as fixed effects, cows as the experimental unit (fixed) and replicated by weeks (random). Because there were no differences in pre-trial performance ($P > 0.05$) between the 2 groups of cows, covariate analysis was not used. Body weights were analyzed as one way ANOVA. Results are provided in the table that follows. Milk and milk component yields were greater with Megalac than with palmitic fatty acid prill. Feed efficiency was also higher with Megalac. Although cows fed palmitic fatty acid prill gained more weight than cows provided with Megalac, weight changes were variable and failed to reach significance. Based on results we conclude that different fatty acids have different digestibilities, absorption and/or differing biological effects post absorption.

Table 1. Daily production parameters and body weight (BW) change over 10 wk for cows fed Megalac or a high palmitic acid fatty acid prill

Variable	Megalac	Palmitic prill	SEM	$P > F$
DMI, kg	28.08	27.89	0.189	0.496
Milk, kg	45.53	42.26	0.435	<0.001
Fat, kg	1.95	1.74	0.026	<0.001
Protein, kg	1.35	1.26	0.013	<0.001
Lactose, kg	2.14	1.98	0.022	<0.001
Solids, kg	5.82	5.37	0.061	<0.001
3.5% FCM, kg	51.32	46.61	0.573	<0.001
FCM/DMI	1.84	1.68	0.020	<0.001

BW change, kg	24.3	37.3	6.35	0.317

Key Words: fat supplementation of cows, Megalac, palmitic acid

W30 Effect of feeding milk fat rich in conjugated linoleic acid on immune response in BALB/c mice. D. P. Bu, R. C. Zhang, and J. Q. Wang*, *State Key Laboratory of Animal Nutrition, Institute of Animal Science, Chinese Academy of Agricultural Sciences, Beijing, China.*

Conjugated linoleic acid (CLA) has been shown to have immunoenhancing properties in mice. We examined the influence of milk fat enriched with CLA on the immune response of BALB/c mice. Seventy 2 BALB/c mice (female 36, 6 mo, BW 18–22g) were housed in 12 cages (n = 6) at constant temperature (22 ± 2°C) and were fed with a normal diets ad libitum, free access to water. Mice were infused either 0.4 mL of saline solution (CK), normal milk fat (P), milk fat enriched with CLA (CLA, contains c9t11CLA of 2.77mg/g fat from cows supplemented with sunflower oil), Immunosuppression induced by cyclophosphamide (Cy), Cy plus normal milk fat

(CyP) or Cy plus milk fat enriched with CLA (CyCLA) through syringe. Mice in CK, P, CLA also received 0.3 mL intraperitoneal saline solution injection while mice in Cy CyFAT, CyFLA received intraperitoneal injection of 0.3 mL cyclophosphamide solution (30 mg/kg BW) every 5 d. Body weight of each mouse was recorded weekly. After 35 d feeding, all mice were killed by cervical dislocation. Spleen and thymus were removed and weighed. The abdomen splenocytes lymphocyte transformation test was conducted by MTT assay to concanavalin A (Con A) (10 mg/L). Compared with CK, weight of spleen and thymus in P and CLA increased ($P < 0.05$). However, mice induced with cyclophosphamide decreased spleen and thymus weight ($P < 0.05$). Ratios of spleen and thymus weight to body weight were not different among treatments. Mice infused with milk fat had greater lymphocyte transformation in response to Con A ($P < 0.05$) than those in control. ConA index were 1.56^{c}, $.98^{b}$, 2.71^{a} in CK, P, CLA and 1.30^{c}, 1.70^{b}, 2.06^{a} in Cy, CyP, CyCLA, respectively. Our results suggest that milk fat enriched with CLA improves some immune responses.

Key Words: milk fat, CLA, immune response

W31 Does supplementing essential fatty acids in the late gestation and the preweaning periods influence future productivity of Holstein heifers? M. Garcia*, L. F. Greco, W. W. Thatcher, J. E. P. Santos, and C. R. Staples, *University of Florida, Gainesville.*

Information on the effect of feeding of long-chain fatty acids (LCFA) on future offspring productivity is lacking. Holstein cows (n = 96) were fed (1) no fat supplement (control; 2.3% dietary fat), (2) hydrogenated LCFA (SFA, Energy Booster 100, Milk Specialties, Eden Prairie, MN; 1.7% of dietary DM), or (3) Ca salts of LCFA containing essential LCFA (EFA; Megalac-R, Arm and Hammer Animal Nutrition, Princeton, NJ; 2.0% of dietary DM) from dry-off to calving. Heifers (n = 56) born from these cows were fed a milk replacer (MR) of low linoleic acid (LLA. 0.56% LA, DM basis) or high LA (HLA, 1.78% LA, DM basis) during the first 60 d of life. A single grain mix was offered between 31 and 60 d of life. Performance of replacement heifers that went on to complete at least 290 DIM (n = 33) was evaluated. Diets did not affect culling rate. Body weight at birth was not influenced by dam diet but ADG for the first 60 d of life was greater for heifers born from dams fed SFA vs. EFA (0.45, 0.48, and 0.42 kg/d for heifers born from control, SFA-, and EFA-fed dams, respectively). Sixty-day intake of LA averaged 6.2 and 12.1 g/d for LLA and HLA heifers, respectively. Type of MR did not influence ADG (0.45 vs. 0.45 kg/d) during the first 60 d of life. After weaning and during the first lactation, heifers were fed diets formulated to meet nutritional requirements. Heifers born from dams supplemented with either fat source (control vs. (SFA + EFA)), tended to have a greater number of AI at first conception (2.6 vs. 1.7, $P = 0.06$) and were older at first calving (24.2 vs. 22.9 mo, $P = 0.02$). Heifers born from dams fed fat prepartum produced more ($P = 0.02$) mature equivalent milk during their first lactation (10,605 ± [CS1] 458, 11,745 ± 486, and 12,559 ± 568 kg for heifers born from control (n = 13), SFA- (n = 11), and EFA-fed dams (n = 9), respectively). Heifers fed HLA MR did not produce more milk than those fed LLA MR (12,011 ± 423 vs. 11,262 ± 403 kg). Fat supplementation during the last 2 mo of pregnancy can "program" calves in utero to produce more milk during their first lactation.
[CS1]Special key strokes

Key Words: heifer, fatty acid, fetal programming

W32 Performance and health responses of dairy calves offered different milk replacer allowances. A. Bach*[1,2], M. Terré[2], and A. Pinto[2], *[1]ICREA, Institut de Recerca i Estudis Avançats, Barcelona, Spain, [2]Department of Ruminant Production, IRTA, Caldes de Montbui, Spain.*

Eighty female Holstein calves (12 ± 4 d old and 41.7 ± 4.3 kg of BW) were blocked by age and assigned to either a maximum of 6 L/d daily milk replacer (MR) allowance (LMR) or a 8 L/d (HMR). Calves were kept individually until 52 d of age and then moved into pens forming groups of 10. Al calves had ad libitum access to a mash starter feed (20.4% CP, 18.5% NDF). Calves in the LMR group received 6 L of MR/d in 3 separate doses whereas calves in the HMR received 8 L of MR/d also distributed in 3 separate feedings. At 52 d of age, calves were moved to pens and pre-weaned by offering 2 L of the same MR/calf twice daily in a trough until the age of 59 d, when MR was further reduced to a single dose of 2 L until the age of 73 d when all calves were weaned. Individual starter feed and MR consumption was recorded on a daily basis until 52 d of age, and on a group-basis until weaning time. Body weight was measured at the beginning of the study and at 52 (pre-weaning), 73 (weaning), 110, 160, and 228 d of age. Data from entrance until pre-weaning were analyzed using an ANOVA (n = 40). The data from pre-weaning to completion of study were analyzed using a 2-level mixed-effects model that accounted for the dependence of calves within pen (n = 4). Solid feed consumption was greater ($P < 0.01$) in LMR (821 ± 42.1 g/d) than in HMR calves (462 ± 42.1 g/d) between 42 and 52 d of age (pre-weaning). Solid feed consumption increased, and LMR showed a more ($P < 0.001$) marked increase than HMR calves. However, HMR calves grew faster ($P < 0.05$) than LMR calves (805 vs. 703 ± 30.7 g/d, respectively) until pre-weaning time, but from pre-weaning to weaning, LMR calves grew more ($P < 0.05$) than HMR calves (977 vs. 857 ± 30.7 g/d, respectively). No differences in feed efficiency and incidence of disease were observed between treatments. It is concluded that before pre-weaning, HMR calves grow more than LMR calves, but between pre-weaning and weaning, LMR grow more than HMR calves overcoming the difference in BW at pre-weaning. As a result, there are no differences in BW at weaning and at 228 d of life and no differences in incidence of disease.

Key Words: efficiency, intake, starter

W33 Consequences of essential oils (cinnamaldehyde and garlic oil) on rumen fermentation and performance of lactating dairy cattle. M. Blanch*[1], A. Viso[1], and A. Bach[2,3], *[1]Novus International Inc., St Charles, MO, [2]ICREA, Barcelona, Spain, [3]Department of Ruminant Production, IRTA, Caldes de Montbui, Spain.*

The objective of this study was to determine the effect of Next Enhance 300 (NE300; cinnamaldehyde and garlic oil encapsulated product) on rumen fermentation and milk production of dairy cows. Sixteen lactating dairy cows (8 rumen-cannulated) participated in a switch-back design with three 4-wk periods and 2 treatments: control (unsupplemented) and NE300 (300 mg NE300/cow/d). Cows were housed in 2 different pens (blocked for parity, DIM, and level of milk production) and received the same TMR diet (16.0% CP, 31.4% NDF). Individual milk production and feed intake were collected throughout the study. All cows were sampled for milk components (fat, protein, lactose, urea, and SCC) on d 0, d 7, d 14, d 21, d 27, and d 28. Cannulated animals were used to collect rumen fluid to determine VFA and ammonia-N concentrations and monitor rumen pH using indwelling pH probes for 3 consecutive days within period. On d 28, rumen samples were collected at 0, 2, 4, 6, and 8 h after the morning feeding. In addition, cows were blood-sampled to determine glucose and insulin concentrations on d 0, d 7, d 14, d 21, and d 28 at 4 h after the morning feeding. Data were analyzed using a mixed-effects model with time entering the model as a repeated measure using each cow within period and treatment as subject. Period and sequence had no effect on any dependent variable measured. In terms of milk yield, there was a significant triple interaction ($P < 0.05$) between treatment, parity, and days on treatment; basically, after 15 d on treatment, multiparous cows

on NE300 produced more milk (approximately 3 kg/d) than multiparous cows on control. Overall feed efficiency was numerically greater (P = 0.11) in NE300 than in control cows (1.46 and 1.33, respectively). In general, blood and rumen parameters were not affected by treatments. Results of this study indicate that NE300 could be an alternative to increase milk yield and feed efficiency in lactating dairy cows.

Key Words: essential oil, dairy cow

W34 Milk fatty acid profile in dairy cows fed with fatty acids unsaturated sources. R. V. Barletta*[1], J. E. Freitas Jr.[1], M. D. S. Oliveira[2], R. Gardinal[1], V. G. C. Lacuna[1], V. P. Bettero[2], B. C. Benevento[1], B. C. Venturelli[1], E. Ferreira de Jesus[2], G. D. Calomeni[1], J. R. Gandra[1], and F. P. Rennó[1], *[1]University of São Paulo, São Paulo, SP, Brazil, [2]University Jlio de Mesquita, Jaboticabal, SP, Brazil.*

The aim of this study was to evaluate the milk fatty acid profile in dairy cows supplemented with unsaturated fatty acids sources. Eight Holstein cows in the mid lactation (80 ± 20 d in milk; mean SD) cannulated in the rumen and abomasums (580 ± 20 kg of weight; mean ± SD) with milk yield of 25 kg/d were assigned randomly into two 4 × 4 Latin squares, fed the following diets: (1) control (C); (2) refined soybean oil (SO) (inclusion of 3% in the total dry matter); (3) whole soybean raw (WS) (inclusion of 16% in the total dry matter); and (4) calcium salts of unsaturated fatty acids (CSFA) (inclusion of 3% in the total dry matter). Milk yield and the dry matter intake were measured daily throughout the experimental period. The milk samples used for evaluating fatty acids profile were obtained at the 16th day of each experimental period, each sample coming from the 2 daily milkings, and were quantified by gas chromatography (Shimadzu GC 2010). Data were analyzed using PROC MIXED of SAS 9.1 according with the orthogonal contrasts (C vs. SO + WS + CSFA), (SO vs. WS + CSFA) and (WS vs. CSFA). No effect of sources of fat in the diets on fatty acid concentrations of short, medium and long chain, varying the carbon number of 6 to 18, total C18 saturated, fully unsaturated C18, and total of saturated and unsaturated (P < 0.05). The concentrations of the isomers C18: 1 *trans*-11 (vaccenic acid), CLA *cis*-9,*trans*-11 CLA and *trans*-10,*cis*-12 were not altered by the experimental diets. No effect was observed in the fat sources used in this study on the profile of fatty acids in milk.

Key Words: linoleic acid, abomasum, whole soybean

W35 Incorporation of n-6 and n-3 fatty acids into plasma lipid fractions of lactating cows: acute effect of abomasal infusions of linoleic and linolenic acids. L. C. Nagengast*, C. L. Preseault, J. C. Ploetz, C. M. Klein, and A. L. Lock, *Michigan State University, East Lansing.*

The effect of abomasal infusions of linoleic (18:2) and linolenic (18:3) acids on the concentration of n-6 and n-3 fatty acids (FA) in plasma lipid fractions over a 24-h period were evaluated in a repeated measures design. Six rumen-fistulated Holstein cows (252 ± 33 DIM and 44 ± 6 kg milk/d) were randomly assigned to 1 of 2 FA treatments. Treatments were abomasal infusions (67 g/d of total FA) of (1) n-6 FA blend (N6) providing 43 g/d 18:2 and 8 g/d of 18:3; or (2) n-3 FA blend (N3) providing 43 g/d 18:3 and 8 g/d 18:2. FA were provided by infusion at 6 h intervals over 24 h. Blood samples were collected on d −2, d −1, and 0 h before the first infusion and 1, 3, 6, 12, and 24 h after initiation of infusions. FA concentration of plasma phospholipids (PL), cholesterol esters (CE), triglycerides (TG), and NEFA was determined. Data were analyzed using PROC MIXED in SAS with hour as the repeated measure. Total FA in each fraction was not altered by treatment. There were marked differences in the FA composition of the individual plasma fractions and in the distribution of n-6 and n-3 FA among fractions. N3 increased the concentration of 18:3 and total n-3 FA in TG, NEFA, and PL (P < 0.01). In TG and NEFA the concentration of 18:3 was highest at 3 h with a 126 and 76% increase compared with N6, respectively (P < 0.001). In PL, 18:3 concentrations started to increase at 3 h, and continued to increase to 24 h when it was 175% higher compared with N6 (P < 0.001). There was a trend for N3 to increase the concentration of 18:3 in CE (P = 0.08), which was 23% higher compared with N6 at 24 h (P < 0.001). Treatment did not affect the concentration of 18:2 or total n-6 FA in TG, NEFA, or CE (P > 0.20), with a trend for N6 to slightly increase the concentration of 18:2 in PL (P = 0.09). Results demonstrate that within 24 h of abomasally infusing 18:3 the concentration of n-3 FA in plasma TG, NEFA, and PL was increased; however, no such increases were observed for n-6 FA in these fractions with 18:2 infusion over a 24-h timeframe.

Key Words: dairy cow, plasma lipid, polyunsaturated fatty acid

W36 Performance, intestinal modulation and blood parameters of calves supplemented with an essential oils blend. F. H. R. Santos[1,2], M. R. Paula*[1,4], D. Lezier[1,3], J. T. Silva[1,3], G. Santos[1,3], and C. M. M. Bittar[1,3], *[1]ESALQ/USP, Piracicaba, Sao Paulo, Brazil, [2]Fapesp, Sao Paulo, Sao Paulo, Brazil, [3]CNPq, Brasilia, DF, Brazil, [4]Capes, Brasilia, DF, Brazil.*

The objective was to evaluate the use of an essential oils blend (EO) via milk-replacer or starter concentrate, with regard to improvements in overall performance and occurrence of diarrhea, as well as intestinal microbiota and blood parameters of calves until 10 weeks of age. The blend of essential oils (Activio Grasp) consisted of cinnamon essential oil, rosemary, oregano and pepper extract. Twenty-seven calves from 1 to 4 d of age were distributed in a randomized block in the following treatments: Control = No EO; MR = 400 mg/kg of EO in milk replacer; and MRS = 200 mg/kg of EO in milk replacer and 200 mg/kg of EO in concentrate starter. Animals were individually housed, received 6 L of milk-replacer/d (20:16; Sprayfo Violeta, Sloten do Brasil Ltda) in 2 meals, and had water and starter concentrate (18% CP; 80% TDN) free-choice. Fecal scores and starter intake were evaluated daily. From the second week until the 10th week of life blood parameters were determined from weekly drawn blood samples. Fecal samples were collected weekly for enterobacteria enumeration. Treatments comparisons, as well as, orthogonal contrast (control vs. MR+MRS) show that feeding EO in milk replacer or starter concentrate did not affect (P > 0.05) performance, blood parameters or intestinal modulation (Table 1).

Table 1. Performance, fecal score and blood parameters of calves supplemented with EO

	Treatment[1]				P <	
	C	MR	MRS	EPM	T	C vs. OE
Starter intake, g/d	589.10	545.70	450.93	55.9	0.205	0.235
Live weight, kg	50.68	43.32	46.61	1.5	0.179	0.185

W37 Glycerol to improve alfalfa utilization: Effects on in vitro gas production and microbial protein synthesis. Á. R. Alfonso Ávila*[1,2], É. Charbonneau[2], C. Lafrenière[1], and R. Berthiaume[3], *[1]Agriculture and Agri-Food Canada, Sherbrooke, Qc, Canada, [2]Département des Sciences Animales, Université Laval, Québec, Qc, Canada, [3]Valacta, Ste-Anne-de-Bellevue, Qc, Canada.*

The increased production of biodiesel in recent years has renewed the interest for the use of glycerol as an energy source in livestock diets. However, when it comes to assessing glycerol in association with forages, data are scarce. The objective of this project is to determine if interactions between glycerol and forages do exist. A 2 × 3 factorial design which consisted of 2 non-structural carbohydrate (NSC) concentrations in alfalfa (high [HNSC] or low [LNSC]) and 3 glycerol treatments (control, 15% crude glycerol [CG] and 15% pure glycerol [PG]), plus one additional treatment (AT: LNSC with 5% sucrose + 5% starch) were evaluated. Five pre-planned contrasts were tested using the 7 treatments: 1) HNSC vs. LNSC alfalfa; 2) with vs. without glycerol; 3) interaction alfalfa and glycerol; 4) CG vs. PG and 5) AT vs. HNSC. Last contrast verified if the addition of exogenous sugars to LNSC had the same effects as feeding HNSC alfalfa. Using in vitro 24-h batch culture with rumen fluid, incubations were performed in triplicates and measured gas production each 10 min for a total of 24 h, whereas ammonia, pH, volatile fatty acids, microbial N (MN) and microbial mass (MM), in vitro DM and NDF, and in vitro true digestibility (IVTD) were determined after 24 h. Statistical differences were declared at $P \leq 0.05$. A decrease in the acetate:propionate ratio was observed with HNSC in comparison to LNSC (2.87 vs. 3.27) and with the addition of glycerol vs. no glycerol (2.78 vs. 3.65). No interaction was observed between alfalfa type and glycerol. Glycerol had no effect on IVTD. Reductions in MM (185.5 vs. 240.5 mg/g DM) and MN production (16.8 vs. 25.8 mg/g of OM apparently digested) were observed with CG in comparison to PG. Also CG tended to produce more CH_4 after 24 h, which agrees with the larger acetic acid production found for CG in comparison to PG. The AT had lower microbial protein synthesis and propionic acid production in relation to HNSC. Although no effect was observed for the degradation and metabolism of alfalfa when using glycerol, results clearly show that the rumen does not respond as well to the addition of CG vs. PG.

Key Words: forage, glycerol

W38 Effect of feeding reduced fat dried distillers grains with solubles on lactation performance of Holstein cows. E. Castillo-Lopez*[1], K. M. Algya[1], T. J. Klopfenstein[1], D. Hostetler[1], K. Karges[2], S. C. Fernando[1], and P. J. Kononoff[1], *[1]University of Nebraska-Lincoln, Lincoln, [2]Dakota Gold Research Association, Sioux Falls, SD.*

The objective of this experiment was to evaluate the effect of feeding reduced fat dried distillers grains with solubles (RFDG) on milk production and milk composition. Twelve multiparous lactating Holstein cows (mean and SD, 89 ± 11 DIM and 674 ± 68.2 kg BW) were randomly assigned in 4 × 4 Latin squares over 21-d periods. Treatments (DM basis) were (1) CONTROL, 0% RFDG; (2) 10% RFDG; (3) 20% RFDG; and (4) 30% RFDG. Cows were milked twice daily at 0730 and 1930 h. Milk production was recorded daily and milk samples were collected during the AM and PM milkings of d 19, 20 and 21 of each period for analysis of milk components. Cows were fed once daily at 0930 to allow for approximately 5% refusals and were allowed access to feed at all times except during milking. Total DMI increased linearly ($P < 0.01$) with the inclusion of RFDG, with estimates of 25.0, 23.8, 25.9 and 27.9 ± 1.38 kg/d for CONTROL, 10, 20 and 30% RFDG, respectively. Milk yield was not affected ($P = 0.78$) by increasing levels of RFDG and averaged 34.0 ± 1.29 kg/d. The percent of milk protein tended ($P = 0.07$) to increase with RFDG inclusion with estimates of 3.08, 3.18, 3.15, and 3.19 ± 0.06% for CONTROL, 10, 20 and 30% RFDG treatments, respectively. The yield of milk protein, however, was similar ($P = 0.23$) across treatments with an average of 1.05 ± 0.04 kg/d. The percent ($P = 0.66$) and the yield ($P = 0.53$) of milk fat were not affected by treatment and averaged 3.66 ± 0.09% and 1.24 ± 0.05 kg/d across treatments, respectively. Results of this experiment indicate that dairy rations can be formulated to include up to 30% RFDG while maintaining lactation performance, demonstrating that RFDG is an effective alternative energy and protein feed source for the dairy industry.

Key Words: by-product, dairy, lactation

W39 Use of crude glycerin for dairy cows. M. I. Marcondes*[1], T. R. Pereira[1], M. Valverde da Silva[2], T. E. da Silva[1], A. S. Trece[1], and W. L. Cardoso[1], *[1]Universidade Federal de Viçosa, Viçosa, Minas Gerais, Brazil, [2]Master Alimentos LTDA, Rio Pomba, Minas Gerais, Brazil.*

The current concern about global warming, and the increasing share of biodiesel in the global energy matrix have increased interest in cultivation and processing of oil seeds. Therefore, this study aimed to evaluate the inclusion of crude glycerin replacing corn grain for medium-low production dairy cows. Twelve Holstein cows were distributed into three 4 × 4 Latin squares, according to milk production. Animals were fed 70% corn silage in dry matter basis, plus concentrate. Corn was replaced in the concentrate by a mixture of crude glycerin and a protein corn co-product called Mazoferm, in the proportion of 0, 33, 66, and 100% in dry matter basis, and those represented inclusions of 0, 4, 8, and 12% of crude glycerin in the diets (%DM). Dry matter and nutrient intake were evaluated, as well as their digestibilities. Milk production and composition were also evaluated. The statistical analysis were carried out using proc MIXED (SAS) with 10% of probability for type I error. The inclusion of glycerin did not affected ($P > 0.10$) DM, NDF and TDN intakes. DM and NDF digestibilities were also not affected by glycerin inclusion ($P > 0.10$). Intake and digestibility of crude protein (CP) have decreased linearly ($P < 0.10$). Ether extract and non-fiber carbohydrate intake have increased linearly ($P < 0.10$). Milk production (MP) and MP corrected for 4% fat (PL4G) were not affected by diets ($P > 0.10$). There was also no significant diet effect ($P > 0.10$) on milk composition (fat, protein, lactose, total solids and somatic cell score). Serum levels (HDL, LDL, VLDL, triglycerides, and glucose) have not been affected significantly by glycerin in the diet ($P > 0.10$), apart from total cholesterol, which decreased linearly with the increasing inclusion of crude glycerin ($P = 0.091$). Crude glycerin can totally replace corn grain ground in diets for cows producing 15 kg of milk.

Key Words: digestibility, intake, milk

W40 Performance, digestion, milk fatty acids, and plasma amino acids in response to the supplementation of methionine and plant extracts to dairy cows. G. G. S. Salvati[1], N. N. Morais Junior[1], F. C. F. Lopes[3], R. A. N. Pereira[2], and M. N. Pereira*[1], *[1]Universidade Federal de Lavras, Lavras, MG, Brazil, [2]Empresa de Pesquisa Agropecuária de Minas Gerais, Lavras, MG, Brazil, [3]Empresa Brasileira de Pesquisa Agropecuária, Juiz de Fora, MG, Brazil.*

Rumen microbial yield and PUN were reduced when 2-hydroxy-4-methylthio butanoic acid isopropyl ester (HMBi, MetaSmart, Adisseo) was added to 15.8% CP, soybean based diets. A mixture of cardol, cardanol (phenolic from the cashew nutshell) and ricinoleic acid (C18:1 c9 hydroxylated at C12 from castor oil) (Essential, Oligobasics) may

affect rumen fermentation. The response of lactating cows to HMBi (35g/d), associated to Essential (10g/d), was evaluated. Twenty-eight Holsteins (211 ± 103 DIM) were fed a common diet for 14d and then a treatment for 29d, in a covariate adjusted randomized block design. Response was evaluated on the last 7d. Treatments were a 2x2 factorial arrangement of the 2 factors, orally dosed to each cow twice per day. Diets had 17% soybean meal, 5.8% raw soybeans, and 18.3% CP. Milk yield did not differ (30.5kg/d, $P > 0.64$), similarly to solids yield, DMI, and total tract digestibility ($P > 0.25$). Milk protein was increased from 3.25% to 3.35% by HMBi ($P = 0.03$). Methionine and histidine as a % of plasma amino acids were increased by HMBi without Essential ($P < 0.04$ for interaction) and Essential decreased isoleucine ($P = 0.03$). Essential without HMBi reduced C15:0 anteiso as a % of milk FA ($P = 0.05$ for interaction) and as a % of odd and branched chain FA (OBCFA) ($P = 0.03$ for interaction). Essential decreased C17:0 iso as a % of FA ($P = 0.02$) and the summations of C15:0 iso + C17:0 iso ($P < 0.01$) and of C15:0 anteiso + C17:0 anteiso ($P = 0.02$). HMBi also reduced C15:0 iso + C17:0 iso as a % of FA ($P = 0.04$). Although OBCFA profile of milk fat indicated a depression in rumen microbes synthesis in response to both HMBi and Essential, the daily excretion of urinary allantoin was similar ($P > 0.70$). HMBi reduced the mean PUN along the day from 18.2 to 15.6mg/dL ($P = 0.03$), markedly at sampling times 0, 1, 2, 3, and 6 h post-feeding, and ruminal ammonia content 12 h post-feeding ($P < 0.01$). HMBi increased milk protein content and decreased PUN, while plant extracts did not induce detectable animal response.

Key Words: essential oil, methionine, odd- and branched-chain fatty acids

W41 Sources of rumen protected fat supplementation on milk yield and composition and ruminal parameters of dairy cows grazing a tropical pasture. F. Batistel*[1], J. De Souza[1], K. C. Welter[2], M. M.V. Silva[1], A. V. Pires[1], V. N. Gouvea[2], D. F. A. Costa[1], and F. A. P. Santos[1], *[1]University of São Paulo, Piracicaba, SP, Brazil, [2]University of São Paulo, Pirassununga, SP, Brazil.*

The objective of this experiment was to investigate the effects of supplementation of lactating cows grazing a tropical pasture with diets containing calcium salts of palm oil (CSPO) or calcium salts of soybean oil (CSSO) on ruminal fermentation and milk production . Five rumen-cannulated cows (90 ± 12 DIM) were used in a 5x5 Latin square and subjected to the following treatments: a) control (no fat); b) 400 g CSPO cow^{-1} d^{-1}; c) 700 g CSPO cow^{-1} d^{-1}; d) 400 g CSSO cow^{-1} d^{-1}; and e) 700 g CSSO cow^{-1} d^{-1}. Treatment periods were 24 d in length. Cows grazed paddocks of *Pennisetum purpureum* and received 8 kg cow^{-1} d^{-1} (DM) of concentrate twice daily. Milk yield was measured every 2 d and milk composition was analyzed every 6 d. Rumen fluid samples were collected on d 22 at 0, 1, 2, 4, 6, 8, 12, 18 and 24 h after feeding concentrate in the morning and analyzed for pH and VFA. Data were analyzed as repeated measures using a mixed model with animal and period as random effects. Both levels of CSPO increased milk yield (17.7 kg d^{-1}). The use of 700 g CSSO decreased milk production (15.9 kg d^{-1}) compared with control and 400 g CSSO (16.7 and 17.1 kg d^{-1}, respectively). Fat supplementation did not affect milk protein, milk casein and milk lactose concentrations. The CSSO reduced milk fat concentration and yield. Addition of 700 g d^{-1} of CSSO decreased milk fat yield at 22% in comparison to control (0.48 vs. 0.62 kg d^{-1}). Both CSPO levels increased milk fat, protein and lactose yield when compared with control and CSSO. Ruminal pH was not affected by fat supplementation. Acetate and butyrate concentrations were higher for 400 g CSPO than 700 g CSSO (70.5 vs. 65.9 mmol ml^{-1} and 13.1 vs. 12.6 mmol ml^{-1}). In addition, valerate and isobutyrate were higher for 400 g CSPO than for 400 g and 700 g of CSSO (1.35 vs. 1.04; 0.98 and 1.30 vs. 1.04; 1.06 mmol ml^{-1}). The decreased concentration of branched-chain fatty acids suggests that microbial growth was affected negatively by CSSO supplementation. Dairy cows grazing tropical pasture supplemented with fat can have an increased milk yield depending of level and source of fat.

Key Words: palm oil, soybean oil, milk

W42 Effect of a live-yeast-based product on colostrum quality and milk yield in first month of lactation on a private dairy farm. C. Julien*[1,2], A. Fernandez[3], and J. P. Marden[3], *[1]INRA, UMR1289 TANDEM, Tissus Animaux Nutrition Digestion Ecosystème et Métabolisme, Castanet-Tolosan, France, [2]Université de Toulouse, INPT ENSAT, INP-ENVT, UMR1289 TANDEM, Castanet-Tolosan, France, [3]Lesaffre Feed Additives, Marcq-en-Baroeul, France.*

The objectives were to (i) evaluate the effect of a live-yeast-based product supplementation during dry period of dairy cows on colostrum quality and milk yield (ii) test the on-farm use of Brix refractometers (Optical-OBR and Digital-DBR) instead of colostrometer (CLM). Fifty Holstein dairy cows of a private farm (Sepx, France) were involved in the trial: 16 cows calving between December 2011 and February 2012 were used as control (CTRL) and the next 34 cows calving between March and September 2012 (YST) received 15 g/d of a mix of live yeast and yeast wall cells (Lesaffre Feed Additives, France) from dry to the calving. Two samples of colostrum were taken at first milking: one was measured within 1h of collection with both CLM and OBR by the farmer. The other sample was frozen for subsequent measurement by DBR (MA871, Milwaukee, WI) taken as reference. Data were analyzed using R.14.1 software with a linear model including the effects of rank of lactation, DIM at first control and treatment. Optical Brix measured on fresh colostrums on-farm and digital Brix measured on thawed colostrums were highly correlated ($R^2 = 0.89$, $P < 0.001$, n = 44). It showed clearly that on-farm measurement with OBR on fresh colostrums is as accurate as lab measurement with DBR on frozen colostrums. On the contrary, IgG content evaluated with CLM and DBR presented a correlation of $R^2 = 0.47$ ($P < 0.001$, n = 44) highlighting a less accurate on-farm assessment of colostrum quality perhaps due to the temperature non-sensitivity of CLM. Supplementation of dry dairy cows with live-yeast-based product did not alter colostrum quality. However, it tended to improved milk yield ($P = 0.13$) and protein yield ($P = 0.096$) measured at first control in the first month of lactation: +15% and +13%, respectively. To conclude, supplementation of cows during dry period with the live-yeast-based product seems not to alter colostrum quality but tended to improve milk and protein yields in first month of lactation. Also, colostrum quality can be easily and more accurately assessed by dairy farmers on-farm by means of a Brix refractometer than by a colostrometer.

Key Words: dairy cow, colostrum, live yeast

W43 Sugar cane silage additive for high production dairy cows. B. T. C. Silveira, M. I. Marcondes, K. G. Ribeiro*, O. G. Pereira, M. G. F. Teixeira, and L. L. Cardoso, *Universidade Federal de Viçosa, Viçosa, Minas Gerais, Brazil.*

Sugar cane silage production process can be an alternative to reduce handling costs in dairy production systems. The objective was to evaluate sugar cane silage for Holstein high production cows. The experiment was carried out at UEPE-GL ranch, at Universidade Federal de Viçosa, Viçosa-MG, Brazil. The treatments were corn silage (CS), with roughage:concentrate relationship of 60:40 in dry matter (DM); and 4 diets based on sugar cane(SC), with roughage: concentrate relationship of 40:60 in DM, as it follows: Sugar cane silage (SCS), Sugar cane silage with *Lactobacillus buchneri*, and sugar cane silage with *Lactobacillus plantarum* plus *Pediococcus pentosaceus* (SCSLP). Fifteen Holstein cows were divided into 3 blocks by milk production (25, 30, 35 kg/d), and they were evaluated during 5 periods of 15 d. Animals were assigned in completely randomized block design in scheme of repeated measures. Diets were isonitrogenous and isoenergetic, and dry matter intake was daily regulated. Milk production was daily recorded in 2 milking, and at the end of each period milk was sampled to analyze milk fat, protein, lactose and total dry extract. Treatment affect milk production with SCS having the lowest production (23.69 kg/d) compared with other treatments ($P = 0.001$). SC is usually a low quality forage, with low fiber digestibility and reduced proportion of soluble carbohydrates, that possibly decreased energy availability for milk production. Sugar cane supplementation improved material quality and allowed similar performance with CS and SCIN. There was no effect of roughage over 4% fat corrected milk production and milk fat, lactose, total dry extract ($P > 0.05$). Milk protein reduced when SCSLP was used ($P = 0.019$), with no acceptable explanation to these results. SCS can replace SCIN or CS for high production cows when additives are used. Supported by CNPQ/FAPEMIG/INCT-CA/FUNARBE

Key Words: *Lactobacillus buchneri*, *Lactobacillus plantarum*, *Pediococcus pentosaceus*

W44 Effects of evaporative cooling prepartum and vitamin E supplementation on performance of Holstein cows during summer in Florida. G. C. Gomes*[1], J. E. Zuniga[1], L. F. Greco[1], L. D. P. Sinedino[1], E. S. Ribeiro[1], N. Martinez[1], R. S. Bisinotto[1], F. S. Lima[1], E. Karakaya[1], M. A. Engstrom[2], J. E. P. Santos[1], and C. R. Staples[1], *[1]University of Florida, Gainesville, [2]DSM, Belvidere, NJ.*

The objective was to evaluate vitamin E (VitE) supplementation above NRC recommendations to cows managed in cooled (C) or noncooled (NC) environments prepartum on performance. Holstein cows (n = 70) were blocked by parity, milk yield, and body weight, and assigned randomly to 1 of 4 treatments arranged in a 2 × 2 factorial starting at 4 wk prepartum. Cows were housed until parturition in either a sand-bedded free-stall barn equipped with fans and sprinklers (C) or in an open lot provided with shade only (NC). After calving, cows were housed together in free-stall facility equipped with fans and sprinklers. All-rac-α-tocopherol (DSM, Belvidere, NJ) was top dressed daily at 1000 IU prepartum and 500 IU postpartum for moderate VitE (M) or 3000 IU prepartum and 2000 IU postpartum for high VitE (H) resulting in treatments: CH, CM, NCH, and NCM. The study lasted from 4 wk pre- to 15 wk postpartum. Measurements included intake of DM, yields of milk and milk components, body weight, respiration rate, and 4 times hourly measurement of vaginal temperatures for 7 d. Data were analyzed by ANOVA for repeated measures with the PROC MIXED of SAS. During prepartum, temperature and humidity index (THI) averaged 74.8 ± 4.9, and cows were exposed to THI > 70 during 85% of the day. Cooling prepartum reduced body temperature by 0.38°C in the afternoon. Results are in Table. Providing evaporative cooling during the last 4 wk of gestation improved lactational performance of dairy cows. Supplementation with VitE above NRC recommendations increased fat and protein concentration of milk, but did not influence yields of milk and milk components.

W45 Macromineral maintenance requirements for Holstein young calves. J. P. P. Rodrigues*[1], J. C. M. Lima[1], M. I. Marcondes[1], M. Campos[2], F. S. Machado[2], A. S. Trece[1], M. M. D. Castro[1], B. P. Moreira[1], and P. G. Castro[1], *[1]Universidade Federal de Viçosa, Viçosa, Minas Gerais, Brazil, [2]Embrapa Gado de Leite, Juiz de Fora, Minas Gerais, Brazil.*

The aim was to determine the calcium (Ca), phosphorus (P), magnesium (Mg), sodium (Na) and potassium (K) retention efficiency and maintenance requirements of Holstein calves from birth to 87 d of age. The comparative slaughter method was used. Fourty-2 male Holstein calves were utilized (3 d of age, 35.56 ± 5.86 kg). Thirty 2 calves were randomized in 4 diets (2; 4; 6; 8 kg of raw milk), with starter (20% CP; 80% TDN; 0.57% Ca; 0.46% P; 0.08% Na; 0.38% K; 0.34% Mg) ad libitum. Each treatment had 8 replications: 4 slaughtered at 57d and 4 slaughtered at 87d. Those animals with 58d were fed Coast-cross hay plus starter ad libitum after weaning. Dry matter intake was registered daily. After slaughtering, the digestive tract was cleaned and empty body weight (EBW) was obtained. Each animal was separated into carcass (CC) and non-carcass components (NCC; head, legs, tail, leather, blood, organs, viscera), both milled using a cutter and sampled after homogenization. The relationship between body weight (BW) and EBW was 0.886. The reference group was used to estimate initial EBW composition. The mineral composition from milk, starter, hay, CC and NCC was performed by inductively coupled plasma mass spectroscopy (ICP-OES). The retained minerals (RM; mg/kg EBW/d) were regressed on mineral intake (MI; mg/kg EBW/d), according to the model: RM = β_0 + β_1*MI. All parameters were tested using the mixed procedure (SAS 9.2). The β_0 values found were −103.41 (P = 0.0147); −13.52 (P = 0.2999); −0.829 (P = 0.7241); −5.595 (P = 0.1382); −0.738 (P = 0.2381) for Ca, P, Na, K and Mg, respectively. These values can be used as the maintenance requirements (mg/kg EBW/d), being the mineral loss when intake as equal to zero. The β_1 values were 0.804 (P = 0.0087); 0.419 (P = 0.0005); 0.216 (P = 0.0009); 0.119 (P = 0.0047); 0.0455 (P = 0.0025) for Ca, P, Na, K and Mg, respectively. Significance of all β_1 parameters suggests that the models use accurate minerals retention efficiency. Highest β_1 for Ca and P may be correlated with the high skeletal growth. The requirements for maintenance (mg/kg EBW/d) can be calculated as the module of β_0. Supported by CNPq/FAPEMIG/INCT CA/FUNARBE/CAPES/EMBRAPA.

Key Words: calcium, calf, phosphorus

W46 In vitro study on the effects of sodium-calcium malate and live yeast on ruminal fermentation and methane production. J. Alcañiz*[1], A. Ortiz[1], M. D. Carro[3], M. J. Ranilla[2], and J. J. Mallo[1], *[1]NOREL S.A., Madrid, Spain, [2]Universidad de León, León, Spain, [3]Universidad Politécnica de Madrid, Madrid, Spain.*

The objective of this study was to analyze the effects of sodium-calcium malate (MS), live yeast (LY) and their combination on in vitro ruminal fermentation and methane production (MP). A system of batch cultures of mixed ruminal microorganisms (BCRM) was used. Experimental treatments were control (no additives), sodium-calcium malate (MS), Live yeast (LY) and combination of both (MSLY). Bottles (120 mL) including 300 mg of a diet (40% forage: 60% concentrate) and 30 mL of a mix solution 1:4 of rumen fluid and buffer solution described by Goering and Van Soest (1970) were used for the incubation. Additives were added at dose of 9 mg MS/BCMR and 1.5 mg LY/BCMR. Bottles were incubated at 39°C for 16 h. At the end of the incubation period, total gas production was measured in each bottle using a pressure transducer and a calibrated syringe. A gas sample was removed from each bottle and stored in a hemoguard vacutainer before analysis for methane by gas chromatography. Bottles were uncapped, the pH was measured immediately, and samples were taken for volatile fatty acids, lactate and ammonia-N analyses. Incubations were replicated 4 times to allow statistical analysis. Data were analyzed using Proc Mixed of SAS. No differences were found between treatments on acetic, butyric, lactic, valeric acid (VA) and MP. PH was similar for all treatments. MS increased propionate (PR) compared with control (319 vs. 287 mmol, $P < 0.01$), reduced VA production (17.3 vs. 19.5, $P < 0.01$) and acetic:propionic ratio (A:P) (2.85 vs. 3.13, $P < 0.05$). LY reduced VA production compared with control (17.1 vs. 19.5, $P < 0.001$). MSLY increased PR (329 vs. 289, $P < 0.001$) isobutiric (17.5 vs. 12.3, $P < 0.001$), isovaleric acid (22.1 vs. 19.8, $P < 0.01$) and total production of volatile fatty acids (1570 vs. 1449, $P < 0.05$) compared with control. MSLY increased also the total ammonia production (229 vs. 202, $P < 0.001$) and reduced gas production (2851 vs. 2923, $P < 0.01$). With this experiment we concluded that combination of additives was the most effective treatment affecting a higher number of parameters. LY only affected VA and MS was the most effective treatment to reduce A:P ratio.

Key Words: malate, live yeast

W47 Yeast supplementation of lactating dairy cows during summer. G. G. S. Salvati[1], N. N. Morais Junior[1], F. F. Cardoso[1], A. C. S. Melo[1], M. Aronovich[3], R. A. N. Pereira[2], and M. N. Pereira*[1], *[1]Universidade Federal de Lavras, Lavras, MG, Brazil, [2]Empresa de Pesquisa Agropecuária de Minas Gerais, Lavras, MG, Brazil, [3]Empresa de Pesquisa Agropecuária do Estado do Rio de Janeiro, Niterói, RJ, Brazil.*

Dairy cows subjected to heat stress have reduced feed intake and increased reliance on glucose, making feeding strategies capable of improving diet digestibility plausible for improving post rumen nutrient flow and performance. The effect of yeast on digestion and performance of lactating cows during the warm summer months of southeast Brazil was evaluated. Cows were individually fed in tie stalls, THI was above 68 for 75.6% of the time. Twenty-eight Holsteins (207 ± 87 DIM) received a standardization diet for 14 d and then a treatment for 70 d, in a covariate adjusted randomized block design with repeated measures over time. Treatments were: Yeast (*Saccharomyces cerevisiae*, strain NCYC 996; Procreatin7, Lesaffre) or Control. Capsules of 10 g were orally dosed to each cow daily, equivalent to 25 × 10^{10} cfu of live cells and 5 × 10^{10} cfu of dead cells. The diet contained corn silage (37.7%), Tifton (7.1%), raw soybeans (4.1%), soybean meal (16.5%), corn (20.7%), citrus pulp (11.9%), 18.3% CP, 37.5% NDF,

and 26.7% starch. Yeast increased the yield of milk (26.7 vs. 25.4kg/d, $P = 0.03$) and solids, especially lactose ($P = 0.03$). Response in milk yield was consistent over time and started on d 5. The daily intake of digestible OM, total tract digestibility of nutrients, urinary allantoin excretion, ruminal pH and protozoa content, chewing pattern along the day, and DMI did not respond to Yeast ($P > 0.21$). There was a trend for increased plasma glucose on Yeast (62.9 vs. 57.3mg/dL, $P = 0.09$), coupled to lowered respiratory frequency (48 vs. 56 breaths/min, $P = 0.02$), at similar rectal temperature ($P > 0.51$). On d 71 to 73, citrus pulp was abruptly replaced by the same amount of corn to induce acidosis. The increased load of starch increased DMI from 7AM to 1PM, and jugular blood pCO_2, HCO_3^-, and base excess, and decreased blood pH ($P < 0.01$). Yeast increased blood pH from 7.32 to 7.34 ($P = 0.02$). Yeast supplementation improved milk yield of cows under heat stress, the mechanism apparently involved regulation of body homeothermia and glucose availability to the mammary gland, but not diet digestibility.

Key Words: *Saccharomyces cerevisiae*, probiotic, yeast

W48 Strategies to modify the biohydrogenation pathways of polyunsaturated fatty acids in the rumen. A. Siurana[1], A. Ferret[1], M. Rodriguez[1], V. Fievez[2], D. Bravo[3], and S. Calsamiglia*[1], *[1]Autonomous University of Barcelona, Spain, [2]Ghent University, Ghent, Belgium, [3]Pancosma, Geneva, Switzerland.*

Two experiments were conducted to determine the effects of lipases and essential oils on rumen fermentation and apparent biohydrogenation of linoleic (LA) and linolenic (LNA) acids. In experiment 1, a 50:50 forage:concentrate diet containing linseed oil (8.3% of DM) was incubated in a batch culture of rumen fluid at 2 pH levels (6.4 and 5.6) in 2 replicated periods. Treatments were: control; lipase 1 and 2 (0.4 and 4 μL/g DM); a lipase inhibitor (0.4 and 2 mg/g DM); Oxy-propyl-thiosulfate (PTSO) (60 and 120 mg/L); Eugenol (EUG) (150 and 500 mL/L) and Cinnamaldehyde (CIN) (150 and 500 mL/L). Samples were collected to analyze ammonia-N, volatile fatty acids (VFA) and the fatty acid (FA) profile. In experiment 2, 8 continuous culture fermenters (1,320 mL) were used in 3 replicated periods (5 d of adaptation and 3 d of sampling). Fermenters were fed 95 g/d of DM of a 60:40 forage:concentrate diet containing 5% DM of linseed oil. Treatments were control, lipase 1 (4 μL/L), PTSO (90 mg/L) and CIN (250 mg/L), and 2 pH levels (6.4 and 5.6). During the last 3 d of each period, samples were taken to analyze VFA, ammonia-N and the FA profile. Lipase 1 increased the apparent biohydrogenation of LNA and reduced the efficiency of intermediary steps of biohydrogenation of LA and LNA in experiment 1, but these results were not observed in experiment 2. The PTSO inhibited the apparent biohydrogenation of LA and LNA and decreased total VFA concentrations. The low pH inhibited the biohydrogenation of LA, increased the t10 C18:1, and decreased total VFA concentrations. Results indicated that effects of lipase 1 observed in the batch culture were not observed in long-term dual flow continuous culture fermentations. Reducing the pH inhibited the ruminal fermentation and increased the alternative pathway of ruminal biohydrogenation. The PTSO modified the pathways of fatty acid biohydrogenation, but the magnitude of the effect was pH-dependent.

Key Words: polyunsaturated fatty acid biohydrogenation, lipase, essential oil

W49 Effect of rumen-protected choline top-dressed during the transition period on milk yield and composition in Holstein dairy cows on two commercial dairies. M. C. Amundson*[1], P. D. Carvalho[1], R. W. Bender[1], R. R. Grummer[1,2], R. D. Shaver[1], and P. M. Fricke[1], *[1]University of Wisconsin-Madison, Madison, [2]Balchem Corporation, New Hampton, NY.*

Pregnant Holstein cows and heifers on 2 commercial farms were blocked by parity and randomly assigned to 2 treatments. Cows (n = 925) in the first treatment were supplemented rumen-protected choline (RPC; Reashure, Balchem Corp., New Hampton, NY) during the transition period, whereas cows (n = 952) in the second treatment were not supplemented (control; CON). All cows were housed together in transition pens, and RPC cows were individually top-dressed 60 g/d RPC while restrained in feedline headlocks from 21 d before to 21 d after calving. Daily milk yield collected by the parlor system and downloaded as a weekly average which was analyzed for the first 14 wk of lactation within parity using PROC MIXED of SAS with treatment, farm, week, and all 2- and 3-way interactions as fixed effects and cow within treatment within farm as a random effect. Milk yield did not differ between RPC vs. CON cows in first (30.5 vs. 30.7, n = 990) or second (41.4 vs. 41.4, n = 440) lactation, whereas third and greater lactation RPC cows tended ($P = 0.06$) to have greater milk yield than CON cows (45.5 vs. 44.3, n = 515). Data from DHI records for monthly milk testing including milk yield, fat, protein, and SCC were analyzed using PROC MIXED of SAS with treatment, lactation, farm, DIM, month, and treatment by lactation, and treatment by farm interactions as fixed effects and cow within treatment within farm within lactation as a random effect. Milk yield did not differ between RPC vs. CON cows in first (30.9 vs. 31.1 kg/d, n = 963) or second (39.2 vs. 39.6 kg/d, n = 427) lactation, whereas third and greater lactation RPC cows had greater ($P < 0.05$) milk yield than CON cows (43.0 vs. 41.4 kg/d, n = 487). Milk fat and protein did not differ between RPC and CON cows (3.78% vs. 3.81% and 3.05% vs. 3.06%, respectively; n = 1,877), whereas RPC cows had a lower ($P = 0.02$) linear SCC compared with CON cows (4.0 vs. 4.1; n = 1,877). We conclude that supplementing RPC during the transition period did not affect milk components but increased milk yield for older cows during and beyond the postfresh supplementation period.

Key Words: choline, milk component, milk yield

W50 Effects of a commercial feed additive on production losses during acute heat stress conditions in Holstein dairy cows. K. A. Davison*[1], R. O. Rodrigues[1], J. A. Davidson[2], N. M. Barkley[1], A. L. Kenny[1], E. C. Adkins[1], and M. R. Waldron[1], *[1]University of Missouri, Columbia, [2]Purina Animal Nutrition Center, Gray Summit, MO.*

The objective of this study was to assess the effects of a commercial carbohydrate-based feed additive on dry matter intake (DMI), milk yield, milk composition, and plasma metabolites during an acute period of heat stress. Forty-eight mid-lactation Holstein dairy cows were blocked according to milk yield, days in milk, and parity and then randomly assigned to one of 2 dietary treatments within block. Treatments were calculated to provide 100g (as fed) daily of either sucrose (control; CTL) or a commercial feed additive (Rally, Purina Animal Nutrition, Shoreview, MN; RAL) administered as part of the total mixed ration (TMR). Cows were individually fed the TMR in 2 daily allotments for a total of 39d; 27.25 ± 0.3 d during thermoneutral (TN) conditions, followed by 11.75 ± 0.3 d during heat stress (HS) conditions (daily cyclical temperatures ranging from 23.8°C to 30.2°C, temperature-humidity index of 69.2 to 75.5) in temperature-controlled environmental chambers. Daily DMI was determined using feed issue and refusal records. Milk yield was recorded daily and milk components were assessed weekly. Blood was sampled twice weekly and analyzed for concentrations of plasma glucose, β-hydroxybutyrate, and nonesterified fatty acids (NEFA). All variables were analyzed using the SAS mixed model ANOVA procedure with repeated measures. There was no significant treatment difference during the TN period for any

of the variables measured. During HS, RAL cows displayed increased DMI (treatment by time, $P < 0.05$) and milk yield (treatment by time, $P = 0.05$) relative to CTL cows. Milk fat percentage tended to decrease to a greater extent in cows fed RAL (treatment by time, $P < 0.07$), but milk fat yield was not different between treatments ($P > 0.20$). Plasma NEFA concentrations of RAL cows were lower (treatment, $P < 0.03$) than those of CTL cows during HS. Feeding RAL before and during a period of acute cyclical HS increased DMI and milk yield, and appeared to favor improved energy balance of mid-lactation dairy cows during HS.

Key Words: Rally, heat stress, dairy

W51 Effect of dietary and metabolizable protein in early lactation on the lactational performance and metabolism of dairy cows. H. M. Dann*[1], P. Ji[1], K. W. Cotanch[1], H. M. Gauthier[1], M. P. Carter[1], S. Y. Morrison[1], J. Darrah[1], Y. Koba[2], and R. J. Grant[1], *[1]William H. Miner Agricultural Research Institute, Chazy, NY, [2]ZEN-NOH National Federation of Agricultural Cooperative Associations, Tokyo, Japan.*

Multiparous Holstein cows (n = 84) were used to evaluate the effect of crude protein (CP) and metabolizable protein (MP) in corn silage-based diets fed during the fresh and early lactation periods on performance and blood metabolites. Treatments were (1) a low-protein diet (L; 15.3% CP, 35.6% NDR, 24.2% starch) for 1 to 91 d in milk (DIM; LL), (2) a high-protein diet (H; 17.0% CP, 33.3% NDR, 24.6% starch) for 1 to 21 DIM and a L diet for 22 to 91 DIM (HL), and (3) a H diet for 1 to 21 DIM and a moderate-protein diet (M; 16.2% CP, 34.4% NDR, 24.5% starch) for 22 to 91 DIM (HM). Diets contained 40% corn silage, 12% haylage, and 48% concentrates. The MP supply at 19.1 kg dry matter intake (DMI) was estimated (NDS v3) to be 1798, 1895, and 1999 g/d for L, M, and H, respectively. Cows were housed in sand bedded freestalls, fed in a Calan Broadbent feeding system, and milked 3× daily. Dry matter intake and milk yield were measured daily. Milk composition was measured weekly starting at wk 2. Serum was collected at 1, 3, 5, 7 10, 13, 16, and 19 DIM and analyzed for blood urea N (BUN) and nonesterified fatty acids (NEFA). After 21 DIM, serum was collected weekly and analyzed for BUN. Data were analyzed as a completely randomized design by ANOVA with the MIXED procedure of SAS using treatment and time as fixed factors and cow within treatment as a random factor. Through the first 91 DIM, treatment did not affect DMI, milk yield, fat content, or protein content. As expected, protein intake and concentrations of milk urea N (MUN) and BUN were highest for HM. Serum NEFA was not affected by treatment (549 ± 36 μEq/L; $P = 0.99$). Milk N efficiency was higher for LL than HM. Diets containing lower crude protein can be fed successfully to cows in early lactation as long as the metabolizable protein supply is adequate.

Table 1.

Item	LL	HL	HM	SE

W52 Influence of an antioxidant supplementation on production and health status of dairy cows. J. McNamara[1], S. Shields*[1], and E. von Hemiendahl[2], *[1]Washington State University, Pullman, [2]Lohmann Animal Health GmbH, Cuxhaven, Germany.*

Vitamin E allows for optimum immune and inflammatory state of dairy cattle, however, it can be a significant cost. Antioxidants scavenge the reactive oxygen species in feed and may be able to spare vitamin E to supply higher amounts to the cow for the endogenous radical defense system. Therefore, our objective was to test the effect of inclusion of Loxidan in a dairy ration to reduce the effective amount of vitamin E necessary to maintain production and health of lactating dairy cattle. The study was a randomized complete block, and cows were individually fed a TMR ad libitum to requirements from 14 to 84 d postpartum. Twenty cows each were allotted to 3 treatments; a control ration to supply 1000 IU per cow per d of vitamin E; the same ration with 150 mg/kg diet of antioxidant blend (Loxidan, Lohmann Animal Health, Cuxhaven, Germany); or a ration to supply 3000 IU per cow per d Vitamin E. There was no effect of treatment on DMI in any parity group. Milk production was the same in multiparous cows on all treatments (35.0 ± 1.2 (SEM) kg/d); however, in 1st lactation animals milk production was greatest ($P < 0.01$) in animals on the high vitamin E, least on lower vitamin E and intermediate on Loxidan. Serum vitamin E was similar between control and Loxidan, and higher on the higher vitamin E treatment. There were no effects on milk composition, body weight or serum glucose, NEFA, or BHBA. A serum indicator of stress, advanced oxidation protein products (AOPP), was lower in animals fed the Loxidan-supplemented or higher vitamin E diet compared with controls, especially in multiparous animals (Treatment × DIM × parity $P < 0.05$). The SCC of these cows was low (58,000) and there was no treatment effect; but there was a treatment × parity interaction ($P < 0.001$) in that SCC in control 2nd lactation animals was 112,000 and in Loxidan treatment 8,000; high vitamin E was 24,000. The results indicate that a lower inclusion rate of vitamin E can be fed if the diet is additionally protected with antioxidants to achieve similar results to a higher rate of vitamin E feeding, and in 1st parity animals a slight increase in milk production.

Key Words: vitamin E, antioxidant, Loxidan

W53 Verifying consistent bioavailability values in rumen-protected lysine. M. R. Culbertson*[1], M. J. Poss[1], F. D. Valdez[1], and D. A. Sapienza[2], *[1]Kemin Industries Inc., Des Moines, IA, [2]Sapienza Analytica LLC, Slater, IA.*

To characterize and predict the release rate and pattern of a rumen-protected amino acid (LysiPEARL, Kemin Industries, Des Moines, IA), an analytical test method was developed and validated. This dissolution test method, adopted from the United States Pharmacopeia (USP), can be used to ensure consistent product performance by characterizing batch-to-batch manufacturing uniformity and corroborate reliable intestinal digestibility of lysine through in vitro bioavailability model correlation. In validating this time release method linearity, repeatability, and accuracy were demonstrated. The use of conductivity as a test method for quantitating lysine dissolution was assessed and accepted in both multifactorial ANOVA ($P > 0.05$) and fit factor ($f_1 \leq 5$ and $f_2 \geq 50 \leq 100$) analyses, as well as by comparing samples using a validated orthogonal test method, high-performance liquid chromatography (HPLC). The method was challenged to detect changes in product resulting in significant dissolution differences in both PEARL size distribution ($P < 0.01$) and coating ($P < 0.01$). Three batches of rumen-protected lysine were manufactured and then characterized by both dissolution and rumen

in vitro by-pass kinetic modeling. The kinetic modeling, based on a combination of rumen degradation and intestinal release information, offered lysine release results consistent with the laboratory validated dissolution method in all product batches cross-examined in this study with an $r^2 = 0.94$. The laboratory dissolution method is an accurate tool to evaluate manufacturing conditions and ensure reproducible intestinal bioavailability when balancing rations with rumen-protected amino acids.

Key Words: bioavailability, dissolution, rumen-protected lysine

W54 Effect of supplying limiting amino acids in diets with reduced CP on milk and protein yield. M. A. C. Danes*[1], G. A. Broderick[1], and C. Parys[2], *[1]University of Wisconsin, Madison, [2]Evonik Industries AG, Hanau, Germany.*

Supplying limiting essential amino acids (EAA) to dairy cows may allow reducing dietary CP without loss of milk and protein yield, thereby increasing N efficiency. This strategy was evaluated by infusing limiting EAA into the abomasum of cows fed diets with reduced CP concentration. Ten Holstein cows were blocked by DIM into 2 5x5 Latin squares with 5 treatments: (1) positive control (16% CP), formulated to meet metabolizable protein (MP) requirements; 14.9% CP with (2) or without (3) EAA infusion; or 13.5% CP diet with (4) or without (5) EAA infusion. All diets contained alfalfa silage, corn silage, high moisture corn, canola meal, soybean meal and soybean hulls. The EAA solutions were prepared according to AminoCow to provide all limiting EAA in each treatment. Data from the last 4 d of each 14-d period were analyzed using Proc Mixed of SAS. Contrasts and LSM are reported in the table. Cows yielded on average 10 kg less milk than expected, making the 14.9% CP diet not MP limiting according to AminoCow, which may explain why no effect was detected on that diet (contrast 3). The 13.5% CP diet did not differ from the positive control (contrast 2) but the predicted balance of EAA indicated that methionine, lysine and histidine were limiting. Infusion of EAA on this diet overcame the deficiency, which increased ECM and tended to increase milk and protein yield (contrast 4). The NRC (2001) model underestimated MP-allowable milk by, respectively, 2.5, 4.2 and 8.2 kg for the 16, 14.9 and 13.5% CP diets. The number of cows used limited statistical power. However, results suggested that the lowest CP diet with supplemental EAA infusion was the best treatment, indicating the advantage of balancing dairy rations for amino acids.

Table 1.

	Treatment					Contrasts[1]			
Variable	16% CP	14.9% CP + EAA	14.9% CP	13.5% CP + EAA	13.5% CP	1	2	3	4
DMI, kg/d	23.2	22.6	23.7	23.8	23.0	NS	NS	NS	NS
Milk, kg/d	35.6	34.5	35.7	36.7	34.6	NS	NS	NS	<0.10
ECM, kg/d	34.5	33.4	34.9	37.1	33.8	NS	NS	NS	<0.05
Fat, kg/d	1.24	1.19	1.27	1.38	1.22	NS	NS	NS	<0.05
Protein, kg/d	1.00	0.98	1.00	1.05	0.98	NS	NS	NS	<0.10
MUN, mg/dL	12.4	10.5	11.4	9.0	8.9	<0.1	<0.01	NS	NS
EUN (%)	26.3	28.8	27.5	32.1	30.8	NS	<0.01	NS	NS

[1]Contrasts: 1 = 16 vs. 14.9; 2 = 16 vs. 13.5; 3 = 14.9 vs. 14.9 + EAA; 4 = 13.5 vs. 13.5 + EAA.

Key Words: amino acid, nitrogen

W55 Baseline bovine plasma concentrations of free amino acids during lactation. T. A. Burnett*[1], A. M. L. Madureira[1], G. Wu[2], J. R. Thompson[1], and R. L. A. Cerri[1], *[1]University of British Columbia, Vancouver, BC, Canada, [2]Texas A&M University, College Station.*

Amino acids play nutritional and regulatory roles in lactation. At present, little is known about changes in their concentrations in the plasma of lactating cows during the entire lactation period. This study was conducted to fill in this gap of knowledge. Eighty-nine lactating Holstein (40 primiparous and 49 multiparous) cows were used throughout the first 9 mo of lactation. Cows were maintained in free stall barns and fed a TMR diet (CP = 17.8%, MP = 48.3g/DM) twice a day through the entire experiment, this ration was maintained for a minimum of 200 d in lactation. Information on health episodes, reproductive status, age of gestation and milk production was recorded. Blood samples were collected using sodium-heparin vacutainers on 9 different days in milk 0, 3, 7, 15, 30, 60, 90, 180 and 270. Samples were taken in 9 cohorts consisting of different cows at the same stage of lactation. Plasma was analyzed quantitatively for 24 amino acids using HPLC methods involving derivatization with o-phthaldialdehyde. Data were analyzed by ANOVA for repeated measures using Proc MIXED of SAS. GLN, THR, CIT, β-ALA, TAU, ALA, and ORN were not affected by days in milk, milk production or reproductive status ($P > 0.10$). There was an effect of days of lactation on concentrations of ASP, ARG, TYP, TRP, MET, VAL, PHE, ILE, PRO and LYS in plasma ($P < 0.01$). Correlations between free amino acids and days of lactation were all negative ($r^2 = 0.09$ to 0.20; $P < 0.01$) with a major decrease in free amino acids occurring between d 60 and 90 of lactation. Changes in ASN, SER, and GLY depended on both days of lactation ($P < 0.01$) and yield of milk production ($P < 0.01$), but no interactions were found. There were negative correlations ($r^2 = 0.10$ to 0.17; $P < 0.05$) between age of gestation and the following amino acids: TAU, TYR, MET, and PHE. In conclusion, concentrations of specific amino acids in plasma decreased after 60 d in milk, independent of milk production. Stage of gestation also affected the concentrations of TAU, TYR, MET, and PHE. Taken together, these results suggest a basis to develop possible new strategies for improving health, lactation and reproduction of cows.

Key Words: amino acid, dairy cattle, reproduction

W56 An evaluation of amino acid utilization in lactating dairy cows consuming DDGS and different levels of fat. H. A. Paz* and P. J. Kononoff, *University of Nebraska-Lincoln, Lincoln.*

Eight multiparous Holstein cows were used in a replicated 4 × 4 Latin square to determine the lactation response and AA utilization when dairy cows were fed either conventional (12% fat) or low-fat (6.6% fat) distillers dried grains with solubles (DDGS). Dietary treatments were 1) Control (CON), no DDGS, 2) 29% conventional DDGS (DG), 3) 29% low-fat DDGS (LF), and 4) 29% low-fat DDGS plus rumen inert fat (LF+RIF). Diets were formulated to be isonitrogenous (18.5% CP) but not isocaloric. Net energy of lactation was estimated to be 1.59, 1.61, and 1.68 Mcal/kg of DM for the LF, CON and LF+RIF, and DG diets, respectively. Periods lasted 21 d with the last 3 d for data collection. Compared with cows fed the CON diet, cows fed diets with DDGS had a greater ($P = 0.03$) DMI (22.7 vs. 26.6 ± 1.14 kg/d) and similar ($P = 0.26$) milk yield (31.8 ± 3.0 kg/d). Milk protein percentage was greater in cows fed diets with DDGS ($P = 0.01$) compared with those fed the CON diet (3.22 vs. 3.09 ± 0.08%) and milk fat percentage was lower ($P = 0.01$) in cows fed the DG diet compared with those fed the other diets (3.14 vs. 3.74 ± 0.18%). Arterial concentration of Lys was similar (11.7 ± 0.96 μg/mL; $P = 0.83$) across diets and concentrations of Leu (38.8 ± 2.62; $P < 0.01$), Met (3.77 ± 0.21 μg/mL; $P < 0.01$), and

Phe (10.9 ± 0.49; $P = 0.03$) increased in diets with DDGS compared with the CON diet (27.9 ± 2.62, 2.96 ± 0.21, and 9.61 ± 0.49 µg/mL, respectively). Arteriovenous differences of essential AA were similar ($P \geq 0.19$) across diets. Extraction efficiencies of Lys and Met did not differ across diets and averaged 59.8 ± 4.84% ($P = 0.54$) and 57.3 ± 0.36% ($P = 0.36$), respectively. For cows fed the CON diet, Met was ranked as the first limiting AA followed by Lys and the opposite was observed for cows fed diets with DDGS. Across diets, Arg was the third limiting AA. Low-fat DDGS can be included at high levels without negative effects on milk yield and milk fat percentage. Despite the fact that diets containing DDGS resulted in a lower supply of lysine, physiological indicators of lysine utilization were not affected.

Key Words: dairy cow, distillers dried grains with solubles, extraction efficiencies

W57 Estimation of the metabolizable methionine contribution of four rumen-protected products using the AUC methodology. L. Faivre[1], Y. Mercier[1], E. Devillard[1], and B. K. Sloan*[2], *[1]Adisseo France, Commentry, France, [2]Adisseo North and Central America, Alpharetta, GA.*

Methionine is one of the most limiting amino acids (AA) for milk protein synthesis and is critical achieving a well-balanced ration for AA. Because the required dietary metabolizable methionine (MMet) concentrations cannot be reached by using conventional feedstuffs, various rumen protected methionine (RPM) sources have been developed. To be effectively used, these RPM sources need to be well characterized for their real contribution of MMet. The aim of the present study was to measure the MMet contribution of 4 RPM products MetaSmart (Adisseo, France), AminoShure-M (Balchem, USA), Pro-Met (Bioscreen, Italy) or a prototype product (Adisseo, France), using the Area Under the Curve (AUC) methodology described by Graulet et al. (2005). Eight nonlactating rumen cannulated Holstein cows fed 75% hay and 25% concentrate were used in a replicated incomplete Latin Square design with 4 periods of one week. They received a spot dose of 50g equivalent methionine via the rumen cannula. Blood samples for methionine concentration assessment were obtained from 8 h before and until 72 h after the spot dose. The AUCs were used to estimate the percentage of MMet. An ANOVA with repeated measures was performed using PROC MIXED of SAS/ STAT software (SAS 9.1.3; SAS Institute Inc., Cary, NC). The proportion of methionine reaching the blood stream was calculated at 54.1 ± 5.9% for MetaSmart, which was consistent with previous data (52.3 ± 3.4%, Graulet et al., 2005). AminoShure-M was statistically lower ($P < 0.001$) than Metasmart and evaluated at 42.4 ± 6.5%. Pro-Met measured at 12.2 ± 4.7% was also significantly lower than AminoShure-M. As for the bioavailability of the prototype product, it was not statistically different from MetaSmart bioavailability and was calculated at 57.4 ± 4.3%. This study suggests that MMet contribution of different RPM can be very variable, and products need to be characterized by approved methodologies to determine their real MMet contribution for an optimal usage.

Key Words: metabolizable methionine, rumen-protected amino-acids, area under the curve

W58 A controlled on farm evaluation of methionine for lactating dairy cows. N. N. Morais Junior[1], G. G. S. Salvati[1], R. C. Oliveira[1], R. A. N. Pereira[2], and M. N. Pereira*[1], *[1]Universidade Federal de Lavras, Lavras, MG, Brazil, [2]Empresa de Pesquisa Agropecuária de Minas Gerais, Lavras, MG, Brazil.*

Controlled on farm trials allows for large number of experimental units. We evaluated the response to the isopropyl ester of 2-hydroxy-4-(methylthio) butanoic acid (HMBi, MetaSmart, Adisseo). Cows were paired blocked and randomly assigned to 2 pens of primiparous and 2 of multiparous, in free stalls. The final data set had 234 Holsteins (215 ± 105 DIM at d 26), 96 primiparous and 138 multiparous. Within parity, a pen received HMBi (30g/d) added to a Control diet. Soybean meal and heated soybeans were the major protein sources. HMBi was manually mixed to the first daily feed delivery by 4 researchers housed at the farm along the experiment. The same batch of TMR was fed to all pens. Cows were fed and milked 3x/d. Milk yield on 3 consecutive days was used for blocking and as covariate in the statistical model. Treatments were offered for 28d and response was evaluated on d 24 to 28. Diets were sampled at each feeding in 5 locations of the feed bunk. Composite TMR samples were frozen. Feed refusals were measured, sampled and frozen. Data was analyzed with Mixed as a randomized block design and intake data used pen as replicate and sampling day as repeated measures over time. The CP of the consumed diet was 17.1% of DM ($P = 0.71$), orts 5.3% of offered ($P = 0.64$), and DMI 19.3 kg/d ($P = 0.59$). Cows had similar BCS and girth perimeter ($P > 0.21$). Milk yield before treatment allocation was 34.6 kg/d ($P = 0.95$) and 34.7 on d 24 to 28 ($P = 0.83$). HMBi increased protein yield (1.096 vs.1.049 kg/d, $P = 0.05$) and content (3.18 vs. 3.07%, $P = 0.03$). PUN was reduced by HMBi (13.9 vs.15.6 mg/dL, $P = 0.02$), but MUN did not respond (15.7 vs.16.4 mg/dL, $P = 0.20$). The urinary allantoin to creatinine ratio was increased by HMBi ($P = 0.03$). HMBi increase the plasma content of 11 amino acids at $P < 0.01$, 2 at $P < 0.07$, and cysteine ($P = 0.60$) and lysine ($P = 0.18$) had non-statistical increases. The total of plasma amino acids was increased by 10.4% of Control ($P < 0.01$), methionine increased by 30.8% ($P < 0.01$), and the increase in other amino acids ranged from 4.4 to 19.2%. HMBi decreased PUN, and increased microbial yield, plasma amino acids, and milk protein yield and content.

Key Words: amino acid, methionine, protein

W59 Forages fertilized with selenium as a way to supplement lactating dairy cows. R. Seboussi*[1], G. F. Tremblay[2], P. Y. Chouinard[1], Y. Chorfi[3], G. Bélanger[2], Y. Couture[3], V. Ouellet[1], and E. Charbonneau[1], *[1]Université Laval, Québec, QC, Canada, [2]Agriculture and Agri-Food Canada, Québec, QC, Canada, [3]Université de Montréal, St-Hyacinthe, QC, Canada.*

Fertilization with Se improves the forage Se concentration, but no data on its impact on lactating cows are available. This study aimed to determine the effect of forages fertilized with Se on the performance of lactating dairy cows. A high Se grass and legume silages (1.5 ppm Se) were produced by fertilizing one fourth of forage fields with 2.5 kg/ha of Selcote Ultra (1% Se wt/wt). The low Se silages (0.06 ppm) were harvested from the remaining area. Thirty-three mid- to late-lactation primiparous Holstein cows were used in an unbalanced randomized block design. Each block of cows entered the experiment when enough animals with similar DIM were available and an average 77-d period of Se-depletion was performed. Cows were then randomly assigned for 42 d to one of the 4 experimental TMR fed ad libitum with diets based as follows: CTRL = low Se silages; ISe = low Se silages supplemented with inorganic Se (sodium selenite); OSe = low Se silages supplemented with organic Se (Sel-Plex); FSe = high Se silages. Pre-planned contrasts were tested: (1) CTRL vs. Se-supplemented diets; (2) ISe vs. OSe and FSe; (3) OSe vs. FSe. The CTRL diet (0.12 ppm) had a lower ($P < 0.001$) Se concentration than ISe (0.70 ppm), OSe (0.79 ppm) and FSe (0.80 ppm) diets, which did not differ statistically in Se concentration. No treatment effects were observed on DMI, milk yield, ECM, FCM and

milk fat and lactose concentrations. Cows fed the ISe diet had lower (P = 0.01) milk protein concentration (3.44%) than cows fed OSe (3.58%) and FSe (3.51%) diets but their milk protein yields were similar. Higher SCC were observed for cows fed CTRL than Se supplemented diet (P = 0.05) but the form of Se supplement had no significant effect. Blood glutathione peroxidase was similar between treatments. Apparent Se digestibility was similar in cows fed CTRL (42.5% of intake) and Se-supplemented diets but it was lower (P = 0.04) in cows fed the ISe diet (38.6%) than OSe (42.2%) and FSe (49.8%) diets. Apparent Se digestibility tended (P = 0.07) to be greater in cows fed the FSe than the OSe diet. Forages fertilized with Se are therefore an effective way to provide adequate levels of dietary Se to dairy cows.

Key Words: lactating cow, selenium, forage

W60 Effect of feeding various dosages of *Saccharomyces cerevisiae* fermentation product on serum markers of the innate and adaptive immune system of multiparous dairy cows. C. M. Shriver-Munsch[1], E. M. Zaworski[1], A. N. Fadden[1], W. K. Sanchez[2], I. Yoon[2], and G. Bobe*[1,3], *[1]Oregon State University, Corvallis, [2]Diamond V Mills, Cedar Rapids, IA, [3]Linus Pauling Institute, Corvallis, OR.*

We previously documented that feeding 56 or 112 g/d of *Saccharomyces cerevisiae* fermentation product (SCFP; Original XP) to transition dairy cows resulted in lower somatic cell counts in milk and lower incidence of clinical mastitis. The objective of this study was to examine how feeding SCFP may improve mammary gland health in transition dairy cows on a commercial dairy farm. Multiparous Holstein cows were given individually a supplement containing either 0 (control: n = 14), 56 (n = 15), or 112 g (n = 13) of SCFP daily during morning lock-up as a top dressing to their total mixed ration. The supplement consisted of 0, 56, or 112 g of XP mixed with 84 g of molasses and 168, 112, or 56 g of corn meal, respectively. Supplement feeding began 28 d before predicted calving date (at least 14 d prepartum) and ended 28 d postpartum. Blood samples were collected weekly and more often around calving to measure serum concentrations of markers of innate (haptoglobin and serum amyloid A) and adaptive immunity (IgG, IgM, and IgA). Feeding SCFP (112 or 56 versus 0 g/d) tended to decrease serum concentrations of serum amyloid A in the last week before calving (13.9 versus 23.4 mg/L; P = 0.06) and increased it in the first week after calving (180 versus 82 mg/L; P = 0.02). Doubling feeding rates of SCFP (112 versus 56 g/d) decreased serum haptoglobin concentrations prepartum (3.4 versus 4.5 mg/L; P = 0.03). Feeding SCFP (112 or 56 versus 0 g/d) tended to decrease serum concentrations of IgM (2.38 ± 0.17 g/L versus 2.93 ± 0.25 g/L; P = 0.07). Our results suggest that feeding *Saccharomyces cerevisiae* fermentation product may alter immune function during the transition period.

Key Words: acute phase protein, immunoglobulin, yeast culture

W61 Effect of feeding various dosages of *Saccharomyces cerevisiae* fermentation product on serum concentrations of macrominerals of multiparous dairy cows. A. N. Fadden[1], E. M. Zaworski[1], C. M. Shriver-Munsch[1], W. K. Sanchez[2], I. Yoon[2], and G. Bobe*[1,3], *[1]Oregon State University, Corvallis, [2]Diamond V Mills, Cedar Rapids, IA, [3]Linus Pauling Institute, Corvallis, OR.*

Feeding 56 g/d of *Saccharomyces cerevisiae* fermentation product (SCFP; Original XP) to transition dairy cows has been reported to promote feed consumption around calving. We hypothesized that greater feed intake may be reflected in improved macromineral status. To test this hypothesis, multiparous Holstein cows were given individually a supplement containing either 0 (control: n = 14), 56 (n = 15), or 112 g (n = 13) of SCFP daily during morning lock-up as a top dressing to their total mixed ration. The supplement consisted of 0, 56, or 112 g of XP mixed with 84 g of molasses and 168, 112, or 56 g of corn meal, respectively. Supplement feeding began 28 d before predicted calving date (at least 14 d prepartum) and ended 28 d postpartum. Blood samples were collected at days −21, −14, −7, −3, −1, −1, 0, 1, 3, 7, 14, 21, and 28 postpartum to measure serum concentrations of calcium, magnesium, and phosphorus. Feeding SCFP (112 or 56 vs. 0 g/d) increased serum concentrations of phosphorus during the supplementation period (6.43 ± 0.11 mg/dL vs. 6.09 ± 0.14 mg/dL; P = 0.03) and calcium in the 48 h around calving (8.26 ± 0.19 mg/dL vs. 7.88 ± 0.18 mg/dL; P = 0.04). Whereas, feeding SCFP (112 or 56 versus 0 g/d) decreased serum concentrations of magnesium (2.49 ± 0.04 mg/dL versus 2.65 ± 0.05 mg/dL; P = 0.005) without reaching levels that may influence feed intake. Doubling feeding rates of SCFP (112 versus 56 g/d) did not significantly alter serum concentrations of calcium, magnesium, and phosphorus (P > 0.10). Our results suggest that feeding *Saccharomyces cerevisiae* fermentation product may be beneficial during the transition period to support the macromineral status of dairy cows.

Key Words: dairy, macromineral, yeast culture

W62 Effect of feeding various dosages of *Saccharomyces cerevisiae* fermentation product on serum indicators of feed intake of multiparous dairy cows. E. M. Zaworski[1], A. N. Fadden[1], C. M. Shriver-Munsch[1], W. K. Sanchez[2], I. Yoon[2], and G. Bobe*[1,3], *[1]Oregon State University, Corvallis, [2]Diamond V Mills, Cedar Rapids, IA, [3]Linus Pauling Institute, Corvallis, OR.*

We previously documented that feeding 56 or 112 g/d of *Saccharomyces cerevisiae* fermentation product (SCFP; Original XP) to transition dairy cows improved SCFP consumption on the day of calving. The objective of this study was to examine how feeding SCFP may improve feed consumption in transition dairy cows. On a commercial farm, multiparous Holstein cows were given individually a supplement containing either 0 (control: n = 14), 56 (n = 15), or 112 g (n = 13) of SCFP daily during morning lock-up as a top dressing to their total mixed ration. The supplement consisted of 0, 56, or 112 g of XP mixed with 84 g of molasses and 168, 112, or 56 g of corn meal, respectively. Supplement feeding began 28 d before predicted calving date (at least 14 d prepartum) and ended 28 d postpartum. Blood samples were collected at days −7, −3, −1, −1, 0, 1, 3, and 7 postpartum to measure serum concentrations of markers of stress (cortisol), inflammation (haptoglobin and serum amyloid A), hunger (visfatin), and energy status (insulin, glucose, BHBA, and NEFA). Feeding SCFP (112 or 56 versus 0 g/d) decreased serum concentrations of cortisol (1.2 vs. 1.9 µg/L; P = 0.007). Feeding SCFP tended to decrease serum concentrations of serum amyloid A before calving (12.6 vs. 20.8 mg/L; P = 0.09) and increased it after calving (162 vs. 75 mg/L; P = 0.04). Doubling feeding rates of SCFP (112 vs. 56 g/d) tended to decrease serum haptoglobin concentrations (7.8 vs. 11.2 mg/L; P = 0.09). No significant effects at $P \leq 0.10$ were observed for serum concentrations of visfatin, insulin, glucose, BHBA, and NEFA. Our results suggest that feeding *Saccharomyces cerevisiae* fermentation product may improve feed intake around calving in part by decreasing cortisol secretion.

Key Words: cortisol, feed intake, yeast culture

W63 Effect of applying a bacterial inoculant to corn silage on the performance of lactating dairy cows. O. C. M. Queiroz[1], F. C. Basso[2], R. Daetz[1], A. Schlaefli[1], J. J. Romero[1], J. H. Shin[1], F. H. Kamada[2], U. Carneiro[2], and A. T. Adesogan*[1], *[1]Department of Animal*

Sciences, IFAS University of Florida, Gainesville, [2]Department of Animal Sciences, UNESP, Jaboticabal, Sao Paulo, Brazil.

The objective was to determine the effect of applying a bacterial inoculant to corn silage on the performance of dairy cows. Corn silage was harvested at 35% DM, treated with or without 150,000 cfu/g of fresh forage of an inoculant containing *Lactococcus lactis* SR 3.54, *Lactobacillus plantarum* CHCC6072, and *Enterococcus faecium* M74 (Chr. Hansen, Denmark) and ensiled in 2 3.7-m wide plastic bags for 186 d. Sixty lactating dairy cows (20 ± 4 DIM) were blocked by parity and milk production and randomly assigned to treatments. Cows were fed a common diet for a 10-d covariate period followed by a 90-d experimental period when a TMR consisting of 35% corn silage, 11% alfalfa hay and 54% of a concentrate was fed. Milk production and DMI of individual cows were recorded daily. Milk and feed ingredients were sampled weekly and chemically characterized. Cows were dosed with chromic oxide for 10 d and fecal samples were collected in the last 5 d to estimate in vivo apparent digestibility. The data was analyzed as a randomized complete block design and the statistical model included treatment, time (repeated), parity, and the interactions. Compared with cows fed silage without inoculant, cows fed inoculated silage had greater yields of milk (38.4 vs. 37.4 kg/d; SEM = 0.23), FCM (38.2 vs. 37.3 kg/d; SEM = 0.22), fat (1.33 vs. 1.30 kg/d; SEM = 0.01) and lactose (1.91 vs. 1.82 kg/d; SEM = 0.01) and greater FCM:DMI ratio (1.72 vs. 1.54 kg/d; SEM = 0.02). Daily DMI (23.2 vs. 25.3 kg/d; SEM = 0.14) and concentrations of milk fat (3.43 vs.3.48%; SEM = 0.01) and protein (2.82 vs. 2.93%; SEM = 0.005) were lower in cows fed the inoculated silage versus the no inoculated silage diet. However, DM (70.7 vs. 71.6%; SEM = 0.92) and NDF digestibility (56.9 vs. 58.6%; SEM = 1.1) were unaffected by treatment. In conclusion, applying the inoculant to corn silage increased milk production and efficiency of feed utilization by lactating dairy cows.

Key Words: silage inoculant, milk yield, *Lactococcus*

W64 Use of virginiamycin and rumen-protect fat, and its association in the diet of crossbred dairy cows grazing tropical pastures. R. C. Silva[1], B. Pessim[3], L. A. Souza[3], J. A. Alves Neto[1], J. M. B. Benatti*[1], A. D. Moreira[1], A. F. Campos[1], P. H. Gonçalves[3], R. D. Signoretti[2], and G. R. Siqueira[2], *[1]Universidade Estadual Paulista – FCAV, Jaboticabal, São Paulo, Brazil, [2]Agencia Paulista de Tecnologia dos Agronegócios - Alta Mogiana, Colina, Sâo Paulo, Brazil, [3]Centro Universitário de Barretos, Barretos, São Paulo, Brazil.*

The study aimed to evaluate virginiamycin (VM), rumen-protected fat (RPF) and its association in the production of dairy cows supplemented and maintained on pasture under rotational stocking Tanzania. A total of 16 crossbred Holstein × Zebu cows (predominantly 3/4 grade of Holstein blood), average live weight of 500 kg, with production at the beginning of the experiment 20 kg / day were distributed in 4 4 × 4 Latin square. The experimental area was 24 paddocks with 1.750 m^2 (total of 4.2 ha) formed with *Panicum maximum* 'Tanzania', irrigated and managed grazing system in flash. The supplement was made up of citrus pulp (79.8 g/kg), soybean hulls (21.7 g/kg), corn germ (256.5 g/kg), peanut meal (30.2 g/kg) refinazil (114.0 g/kg), corn (430.0 g/kg) and mineral core doped Factor Premium (Premix, Patrocinio Paulista-SP) (67.8 g/kg). Treatments consisted of control; VM (35 mg/kg of concentrate) RPF protected fat soybean oil (1% DM of concentrate) and VM (35 mg/kg of concentrate) associated with RPF (1% DM of concentrate), the experimental unit was the animal. The variables were analyzed using the SAS software (version 9.0) using the PROC MIXED considering significant difference $P < 0.10$. There was no interaction for any of the variables ($P > 0.10$). The inclusion of RPF did not affect milk production ($P = 0.155$), with an average of 17.17 kg/d, the VM has increased from 16.92 to 17.42 kg/d ($P = 0.087$). In milk yield corrected for 4% of fat, the use VM increased milk production at 0.66 kg/d ($P = 0.034$) and RPF decreased by inclusion of 0.75 kg/d ($P = 0.017$). The inclusion of RPF decreased ($P < 0.10$) percentages of total solids, lactose and nonfat dry extract and did not alter the percentages of fat, protein and milk urea nitrogen. The VM reduced the protein ($P = 0.098$) and did not alter the other characteristics of milk. The virginiamycin supplementation in dairy cows grazing grass Tanzania increases milk production while maintaining quality. The use of RPF reduced milk production correct for 4% of fat.

Key Words: fodder, milk additive, supplement

W65 Influence of an antioxidant supplementation on adipose and liver transcriptome in early lactation dairy cattle. J. McNamara*[1], S. Shields[1], J. Thomson[2], and E. von Heimendahl[3], *[1]Washington State University, Pullman, [2]Montana State University, Bozeman, [3]Lohmann Animal Health GmbH, Cuxhaven, Germany.*

Vitamin E supplementation to dairy cattle can support a stronger immune and inflammatory system, but is expensive and can itself be oxidized. Antioxidants scavenge the reactive oxygen species in feed and could spare vitamin E in the ration. Therefore, greater amounts of vitamin E are absorbed and are available for the endogenous radical defense system. Our objective was to test the effect of inclusion of an antioxidant added to the feed to reduce the vitamin E necessary to maintain production and health of lactating dairy cattle. In addition we were interested to know if vitamin E could alter the expression of key immune or inflammatory functional genes in adipose and liver. The study was a randomized complete block, and cows were fed a TMR ad libitum to requirements from 14 to 84 d postpartum. Twenty cows each were allotted to 3 treatments; a control ration containing 1000 IU/kg vitamin E; the same ration with 150 mg antioxidant (Loxidan, Lohmann Animal Health, Cuxhaven) per kg DM or a ration with 3000 IU/kg vitamin E. Adipose and liver samples were taken at 7 and 28 DIM, RNA was prepared and samples were analyzed on the Affymetrix Bovine gene array chip, with the data analyzed using Genesifter by Geospiza. Plasma Vitamin E was higher ($P < 0.01$) in higher vitamin E compared with control with or without Loxidan. In primiparous animals, milk production was highest ($P < 0.01$) in animals on the high vitamin E, intermediate on low vitamin E with Loxidan and lowest on control. In the adipose transcriptome showed 27 genes improving response to stress that increased in animals fed Loxidan; in the liver 18 genes controlling antioxidant activity increased in animals fed Loxidan ($P < 0.05$ for all). Higher vitamin E feeding showed 5 genes controlling immune processes increased compared with control. The advanced oxidation protein products were lower ($P < 0.05$) in higher vitamin E or Loxidan-Low vitamin E compared with controls. A lower inclusion rate of vitamin E can be fed if the diet is additionally protected with antioxidants to maintain production and may improve immune and inflammatory status.

Key Words: vitamin E, lactation, antioxidant

W66 Effect of *Saccharomyces cerevisiae* live cells on milk yield and digestibility of buffalo cows. F. Masucci[1], G. De Rosa[1], CMA Barone[1], P. Parente[1], ML Varricchio[1], A. Di Francia[1], and E. Chevaux*[2], *[1]Università di Napoli Federico II, Dipartimento di Agraria, Portici (NA), Italy, [2]Lallemand SAS, Blagnac, France.*

The effects of *Saccharomyces cerevisiae* strain CNCM I-1077 dietary supplementation were examined in lactating buffalo cows. On a farm

in Caserta province, 44 buffalo cows were divided into Control and Saccharomyces groups balanced for age (on average, 52.7 ± 2.1 mo), days in milk (120 ± 64 d) and milk production (9.2 ± 1.37 kg/head/d). The groups were fed the same total mixed ration (TMR) that was supplemented, in Saccharomyces group, with 50 g/day of yeast supplement (Levucell SC), corresponding to 10×10^9 cfu/day live cells. The experimental period lasted 16 weeks. At the beginning and at the end of this period, each cow was weighted and scored for BCS. Every 2 weeks milk yield of each cow was measured and sampled; DMI was also evaluated on pen basis. At the end of experimental period, total tract in vivo digestibility was evaluated by using acid insoluble ash as indigestible marker. Milk traits and estimated mozzarella cheese yield were analyzed by a linear mixed model for repeated measures including the effects of diet, time and the interaction diet*time. The effect of diet on DMI, BCS and digestibility coefficients were analyzed by one-way ANOVA. No differences ($P > 0.05$) were found between the dietary groups for live weight (663.0 vs. 689.6 kg, respectively for Control and Saccharomyces group, SEM 11.8) and BCS (6.33 vs. 6.11 SEM 0.39). Saccharomyces supplemented cows presented higher ($P < 0.05$) TMR-DMI (16.1 vs. 16.5 kg/d, SEM 0.11) and milk yield (7.6 vs. 8.3 kg/head/d, SEM 0.251). Although milk fat (9.10 vs. 9.64%, SEM 0.254) and milk protein (5.39 vs. 5.34%, SEM 0.10) were not influenced by the treatment ($P > 0.05$), Saccharomyces group had greater ($P < 0.01$) estimated mozzarella yield (2.17 vs. 2.45 kg/d SEM 0.075). Total tract in vivo digestibility coefficients of dry matter, organic matter, crude protein and NDF were significantly higher in Saccharomyces compared with Control group. Overall, live yeast supplementation to lactating buffaloes significantly increased milk production, without decreasing milk quality, live weight and BCS.

Key Words: buffalo cow, live yeast, milk production

W67 Effects of arginine concentration on the in vitro expression of casein and mTOR pathway related genes in mammary epithelial cells from dairy cattle. M. Z. Wang[1,2], B. L. Xu[1], D. P. Bu[2], J. Q. Wang[2], and J. J. Loor*[3], *[1]Yangzhou University, Yangzhou, China, [2]State Key Laboratory of Animal Nutrition, Beijing, China, [3]University of Illinois, Urbana.*

Arginine is a conditionally-essential amino acid that is taken up by bovine mammary gland in excess of its output in milk. In this study we evaluated the effects of arginine level on the expression of casein and signaling pathway-related genes in mammary epithelial cells. The treatments (applied for 24 h) were designed to be devoid of Arg 0X (control; 0.00 mg/L), resemble the profile of Arg in casein (Arg 1X; 278.00 mg/L), be deficient, Arg 0.25X; 69.50 mg/L) and Arg 0.5X (139.00 mg/L), or be in excess of the amount in casein, Arg 2X (556.00 mg/L), Arg 4X (1,112 mg/L), and Arg 8X (2,224 mg/L). Cultures were run in triplicate for each treatment. An ANOVA with Arg level as fixed effect and replicate as random effect was used for statistical analysis. Treatment means were separated using Fisher's least significant difference pair-wise comparisons. The expression of CSN1S, CSN3 and mTOR in the experimental groups was higher than those of the control group ($P < 0.05$). Except for Arg 0.25X and Arg 8X ($P > 0.05$), the expression of CSN1S2, CSN2 and JAK2 in other experimental groups was higher ($P < 0.05$) than those in the control group. Except for Arg 8X ($P > 0.05$), the expression of STAT5 in the other experimental groups was higher than those of the control group ($P < 0.05$). It was also observed that, except for Arg 0.5X, S6K expression was higher in other experimental groups than the control group ($P < 0.05$). In contrast, except for Arg 0.25X, the other experimental groups resulted in lower 4EBP1 expression than the control group ($P < 0.05$). Among groups, the expression of CSN1S1, CSN1S2, CSN2, CSN3, JAK2, STAT5, mTOR and S6K gene was highest with Arg 2X ($P < 0.05$); the reverse was true for 4EBP1 gene, with the lowest expression in this group ($P < 0.05$). Taken together, arginine appears to play an important role in the transcriptional regulation of casein genes and mTOR related genes in bovine mammary epithelial cells.

Key Words: mammary, milk protein, nutrition

W68 Essential amino acid signal on translation regulation pathways in mammary tissue. S. I. Arriola Apelo*[1], L. M. Singer[1], X. Lin[2], and M. D. Hanigan[1], *[1]Department of Dairy Science, Virginia Polytechnic Institute and State University, Blacksburg, [2]Animal Science and Technology College, Shandong Agriculture University, Shandong Province, China.*

Signaling pathways regulate rate of protein translation in the mammary gland. The quantitative effects of Ile, Leu, Met, and Thr on mammalian target of rapamycin (mTOR) and eukaryotic initiation factor (eIF) 2 pathways were studied with a central composite design consisting of 4 central runs, 2 axial runs per AA, and a complete 2^4 factorial. The central run was set to 35% of the concentration of Dulbecco's Modified Eagle Medium (DMEM) for each of the above AA. Axial runs were set to 0 and 100% of DMEM. Factorial runs were set at 20 and 50% of DMEM. Mammary tissue slices (0.12 ± 0.02 g) from 5 lactating dairy cows were incubated 4 h at 37°C in 5 mL of treatment media enriched with [$^2H_5$] Phe. Western immunoblotting was performed to identify total and site-specific phosphorylated mTOR (Ser2448), eukaryotic elongation factor (eEF) 2 (Thr56), ribosomal protein (rp) S6 (Ser235/236), and eIF2a (Ser51). The statistical model included individual AA linear and quadratic effects and one-way interactions as fixed continuous effects, and cow as a random effect. Neither linear and quadratic amino acid effects nor interactions among them were significant for eIF2a (Ser51) phosphorylation. In the mTOR pathway, AA did not affect mTOR phosphorylation. However, phosphorylation of eIF2 and mTOR were negatively correlated (−0.28, $P < 0.001$) as expected. Downstream of mTOR, Leu ($P = 0.027$) inhibited eEF2 phosphorylation, which is known to stimulate translation elongation. The effect of Leu tended to be affected by concentrations of Ile (Leu*Ile, $P = 0.058$) and Thr (Leu*Thr, $P = 0.093$). Phosphorylation of mTOR was negatively correlated with that of eEF2 (0.31, $P < 0.001$). Interestingly, rpS6 phosphorylation was linearly affected by concentrations of Ile (Ile, $P = 0.013$), but not of Leu, and this response was affected by Thr (Ile*Thr, $P = 0.007$). Phosphorylation of rpS6 and eEF2 were negatively correlated (0.38, $P < 0.001$), and the former tended to be correlated with mTOR phosphorylation (0.15, $P < 0.086$). These results are in agreement with previous ones where independent effects of Leu and Ile on translation regulation were observed.

Key Words: essential AA, mTOR pathway, protein translation

W69 Effects of two different ruminant methionine technologies on milk and milk component production across a range of metabolizable methionine adequacy. R. S. Ordway*[1], C. G. Schwab[2,3], B. K. Sloan[4], and N. L. Whitehouse[2], *[1]Balchem Corporation, New Hampton, NY, [2]University of New Hampshire, Durham, [3]Schwab Consulting LLC, Boscobel, WI, [4]Adisseo North and Central America, Alpharetta, GA.*

Methionine is often considered the first limiting AA in dairy cow diets and providing more metabolizable Met (MP-Met) in diets in the form of ruminant Met products may have positive consequences on lactational performance and the efficiency of utilization of metabolizable protein

(MP). Ruminant Met products can only be used effectively in ration formulation if they are well characterized in terms of the quantity of MP-Met they provide per unit of product and it is reasonable to assume that diets adequate in MP-Met would not elicit a milk or milk component response to additional MP-Met. Forty multiparous lactating Holstein dairy cows were used in a replicated randomized complete block split plot 5 × 5 Latin square design with a 2 × 2 × 5 factorial arrangement of treatments. The main effects were (1) 2 levels of dietary Met adequacy [Limiting (L) or Adequate (A)]; (2) 2 forms of dietary Met (encapsulated DL-Met, Smartamine M (S), or the dry isopropyl ester of the Met analog, MetaSmart (M); and (3) 5 incremental levels (0, 3, 6, 9, or 12 g/d) of supplementary estimated MP-Met. The basal diets were formulated to meet NRC (2001) requirements for energy and nutrients and were identical except for predicted Met in MP (L: 1.81% and A: 2.31%). The Lys to Met ratios in MP for the L and A diets were 3.73:1 and 2.94:1, respectively. Smartamine M was used to make the basal diet adequate in MP-Met and significance was declared at $P < 0.05$. There were no differences in DM intake, milk fat yield, or milk urea N across treatments. There was a linear decrease in milk yield, protein yield, and lactose yield and a linear increase in fat concentration for AS. There was a linear increase in milk protein concentration for both LS and LM and a linear increase in milk protein yield for LM only. The results of this research indicate that the Met status of the basal diet and the source of supplemental dietary Met affect the response in milk and milk component production differently and also provide evidence that Met analogs are metabolized differently than DL-Met.

Key Words: methionine, methionine analogue, amino acids

W70 Performance and health of Holstein dairy calves fed Peptide Powder 80 or hydrolyzed wheat protein as alternative protein sources in milk replacers. H. Chester-Jones*[1], D. Dean[2], D. Ziegler[1], K. Halpin[2], M. Raeth-Knight[3], and D. Carlson[4], *[1]University of Minnesota Southern Research and Outreach Center, Waseca, [2]International Ingredient Corporation, St. Louis, MO, [3]University of Minnesota, St. Paul, [4]Milk Products, Chilton, WI.*

One-hundred twelve (2–4 d old) individually fed Holstein heifer calves (39.7 ± 0.7 kg) were randomly assigned to 1 of 4 treatments in January, 2012 to evaluate pre- (d 1 to 42) and post-weaning (d 43 to 56) calf performance and health when partially replacing milk protein in milk replacers (MR) with Peptide Powder 80 or hydrolyzed wheat protein. Peptide Powder 80 (International Ingredient Corp., St. Louis, MO) is a novel protein source designed for MR made up of hydrolyzed vegetable proteins and yeast (80% CP, % DM). All calves were fed a non-medicated 20% protein:20% fat MR at 0.284 kg in 1.99 L water (12.5% solids) 2× daily for the first 35 d and 1× daily from d 36 to weaning at d 42. Calf starter (CS; 18% CP, as-fed) and water were offered free choice d 1 to 56. Day 1 to 14, 1:1 neomycin:oxytetracycline was added to the MR solution to provide 22 mg/kg BW/d. Lysine and total sulfur amino acid concentrations in MR were balanced across all treatments with the use of synthetic AA. Treatments (TRT) were (1) Control all milk MR; (2) MR with 33% of the CP replaced by hydrolyzed wheat protein; (3) MR with 33% of the CP replaced by Peptide Powder 80; and (4) MR with 33% of the CP replaced by Peptide Powder 80 and additional Thr and Trp to be equivalent to TRT 1. There were no pre- or post-weaning ADG, CS, DMI and hip height (HH) differences ($P > 0.05$). Overall 56 d total BW gain, CSI, DMI and HH gain averaged 36.9 kg, 47.2 kg, 68.4 kg and 10.25 cm, respectively. Gain:feed (d 1 to 56) was higher ($P < 0.05$) for calves on TRT 2 (0.56) vs. those fed TRT 3 and 4 (0.53), but G:F did not differ between TRT 1 calves (0.54) and calves fed TRT 3 or 4. There were no TRT differences in scouring d and treatment costs. Under the conditions of this study, partially replacing milk protein in MR with Peptide Powder 80 or hydrolyzed wheat protein resulted in similar calf performance.

Key Words: Holstein calves, milk replacer protein sources, performance

W71 Effects of feeding LysiPEARL and rumen-protected lysine sources on plasma lysine concentration in lactating dairy cows. W. D. Weich*[1], K. F. Kalscheur[1], F. R. Valdez[2], and C. A. Macgregor Jr.[3], *[1]South Dakota State University, Brookings, [2]Kemin Industries, Inc., Des Moines, IA [3]Soy Best, West Point, NE.*

A common method to balance for metabolizable protein lysine in lactating dairy cows is to feed commercial sources of rumen-protected (RP) lysine. The objective of these experiments was to evaluate the effects of feeding a source of RP-lysine on plasma lysine. In the first experiment, 40 Holstein cows were fed a common diet randomly assigned to one of 5 topdress treatments: (1) Control, (2) Lysine HCl, (3) Aminoshure-L (Balchem Inc., New Hampton, NY), (4) LysiPEARL (Kemin Industries Inc., Des Moines, IA), and (5) USA Lysine (Kemin Industries Inc.). Each lysine treatment provided 150 g/h/d of lysine HCl and were blended into 900 g of ground corn and fed so treatments were consumed before availability of the daily TMR. Jugular blood samples were taken at 2 h intervals starting at feeding and analyzed for plasma amino acid (AA) concentration. Responses of plasma lysine concentrations compared with control were summed for each plasma collection to demonstrate overall change. Cows fed LysiPEARL (171 mg/dL) and USA LYSINE (256 mg/dL) had greater ($P < 0.10$) lysine concentrations, while cows fed Aminoshure-L (40 mg/dL) and Lysine HCl (86 mg/dL) were not different ($P > 0.10$) from cows fed Control. In the second experiment, LysiPEARL was added to fresh soy gums which were then added to mechanical extracted soybean meal (MES) (Soy Best; West Point, NE). Eight Holstein dairy cows were randomly assigned to one of 2 treatments. The first treatment diet contained 2.27 kg MES fortified with LysiPEARL (TRT), while the second treatment contained 2.27 kg MES without the LysiPEARL addition (CON). Diets were fed for 8 d and jugular blood samples were collected at 0.5 h before feeding and at 2 h intervals for 20 h on d −1 and d 8. Plasma AA data were summarized and expressed as a change from baseline determined on d −1. Plasma lysine for cows fed TRT (33.3 mg/dL) was greater ($P < 0.10$) compared with cows fed CON (21.4 mg/dL). In conclusion, results demonstrate LysiPEARL products are effective in increasing plasma lysine concentration when fed alone or when inserted into gums and combined with MES.

Key Words: rumen-protected lysine, mechanical extracted soybean meal

W72 Impact of fiber and monensin in texturized calf starters when fed in the nursery phase on calf health and performance in both the nursery and grower phases. D. Ziegler*[1], B. Ziegler[2], H. Chester-Jones[1], D. Schimek[2], and M. Raeth-Knight[3], *[1]University of Minnesota Southern Research and Outreach Center, Waseca, [2]Hubbard Feeds Inc., Mankato, MN, [3]University of Minnesota, St. Paul.*

One-hundred four (2–4 d old) individually fed Holstein heifer calves (41.2 ± 0.72 kg BW) were randomly assigned in a 2 × 2 factorial design to evaluate calf performance and health when fed texturized calf starters (CS) with varying fiber levels with and without monensin (M).The effect of the nursery diets on later calf performance were observed in group pens (7 heifers/pen) when fed a common diet from 9 to 25 wk of age. All nursery calves were fed a non- medicated 20% protein:20% fat milk replacer (MR) at 0.284 kg in 1.99 L water (12.5% solids) 2x daily

for the first 35 d and 1x daily from d 36 to weaning at 42 d. Calf starter (CS; 18% CP, as-fed) and water were fed free choice d 1 to 56. Day 1 to 14, 1:1 neomycin:oxytetracycline was added to the MR solution to provide 22 mg/kg BW/d. Treatments were 1), Lower fiber (LF) CS with 0 mg/kg M; 2), LF CS with 49.5 mg/kg M; 3), Higher fiber(HF) CS with 0 mg/kg M and 4), HF CS with 49.5 mg/kg M. LF CS avg. 8.5% ADF and 16.4% NDF. HF CS avg 12.3% ADF and 18.3% NDF. Over 56 d in the nursery phase, calves fed CS with M had lower gains ($P = 0.007$) total CS and total DMI ($P = 0.02$) regardless of fiber level. There were no treatment health costs, gain/feed or hip height (HH) gain differences ($P > 0.05$). In the grower phase, heifers were limit-fed a common 16% CP grain mix daily (2.73 kg/heifer, d 1 to 56 and 2.27 kg/heifer, d 57 to 112) with free choice hay. There were CS × M treatment interactions ($P = 0.05$) for gain over the 112 d grower phase. There were no differences ($P > 0.05$) in HH for the grower period but CS × M interactions ($P = 0.04$) for HH were observed for the combined study periods. Under the conditions of the nursery phase, through 56 d, calves fed M had lower intakes and gains. Fiber level had no gain affects. There were indications of compensatory growth over the 112 d grower period from calves fed CS with M in the nursery phase.

Key Words: calf performance, calf starter, monensin and fiber levels

W73 Manual manipulation of calf starter for calves fed milk replacer: Effects on growth, starter intake, and weaning. N. E. Guindon, R. G. Cabral*, N. T. Antaya, N. L. Whitehouse, and P. S. Erickson, *University of New Hampshire, Durham.*

Thirty-six Holstein heifer calves were assigned at birth to 1 of 4 treatments in a 2 × 2 factorial arrangement of treatments in a randomized complete block. The objectives of this study were to determine if manually stirring calf starter resulted in increased dry matter intake (DMI), growth and improved weaning in calves fed a high protein milk replacer (HPMR). Treatments were (1) conventional MR (CMR)+ calf starter with no stirs, (2) CMR+ calf starter with stirs at 1030 and 1400 h, (3) HPMR + calf starter, and (4) HPMR + calf starter with stirs at 1030 and 1400 h. All calves had free-choice water. Milk replacer was fed twice daily. Calves were on treatment for 6 wk and weaned at wk 7 (fed MR once daily) and tracked for 1 wk until d 56. Stirs/no stirs continued until d 56. Water intake ($P < 0.001$), average daily gain (ADG) ($P < 0.0001$), DMI ($P < 0.0001$), and feed efficiency (ADG/DMI, $P < 0.01$) were increased in HPMR-fed calves compared with calves fed CMR preweaning (2.24 L/d vs. 0.97 L/d; 0.60 kg/d vs. 0.28 kg/d; 1.23 kg/d vs. 0.79 kg/d; 0.48 vs. 0.30, respectively). Calves fed HPMR had greater wither height gain ($P < 0.001$), and hip height gain ($P < 0.02$) compared with calves fed CMR preweaning (0.21 cm/d vs. 0.15 cm/d, respectively, for hip and wither height gains). Calves that had starter stirred ate less DM ($P < 0.05$) and tended to eat less starter ($P < 0.1$) compared with calves that did not have starter stirred (0.97 kg/d vs. 1.05 kg/d; 0.23 kg/d vs. 0.3 kg/d, respectively). During wk 7, calves formerly fed HPMR ate less ($P < 0.0001$) starter than calves fed CMR (0.50 vs.1.18 kg/d, respectively), but more ($P < 0.0001$) MR (1.13 kg/d vs. 0.45 kg/d). Calves that had their starter stirred tended ($P < 0.10$) to eat less starter and DM than calves that did not have their starter stirred (823 g/d vs. 979 g/d; 1.61 kg/d vs. 1.77 kg/d respectively). Postweaning, calves formally fed HPMR ate less starter ($P < 0.01$) than calves fed CMR (1.22 kg/d vs. 1.69 kg/d respectively). Manual manipulation of starter did not improve growth or DMI preweaning, weaning and postweaning phases in calves fed either HPMR or CMR.

Key Words: calf, milk replacer, starter

W74 Effect of 2-hydroxy-4-methylthio-butanoic acid (HMTBa) on ruminal fermentation, digestibility, and performance of lactating dairy cows. C. Lee[1], J. Oh*[1], A. N. Hristov[1], and G. I. Zanton[2], *[1]Department of Animal Science, The Pennsylvania State University, University Park, [2]Novus International Inc., St. Charles, MO.*

HMTBa has been shown to stimulate microbial protein production in continuous culture and also has methionine-sparing effect in vivo. The objective of this experiment was to test the effect of HMTBa on ruminal fermentation and microbial protein synthesis, nutrient digestibility and urinary N losses, and performance of dairy cows. Eight multiparous lactating Holstein dairy cows (51 DIM, SD = 3.9) were assigned to 4 treatments in a replicated 4 × 4 Latin square trial. The basal diet was formulated to meet or exceed NRC (2001) recommendations and contained corn silage, grass hay, ground corn grain, whole heated soybeans, soybean meal, canola meal, cottonseed hulls, and other minor ingredients (DM basis: 15.9% CP and 33% NDF). Treatments were 4 levels of HMTBa, fed through the mineral/vitamin premix: 0 (control), 0.05, 0.10, and 0.15% (DM basis). Each experimental period was 28 d, including 21 d for adaptation. Ruminal ammonia and microbial N were labeled through a 6-d intraruminal infusion of $^{15}NH_4Cl$. Treatment had no effect on DM intake (28.4 to 28.9 kg/d; $P \geq 0.64$), milk yield (44.6 to 45.0 kg/d; $P \geq 0.46$), and feed efficiency and milk composition ($P \geq 0.12$). Total tract apparent digestibility of nutrients was also not affected ($P \geq 0.08$) by treatment, except digestibility of CP decreased quadratically ($P = 0.01$) with HMTBa supplementation. Fecal, but not urinary, and total excreta N losses were increased ($P = 0.004$ to 0.05; quadratic responses) by HMTBa. Ruminal pH and ammonia concentration were not affected by treatment ($P \geq 0.21$). Concentrations of acetate and propionate were not affected by treatment ($P \geq 0.08$), but butyrate concentration was decreased linearly ($P = 0.03$) by HMTBa. Concentration of microbial N in reticular small and large particulate phases and whole digesta tended to be numerically increased ($P \leq 0.17$) by HMTBa. In conclusion, HMTBa had no effect on intake and performance, decreased dietary CP digestibility, and tended to increase the concentration of microbial N in reticular digesta in the conditions of this crossover trial.

Key Words: dairy cow, rumen microbial protein, 2-hydroxy-4-methylthio-butanoic acid

W75 Yeast-derived microbial protein supplementation of dairy calves. V. A. Silveira[1], K. P. Freire[1], A. V. Siqueira[1], P. A. M. Barros Junior[1], I. M. Lima[2], M. S. Zoni[3], W. Giardini[4], R. Almeida*[2], and M. N. Pereira[1], *[1]Universidade Federal de Lavras, Lavras, MG, Brazil, [2]Universidade Federal do Paraná, Curitiba, PR, Brazil, [3]Milkonsult, Castro, PR, Brazil, [4]Alltech do Brasil, Araucária, PR, Brazil.*

Yeast-derived microbial protein (YMP) is a source of high quality protein and peptides. The supplementation of YMP to dairy calves before and after the weaning phase was evaluated. Fifty-eight Holstein calves, 32 milk-fed and 26 weaned, were paired blocked within rearing stage by body weight, and were randomly assigned to YMP (Demp, Alltech) or Control for 21d. Calves were forced fed 250mL of milk or water once per day, added or not of 40g/d of YMP. Calves were group fed by automatic feeders (DeLaval calf feeder CF150X) with whole pasteurized cow milk (20L) added of milk and milk replacer powder (1kg). A calf starter concentrate was offered ad libitum to all calves, and weaned calves also had access to ryegrass hay and haylage. Body weight was obtained at 7-d intervals at 2PM, rectal temperature was measured daily at 2PM, fecal (1 = normal, 4 = watery) and activity (1 = active, 4 = recumbent) scores daily, as well as the cost of medications. Data obtained over time was analyzed with Mixed of SAS with a model containing the fixed effects of rearing stage, block within rearing stage,

treatment, interaction of treatment and rearing stage, time, and its 2 and 3 term interactions. The mean square for calf within treatment tested the treatment effect. Mean age at experimental d1 for milk-fed calves was 50.7 ± 21.9 for Control and 49.9 ± 21.7 for YMP, and for the weaned calves it was 113.0 ± 16.9 and 115.0 ± 17.8, respectively. The mean BW of milk-fed calves was 98kg and of weaned calves 163kg. The intake of fluid diet by milk-fed calves was 7.4 and 7.5L/d for Control and YMP, respectively ($P = 0.53$). There was an interaction of treatment, time and rearing stage for daily gain ($P < 0.01$). Calves during the milk-fed phase gained 1.186g/d for Control and 1.211g/d for YMP, and for the weaned phase it was 1.212g/d and 1.421g/d, respectively (SEM = 0.055). There was no detectable effect on the cost of medications ($P > 0.28$) or rectal temperature ($P > 0.35$), and treatment did not affect the frequency of fecal or activity scores ($P > 0.53$, Chi-Square). The supplementation of YMP after weaning increased the daily gain of calves raised on an accelerated early nutrition program.

Key Words: calf feeding, calf, yeast-derived microbial protein

W76 Effect of supplementing vitamin E and β-carotene to prepartum Holstein cattle on health and reproductive responses. D. Wang[1], M. Garcia*[1], R. S. Bisinotto[1], N. Martinez[1], F. S. Lima[1], L. F. Greco[1], J. H. Shin[1], A. M. M. DiCalaça[1], A. L. Ranieri[1], B. L. Artiaga[1], E. K. Ganda[1], G. C. Gomes[1], L. F. V. Becker[1], S. C. Soares[1], V. S. Rezende[1], M. A. Engstrom[2], J. E. P. Santos[1], and C. R. Staples[1], *[1]University of Florida, Gainesville, [2]DSM, Parsippany, NJ.*

Objectives were to improve health and reproductive performance of Holstein cattle by drenching antioxidants during the periparturient period. At 23 d before the expected calving date, Holsteins were blocked by parity and randomly assigned to one of 4 treatments arranged in a 2 × 2 factorial design. Factors were drenching with vitamin E (VitE; 0 or 14,000 IU/drench) and β carotene (BC; 0 or 5 g/drench). Animals were drenched at approximately d −23, −12 and 0 relative to calving. Cows were monitored daily during the first 10 DIM for rectal temperature and vaginal discharge. Cows were presynchronized with 2 injections of $PGF_{2\alpha}$ at 46 ± 3 and 60 ± 3 DIM. Cows not inseminated in estrus after the second $PGF_{2\alpha}$ injection were enrolled in a 5-d timed AI protocol starting at 72 ± 3 DIM. The occurrence of retained fetal membranes (RFM) was included in the model to analyze for metritis (MT), puerperal metritis (PMT), and fever (≥39.5°C). The incidence of RFM was 7.3% (52/708). Drenching BC to animals with RFM reduced ($P \leq 0.04$) the incidence of PMT (31.0 vs. 65.2%) and fever (41.4 vs. 69.6%). Drenching VitE tended to reduce ($P = 0.08$) the incidence of MT (24.2 vs. 27.9%) and reduced ($P \leq 0.04$) the incidence of PMT (10.6 vs. 13.5%) and fever (32.7 vs. 36.7%). However, clinical endometritis (Metricheck) at 24 DIM was not affected by treatments. Drenching primiparous cows with BC reduced ($P = 0.04$) the incidence of mastitis (64.0 vs. 52.9%) but not multiparous cows (45.3 vs. 51.0%). Number of cases of mastitis and DIM at first mastitis were not affected by treatments. Eighty percent of cows had detectable corpus luteum by 63 DIM (n = 606) using ultrasound and was unaffected by treatment. Pregnancy at 60 d post AI (palpation) to first and second AI was not affected by treatments and averaged 27.8 and 33.5% for all inseminated cows, respectively. Pregnancy at 300 DIM was 73.8% for all cows (463/627) whereas proportion of culling was 33.2% with no effect of treatments. Drenching antioxidants prepartum and at calving improved some health measures but did not influence reproductive outcomes of Holstein cows.

Key Words: cow, antioxidant, reproduction

W77 Optimal lysine and methionine concentrations for milk protein production as determined with the latest versions of Dairy NRC (2001) and AMTS-Cattle. N. L. Whitehouse*[1], C. G. Schwab[1,2], T. Tylutki[3], and B. K. Sloan[4], *[1]University of New Hampshire, Durham, [2]Schwab Consulting LLC, Boscobel, WI, [3]Integrated Solutions for Sustainable Agriculture, Cortland, NY, [4]Adisseo North and Central America, Alpharetta, GA.*

We previously reported optimal concentrations for lysine (Lys) and methionine (Met) in metabolizable protein (MP) for NRC (2001), CPM (v.3.0.10), and AMTS (v.2.1.1) (Whitehouse et al., 2009; J. Dairy Sci. Vol. 92, E-Suppl.1). The indirect dose-response approach adopted by NRC (2001) was used to generate the dose-response plots, employing the same data set as used by NRC (2001). Since then, an updated version of NRC (v.1.1.9) and v.3.3.4 of AMTS have been released and are being used. The only change made to NRC (2001) affecting predicted nutrient supply was to fix the fractional passage rate (kp) equation for dry forages. Changes in AMTS affecting nutrient supply are the following changes in the feed library of CNCPS v. 6.1: changing protein pool A1 from NPN to ammonia N, assigning soluble true protein to protein pool A2, changing the fractional digestion rates (kd) for protein pools A1 and A2, and a refinement and standardization of the chemical composition of feeds in the feed library as described by Higgs et al. (2012; Cornell Nutrition Conference Proc.). This was done to better predict MP allowable milk. The objective of this work was to use the same trial data set as used previously to estimate the requirement values for Lys and Met in MP for the updated versions of NRC (2001) and AMTS. The dose-response plots were generated as described in NRC (2001). The resulting breakpoint estimates for the required concentrations of Lys and Met in MP for maximal content and yield of milk protein and the optimal Lys/Met ratios for both versions of each model are shown below.

Table 1.

	Original NRC	Revised NRC	AMTS v. 2.1.1	AMTS v.3.3.4
Protein content				
Lys	6.80	6.83	6.68	6.97
Met	2.29	2.28	2.40	2.53
Lys:Met ratio	2.97:1	3.00:1	2.78:1	2.75:1
Protein yield				
Lys	7.10	7.14	6.74	6.93
Met	2.52	2.37	2.31	2.34
Lys:Met ratio	2.82:1	3.01:1	2.92:1	2.96:1

Key Words: lysine requirement, methionine requirement, model

W78 Lactational and systemic response of lactating dairy cows to duodenal infusions of lysine, methionine, and branched-chain amino acids. S. C. Li*[1], D. P. Bu[2], Y. D. Zhang[2], and J. Q. Wang[2], *[1]University of Manitoba, Winnipeg, MB, Canada, [2]State Key Laboratory of Animal Nutrition, Institute of Animal Science, Chinese Academy of Agricultural Sciences, Beijing, China.*

Four primiparous ruminal- and duodenal-fistulated Holstein dairy cows (BW 525 ± 14 kg, DIM 176 ± 18 d) were used to investigate the effects of duodenal infusion of lysine (Lys), methionine (Met), and branched-chain amino acids (BCAA) on lactational performance and plasma metabolites. Cows were fed a basal total mixed ration containing 8% alfalfa hay, 17% grass hay, 25% corn silage, and 50% concentrate (DM basis). After 10-d adaptation to the basal ration, 4 cows were randomly assigned in a 4 × 4 Latin square design with four 8-d continuous duodenal infusions

of the following amino acid mixtures: (1) 40 g/d of Lys, 19 g/d of Met and 75 g/d of BCAA consisted of 40% leucine (Leu), 40% isoleucine (Ile) and 20% valine (LMB); (2) LMB with BCAA removed (LM); (3) LMB with Met removed (LB); and (4) LMB with Lys removed (MB). Feed and milk samples were collected in the last 4 d of AA infusion, and jugular vein blood was sampled at the last day of the infusion. Dry matter intake (18.2 kg/d), milk yield (16.98 kg/d), milk concentration of fat (4.91%), lactose (4.57%), casein protein (2.80%), and whey protein (0.95%) were not affected by treatments. No effect of the treatments was observed on plasma Lys concentration (85.8 μ*M*). Plasma Met concentration was higher in LM cows compared with that in LMB, LB, and MB cows (102.9 vs. 65.6, 79.4, and 68.9 μ*M*, respectively; $P < 0.01$). Plasma Ile and Leu concentrations were higher ($P < 0.01$) in LMB and LB cows (147.8 and 100.6, 171.2 and 113.3 μ*M*, respectively) compared with that in LM and in MB cows (115.7 and 92.0, 126.0 and 96.9 μ*M*, respectively). Valine was not affected by the treatments (167.3 μ*M*). No treatment effect on blood glucose and insulin was observed (3.82 m*M* and 0.71 ng/mL, respectively). IGF-1 in plasma tended to be lower in MB cows than that in LMB, LM and LB cows (221.6 vs. 238.2, 252.5, and 249.0 ng/mL, respectively; $P = 0.07$). The results indicated that Lys was limited AA to the basal diet used in the study as plasma Lys was not affected by all treatments, as well as a tendency of lowered IGF-1 when Lys was not infused.

Key Words: branched-chain amino acid, dairy cow, lysine

W79 Influence of combination of *Salix babylonica* extract with mineral/vitamin mixture on in vitro gas production kinetics and dry matter degradability of total mixed ration. A. Z. M. Salem*[1], M. M. Y. Elghandour[1], H. Gado[2], L. M. Camacho[3], R. Rojo[4], and J. L. Borquez[1], *[1]Facultad de Medicina Veterinaria y Zootecnia, Universidad Autonoma del Estado de Mexico, Mexico, [2]Animal Production Department, Faculty of Agriculture, Ain Shams University, Qalubia, Egypt, [3]Facultad de Medicina Veterinaria y Zootecnia, Universidad Autonoma de Guerrero, MexicoCd. Altamirano, Guerrero, Mexico, [4]CU-UAEM Temascaltepec, Universidad Autonoma del Estado de Mexico, Mexico.*

The aim of this study was to determine effects of increasing doses of the Salix babylonica extract (SB) and mineral/vitamin mixture (MV) or their combination, as additives, on in vitro gas production and some ruminal fermentation parameters of a total mixed ration of concentrate with corn silage (TMR - 50:50 on DM basis). Four levels of SB extract (0, 0.6, 1.2 and 1.8 mL/g DM) and others of MV (0, 0.5, 1.5 and 2.5 g/100 g DM). Ruminal fluid was obtained from 2 Brown Swiss cows fitted with permanent rumen cannulas fed a TMR of a 50:50 commercial concentrate and alfalfa hay ad libitum. Samples of TMR were weighed into 120 mL serum bottles with appropriate addition of SB extract and then 10 mL of particle free ruminal fluid was added to each bottle followed by 40 mL of the buffer solution and finally, MV doses were added. The GP was recorded at 2, 4, 6, 8, 10, 12, 24, 48 and 72 h of incubation. After 72 h, the incubation was stopped and the pH of the mixture was determined and filtrate used to determine dry matter degradability (DMD), partitioning factor (PF_{72}), gas yield (GY_{24}), in vitro organic matter digestibility (OMD), metabolizable energy (ME), short chain fatty acids (SCFA), and microbial protein production (MCP). Individual addition of SB extract linearly and quadratically increased ($P < 0.05$) GP during all the incubation times, while the addition of MR was linearly increased ($P < 0.05$) GP produced at 48 and 72 h of incubations. The addition of MV was only quadratically increased asymptotic GP ($P = 0.038$). The SB × MR interaction increased ($P = 0.01$) lag time and GP ($P < 0.05$) during the first 36 h of incubation. Addition of SB linearly and quadratically increased ($P < 0.05$) all fermentation parameters except DMD and rumen pH. The addition of MV had only quadratically increased ($P < 0.05$) of pH, PF_{72}, GY_{24} and MCP. Combination of SB × MV increased ($P < 0.05$) DMD, OMD, ME, PF_{72} and SCFA. Combination of *Salix babylonica* extract with mineral/vitamin mixture could be affect positively on ruminal fermentation.

Key Words: gas production, minerals/vitamin, ruminal fermentation

W80 Effects of different feeding frequencies on feedlot performance and carcass traits of feedlot Nellore cattle. T. V. B. Carrara*[2,3], J. Silva[2], M. C. S. Pereira[2], A. L. N. Rigueiro[2], D. H. M. Watanabe[2], D. D. Estevam[2], D. P. Silva[2], D. V. F. Vicari[2], C. A. Oliveira[2], I. C. Batista Junior[2], M. D. B. Arrigoni[1], F. T. V. Pereira[2], D. J. C. Oliveira[4], G. P. Mateus[4], D. D. Millen[2], *[1]São Paulo State University (UNESP), Botucatu, Brazil, [2]São Paulo State University (UNESP), Dracena, Brazil, [3]Supported by FAPESP, São Paulo, Brazil, [4]APTA, Andradina, São Paulo, Brazil.*

This study, conducted at the São Paulo State University feedlot, Dracena Campus, Brazil, was designed to determine the effects of different feeding frequencies on overall feedlot performance and carcass traits of Nellore cattle. The experiment was designed as a completely randomized block, replicated 12 times, in which 48 18-mo-old yearling Nellore bulls (358.2 ± 19.4 kg) were fed in individual pens for 94-d according to the following treatments: (1) feeding one time daily (1×; 0800), (2) feeding 2 times daily (2×; 0800 and 1400), (3) feeding 3 times daily (3×; 0800, 1100 and 1400), and (4) feeding 4 times daily (4×; 0800, 1100, 1400 and 1700). The adaptation program consisted of ad libitum feeding of 2 adaptation diets over period of 14-d with concentrate level increasing from 60% to 86% of diet DM. The finishing diet contained: 67.0% cracked corn grain, 14.0% sugarcane bagasse, 9.0% soybean hulls, 5.5% soybean meal, 4.0% supplement containing 30% of urea, and 0.5% limestone (DM basis). Orthogonal contrasts were used to assess linear, quadratic, and cubic relationship between feeding frequency and the dependent variable. Feeding frequency did not affect ($P > 0.10$) dressing percentage (1× = 55.0%; 2× = 54.6%; 3× = 56.1%; 4× = 55.6%), and DMI in kilos (1× = 7.75 kg; 2× = 7.95 kg; 3× = 8.44 kg; 4× = 8.10 kg) or as % of BW (1× = 1.91%; 2× = 1.98%; 3× = 2.04%; 4× = 1.97%). However, as feeding frequency increased, ADG (1× = 0.979 kg; 2× = 0.961 kg; 3× = 1.175 kg; 4× = 1.138 kg) final BW (1× = 449.8 kg; 2× = 445.4 kg; 3× = 467.4 kg; 4× = 463.6 kg), G:F ratio (1× = 0.128; 2× = 0.121; 3× = 0.141; 4× = 0.142) and HCW (1× = 246.9 kg; 2× = 243.0 kg; 3× = 263.1 kg; 4× = 258.1 kg) linearly increased ($P < 0.05$). The HCW was also affected ($P = 0.01$) cubically as feeding frequency increased. Thus, based on the results of this study, increasing feeding frequency affected feedlot performance and carcass traits of Nellore cattle. In a practical way, feeding yearling Nellore bulls 3 times daily seems to be the most feasible option, as beef prices are generally based on HCW.

Key Words: frequency, HCW, zebu

W81 Growth performance and carcass traits in Alpine male goat kids supplemented with hydroponic green fodder from wheat and corn. M. Guerrero Cervantes*[1,4], A. S. Juárez Reyes[1,4], F.G. Ríos Rincón[2,4], M. A. Cerrillo Soto[1,4], H. Bernal Barragán[3,4], and C. Angulo Montoya[3], *[1]Universidad Juárez del Estado de Durango, Durango, Durango. México, [2]Universidad Autónoma de Sinaloa, Culiacán, Sinaloa. México, [3]Universidad Autónoma de Nuevo Léon, San Nicolás de los Garza, Nuevo Léon. México, [4]Red Internacional de Nutrición y Alimentación en Rumiantes, México.*

This study was carried out to determine the effect of supplementing hydroponic green wheat (HGW; *Triticum aestivum* L.), or hydroponic green corn (HGC; *Zea mays*) on growth performance and carcass traits of Alpine male goat kids fed an oat-straw (OS) based diet. Twenty-five Alpine intact male kids (160 d of age; 20 ± 3 kg BW), were placed during 13 wk, in individual pens, assigned to 5 groups of 5 kids each, and fed with diets calculated according to the French system to balance for intestinal digestible protein (g/d), derived from nitrogen (IDPN) and from energy (IDPE). Diets were composed as follow: T1:50% OS, 35% HGW, 15% rolled corn (RC); T2:50% OS, 35% HGC, 15% cottonseed meal (CSM); T3:50% OS, 30% RS and 20% CSM; T4:50% OS, 18% HGW, 19% RS and 13% CSM; T5:50% OS, 18% HGC, 13% RS and 19% CSM. Data of daily weight gain, DMI, feed conversion and carcass traits were analyzed by ANOVA according to a completely randomized block design, using the initial BW as covariate. Orthogonal contrasts were used to compare diets with HGW and with HGC. The T2 was lower ($P \leq 0.01$) DMI (691 g/d) and feed conversion (8.7:1) was greater ($P \leq 0.05$) than in others. Intake of IDPN (60 g/d) and IDPE (61 g/d) was higher in T4 than in others. Highest ribeye area (8.5 cm^2) was registered by T5. Goat kids fed diets supplemented with HGC performed better ($P \leq 0.05$) than with HGW. In conclusion, feeding growing kids with HGC supplemented diets improved feed conversion and ribeye area and is a valuable alternative to counter high costs of concentrate feeding.

Table 1. Intake, feed conversion and carcass composition traits in Alpine male kids

	T1	T2	T3	T4	T5	SEM	P-value
Daily weight gain (g)	76	81	86	67	88	15.3	0.2051
Daily DMI (g)	798[a]	691[b]	792[a]	806[a]	791[a]	44.6	0.0001
IDPN intake (g/d)	57[ab]	45[b]	57[a]	60[a]	56[a]	4.2	0.0001
IDPE intake (g/d)	60[a]	50[b]	59[a]	61[a]	57[ab]	4.2	0.0001
Feed conversion[1]	10.6[ab]	8.7[b]	9.3[ab]	12.1[a]	9.4[ab]	1.6	0.0011

W82 Molecular cloning and characterization of a novel cellulase with xylanase activity from a metagenomic library of goat rumen. C. Y. Fan[1], H. Q. Jiang[1], Y. H. Zhang[1], X. Z. Sun[1], and J. B. Cheng*[1,2], *[1]College of Animal Science and Technology, Anhui Agricultural University, Hefei, China, [2]State Key Laboratory of Animal Nutrition, Institute of Animal Science, Chinese Academy of Agricultural Sciences, Beijing, China.*

Ruminal microbiome has been as a rich source of cellulase not only for feed but also for bioenergy industry. However, this enzyme source is largely untapped because more than 85% of the ruminal microbes have not been cultivated. The objective of this study was to identify novel cellulase gene from a bacterial artificial chromosome (BAC) library and further to analyze its characteristics. BAC library was constructed using genomic DNA isolated from goat ruminal content. Screening of the clones with cellulase activity was performed on LB agar plates supplemented with 1% carboxymethyl cellulose sodium (CMC) and 12.5 mg/L chloramphenicol. The positive clones were extracted and

partially digested with Sau3AI. The 2–5kb digested DNA fragments were subcloned in pUC19 digested with *Bam*HI and introduced into *E. coli* DH5α. The gene responsible, Cel28a, contains an open reading frame consisted of 1,596 bp nucleotides that encoded 509 amino acid residues, with a typical N-terminal signal peptide of 22 amino acid residues with a molecular mass of 55 Da. A phylogenetic analysis of amino acid sequence with other cellulase enzymes suggested that cel28a belongs to glycosyl hydrolase family 5. The recombinant pET28a(+)/cel28a gene was overexpressed in *E. coli* BL21(DE3) cells to overproduce the cellulase protein with dual histidine tag at its C-terminus and N terminus. The recombinant cellulase was purified by affinity chromatography using nickel-nitrilo-triacetic acid agarise resin (Ni-NTA). The optimal substrate for cel28a to hydrolyze was CMC among CMC, oat spelt xylan, filter paper, birch wood xylan, and microcrystalline cellulose. The preference of the substrate with CMC, oat spelt xylan, and birch wood xylan indicates that cel28a is a cellulase with xylanase activity. The optimum temperature for Cel28a was 50°C, but the activity of Cel28a reduced quickly when temperature was above 60°C. The activity of Cel28a was more than 60% in the range of pH 4–6, and the optimum pH was 5.0 at 40°C using CMC and oat spelts xylan as substrate.

Key Words: cellulase, metagenome, rumen

W83 Effects of restricted versus conventional dietary adaptation over periods of 6 and 9 days on feedlot performance and carcass characteristics of Nellore cattle. A. Perdigão*[1,3], M. D. B. Arrigoni[1], D. D. Millen[2], R. S. Barducci[1], M. A. Factori[1], L. M. N. Sarti[1], M. C. S. Franzoi[1], L. C. Vieira Junior[1], M. T. Cesar[1], F. A. Ribeiro[1], D. F. Broleze[1], A. L. C. Brichi[1], and R. F. Pessin[1], *[1]São Paulo State University (UNESP), Botucatu, Brazil, [2]São Paulo State University (UNESP), Dracena, Brazil, [3]Supported by FAPESP, São Paulo, Brazil.*

This study, conducted at the São Paulo State University feedlot, Botucatu Campus, Brazil, was designed to determine effects of restricting intake of the final finishing diet (REST) as a means of dietary adaptation compared with diets increasing in concentrate (STEP) over periods of 6-d and 9-d on overall feedlot performance and carcass traits. The experiment was designed as a randomized completely block with a 2 × 2 factorial arrangement, replicated 6 times (5 bullocks/pen), in which 120 22-mo-old yearling Nellore bulls (352.03 ± 19.61 kg) were fed in 24 pens for 84-d according to the treatments: STEP for 6-d, STEP for 9-d, REST for 6-d, and REST for 9-d. The STEP program consisted of ad libitum feeding of 2 adaptation diets over periods of 6-d or 9-d with concentrate level increasing from 61 to 85% of diet DM. The REST program consisted of restricted intake of the final diet (85% concentrate) with programmed increases in feed offered until yearling bulls reached ad libitum access over periods of 6-d or 9-d. A ($P < 0.05$) protocol main effect was observed for ADG (STEP = 1.431 kg; REST = 1.332 kg), DMI (STEP = 9.26 kg, REST = 8.72 kg) and DMI as % of BW (STEP = 2.25%, REST = 2.14%). However, no ($P > 0.10$) protocol main effect was observed for G:F (STEP = 0.154, REST = 0.153), HCW (STEP = 258.5 kg, REST = 260.7 kg) and dressing percentage (STEP = 55.1%, REST = 55.1%). No ($P > 0.10$) days main effect was observed for any of the feedlot performance and carcass traits variables evaluated: ADG (6-d = 1.393 kg; 9-d = 1.370 kg), DMI (6-d = 9.03 kg; 9-d = 8.95 kg), DMI as % of BW (6-d = 2.20%; 9-d = 2.19%), G:F (6-d = 0.154; 9-d = 0.153), HCW (6-d = 262.1; 9-d = 257.0), and dressing percentage (6-d = 55.1%; 9-d = 55.1%). Animals in STEP protocol presented greater ADG because they consumed more feed, as G:F was similar when compared with animals in REST protocol. The adaptation in 6-d did not negatively affect overall feedlot performance and carcass traits of Nellore cattle.

Key Words: adaptation, feedlot, Nellore

W84 Effect of calf conditioning either before or at weaning during the dry season in northeast Mexico. R. G. Altamirano*[1], E. G. Ornelas[2,4], H. B. Barragán[2,4], R. A. Ramírez[2], and E. C. Gallegos[3], *[1]Instituo Nacional de Investigaciones Forestales, Agrícolas y Pecuarias (INIFAP), Campo Experimental Las Huastecas,, Altamira, Tamaulipas, México, [2]Universidad Autónoma de Nuevo León, Facultad de Agronomía,, General Escobedo, Nuevo León, México, [3]Universidad Nacional Autónoma de México, Fac. Medicina Veterinaria y Zootecnia,, Martínez de la Torre, Veracruz, México, [4]Red Internacional de Nutrición y Alimentación en Rumiantes, México, D.F., México.*

The effect of 3 conditioning strategies was evaluated from February through April 2012 upon 48 calves (27 females and 21 males) from a herd in Aldama, Tamaulipas. Twenty-eight days before weaning, calves with initial body weight of 121.0 kg were randomly assigned to 3 treatments: Control group (CG), without conditioning; Conditioning 28 d before weaning (CBW), and Conditioning at weaning (CAW). Conditioning consisted in application of internal and external parasite control, vitamins ADE via IM vaccination against common bacterial and viral diseases and offering a 35% CP supplement at 20 g/kg $LW^{0.75}$ per day. Body weight of 12-h fasted animals was registered and sample collected at days: −28, 0 (weaning), 28, 56 and 84. Response variables were average daily gain (ADG), internal parasite load (McMaster technique), serological immune response (IBR and BVD neutralizing antibodies testing), and incidence of clinical disease. Animals grazed pastures of Guineagrass (*Panicum maximum*), 7.1% CP and 62.8% NDF and African stargrass (*Cynodon plectostachyus*), 7.4% CP and 79.3% NDF. Data were analyzed according to a completely randomized design with 2 × 3 factorial arrangement of treatments. No interaction and sex effects ($P > 0.05$) were found. During the last 28 d before weaning, ADG of CBW calves was higher ($P < 0.05$) than the other 2 treatments (1,068 vs 411 and 409 g/d). After weaning, and up to d 84, ADG of conditioned calves was higher ($P < 0.05$) than control (614, 526 and 301 g/d, for CBW, CAW and CG, respectively). There were no differences among groups ($P > 0.05$) for nematode internal parasite load. There were more sick animals ($P < 0.05$) in the CG than in the conditioning treatments (10 vs. 3). Geometric mean (GM) of neutralizing antibodies titers showed that the serological response in vaccinated animals at d 84 was higher ($P < 0.05$) against BVDV than BoHV-1, but there was no difference ($P > 0.05$) between CBW and CAW. The CG group did not develop antibodies at d 84 against both viruses. Conditioning before or at weaning during dry season had positive effect on performance of weaned calves.

Key Words: calf, conditioning, weaning

W85 Effect of TMR particle size or rumen pH on diet and feed preference in lactating dairy cows. A. D. Kmicikewycz* and A. J. Heinrichs, *Pennsylvania State University, University Park.*

The objective of this study was to investigate effects of TMR particle size and rumen pH on diet and feed preference in lactating dairy cows. Twelve (8 ruminally cannulated) Holstein cows (91 ± 40 DIM, 695 ± 95 kg, and parity of 2.91 ± 1.16; mean ± SD) were used in a replicated 4 × 4 LSD with 4 21-d periods. Cows were assigned to squares by parity and randomly assigned to treatment. Diets contained corn silage (CS) with long (L) or short (S) particle size and were fed with 0 (L,S) or 5% (LH, SH) supplemental late cutting fine orchardgrass hay (11.7% CP, 56.0%

NDF); CS and ground corn comprised 23.2% and 11.1% of ration DM, and TMR contained 30.9% starch. Animals were housed individually, milked 2×/d, and fed 1×/d for 10% refusal rate. Each period consisted of 14 d adaptation followed by 3 d designated as baseline for feed intake. Day 17 was baseline for feed preference and rumen conditions. On d 18 DMI was restricted to 75% of baseline intake. On d 19, 4 kg (as-fed) fine ground wheat was mixed into the rumen digesta of each cow before feeding via rumen cannulas to provide a subacute rumen acidosis challenge. Data was analyzed using MIXED procedure of SAS. The rumen challenge successfully decreased rumen pH (5.39), but baseline weighted average rumen pH for all diets was very low (5.52). Average minimum rumen pH decreased from 5.06 to 4.92, and acetate, butyrate, valerate, and isobutyrate increased on challenge d. Treatments with long CS had lower DMI ($P < 0.05$) during baseline. Cows fed SH had greater DMI during challenge d compared with S, L, and LH. There was no difference in H DMI between baseline and challenge d. No differences were found for particle size selection or H preference between days for each diet. Milk yield was greatest for cows fed SH and lowest for L and LH (45.8, 44.1, 42.8 and 42.4 kg/d for SH, S, L and LH; $P < 0.05$). Milk fat, 1.49 kg/d, and protein, 1.40 kg/d, were greater ($P < 0.05$) in cows on diet SH than all other diets. Results of this study indicate prolonged low ruminal pH does not change preference for grass hay or longer forage particles.

Key Words: particle size, acidosis, ruminal pH

W86 Nutritional maintenance requirements and true absorption coefficients of calcium and phosphorus in ¾ Zebu × ¼ Holstein crossbred bulls. L. F. Prados*, S. C. Valadares Filho, A. N. Nunes, E. Detmann, D. Zanetti, D. R. Costa, S. A. Santos, L. D. S. Mariz, P. M. Amaral, L. C. Alves, and A. C. B. Menezes, *Universidade Federal de Viçosa, Viçosa, Minas Gerais, Brazil.*

The objective of this study was to determine the maintenance requirements and true absorption coefficients for calcium and phosphorus in 3/4 Zebu × 1/4 Holstein crossbred bulls fed with different levels of calcium and phosphorus in diets. Eighteen 3/4 Zebu × 1/4 Holstein bulls with an initial mean body weight of 214 ± 4 kg and a mean age of 11 ± 0.2 mo were used in this study. These animals were assigned in a completely randomized design with 3 × 3 factorial arrangement. Three levels of calcium and phosphorus (low, medium and normal) and 3 periods of feedlot (56, 112 and 168 d) were tested. The 3 levels of calcium and phosphorus were low (1.8 and 2.2 g/kg), medium (3.0 and 2.4 g/kg), and normal (4.2 and 2.6 g/kg), respectively, for calcium and phosphorus in a dry matter basis. The diets were isonitrogenous (12.6%) and consisted of corn silage and concentrate (60:40) on a dry matter basis. To assess the excretions of Ca and P total fecal collection was performed for 3 d at the end of each feedlot period. Using the relationships between absorption and intake for calcium and phosphorus were obtained the daily maintenance requirements of Ca and P of 9.55 and 14.36 mg/EBW/d. Through the same regression, the true absorption coefficients of Ca and P were found to be 0.69 and 0.66, respectively. The maintenance requirement for Ca was lower than the amount recommended by the NRC (2000) (15.4 mg/BW/d). The P level recommended by the NRC (2000) is 16 mg/BW/d and is similar to the requirement value determined in this study. The true absorption coefficient for Ca was higher than the 0.55, value recommended by BR-CORTE (2010) but was similar to the value of 0.68 recommended by the ARC (1980). The absorption coefficient of P was similar to the value used by BR-CORTE (2010) (0.68). In conclusion, the maintenance requirements of Ca and P in 3/4 Zebu × 1/4 Holstein crossbred are, respectively, 9.55 and 14.36 mg/EBW/d.

Key Words: calcium, mineral requirement, phosphorus

W87 Dynamic shifts of rumen functional bacteria associated with forage types by quantitative real-time PCR. X. L. Hu, J. Q. Wang*, S. G. Zhao, J. W. Zhao, and D. P. Bu, *State Key Laboratory of Animal Nutrition, Institute of Animal Science, Chinese Academy of Agricultural Sciences, Beijing, China.*

Ruminal microbiota is highly responsive to changes in diet and feeding regimen. This study was conducted to quantify the population of rumen dominant functional bacteria of Chinese Holstein cows fed forage based diets by real-time PCR. Forty-eight Chinese Holstein cows were blocked based on DIM and milk yield and randomly assigned to 3 treatments to evaluate the effect of the different diets on the quantity of rumen microorganism. The 3 treatments consisted of different roughage supplements which was MF (alfalfa plus corn silage, soybean meal), CSA (straw, soybean meal), CSB (straw, cottonseed and rapeseed meal). The experiment was conducted for 107 d and consisted of 2 periods. Period 1 lasted 91 d, during which cows were fed the 3 different diets (MF, CSA, CSB). Period 2 lasted 16 d and all animals were fed MF. Rumen fluid was collected by inserting a flexible plastic tube into the rumen before and after feeding on d 91 and 107. Then the rumen microbial DNA was extracted by CTAB plus bead beating DNA extraction method. Species-specific PCR primers were chosen from the literature to amplify partial 16S rDNA regions. The copy number of rumen microbiota was detected by quantitative real-time PCR. qRT-PCR analysis detected significant increases ($P < 0.05$) in the quantity (copies in per ml rumen fluid) of domain bacteria, *Prevotella bryanti*, *Ruminococcus albus*, *Selenomonas ruminantium*, and *Megasphaera elsdenii* in treatment MF than that of CSA and CSB on d 91 before feeding. And after feeding on d 91, *Prevotella brevis* and *Fibrobacter fuccinogene* in group CSA was significantly greater ($P < 0.05$) than group MF, *Ruminococcus albus* in group MF was significantly greater ($P < 0.05$) than CSA and CSB. There was not any difference on d 107 of period 2 among the 3 groups both before and after feeding. We concluded that the change of diets did produce an effect on the population of rumen functional bacteria, especially some bacteria which take part in the degradation of cellulose and protein.

Key Words: dietary change, population, rumen bacteria

W88 Effects of a corn straw or mixed forage diet on mRNA expression of genes related to glucose metabolism in the liver of dairy cows. W. Q. Li[1,2], D. P. Bu[1], J. Q. Wang*[1], X. M. Nan[1], and L. Y. Zhou[1], *[1]Institute of Animal Science, Chinese Academy of Agricultural Science, Beijing, China, [2]College of Life Science, Henan Agricultural University, Zhengzhou, China.*

Our objective was to identify the response of genes related to hepatic glucose metabolism to diets with different forage sources. Ten Chinese Holstein dairy cows in mid-lactation (DIM 100+10 d, BW 550 ± 50 kg) were randomly assigned to mixed forage diet (MF) with Chinese wildrye, alfalfa hay and corn silage as the forage source or corn straw diet (CS) with corn straw as the forage source. Diets were formulated to be isoenergetic and iso-nitrogenous. After 30-d experimental period, biopsy section of liver and blood samples were obtained at 0630h (before feeding). Expression of 28 genes coding for rate-limiting enzymes in hepatic gluconeogenesis pathway, pentose phosphate pathway, glycogen synthesis pathway, glycogen decomposition pathway, glycolysis pathway, glucose aerobic oxidation pathway, glucose transporters was detected with qRT-PCR. Statistical significance was evaluated by unpaired *t*-test analysis with SAS 9.0 software. Significance was declared at $P < 0.05$. Results showed that MF led to marked upregulation of PEPCK and G6P involved in hepatic gluconeogenesis pathway. No significant differences were observed in mRNA expression of genes involved in other glucose

metabolism pathways. Higher relative percentage mRNA abundance of G6P (22.58%), representing the important gluconeogenic enzyme and also catalyzing the last step in glycogenolysis, underscored its importance for ruminant hepatic glucose metabolism. Relative abundance of GLUT2 was the highest among hepatic glucose transporters. It was concluded that to respond to different roughage sources, genes involved in gluconeogenesis pathway and glycogen decomposition pathway had higher mRNA abundance percentage. And different roughage sources had little effect on else bovine hepatic glucose metabolism pathways and glucose transporter protein. This research paves the way for nutrient-gene interactions in dairy cows.

Key Words: diet, gluconeogenesis, glucose

W89 PCR-DGGE analysis reveals distinct diversity in the rumen bacterial community of dairy cows fed a corn straw or mixed forage diet. D. Jin, D. P. Bu*, S. G. Zhao, and J. Q. Wang, *Institute of Animal Science, Chinese Academy of Agricultural Sciences, Beijing, China.*

Forage is an important component of diets for ruminant animals and vital in maintaining rumen function and health. The purpose of this study was to compare rumen bacterial community from cows fed different diets. Twelve healthy Chinese Holstein dairy cows fitted with rumen cannula and similar body weights were randomly assigned to 2 treatments: high forage diet (MF; forage:concentrate = 60:40) with Chinese wildrye, alfalfa hay, and corn silage as forage sources (n = 6) or low forage diet (CS; forage:concentrate = 40:60) as forage sources (n = 6). The solid and liquid fractions of rumen digesta were collected for the successive 3 d on the 13th week of the experiment. Total DNA were extracted and analyzed by denaturing gradient gel electrophoresis (DGGE) with subsequent cluster and sequence analysis. The DGGE profiles showed the quantity and optimal density of the DGGE bands in CS group were different from MF group. In addition, the DGGE-derived dendrograms showed that diet caused some changes both in liquid and solid-associated bacterial diversity. Shannon-Weiner index showed no difference ($P > 0.05$) between the 2 groups for liquid-associated bacteria, but it was lower ($P < 0.01$) in CS group than that in MF group for solid-associated bacteria. Some bands from CS group were less compared with MF group and sequences analysis of these different bands showed that diversity of *Prevotella* sp., *Acetivibrio ethanolgignens* and *Clostridium* sp. decreased in CS group. The other uncultured bacteria belonging to the phylum *Bacteroidetes*, *Firmicutes*, *Tenericutes* and *Proteobacteria* had some changes between the 2 groups. In conclusion, there is unique bacterial community and low diversity in the rumen of dairy cows fed the diet of corn straw.

Key Words: corn straw, DGGE, rumen bacteria

W90 Comparison of purine bases and nitrogen-15 for quantifying microbial protein synthesis using three marker systems and different sampling sites in cattle fed diets with sugar cane or corn silage. P. P. Rotta*[1], S. C. Valadares Filho[1], E. Detman[1], F. A. C. Villadiego[1], E. M. G. Burgos[1], A. A. G. Lobo[1], and J. A. Bendassoli[2], *[1]Universidade Federal de Vicosa, Viçosa, Brazil. [2]Universidade de Sao Paulo, Sao Paulo, Brazil.*

This study evaluated the use of 2 microbial markers [purine bases (PB) and ^{15}N] in 3 collection sites (abomasum, omasum and reticulum) and using 3 marker systems (single, double and triple) to estimate the synthesis of microbial nitrogen (MN) and the microbial protein synthesis efficiency (MPSE) in growing beef cattle. Eight ruminally and abomasally crossbred (Holstein × Zebu) bulls, with an average BW of 353 ± 36.9 kg, were used in two 4 × 4 Latin squares balanced for residual effects. The experimental diets studied were as follows: (1) 60% corn silage + 40% concentrate; (2) 40% corn silage + 60% concentrate; (3) 60% sugar cane + 40% concentrate; and (4) 40% sugar cane + 60% concentrate. Eight samples of abomasal, omasal and reticular digesta were collected in 9-h intervals for 3 d. Interactions ($P < 0.05$) were observed for MN between collection sites and microbial markers. In addition, interactions were also observed ($P < 0.05$) for the MPSE between the marker systems and the microbial markers. For PB, the greatest ($P < 0.001$) value of MN was observed for the digesta collected from the abomasum and reticulum. In contrast, for ^{15}N, the greatest ($P < 0.001$) value was observed for the digesta collected from the omasum. MN was similar ($P > 0.05$) for digesta collected from the abomasum when using both PB and ^{15}N. However, for digesta collected in the omasum, the greatest ($P < 0.001$) value was observed when ^{15}N was used. The triple marker system exhibited the greatest ($P < 0.01$) value for MN compared with the single and double marker systems. The use of ^{15}N is recommended to estimate the MN and the MPSE. In addition, the omasum is the recommended site for the collection of digesta. The triple marker system (cobalt EDTA (Co-EDTA) + ytterbium acetate (YbAc) + indigestible neutral detergent fiber (iNDF) is recommended for the above mentioned estimates.

Key Words: abomasum, omasum, reticulum

W91 Characterization of the dynamics in rumen bacterial community of cows fed three different diets using PCR-DGGE and qPCR. D. Jin[1], D. P. Bu*[1], S. G. Zhao[1], J. Q. Wang[1], and Z. T. Yu[2], *[1]Institute of Animal Science, Chinese Academy of Agricultural Sciences, Beijing, China, [2]Department of Animal Sciences, The Ohio State University, Columbus.*

Vital to the health and productivity of dairy cattle are rumen bacteria, and diet composition is the most important driver of bacterial community dynamics. This study examined bacteria communities in the rumen of dairy cows fed 3 different diets. Forty-eight Chinese Holstein dairy cows with similar days-in-milk and body weights were randomly assigned to 3 treatments mainly differing in forage source: MF diet (alfalfa hay, corn silage and soybean meal), CSA (corn straw and soybean meal) and CSB (corn straw, cottonseed and rapeseed meal). The cows were fed their assigned diet twice daily for 91 d, after which all were shifted to the MF diet. Rumen contents were collected by inserting a flexible plastic tube into the rumen and were performed at d 31, 61, 91, and 107 of the experiment before and after morning feeding. Bacterial community structure was analyzed using denaturing gradient gel electrophoresis (DGGE), with select DGGE bands being sequenced. The DGGE profiles showed clear difference among the 3 diets after feeding for 31 d, with the overall similarity being only 51%. As expected, the MF diet resulted in more unique bands than the CSA and CSB diets. The DGGE fingerprints became less difference among the 3 diets at d 61 and 91 compared with d 31, suggesting gradual adaptation of rumen bacteria to the diets. Analysis from the sequenced DGGE bands showed that genera *Vibrio*, *Prevotella*, *Brevundimonas*, and *Clostridium* were dynamic and affected by the diets. One distinct band appeared in the MF group, and sequencing of this band revealed a sequence identity being 90% identical with Vibrio sp. The qPCR quantification showed that this uncultured bacterium had a higher ($P < 0.001$) abundance in the MF group than in the other 2 groups at d 91, but it had a higher population in all 3 groups at d 107. In conclusion, different forage types changed

structure and populations of rumen bacterial community, and there was a unique bacterial community with high diversity in the rumen of dairy cows fed mixed forage.

Key Words: DGGE and qPCR, forage, rumen bacteria

W92 Heart rate and milk production of dairy cows fed with three different strategies in early lactation. D. A. Mattiauda*, P. Chilibroste, M. Carriquiry, J. P. Marchelli, and A. C. Espasandin, *Departamento de Produccion y Pasturas, Facultad de Agronomia, UdelaR, Uruguay.*

Heart rate (HR) was proposed as a good estimator of heat production in beef and dairy cows. Twenty-four Holstein multiparous cows (697 ± 30 kg BW, 3.3 ± 0.1 BCS, 3.3 ± 0.5 lactations) were used in a randomized block design to study the effect of feeding strategies (corn silage allocation) during early lactation on milk yield and HR. Cows were allocated in 3 different feeding strategies: T1) total mixed ration (TMR) offered in a dry lot pen; T2) pasture grazing offered one session (7 h) + TMR offered during the evening in a dry lot pen and T3) pasture grazing in 2 sessions (14 h) + TMR offered in the grazing paddock. All diets were formulated to offer 50 Mcal ENL and > 16.5% CP (dry matter basis). Heart rate (n = 4/treatment) (beats/min) was registered by implanted HR radiotransmitters each 15 s during 5 consecutive days at the beginning (14 ± 5 d in milk, DIM) and the end of experimental period (40 ± 5 DIM). Treatment effects were analyzed by ANOVA and LSmeans by treatment were obtained. Milk yield was greater in T1 than T2 and T3 cows (35.5, 30.1 and 29.6 ± 0.8 kg/d for T1, T2, and T3, respectively; $P < 0.001$). Heart rate at 10 DIM did not differ among treatments (93 ± 20, 110 ± 17 and 86 ± 25 beats/min for T1, T2, and T3, respectively; $P = 0.68$) but a trend ($P = 0.12$) was observed at 40 DIM being greater in T2 than T1 and T3 cows (89 ± 8, 114 ± 9 and 81 ± 11 beats/min, for T1, T2 and T3, respectively). The trend for greater HR in T2 cows was not directly associated with greater energy cost for milk production (as was greater in T1 cows) or walking activity (as was greater in T3 cows). Therefore results could suggest that T2 cows spent more energy associated to stress for feed competition (during grazing or at feed-troughs).

Key Words: dairy, feeding strategy, heart rate

W93 Assessment of in vitro fermentation characteristics of grass-legume mixed pasture forages with their different composition ratios using continuous cultures. C. T. Noviandi[1], K. Neal[1], J.-S. Eun*[1], D. R. ZoBell[1], M. D. Peel[2], and B. L. Waldron[2], *[1]Department of Animal, Dairy, and Veterinary Sciences, Utah State University, Logan, [2]Forage and Range Research Laboratory, USDA-ARS, Logan, UT.*

A continuous culture experiment was performed to investigate effects of tall fescue (TF)-legume mixed pasture forages [TF-alfalfa (TF+ALF), TF-birdsfoot trefoil (TF+BFT), or TF-cicer milkvetch (TF+CMV)] with 3 different composition ratios at 25:75, 50:50, or 75:25 on a DM basis on in vitro fermentation characteristics. Nine dietary treatments were tested in a completely randomized design with a 3 (TF-legume mixtures) × 3 (TF:legume ratios) factorial arrangement (n = 3). Each culture fermentor was offered a total of 15 g DM/d in 4 equal portions at 0600, 1200, 1800, and 2400 h. Average daily culture pH ranged from 6.10 to 6.29 and was affected by TF-legume mixture and composition ratio ($P < 0.01$). Total VFA concentration averaged 51.4 mM and was not affected by treatments. While acetate concentration was similar across treatments, propionate concentration increased by the TF+CMV ($P < 0.01$). Decreasing legume proportion in the forage mixtures decreased propionate concentration ($P = 0.03$) regardless of forage types. Acetate-to-propionate ratio was higher ($P = 0.03$) with the TF+ALF compared with the TF+BFT and the TF+CMV. Ammonia-N concentration decreased ($P < 0.01$) with the TF+CMV compared with the TF+ALF, and it further decreased in cultures receiving the TF+BFT ($P < 0.01$). In addition, decrease in ammonia-N concentration ($P < 0.01$) was noticed when legume proportion in forage mixtures decreased. Offering the TF+BFT decreased methane production, whereas the methane production decreased by increasing legume proportion in all forage mixtures ($P < 0.01$). Overall results of this study indicate that TF+legume mixtures at a relatively high proportion of legume favorably shifted in vitro fermentation pathways by producing more propionate and less ammonia-N and methane. The beneficial effects with the TF+BFT may have resulted from condensed tannins in birdsfoot trefoil, while unique plant cellular structure of cicer milkvetch in the TF+CMV may contribute to the positive effects.

Key Words: continuous culture, in vitro fermentation, tall fescue-legume mixed pasture forage

W94 Cost structure and economic assessment of Spanish Assaf dairy sheep farms. M. J. Milan[1], F. Frendi[1], R. Gonzalez-Gonzalez[2], and G. Caja*[1], *[1]Ruminant Research Group (G2R), Universitat Autonoma de Barcelona, Bellaterra, Spain, [2]GEO, Benavente, Zamora, Spain.*

A total of 20 dairy sheep farms of Assaf breed, located in the Spanish Autonomous Community of Castilla y León (Provinces of León, Palencia, Valladolid and Zamora) and included in a group for receiving technical support (GEO, Gestión Empresarial de Ovino), were used to study their production cost structure during 2008 and for assessing their economic profitability. On average, farms had 89.2 ± 38.0 ha (own, 38%), 592 ± 63 ewes, yielded 185.9 ± 21.1 × 10^3 L/yr (316 ± 15 L/ewe) and were attended by 2.3 ± 0.2 annual working units (family, 64%). Total annual income was US$252.7 ± 29.9 × 10^3 coming from milk (78.6%), lamb (13.2%), culled ewes (0.5%) and other sales (0.8%, wool and manure) and completed with the European Union sheep subsidy (6.9%). Total annual costs were US$240.2 ± 24.6 × 10^3 addressed to attend feeding (62.0%), labor (18.3%), equipment maintenance and depreciation (7.6%), animal health (2.5%), financial (2.5%), energy, water and milking supplies (2.2%), milk recording (0.5%), and others costs (4.4%; assurances, shearing, association fees, etc). Mean dairy sheep farm profit per year was US$12.5 ± 7.7 × 10^3, being US$12.1 ± 10.8 per ewe, on average, and dramatically varying between US$–50.3 and 107.8 per ewe among farms. Only 60% farms were able to pay all the costs, the rest having negative exercises. Nevertheless, annual net margin was US$40.3 ± 8.5 × 10^3 on average, varying between US$0.8 and US$258.0 × 10^3 among farms. In this case, without including the opportunity costs, all farms had positive exercises. Annual cost and income (US$/ewe) functions depended on productivity (x, L/ewe) and were: $C = 207.7 + 0.653 \cdot x$ ($r^2 = 0.50$), and $I = 101.6 + 1.027 \cdot x$ ($r^2 = 0.88$), respectively, being the break-even point 284 L/ewe. Studied farms were on general of familiar type, medium-large sized, fully devoted to milk production and, most of them, economically profitable at nowadays. Flock size, milk yield and feeding costs were a key for dairy sheep farm profitability. Finally, according to the increasing trend expected for agricultural commodity prices, a proportional increase in milk price will be necessary to maintain their future profitability.

Key Words: cost, dairy sheep, profitability

W95 Effects of feeding teff hay-based diets on growth performance and ruminal fermentation profiles of growing beef steers and dairy heifers. J. E. Creech[1], J. M. Vera[2], C. T. Noviandi[2], J.-S. Eun*[2], A. J. Young[2], and D. R. ZoBell[2], *[1]Department of Plants, Soils, and Climate, Utah State University, Logan, [2]Department of Animal, Dairy, and Veterinary Sciences, Utah State University, Logan.*

Teff (Erogrostis tef [Zucc.], Poaceae) is a warm-season annual grass and has attracted much interest among hay growers in the United States due to its rapid growth, palatability, and high quality and yield. The objective of this study was to assess growth performance and ruminal fermentation of growing beef steers and dairy heifers when fed teff hay-based diets. Twelve growing beef steers and 12 dairy heifers were used in a completely randomized design to test 2 dietary treatments: alfalfa hay-based TMR (AHT) and teff hay-based TMR (THT). In beef steer diets, the AHT contained 20.5% alfalfa hay and 43.0% corn silage, whereas the THT had 44.0% teff hay and 20.7% corn silage. In dairy heifer diets, the AHT contained 54.1% alfalfa hay and 24.8% corn silage, while the THT had 8.5% alfalfa hay, 42.0% teff hay, and 11.3% corn silage. All animals were placed in individual pens, and the experiment lasted 12 wk. Intake of DM increased by feeding the THT to beef steers and dairy heifers ($P = 0.01$). Dietary treatments did not affect ADG of beef steers; however, feeding the THT to dairy heifers increased ($P = 0.02$) ADG. Dietary treatments did not affect G:F in both beef steer and heifer diets. Ruminal pH averaged 6.54 or 6.51 in beef steer or dairy heifer diets, respectively, and did not differ between diets. Feeding the THT decreased total VFA concentration by beef steers and dairy heifers ($P < 0.02$). Feeding the THT to beef steers increased acetate proportion ($P = 0.02$), but the THT decreased propionate proportion ($P < 0.01$), resulting in increased acetate-to-propionate ratio due to feeding the THT ($P < 0.01$). In contrast, feeding the THT to dairy heifers tended to decrease acetate proportion ($P = 0.10$), but the THT increased propionate proportion ($P = 0.05$). Although feeding the THT decreased ruminal fermentation by beef steers and dairy heifers evidenced by decreased VFA concentration, the THT increased DMI of beef steers and dairy heifers, leading to no negative effects on growth performance. Teff can be a viable lower-cost alternative to feeding alfalfa in growing beef steers and dairy heifer diets.

Key Words: teff hay, beef steers, dairy heifers

W96 Comparison of in situ versus in vitro methods of fiber digestion at 120 and 288 hours to quantify the indigestible NDF fraction of corn silage samples. R. W. Bender*, D. E. Cook, F. Lopes, and D. K. Combs, *University of Wisconsin-Madison, Madison.*

The indigestible NDF (iNDF) as a proportion of NDF in forages is commonly calculated from the ratio: (2.4 × acid detergent lignin)/NDF. Our objective was to compare estimates of iNDF based on lignin ratio, to in vitro (IV) and in situ (IS) measurements. Thirteen corn silage samples were dried and ground through a 1-mm screen in a Wiley mill. Acid detergent lignin (ADL) was determined by NIR analysis. A 2 × 2 factorial trial was conducted, with method of iNDF analysis (IS vs. IV) and incubation time (120 vs. 288 h) as factors. Four sample replicates were utilized, and approximately 0.5 g/sample was weighed into each Ankom F57 bag (Ankom Technology, Macedon, NY; pore size = 25 μm) for all techniques. The IV-120 (37.8%) had a higher ($P < 0.01$) proportion iNDF than all other methods; IS-120 (32.1%) and IV-288 (31.2%) techniques were similar, but were both higher ($P < 0.01$) than the IS-288 technique (25.7%). Utilizing the NIR lignin values to calculate the ratio of iNDF to lignin (Table 1) yielded similar results: IV-120 had a higher ($P < 0.01$) ratio (5.9) than all other methods; IS-120 (5.0) and IV-288 (4.8) techniques were similar, but were both higher ($P < 0.01$) than the IS-288 technique (4.0). Thus, digestibility techniques at different times yielded vastly different estimates of iNDF. All techniques also yielded ratios that were higher than the commonly used ratio of 2.4 × lignin.

Table 1. In situ vs. in vitro methods of fiber digestion at 120 and 288 h to quantify iNDF

	iNDF, % of NDF		iNDF / Lignin	
	in vitro	in situ	in vitro	in situ
120 h	$37.8^{a} \pm 1.4$	$32.1^{b} \pm 1.4$	5.9^{a}	5.0^{b}
288 h	$31.2^{b} \pm 1.5$	$25.7^{c} \pm 1.2$	4.8^{b}	4.0^{c}

Key Words: indigestible NDF, fiber digestion, lignin

W97 Composition of gain and its relationship to residual feed intake and gain. M. L. Nascimento*[1], A. S. Chaves[1], R. R. Tullio[2], M. M. Alencar[2], A. N. Rosa[3], and D. P. D. Lanna[1], *[1]University of Sao Paulo, Piracicaba, SP, Brazil, [2]Embrapa Cattle Southeast, Sao Carlos, SP, Brazil, [3]Embrapa Beef Cattle, Campo Grande, MS, Brazil.*

Residual feed intake and gain (RIG), a combination between residual feed intake (RFI) and residual gain (RG), was recently proposed as a new index for genetic selection of beef cattle. The objective of this work was to examine the relationship between gain composition of Nellore steers and RIG. Data set from 3 years of study were used, totaling 363 steers. The animals were individually fed twice daily with 5% of orts, for at least 70 d (2.8 Mcal ME/kg DM; 13.5% CP). Body weight (BW) was measured at 14-d intervals and ultrasound measurements on 11–12th-rib (fat thickness and ribeye area) obtained at the start, middle and final of the experimental period. Final and initial empty BW energy were estimated by an equation for Nellore (EBW Energy = −126.73 + 10.88 × ribeye area + 70.01 × fat thickness; $R^2 = 0.73$), the retained energy was calculated by difference. To estimate the proportion of protein and fat in the gain, the composition of the fat-free dry matter was held constant. Daily gain was estimated by regression slope between BW and days on feed. Mixed models were used to obtain RFI and RG, where contemporary group (CG), based on year, animal origin and pen type was considered as random. The RIG was calculated as −1 × RFI + RG, both standardized to a variance of 1. The animals were classified as low, medium and high RIG (mean ± 0.5 SD). High and low classes were compared using mixed model, RFI class and CG were considered as fixed effects, sire as random, and initial age as covariate. DMI of high-RIG animals (efficient) was 11.5% lower and ADG was 24.2% greater compared with low-RIG animals ($P < 0.01$) without differences in final BW ($P > 0.10$). There was no relationship between RIG and fat thickness gain ($P > 0.05$), however, efficient animals had greater ribeye area gain ($P < 0.01$). The efficient animals retained 0.40 Mcal less energy/kg of gain ($P < 0.05$). Consequently, empty body gain composition was different, where efficient animals had less fat and more protein ($P < 0.05$).The phenotype selection based on RIG can select animals with lower DMI and higher ADG, whose higher efficiency can be partially explained by changes in body gain composition.

Key Words: beef cattle, fat thickness, ribeye area

W98 Estimation of bacterial protein in rumen digesta using DNA markers. C. J. R. Jenkins*, E. Castillo-Lopez, S. C. Fernando, and P. J. Kononoff, *University of Nebraska, Lincoln.*

The objective of this study was to use DNA as bacterial markers to estimate and compare the concentration of bacterial crude protein (BCP) in solid and liquid portions of rumen digesta. Using a completely randomized design, 2 multiparous, lactating Holstein cows (average DIM 14 ± 4 d, average BW 618 ± 40 kg, average DMI 23 ± 4 kg/d, average milk yield 34 ± 10 kg/d), fitted with ruminal cannulas were fed the same diet once daily at 0930 h. Every 4 h over a 24 h period, a sample of approximately 1.5 kg of rumen contents was collected from each cow and was strained through 4 layers of cheesecloth. Particle associated bacteria (PAB) was separated from the solid portion of rumen contents by adding PBS buffer and blending the mixture in a commercial blender, followed by straining through 4 layers of cheesecloth. Fluid collected after blending, as well as fluid retained from the initial straining, each underwent differential centrifugation, yielding bacterial pellets consisting of fluid associated bacteria (FAB) and PAB. DNA was then extracted from bacterial pellets and from the non-centrifuged samples of ruminal fluid and particles. The DNA from the bacterial pellets, ruminal fluid, and ruminal particle samples were subjected to real-time PCR using the TaqMan assay. Primers and a probe were designed from DNA encoding part of the 16s rRNA. The relative abundance of bacterial DNA tended to be higher ($P = 0.09$) in the solid portion (209.5 ± 26.6 mg BCP/g DM) than in the liquid portion (106.4 ± 43.6 mg BCP/g DM). Results suggest that BCP is detected in both the solid and liquid portion of rumen digesta and that it is found in higher concentrations in the solid portion.

Key Words: bacteria, marker, PCR

W99 Effect of a commercially available natural plant extract on intake and milk production of dairy cows. Y. Ying, M. Niu, A. R. Clarke, and K. J. Harvatine*, *Penn State University, University Park.*

The objective was to determine the ability of a commercially available natural plant extract (VéO Premium; Phode Laboratories, Terssac, France) to stimulate intake and its effects on milk production and feeding behavior of dairy cows. Two experiments (EXP) were conducted. First, 11 early-lactation dairy cows were used in a switchback design (EXP 1; 77 ± 15 DIM, Mean ± SD) and second 15 mid-lactation Holstein cows were utilized in a crossover design (EXP 2; 157 ± 44 DIM, Mean ± SD). Treatments were control (no supplement) or VéO fed at 4 and 4.5 g per head/d in a ground corn carrier in EXP 1 and 2, respectively. Diets were formulated to 31.5 and 31.0% NDF (EXP 1 and 2, respectively) and 17% crude protein. Treatment periods were 21 and 14 d (EXP 1 and 2, respectively) with the final 7 d used for sample and data collection. There was no effect of treatment on yield of milk, 3.5% FCM, fat, protein, or lactose in either experiment. There was also no effect of treatment on DMI or feed efficiency (FCM/DMI). Mean yield of 3.5% FCM was 53.3 and 39.9 kg/d and mean DMI was 33.0 and 27.3 kg/d across treatments for EXP 1 and 2, respectively. Additionally, there was no effect of treatment on milk FA profile in EXP 1 or average meal size or number of meals per day in EXP 2, but there was a tendency for the supplement to increase eating rate. In EXP 1, plasma insulin concentration 1 h before feeding was higher for the supplement cows compared with the control (3.36 vs. 2.13 μIU/mL; $P < 0.01$). The high level of intake in EXP 1 may have caused physical fill limitation of intake and prevented an increase in intake, however the supplement also did not increase intake in mid-lactation cows with more moderate levels of intake (EXP 2). Increased insulin before feeding may indicate a change in glucose homeostasis.

Key Words: feeding pattern, intake, plant extract

W100 Productive performance, hepatic function and nutrients utilization of dairy cows fed with *Jatropha curcas* L. seed meal treated with sodium hydroxide. A. S. Oliveira*[1], J. G. Souza[1], C. V. Araujo[1], A. Takaoka[1], D. C. Moura[3], M. C. Souza[1], E. Peron[1], J. T. Zervoudakis[3], L. S. Cabral[3], S. Mendonca[2], L. F. Moreno[1], P. H. N. Cruz[1], L. M.G. Olini[1], K. R. R. Amorim[1], F. G. Ribeiro[1], *[1]Mato Grosso Federal University, Campus Sinop, Sinop, Mato Grosso, Brazil, [2]Brazilian Agricultural Research Corporation's, Brasilia, DF, Brazil, [3]Mato Grosso Federal University, Campus Cuiaba, Cuiaba, Mato Grosso, Brazil.*

Twelve Holstein × Zebu crossbreed cows (127 ± 60 DIM, 476 ± 64 kg BW) were distributed in three 4 × 4 Latin squares, with 4 periods of 21 d (7 d of mensurations) to evaluate the effect *Jatropha curcas* L. seed meal treated with 7% of sodium hydroxide (JCM 20.0% of CP, 1.65% of ether extract, 0.16% of Na and 0.145 mg of phorbol esters (PE)/g DM) in concentrate (0, 10, 20 and 30% of DM) on performance, hepatic function and nutrients utilization. Cows were fed with pasture of *Panicum maximum* 'Mombaça' (15.0% of CP, 64.8% of NDF, DM allowance of 11.8% BW/d) and offering 4 kg/d of isonitrogen concentrates (19.8% of CP). Intake pasture was estimate using external maker fecal output (TiO_2) and indigestible NDF. Spot urine samples were obtained after milking on 20 d of each period. Data were analyzed using model mixed and applied Williams test to comparison of means for quantitative data. Alkaline treatment reduced 67.9% the PE in JCM. Pasture intake ($P = 0.965$; 8.2 kg DM/d) was not affected by JCM. Concentrate DM intake (3.51, 3.28, 2.73 and 1.80 kg/d) was not affected ($P = 0.143$) until 20% of JCM, but was reduced ($P = 0.029$) with 30% of JCM. PE intake increased with JCM level ($P = 0.001$; 0, 0.103, 0.166 and 0.163 mg/kg BW/d) but serum concentrations of aspartate aminotransaminase (91.4 IU/L; $P = 0.759$), alanine aminotransaminase (46.5 IU/L; $P = 0.29$) and gamma-glutamyltransferase (14.7 IU/L; $P = 0.628$) were not affected by JCM. OM digestibility (73.5, 70.9, 70.7 and 69.2%) of diet was reduced ($P = 0.014$) with 30% of JCM. Rumen microbial crude protein synthesis (1.32, 1.23, 1.10 and 1.01 kg/d) was reduced ($P = 0.049$) from 20% of JCM. Milk yield (11.0, 10.7, 9.5 and 9.4 kg/d) was not affected ($P = 0.607$) until 10% of JCM, but was reduced ($P < 0.001$) from 20% of JCM. Milk crude protein (3.18%; $P = 0.441$), milk fat (3.0%; $P = 0.895$), body condition score (2.9; $P = 0.279$) and milk N/intake N (18%; $P = 0.556$) were not affected by JCM. The JCM can be included in up to 10% in DM concentrate without affect productive performance, hepatic function and nutrients utilization of Holstein × Zebu crossbreed cows.

Key Words: phorbol ester

W101 Effects of heat stress and plane of nutrition on fecal composition of lactating dairy cows. J. D. Allen*[1,2], L. W. Hall[2], G. Xie[2,4], R. J. Collier[2], L. H. Baumgard[3], and R. P. Rhoads[2,4], *[1]Northwest Missouri State University, Maryville, [2]University of Arizona, Tucson, [3]Iowa State University, Ames, [4]Virginia Polytechnic Institute and State University, Blacksburg.*

The purpose of the study was to delineate the effects between heat stress (HS) and plane of nutrition on fecal nutrient composition. In 2 replications, multiparous cows (n = 12; parity = 2; 305 ± 33 DIM; 665 ± 18 kg BW) housed in climate chambers were fed a TMR consisting primarily of alfalfa hay and steam-flaked corn and subjected to 2 periods (P): (1) thermoneutral (TN) conditions (18°C, 20% humidity) with ad libitum intake for 9 d and (2) either HS conditions (cyclical temperature 31–40°C, 20% humidity: min THI = 73, max THI = 86) fed for ad libitum intake (n = 6), or pair-fed in TN conditions (PFTN, n = 6) for 9 d. Rectal temperature (Tre) and respiration rate (RR) were measured thrice daily at 0600, 1400 and 1800 h. Fecal samples were collected on d 1, 3, 5, 7, and 9 of each period for analyses of DM, NDF, ADF, CP,

ash, and starch. Data was analyzed as a complete random design, with cow as experimental unit, day as repeated measure, and each cow's P1 fecal concentration as a covariate. During P2, HS cows had a 1.8°C increase in Tre and a 3-fold increase in RR compared with PFTN cows ($P < 0.01$). Heat stress reduced ($P < 0.01$) DMI by 20% and by design PFTN cows had similar intake reductions. Milk yield was decreased 12% during HS and 8% in PFTN cows. Fecal dry matter tended ($P < 0.10$) to be higher in PFTN cows (16.6%) compared with P1 (15.8%) and HS (15.8%) cows. Fecal fiber components, NDF and ADF, were lower ($P < 0.01$) in PFTN cows (44.5 and 29.0%, respectively) compared with P1 (48.5 and 33.9%) and HS (47.1 and 32.6%) cows. Fecal starch was lower ($P < 0.05$) in HS cows (1.90%) compared with P1 (2.4%) and PFTN (2.8%) cows. There was no difference ($P > 0.10$) in fecal ash and CP. A period by day effect was seen in NDF, ADF, and starch ($P < 0.05$). Results indicate heat stress reduces fecal starch concentration, and lowered DMI reduces fecal NDF and ADF concentrations.

Key Words: dairy cow, fecal composition, heat stress

W102 Long-term performance of growing dairy heifers fed increased dietary fat from dried distillers grains. J. L. Anderson*, K. F. Kalscheur, A. D. Garcia, and D. J. Schingoethe, *South Dakota State University, Brookings.*

The objective of this study was to determine if feeding increased dietary fat from dried distillers grains with solubles (DDGS) to pre-pubertal dairy heifers influenced long-term performance. During the pre-pubertal growth phase, 33 Holstein heifers (133 ± 18 d old) were used in a 24-wk randomized complete block design with 3 treatment diets. Diets were (1) control (C) that contained 15.9% (DM basis) ground corn and 17.9% soybean products, (2) low-fat (LFDG) that contained 21.9% reduced-fat DDGS and 11.9% ground corn, and (3) high-fat (HFDG) that contained 33.8% traditional DDGS. All diets contained 39.8% grass hay, 24.8% corn silage, and 1.5% vitamins and minerals. Although diets were isonitrogenous and isocaloric, HFDG was formulated to contain 4.8% fat versus 2.8% in C and LFDG. Previous results demonstrated that growth performance was maintained, despite differences in metabolic profiles. Also, previous results indicated that heifer fed HFDG were pubertal earlier. Post-trial production data (farm and DHIA records) for each heifer was collected during the first 4 mo of lactation. Body weights, body condition scores, and frame measurements were taken 3 wk prepartum and at calving. Treatment did not affect ($P > 0.05$) age at conception or age at calving. At calving, wither height was shorter ($P = 0.03$) for heifers fed HFDG compared with other diets. For heifers fed LFDG milk production was greater (33.04, 36.40, 34.7 kg for C, LFDG, and HFDG, respectively; SEM = 1.35; $P = 0.03$) and milk protein yields tended to be greater (0.98, 1.08, and 1.03 kg; SEM = 0.043; $P = 0.06$) compared with heifers fed C. Heifers fed HFDG had similar milk production compared with C. Milk fat and energy-corrected milk yield were similar among treatments. Feeding increased dietary fat from DDGS during the pre-pubertal growth phase maintained milk production despite previous findings indicating differences in puberty. Based on these findings, producers can feed dietary fat from DDGS as a replacement for starch from corn as an energy source for pre-pubertal heifers without detriment to long-term performance.

Key Words: dairy heifer, distillers grain, long-term performance

W103 Validation and recovery rates of an indirect calorimetry headbox system used to measure heat production of cattle. A. J. Foth*[1], T. Brown-Brandl[2], H. C. Freetly[2], M. D. Hayes[2], and P. J. Kononoff[1], [1]*University of Nebraska-Lincoln, Lincoln,* [2]*USDA Meat Animal Research Center, Clay Center, NE.*

A headbox system was constructed at the University of Nebraska-Lincoln to determine heat production from dairy cattle using indirect calorimetry. The system was designed for use in a tie-stall barn to allow the animal to be comfortable and was mounted on wheels to transport between animals between sampling days. The frame was constructed out of aluminum angle iron with sides of plexiglass for other animals to remain within sight. The system continuously sampled gas produced in the headbox and directed it into foil bags, allowing for analysis of O_2, CO_2 and methane concentrations. To validate the data collected by 3 constructed units, alcohol burning lamps containing 100% ethyl alcohol were placed inside, ignited and burned for 2 h. The rate of gas flowing out of the system was recorded and samples of gas entering and exiting each of the sealed headboxes was collected into 44 L sample bags and later analyzed. The difference between gas concentrations from incoming and outgoing air, corrected to standard temperature and pressure, was calculated and the amount of O_2 consumed and CO_2 produced during the sampling time was compared with the theoretical amount of each of these gases calculated based upon the amount of alcohol burned, giving the recovery rate of each gas. Two runs were carried out on 2 separate occasions for each unit and the results can be found in Table 1. Recovery rates for O_2 and CO_2 averaged 101.3 ± 2.72% and 100.5 ± 3.59% suggesting that these units may be used to adequately estimate gas exchange and for indirect calorimetry to indirectly determine heat production.

Table 1. Means and standard deviations of 2 lamp runs on headboxes 1, 2, and 3

	Headbox 1		Headbox 2		Headbox 3	
	Mean	SD	Mean	SD	Mean	SD
Average gas flow (m^3/min)	0.94	0.01	0.97	0.01	1.03	0.03
O_2 consumed (L)	175.4	21.1	144.9	12.4	134.0	1.77
CO_2 produced (L)	116.3	11.74	95.5	4.60	89.6	4.10

W104 Energy requirement of Holstein calves. J. C. M. Lima[1], J. P. P. Rodrigues[1], M. I. Marcondes*[1], F. S. Machado[2], A. S. Treece[1], M. M. D. Castro[1], J. L. C. Dias[1], and T. Araújo[1], [1]*Universidade Federal de Viçosa, Viçosa, Minas Gerais, Brazil,* [2]*Embrapa Gado de Leite, Juiz de Fora, Minas Gerais, Brazil.*

This study aimed to evaluate energy requirements in dairy calves. Forty-two male Holstein calves, at 3 d of age and with an average live weight of 35.56 ± 5.86 kg, were used. Ten animals were slaughtered to compose the reference group, and the remaining animals were distributed into a completely randomized design. The treatments consisted of different amounts of milk, which were: 2, 4, 6 and 8 L milk/head/d, fed twice a day, in 8 replications. The animals were fed milk until they reached 58 d. Four animals per treatment were slaughtered at 59 d, while others started to receive Coast cross hay plus starter, and they were subsequently slaughtered at 87 d. After slaughter, 2 samples were obtained for each animal, called carcass and non-carcass. The retained energy was estimated by determining energy concentration in carcass

and non-carcass samples, and diminishing by the initial body energy concentration. The HP of each animal was estimated as: $HP = \beta_0 \times e^{(\beta_1 \times MEI)}$, where MEI is metabolizable energy intake. Digestible energy intake (DEI) was obtained by controlling protein, fat and carbohydrates daily intake, which were multiplied by 5.6, 9.4, and 4.2 Mcal/kg, respectively, and by their respectively digestibilities. MEI of each animal was obtained by the equation: MEI = DEI × (0.96 × DMI + 0.88 × (1 − DMI)), where DMI is the proportion of milk intake in dry matter intake. Net (NEm) and metabolizable (MEm) energy requirements for maintenance were obtained as a function of heat production (HP) and metabolize energy intake (MEI), while net energy requirements for gain (NEg) were obtained as a function of empty body weight (EBW) and empty body gain (EBG). The NEm and MEm were respectively 85.2 and 143.4 kcal/$EBW^{0.75}$/d. The efficiency of utilization of metabolizable energy for maintenance (k_m) was 59.41%. The equation obtained for NEg and efficiency of utilization of metabolizable energy for gain (k_g) were, respectively, NEg (Mcal / d) = 0.0931 × $EBW^{0.75}$ × $EBG^{1.454}$, and 38.07%. The efficiencies of energy deposition as protein and fat were 67.69% and 60.73%, respectively. The equations suggest that net and metabolizable energy requirements for maintenance of Holstein calves exceed those commonly use in the dairy industry.

Key Words: calf, gain, maintenance

W105 Brown marmorated stink bug odor compounds do not transfer into milk in lactating dairy cattle by feeding bug-contaminated corn silage. R. L. Baldwin VI*[1], A. Zhang[2], S. W. Fultz[3], S. Abubeker[2], C. Harris[2], E. E. Connor[1], and D. L. Van Hekken[4], *[1]USDA, ARS, BFGL, Beltsville MD, [2]USDA, ARS, IIBBL, Beltsville MD, [3]University of Maryland Extension, Frederick, [4]USDA, ARS, EERC, Wyndmoor, PA.*

Brown marmorated stink bug (BMSB), *Halyomorpha halys*, is an emerging invasive species of grave concern to agriculture as a polyphagous plant pest with potential negative effects on the dairy industry. We sought to determine the risk of including BMSB contaminated silage in lactating dairy cow rations. First, 6 dairies, either highly infested (n = 3; 30 to 100 bugs per stalk) or not infested (n = 3) were sampled to assess prevalence of bug secretion compounds tridecane and E-2-decenal (odor component) in silage and milk. Second, using wild BMSB, a mini-silo dose response experiment (adding 100, 50, 25, 10, and 1 fresh crushed bugs/0.5 kg chopped corn) was conducted to assess the effect of ensiling on BMSB odor compounds. Finally, synthetic BMSB secretion compounds (10 g tridecane and 5 g E-2-decenal) were ruminally infused 2 times daily over 3 d and samples of milk, urine, and rumen fluid were collected to evaluate disposition. Samples were analyzed by solid phase microextraction (SPME) and gas chromatography-mass spectrometry (GC-MS). Milk production and feed composition were unaffected ($P > 0.05$) when BMSB contaminated silage was fed. Moreover, no E-2-decenal was detected in silage nor milk (detection threshold = 0.00125 ppm). Dose response of tridecane in mini-silo samples exhibited a linear relationship ($R^2 = 0.78$) with BMSB added; however, E-2-decenal was completely decomposed and undetectable in spiked mini-silos after ensiling. Both synthetic secretion compounds infused into rumen were undetectable in all milk and urine samples. Content of E-2-decenal was also not detectable in rumen fluid; however, tridecane was detected at 15 min post-infusion but not present thereafter. Feed intake was unaffected by infusion treatment and BMSB secretion compounds were not observed in milk. Compounds from the metathoracic gland of BMSB are not able to contaminate milk due to either the ensiling process or metabolism within the rumen. Concern over BMSB odor compounds contaminating the fluid milk supply even on highly infested farms is not warranted.

Key Words: brown marmorated stink bug, milk taint, lactating dairy cow

W106 Effects of restricted versus conventional dietary adaptation over periods of 9 and 14 days on total-tract digestibility of dry matter and starch of feedlot Nellore cattle. A. L. N. Rigueiro[2], D. H. M. Watanabe[2], M. C. S. Pereira[2], J. Silva[2], T. V. B. Carrara[1], M. C. S. Franzoi[1], R. S. Barducci[1], M. D. B. Arrigoni[1], F. Perna Junior[4], M. Caetano[3], D. P. D. Lanna[3], and D. D. Millen*[2], *[1]São Paulo State University (UNESP), Botucatu, São Paulo, Brazil, [2]São Paulo State University (UNESP), Dracena, São Paulo, Brazil, [3]University of São Paulo (USP), Piracicaba, São Paulo, Brazil, [4]University of São Paulo (USP), Pirassununga, São Paulo, Brazil.*

This study was designed to determine effects of restricting DMI of the final finishing diet (REST) as a means of dietary adaptation compared with diets increasing in concentrate (STEP) over periods of 9-d and 14-d on total-tract digestibility of DM and starch of feedlot Nellore cattle. The experiment was designed as a completely randomized block with 2 × 2 factorial arrangement, replicated 6 times (5 bullocks/pen), in which one hundred twenty 22-mo-old yearling Nellore bulls (361.3 ± 30.2 kg) were fed in 24 pens for 84 d according to the treatments: STEP for 9-d and 14-d, REST for 9-d and 14-d. Measures over time were taken on d 5, 10, 15, and 20 of experimental period. The STEP program consisted of ad libitum feeding of 3 adaptation diets over periods of 9-d or 14-d with concentrate level increasing from 55% to 85% of diet DM. The REST program consisted of restricted intake of the final diet (85% concentrate containing 55% of high moisture corn) with programmed increases in feed offered until yearling bulls reached ad libitum access over periods of 9-d and 14-d. Fecal samples were collected just before morning (0800 h) and afternoon (1500 h) meals, and a composite sample per pen in each day was made. It was observed ($P < 0.05$) an interaction between protocols, length of protocols and days for DM and starch digestibility. Yearling bulls adapted for 14-d had greater DM digestibility on the first day of the finishing period (15-d: STEP in 14-d = 79.05%, REST in 14-d = 78.05%) than those adapted for 9-d (10-d: STEP in 9-d = 68.04%, REST in 9-d = 69.39%); however, no differences ($P > 0.10$) between treatments were observed on d 15. Moreover, yearling bulls in REST for 14-d and STEP during 9-d did not present differences ($P > 0.10$) in starch digestibility over days of collection. However, yearling bulls adapted in REST for 9-d and STEP during 14-d ($P < 0.05$) only proved to be able to digest starch like those in REST for 14-d and STEP for 9-d on d 15. Thus, according to present data, yearling Nellore bulls should be adapted in 14 d, regardless of the protocol.

Key Words: adaptation, digestibility, Nellore

W107 Improvements in feed efficiency via rumen-protected amino acid supplementation limited by ration formulation software. T. R. McGill* and M. D. Hanigan, *Virginia Polytechnic Institution and State University, Blacksburg.*

To avoid nutrient limitations, MP requirements are often overestimated in the formulation of dairy cow rations. Overfeeding of N results in increased expenses for producers and increased N excretion to the environment. Thus, improvements in the efficiency of dairy cow feeding provide economic and environmental incentives. Previous improvements in feed efficiency have come via the dilution of maintenance through increased production. To achieve further improvements, it is necessary to explore approaches such as supplementation of limiting AA's in rumen protected (RP) form to diets low in MP. The goal of this study was to better illustrate the mechanism of lactation response to RPAA, and to evaluate the effect of RPAA products on milk yield. Four diets were fed to 36 multiparous Holstein dairy cows in a 4 × 4 Latin square design. Diets were (1) positive control diet with 17.1%CP (+Con), (2) negative control diet containing 15.4%CP (−Con), (3) −Con diet supplemented with 20 g/d/cow of RP methionine (RPM), and (4) −Con diet supplemented with 20 g/d/cow of RP methionine and 60 g/d/cow of RP lysine (RP M/L). Data were analyzed using the MIXED procedure in SAS 9.2. Milk yield was not significantly different between groups, suggesting that protein was not sufficiently limiting to affect production. Concentrations of MUN from cows fed –Con, RPM and RP M/L diets were significantly lower than that of cows fed +Con diet ($P < 0.0001$), suggesting improved efficiency of N metabolism in cows fed diets low in MP. The 2001 NRC formulation software was used to formulate diets. The predicted metabolizable protein balance of the –Con diet was −262 g/d, and predicted a 17.5% decrease in MP Allowable Milk compared with the +Con. This inaccuracy illustrates the need for improvement in dairy nutrition models. Model inaccuracies contribute greatly to inefficiencies in dairy cow feeding, and must be evaluated in the effort to improve dairy cow feed efficiency. Such improvements could act synergistically with RPAA supplementation to more closely match nutrient composition in feed to nutrient requirements of dairy cows.

Key Words: rumen-protected amino acid, feed efficiency, NRC

W108 The effect of a two ration feeding regimen on feed intake, milk production and composition, and plasma hormones and metabolites in dairy cows. M. Niu*, Y. Ying, P. A. Bartell, and K. J. Harvatine, *Penn State University, University Park.*

There is a circadian pattern of feed intake, milk synthesis, and plasma metabolites in dairy cows consuming a single TMR fed once a day. The object of this study was to determine if feeding multiple rations over a day that compliment theses rhythms would improve milk production. Twelve Holstein cows were used in a replicated 3 × 3 Latin square design with 21 d periods in an automated feed observation system that recorded feed weight every 10 s. Diets were control (Con; 32% NDF, 25% starch), a low forage and high fermentable starch diet (L; 28% NDF, 32% starch, 56% corn silage and 14% steamflaked corn), and a high fiber diet (H; 33.5% NDF, 22% starch, 43% corn silage and no steamflaked corn). The L and H diets were balanced to provide the same composition as the control diet when combined in a 1:3 ratio of L:H. Con was fed control diet at 0700 h, the high/low treatment (HL) was fed H at 0700 h and L at 2200 h, and the low/high (LH) treatment was fed L at 0700 h and H at 1100 h. Daily variables were analyzed by a mixed model and the contrasts were Con vs. HL and HL vs. LH. Time course data were analyzed using repeated measures and the contrasts were tested at each time point. DMI was decreased by 1.3 kg/d by HL compared with LH ($P < 0.05$). There was no difference between Con and HL for milk yield and composition, but milk fat percent was higher in HL compared with LH ($P < 0.05$, 3.61 vs. 3.44%) and HL tended to increase milk fat yield compared with LH ($P < 0.10$). Milk yield was 1.8 kg higher and fat percent was 0.38 units lower at the 0500 h milking compared with the 1700 h milking, but milk fat yield did not differ. Blood samples were collected from the tail vein at 8 times to represent the course of a day at the last 3 d of each period. There was no effect of treatment on plasma NEFA and BUN concentration, but plasma glucose was decreased 2.5 mg/dL by HL compared with Con ($P < 0.05$). Feeding HL reduced DMI and increased milk fat yield compare with the LH, but feeding multiple rations over the day had little effect on DMI or milk yield and components compared with a single TMR.

Key Words: dairy cows, milk production, multiple rations per day

W110 Developing techniques to determine the metabolizable methionine content of ruminant products. R. S. Ordway*[1], C. G. Schwab[2,3], B. K. Sloan[4], and N. L. Whitehouse[2], *[1]Balchem Corporation, New Hampton, NY, [2]University of New Hampshire, Durham, [3]Schwab Consulting LLC, Boscobel, WI, [4]Adisseo North and Central America, Alpharetta, GA.*

Several methods have been used to determine the effectiveness of ruminant Met supplements in providing metabolizable Met (MP-Met) to dairy cows. Measuring differences in the slope of changes in milk protein or plasma free Met concentrations to increasing intakes of a Met supplement are 2 of the most promising. A randomized split plot 5 × 5 Latin square using 20 lactating cows in a 2 × 2 × 5 factorial arrangement of treatments was employed using 10 d periods with the last 4 d used for milk and blood sampling. Main effects were Met adequacy of basal diet (1.8 or 2.3 MP-Met as a % of MP), Met supplement [Smartamine M (S) or dry MetaSmart (M)] and level of Met supplementation (0, 3, 6, 9 and 12 g/d MP-Met). Basal diets met NRC (2001) requirements and contained 6.8% Lys in MP. Additional S was used to achieve the high MP-Met basal diet. S and M were estimated to supply 600 and 222 g of MP-Met/kg of product, respectively. The response criteria evaluated were milk protein content (MPC), milk protein yield (MPY), plasma Met (PM) and total plasma sulfur AA (TPSAA). Three blood samples were taken from the tail vein daily at 2-h intervals after the am feeding on d 7–10 of each experimental period. Plasma samples were centrifuged, deproteinized and composited within and across days and analyzed in duplicate for AA content. For each response parameter, linear regression equations were derived for each product at each level of Met adequacy. On the limiting MP-Met basal diet, both Met supplements increased MPC 0.009 units/g MP-Met with a SE of 0.002; a precision of ± 20%. Both M and S improved MPY 9 and 6 g per g of MP-Met, respectively, with SE of >2.6 and an imprecision of >40%. For S, irrespective of level of MP-Met adequacy, both PM and TSAA increased in a linear fashion ($r^2 > 0.78$) with a precision of ± 10%; however, the predictability was poor for M ($r^2 < 0.33$). It appears PM or TPSAA are the most appropriate response parameters to use to predict the MP-Met contribution of rumen protected DL-Met sources, but they are unsuitable for products where the analog rather than DL-Met is absorbed.

Key Words: amino acid methodologies, encapsulated methionine, methionine analogue

W111 The effect of various dietary metabolizable proteins to metabolizable energy ratios on ovarian follicular activities in prepubertal Holstein heifers. H. R. Motalebei, M. Dehghan-Banadaky*, K. Rezayazdi, and H. Kohram, *Department of Animal Science, University of Tehran, Karaj, Tehran, Iran.*

The objective of the present study was to evaluate the effects of various metabolizable protein (MP) to metabolizable energy (ME) ratios on ovarian follicular dynamics in prepubertal Holstein heifers. Twenty-four Holstein heifers, weighing 217 kg, 210 ± 28 d old, were used in the trail. Heifers were randomly assigned to 3 rations of MP per day: (1) control, MP based on NRC (34.57 g), (2) 10% MP less than NRC (31.14 g), (3) 10% MP more than NRC (38 g). Metabolizable energy in all rations was based on NRC requirements (14 Mcal per day). Rations were formulated by NRC (2001) software. After 70 d of feeding, the estrous synchronization were done using 2 IM injection of PGF2α (Vetalyse, Dinoprost, Aburaihan, Iran), 11 d apart and ovarian ultrasonography (Pie medical, Falco 100, 8 MHz) was performed once daily over 10 d period from the day of estrus. The ovarian follicles were counted and classified as: class 1 (total, ≥ 2 mm), class 2 (small, 4–6 mm), class 3 (medium, 7–9 mm), class 4 (large, ≥ 10 mm) and class 5 (medium and large ≥7 mm). The results showed that there were no differences ($P > 0.05$) between rations in classes 1 to 4, but class 5 follicles were higher ($P < 0.05$) in ration 1 than rations 2 and 3. It is concluded that 10% MP less than NRC rations may had the beneficial effect on the ovarian activity in prepubertal heifers.

Table 1. The effects of various ratios of MP to ME on ovarian follicular activities (no. and class of follicles) in prepubertal heifers

	MP/ME (g/Mcal)				
No. of follicles	34.57	31.14	38	*P*-value	SEM
Class 1 (total, ≥2 mm)	13.67	13.58	14.08	NS	0.525
Class 2 (small, 4-6 mm)	9.64	8.30	9.10	NS	0.503
Class 3 (medium, 7-9 mm)	0.64	0.94	0.61	NS	0.131
Class 4 (large, ≥10 mm)	0.50	0.43	0.32	NS	0.930
Class 5 (medium and large, ≥7 mm)	1.09	1.79	0.94	0.03	0.243

Key Words: metabolizable protein, metabolizable energy, ovarian follicle

W112 Ruminal fermentation profile of cows fed diets containing dried distillers grains with solubles associated with risk factors for milk fat depression. H. A. Ramirez Ramirez* and P. J. Kononoff, *University of Nebraska-Lincoln, Lincoln.*

Four ruminally-cannulated Holstein cows, averaging (±SD) 114 ± 14 DIM and 662 ± 52 kg BW were used in a 4 × 4 Latin Square to test the effects of high dietary oil and starch as risk factors associated with milk fat depression (MFD) on ruminal fermentation when feeding of a diet containing dried distillers grains with solubles (DDGS). Formulation of the experimental diets included corn oil and ground corn to increase crude fat (CF) and starch levels. In each of the 21-d periods cows were assigned to one of 4 dietary treatments (values expressed on a DM basis): control ration containing 20% DDGS but no risk factors associated with MFD (CON; CF 5.4%, starch 20%); CON with added oil (OIL; CF 6.4%, starch 20%); CON with added starch (STARCH; CF 5.6%, starch 26%); and CON with added oil and starch (COMBO; CF 6.5%, starch 25%). There was a significant effect ($P < 0.01$) of diet on milk fat concentration (MF%) (3.19, 2.75, 2.88 and 2.21 ± 0.18% for CON, OIL, STARCH and COMBO, respectively). Ruminal pH and NH_4 were not affected by treatment (averaging 5.97 ± 0.08 and 14.5 mg/dL across treatments). Total concentration of VFA was similar for CON, OIL and STARCH (119 ± 3.64 mmol/L) whereas COMBO was lower ($P < 0.01$; 111 ± 3.64 mmol/L). Molar proportion of acetate (Ac) was affected by treatment ($P < 0.01$) being higher for CON compared with OIL, STARCH and COMBO (64.6 versus 61.9 ± 1.44 mol/100 mol). Treatment also had a significant effect ($P < 0.01$) on propionate (Pr) which was highest for COMBO, followed by OIL and STARCH; and lowest for CON (25.3, 24.5 and 22.0 ± 1.53 mol/100 mol). Concomitant with these changes Ac:Pr tended ($P = 0.12$) to decrease with the addition of risk factors (2.97, 2.64, 2.62 and 2.45 ± 0.21 for CON, OIL, STARCH and COMBO, respectively). Feeding a diet with 20% DDGS resulted in higher concentration of Ac and low Pr; by adding high levels of oil and starch to such diet these parameters were inverted resulting in a tendency to decrease Ac:Pr and reduced MF% possibly due to shifts in ruminal environment which may affect microbial metabolism and milk fat synthesis.

Key Words: ethanol by-products, ruminal pH, VFA

W113 The protein binding capacity of protein-precipitable phenolics from 10 warm-season perennial forage legumes. H. D. Naumann*[1,2], J. P. Muir[2], B. D. Lambert[2,3], A. E. Hagerman[4], and L. O. Tedeschi[1], *[1]Texas A&M University, College Station, [2]Texas A&M AgriLife Research, Stephenville, [3]Tarleton State University, Stephenville, TX, [4]Miami University, Oxford, OH.*

Condensed tannins (CT) are protein-precipitable phenolic compounds (PPP) that bind to proteins and potentially reduce ruminal protein breakdown. Ruminants consuming forages containing biologically active CT could experience an increase in ruminal-bypass protein. The objectives of this study were to determine the PPP concentration and amount of protein bound (PB) by PPP, as well as the protein binding capacity of PPP produced by warm-season perennial legumes commonly consumed by ruminants. Ten warm-season perennial legumes: *Leucaena retusa*, *Desmanthus illinoensis*, *Lespedeza stuevei*, *Mimosa strigillosa*, *Neptunia lutea*, *Desmodium paniculatum*, *Arachis glabrata*, *Lespedeza cuneata* and 2 ecotypes of *Acacia angustissima* var. *hirta* were evaluated. Protein-precipitable phenolics were determined by reacting crude plant extracts with bovine serum albumin. The amount of PB was determined by nitrogen analysis of the protein-phenolic residues. The PB to PPP ratio (PB:PPP) was used to evaluate the difference in protein binding capacity among the forage legumes surveyed. *Arachis glabrata*, included as a negative control, contained no PPP. *Desmodium paniculatum* had the greatest PPP concentration (193.9 g/kg DM; $P < 0.0001$). The greatest amounts of PB ($P < 0.0001$) were measured in *L. stuevei* and *M. strigillosa* (74.8 and 74.6 g/kg DM, respectively). The least amount of PB was demonstrated by *L. retusa*. The greatest protein binding capacities ($P < 0.05$) were demonstrated by PPP from *L. cuneata*, *D. illinoensis* and *M. strigillosa*, which had PB:PPP of 0.74, 0.67 and 0.61, respectively. Protein-precipitable phenolics from *D. paniculatum*, *L. retusa* and 2 ecotypes of *A. angustissima* demonstrated the least ($P < 0.05$) protein-binding capacities (PB:PPP = 0.17, 0.38, 0.36, and 0.31, respectively). The protein binding capacity of PPP from *L. cuneata* was more than 4 times greater than that of *D. paniculatum*, which had a PPP concentration almost 4 times greater than *L. cuneata*. Differences in protein binding capacity of PPP could translate into differences in biological value of forages consumed by ruminants, especially as it relates to ruminal escape protein.

Key Words: bypass protein, legume

W114 Ruminal degradability in vitro by sub-products of the biodiesel industry. A. L. Silva, M. I. Marcondes*, F. C. Sousa, L. S. Knupp, C. M. Velloso, C. S. Cunha, and J. P. P. Rodrigues, *Universidade Federal de Viçosa, Viçosa, Minas Gerais, Brazil.*

The in vitro gas production technique is capable of simulating the ruminal environment, reflecting the rate and extent at which the components are fermented by the rumen microorganisms. The objective was to study the rumen fermentation kinetics of 18 by-products from the biodiesel industry, with potential for use for feeding ruminants, using in vitro gas production technique. The feeds studied were: cottonseed (*Gossypium* spp. L.) meal and cake; babassu (*Orbignya speciosa*) cake; canudo de pito (*Mabea fistulifera* Mart) meal; crambe (*Crambe abyssinica*) meal and cake; palm kernel (*Elaeis guineensis*) cake; sunflower (*Helianthus annuus*) meal and cake; licuri nut (*Syagrus coronata*) cake; macauba fruit (*Acrocomia aculeata*) cake; castor seed (*Ricinus communis*) meal detoxified with lime; forage radish (*Raphanus sativus*) cake; 2 jatropha (*Jatropha curcas*) cakes; 2 peanut (*Arachis hypogaea*) cakes; and soybean (Glycine max) meal. Feeds were grouped, according to the rumen fermentation kinetic parameters, in 6 different groups. It was used multivariate analysis by Ward's minimum-variance method, and adopted an R^2 of 0.8. Soybean meal was used as control treatment. Parameters evaluated were: gas production from fibrous carbohydrates (VfFC), gas production from nonfibrous carbohydrates (VfNFC), degradation rate of fibrous carbohydrates (kdFC), degradation rate of nonfibrous carbohydrates (kdNFC) and lag time (lag). The VfNFC varied from 16.72 to 200.07 mL for the macauba fruit cake and peanut cake II, respectively. While the VfFC varied from 53.09 to 242.12 mL for the palm kernel cake and macauba fruit cake, respectively. Mean kdFC values varied from 0.002 to 0.039%/h for the licuri nut cake and forage radish cake, respectively. The kdNFC for palm kernel cake and macauba fruit cake varied from 0.022 to 0.430%/h, respectively. Mean lag values varied from 0.0001 to 5.2029 h for the cottonseed cake and palm kernel cake, respectively. The sub-products forage radish cake and cottonseed, crambe and sunflower meals, contained in the group 1, showed similar quality to soybean meal. Thus, these feeds have potential to replace soybean meal in ruminant rations.

Key Words: carbohydrate, degradation rate, ruminants

W115 Urinary and blood characteristics in cattle fed low-quality tropical forage in response to infrequent nitrogen supplementation. L. M. A. Rufino*, E. Detmann, J. P. P. Rodrigues, L. H. R. Silva, S. C. Valadares Filho, M. F. Paulino, and M. O. Franco, *Universidade Federal de Viçosa, Viçosa, Minas Gerais, Brazil.*

The effects of supplementation with rumen degradable protein (RDP) using 2 frequencies of supplementation on urinary and blood characteristics were evaluated in cattle fed low- quality tropical forage. Five crossbred steers, with average BW of 257 ± 18 kg, were used in a 5 × 5 Latin square design. Five treatments were evaluated: 1.control (without supplementation); 2.daily supplementation supplying 30% of the daily RDP requirements (30/D); 3.daily supplementation supplying 60% of the daily RDP requirements (60/D); 4.supplementation every 3 d supplying 30% of 3 d based requirements of RDP (30/I); and 5.supplementation every 3 d supplying 60% of 3 d based requirements of RDP (30/I). The animals were fed ad libitum with Tifton 85 hay (4.5% of crude protein). The supplement was composed of 85% casein and 15% urea: ammonium sulfate (9:1). The experimental periods lasted 24 d, being 9 d for adaptation to the treatments. The total urine collection was performed from d 16 to 18 and the excretions of urea nitrogen (UN) and 3-methylhistidine (3MH) were evaluated. Blood samples were taken from d19 to 21 via the jugular vein every 6 h (6 h, 12 h, 18 h, and 24 h) and composed on a daily basis. The concentrations of serum urea nitrogen (SUN) and plasma amino acids (PAA) were evaluated. The different collection days were considered as repeated measures. The treatments did not affect ($P > 0.10$) 3MH and PAA. The supplementation increased ($P < 0.01$) the UN and SUN. Among supplements, only a difference between amounts of RDP was detected ($P < 0.01$) for these variables, being the greatest values observed when 60% of RDP requirements were supplied. Moreover, there was a day × treatment interaction ($P < 0.01$) for both SUN and UNU. There were variations among days ($P < 0.01$) only for treatments 30/I and 60/I. In both treatments, there was an increase in SUN on d 2 of collection with return on 3rd day at concentrations similar to those observed on d 1. Infrequent nitrogen supplementation changes the nitrogen metabolism of cattle fed low-quality tropical forage.

Key Words: metabolism, nitrogen, recycling

W116 Small intestinal digestion of raw cornstarch in cattle is increased by duodenal infusion of non-essential amino acids or casein. D. W. Brake*, E. C. Titgemeyer, E. A. Bailey, and D. E. Anderson, *Kansas State University, Manhattan.*

Previous research demonstrated that small intestinal starch digestion (SISD) in cattle may be increased by postruminal infusion of casein, but reports on effects of amino acids (AA) are limited. We evaluated effects of AA on SISD in cattle. Five duodenally and ileally cannulated steers (initial BW = 259 kg) were used in a 5 × 5 Latin square with 6-d periods. All cattle were fed 4.8 kg DM/d of a soybean hull-based diet and received continuous duodenal infusions of raw cornstarch (1.5 kg/d) and Cr-EDTA in 12.6 L/d volumes. Treatments were infused duodenally and included (1) control, (2) 424 g/d casein, (3) 393 g/d AA mimicking casein (CASAA), (4) 192 g/d AA mimicking the essential AA in casein (EAA), and (5) 200 g/d AA mimicking the non-essential AA in casein (NEAA). On d 6 of each period, 6 spot samples of ileal digesta and feces were composited and subsequently analyzed. Flow of starch to the ileum tended ($P = 0.08$) to be less when cattle received casein, CASAA, or NEAA. Additionally, SISD was greatest ($P \leq 0.05$) with CASAA and least with control. When cattle were infused with EAA, SISD did not differ from control, and SISD was intermediate to control and CASAA when cattle received casein or NEAA. Flows of ethanol-soluble oligosaccharides to the ileum were greatest ($P = 0.01$) with EAA and casein, least for control and NEAA, and intermediate for CASAA. Glucose flows to the ileum averaged 61 g/d and were not affected ($P = 0.26$) by treatment. Large intestinal starch digestion tended ($P = 0.06$) to be less and starch flow to the feces was greater ($P = 0.04$) for control and NEAA than for CASAA and casein. Postruminal starch digestion was least ($P = 0.03$) for control and NEAA. Apparently, SISD in cattle receiving continuous infusion of raw cornstarch is improved by AA similar to casein, and this response was mimicked by NEAA but not EAA.

Key Words: amino acid, cattle, small intestinal starch digestion

W117 Relationships between malt characteristics and feed value of malt barley grain. S. Ding*[1,2], M. Oba[2], M. L. Swift[3], W. Z. Yang[1], and T. A. McAllister[1], *[1]Lethbridge Research Center, Agriculture and Agri-Food Canada, Lethbridge, AB, Canada, [2]Department of Agricultural, Food and Nutritional Science, University of Alberta, Edmonton, AB, Canada, [3]Alberta Agriculture and Food, Lacombe, AB, Canada.*

Grain producers in western Canada prefer to grow malt barley over feed barley as malt barley is more economically attractive. However, less half of the malt barley produced qualifies as malt grade with the

remainder used as feed grain. Feed value of malt barley is rarely considered by grain growers and as such, there is a paucity of information available. The objective of this study was to examine the relationship of malt characteristics with chemical composition and DM digestibility (DMD). Five-hundred and 60 malt barley samples were collected across western Canada in 2007. Five malting characteristics including fine malt extract (FEXT), diastatic power (DP), α-amylase (ALPH), β-glucan (GLU) and friability (FRI) were selected due to a potential correlation to nutrient content and DMD of malt barley. Digestibility of DM was evaluated by grinding the samples through 6-mm and incubated for 24 h in batch culture. Samples were ground to 1-mm for determination of CP, NDF and starch. Correlation coefficient was analyzed using CORR procedure of SAS. FEXT (%), DP (°L), ALPH (D.U.), GLU (ppm), and FRI (%) ranged from 74 to 85, 110 to 220, 57 to 97, 51 to 580 and 34 to 110, respectively. The concentrations (% DM) of CP, starch and NDF ranged from 8.1 to 16.5, 55.6 to 67.4, and 17.2 to 21.2, respectively. Digestibility of DM (%) averaged 39.5 and ranged from 26.8 to 56.6. Protein concentration of malt barley was negatively correlated ($P < 0.01$) with FEXT ($r = -0.89$) and FRI ($r = -0.70$), but positively correlated with DP ($r = 0.63$). The starch concentration was negatively correlated ($P < 0.01$) with DP and ALPH ($r = -0.56$ and $r = -0.57$, respectively). Neither malt characteristics nor chemical composition of malt barley were correlated ($-0.24 < r < 0.28$) with DMD. These results indicate that some malt characteristics could be used as reliable criteria to select malt barley for use as feed barley. This work also demonstrates the substantial variation in chemical composition of commercially available malt barley and emphasizes the need to have an accurate and rapid means of quality assessment at the point of sale.

Key Words: batch culture, chemical composition, malt barley

W118 Investigation of dietary fiber as a potential source of trace mineral antagonism in ruminants. G. I. Zanton* and P. Fisher, *Novus International Inc., St. Charles, MO.*

Dietary fiber has been implicated as a potential antagonist against trace mineral absorption in non-ruminants at fiber concentrations significantly lower than those which would be present in ruminant diets. The magnitude of the interaction between fibrous ingredients and trace minerals has not been characterized under ruminant relevant conditions. To address this question, fibrous feedstuffs were ground through a 1 mm screen and pre-incubated in 39°C distilled water under shaking for 2 h. Insoluble material was filtered and dried for 24 h. A quantity of dried, insoluble material was weighed into 15 mL centrifuge tubes to which 10 mL of solutions containing sulfate salts of Zn or Cu were added. Tubes were shaken for 24 h at 39°C, centrifuged for 15 min at 500 × *g*, the supernatant was filtered (0.2 μm), and analyzed for mineral concentration with ICP-OES. Percent mineral bound (%MB) to fiber was determined by the difference between final and initial concentration in solution. Several experiments were conducted with wheat straw (WS) as the fiber source to evaluate %MB and the effects of: pH (3.0 and 5.5–6.5) and Zn or Cu levels (15–1000 ppm); changing WS (12.5–100 g/L) and Zn or Cu (15–1000 ppm) levels; increasing levels of Ca (0.125–25 g/L) on Zn binding; and altering both Zn and Cu levels (16–250 ppm). In addition, the effect of rumen degradation (16 h) on Zn binding was evaluated with different fibrous feeds. Under all conditions evaluated, increasing level of Zn or Cu decreased %MB to the fiber. Lower pH reduced %MB whereas increasing the level of fiber increased %MB. Increasing the level of Ca or Cu in solution decreased the binding of Zn to the fiber, whereas increasing the level of Zn did not appreciably affect the binding of Cu. Incubation of the feeds in the rumen significantly reduced the binding of Zn (78.9 vs 74.4% bound by fiber sources for $t = 0$ and 16, respectively; $P < 0.01$). Zn binding ranged from 56 to 92% for the feedstuffs evaluated with the following ranking: timothy hay < WS < alfalfa hay < wheat bran < oat bran. It is concluded that fiber can bind a significant percentage of Zn and Cu under ruminant relevant conditions.

Key Words: trace mineral, fiber, antagonisms

W119 Forage intake and digestibility by Katahdin ewes offered bermudagrass hay supplemented with apple cider vinegar. W. B. Smith*[1], E. A. Backes[1,2], J. D. Caldwell[2], K. P. Coffey[1], and A. N. Young[1], *[1]Department of Animal Science, University of Arkansas Division of Agriculture, Fayetteville, [2]Department of Agriculture and Environmental Science, Lincoln University, Jefferson City, MO.*

Currently, some small ruminant producers are supplementing with apple cider vinegar (ACV) for increased fiber digestion and feed efficiency. However, no scientific data are available to justify this practice. Our objective was to determine intake and in vivo digestibility of bermudagrass hay by ewes supplemented with different levels of ACV. Sixteen non-pregnant, nonlactating Katahdin ewes (3 to 4 yr of age; 65.9 ± 1.16 kg initial BW) were allocated randomly to 1 of 4 treatments: 0, 10, 20 or 30 mL ACV/d. Ewes were housed in individual 1.4 × 4.3 m pens fitted with rubber mats. Each ewe was offered a 100 g mixture of cracked and ground corn at approximately 1500 h daily, and the allotted level of ACV was incorporated into the mixture. Hay from large round bales of predominantly bermudagrass (72.4% NDF, 36.3% ADF) was chopped using a bedding chopper to an approximate fiber length of 2.5 cm and offered ad libitum to each ewe through a 10-d adaptation period followed by 6 d of total fecal collections. Data were analyzed using SAS PROC MIXED, where animal served as the experimental unit. Level of inclusion of ACV did not affect DM intake ($P = 0.17$), digestible DM intake ($P = 0.22$), DM digestibility ($P = 0.52$), NDF digestibility ($P = 0.23$), or ADF digestibility ($P = 0.13$). Based on these data, ACV is not a viable supplement for enhancing digestibility of bermudagrass hay at levels of inclusion up to 30 mL/d.

Key Words: apple cider vinegar, dry matter digestibility, Katahdin

W120 Evaluation of microwave irradiation effects on ruminal and postruminal degradation of guar meal. S. N. Garajeh[2,1], A. Taghizadeh*[1], N. M. Sis[2], F. P. Khajehdizaj[1], and B. B. Nobari[1], *[1]Department of Animal Science, Faculty of Agriculture, University of Tabriz, Tabriz, Eastern Aazarbaijan, Iran, [2]Department of Animal Science, Shabestar branch, Islamic Azad University, Shabestar, Iran.*

Knowledge of the extent of RUP is important in formulating diets with adequate RDP to support rumen microorganisms. When protein degradation in the rumen exceeds the microbes ability to assimilate N into microbial crude protein (MCP), excessive rumen ammonia concentrations can occur. The DM of 1 g sample of guar meal (DM 95.5%, CP 49.6%, NDF 15.1%, ADF 6.6%, EE 4.7% and OM 94.9%) in duplicate was determined and water was added to increase the moisture content of 1kg guar meal to 300 g/kg. Approximately 500 g of samples were subjected to microwave irradiation (Butane microwave BC380W) at a power of 900w for 2 and 4 min, separately. The ruminal and postruminal degradation were determined according to Gargallo et al. (2006) with 3 fistulated sheep fed diet containing 60:40 hay to commercial concentrate. Ruminal degradability of guar meal DM and CP were decreased linearly ($P < 0.0001$) as microwave irradiation time increased. Similar result was observed for postruminal degradation of guar meal CP. It seems that

microwave treatment resulted in decreasing protein solubility and led to decrease in CP degradation. When secondary and tertiary structures of a protein are unfolded, hydrophobic groups interact and reduce water binding. Moreover, hydrophobic interactions lead to aggregation followed by coagulation and precipitation, probably reducing ruminal CP degradability.

Table 1. Ruminal and postruminal degradability of DM and CP of untreated and microwave treated guar meal

	Microwave treated				Contrast	
	Untreated	2 min	4 min	SEM	Linear	Quadratic
Ruminal degradability for 12 h incubation (%)						
DM	84.8	75.4	69.8	1.09	<0.0001	0.1841
CP	79.2	73.7	59.3	1.45	<0.0001	0.0350
Postruminal degradability (%)						
DM	76.3	81.1	79.1	0.58	0.0140	0.0030
CP	95.3	90.5	93.0	0.21	0.0003	<0.0001

Key Words: microwave irradiation, guar meal, ruminal and postruminal degradation

W121 Effect of feeding a corn straw or mixed forage diet on rumen fermentation parameters and ruminal papillae morphology in dairy cows. X. X. Weng[1,2], J. Q. Wang*[1,2], D. P. Bu[1], Y. D. Zhang[1], and F. D. Li[2], *[1]State Key Laboratory of Animal Nutrition, Institute of Animal Science, Chinese Academy of Agricultural Sciences, Beijing, China, [2]College of Animal Science and Technology, Gansu Agricultural University, Lanzhou, China.*

Papillae protruding from the rumen wall greatly increase the surface area for absorption of nutrients, and diets play an important part for papillae development. The objective of this study was to determine the effect of dietary forage sources on rumen fermentation parameters and ruminal papillae morphology in dairy cows. Ten primiparous and rumen-cannulated Holstein dairy cows averaging 127 ± 13 d in milk (mean ± SD) were randomly assigned to mixed forage diet (MF, forage: concentrate = 60: 40) with Chinese wildrye, alfalfa hay and corn silage as the forage source or corn straw diet (CS, forage: concentrate = 40: 60) with corn straw as the forage source. Diets were formulated to be iso-energetic and iso-nitrogenous. The experiment lasted for 63 d. Samples of rumen fluid were collected via cannula every 6 h over a 72-h duration starting on d 37 of experiment period to analyze pH, ammonia and VFA concentrations. At the end of experiment, rumen papillae were biopsied from the ventral sac and observed using light and transmission electron microscope. Results showed that cows fed MF diet had higher ($P < 0.01$) ruminal acetate concentrate and ratio of acetate to propionate, and lower concentrations of ammonia-N ($P < 0.01$), propionate ($P < 0.05$), butyrate ($P < 0.01$), isobutyrate ($P < 0.01$), valerate ($P < 0.01$) and isovalerate ($P < 0.01$) than cows fed CS diet. Microscopic examination revealed a reduction ($P < 0.01$) in the width of papillae when cows fed MF diet. No significant differences ($P > 0.05$) were found for the thickness of stratum corneum, stratum granulosum, stratum spinosum, and stratum basale between dietary treatments. Biopsied papillae exhibited a decline in cellular junctions, large spaces between cells, moderate sloughing of the stratum corneum, and an accelerated migratory state in all strata below the stratum corneum in cows fed CS diet. These results suggest that increasing permeability throughout the ruminal epithelium caused by a decline of cellular junctions may be deleterious to the animal's health when cows were fed CS diet.

Key Words: forage source, morphology, ruminal papillae

W122 Effects of pistachio by-product as a replacement for alfalfa hay on milk fatty acid composition in Saanen dairy goats fed a diet containing fish oil. M. H. Ghaffari[1], A. M. Tahmasbi[1], M. Khorvash[2], A. H. Ghaffari[1], and S. Kargar*[2], *[1]Faculty of Agriculture, Excellence Center in Animal Science, Ferdowsi University of Mashhad, Mashhad, Iran, [2]Department of Animal Sciences, Faculty of Agriculture, Isfahan University of Technology, Isfahan, Iran.*

The objective of this study was to evaluate the effect of feeding pistachio by-product (PBP) as a replacement for alfalfa hay (AH) on milk fatty acid composition in Saanen dairy goats fed a diet containing fish oil. Fifteen multiparous lactating Saanen goats (on d 25 postpartum; average BW of 38.2 ± 1.2 kg) were randomly assigned to one of 3 treatments in a completely randomized design with 5 goats per treatment. Treatments consisted of feeding the following diets: 1) control (alfalfa hay), 2) 30% PBP, 3) 30% PBP + polyethylene glycol (PEG; 0.1% DM). The experiment lasted 21 d, including 16 d of treatment adaptation and 5 d of data collection. The milk fatty acid composition is presented in Table 1. Data were analyzed using the PROC MIXED procedure of SAS.The goats fed PBP (with and without PEG) had higher amounts of C16:0, and trans - C18:1 isomer in milk fat than those fed AH, while C24:0 was detected at higher concentrations in the goats fed AH ($P < 0.05$) than those of the others. Overall, different treatments did not affect saturated (SFA), mono (MUFA) and polyunsaturated fatty acid (PUFA) concentrations in milk fat. The concentrations of trans fatty acids (TFA) were higher ($P < 0.05$) for PBP and PBP-PEG than those fed AH. However, no significant differences were detected in the concentrations of short (SCFA), medium (MCFA) and long chain fatty acids (LCFA) among treatments. These findings reveal that feeding of PBP as a replacement for AH in the diet of dairy Saanen goats can modify the fatty acid profile of milk in dairy goat.

Table 1. Effect of treatments on milk FAs (g/100 g of total FA)

	Treatments				
Item	AH	PBP	PBP+PEG	SEM	*P*-value
C16:0	18.51[b]	24.08[a]	23.63[a]	0.50	0.03

W123 Effects of pistachio by-product as a replacement for alfalfa hay on ruminal fermentation, blood metabolites, and milk yield and composition in Saanen dairy goats fed a diet containing fish oil. M. H. Ghaffari[1], A. M. Tahmasbi[1], M. Khorvash[2], A. Naserian[1], and S. Kargar*[2], *[1]Faculty of Agriculture, Excellence Center in Animal Science, Ferdowsi University of Mashhad, Mashhad, Iran, [2]Department of Animal Sciences, College of Agriculture, Isfahan University of Technology, Isfahan, Iran.*

The objective of this study was to evaluate the effect of feeding pistachio by-product (PBP) as a replacement for alfalfa hay (AH) on their milk fatty acid composition in Saanen dairy goats fed a diet containing fish oil. Fifteen multiparous lactating Saanen goats (on d 25 postpartum; average BW: 38.2 ± 1.2 kg) were randomly assigned to the 3 treatment diets in a completely randomized design with 5 goats per treatment. Treatments

consisted of feeding the following diets: (1) control (alfalfa hay), (2) 30% PBP, (3) 30% PBP + polyethylene glycol (PEG, 0.1% DM). The experiment lasted 21 d, including 16 d of adaptation to the experimental diets followed by a 5-d sampling period for determining the milk yield and composition. Ruminal fluid samples were taken at 3 h after morning feeding on 20 d of the experiment. Blood samples from all the goats were obtained from the jugular vein 3 h after the morning feeding on 21 d of the experiment. Data were analyzed using the PROC MIXED procedure of SAS. The goats fed PBP had a lower ($P < 0.05$) dry matter intake (DMI) than the other treatments. There was no significant difference between the rumen pH, milk yield and composition among treatments, while rumen ammonia-N concentration was lower ($P < 0.01$) in goats fed PBP than the other treatments. There were no significant differences between treatments for blood metabolites. These findings reveal that feeding of PBP as a replacement for AH in the diet of dairy Saanen goats had no adverse effect on ruminal fermentation and blood metabolites.

Table 1. Effects of treatments on milk, rumen, and blood parameters

	Treatment				
Item	AH	PBP	PBP+PEG	SEM	*P*-value

W124 Effects of pistachio by-products as a replacement for alfalfa hay on rumen bacteria involved in biohydrogenation of Baluchi male sheep. M. H. Ghaffari[1], A. M. Tahmasbi[1], A. H. Ghaffari[1], A. Naserian[1], and S. Kargar*[2], *[1]Faculty of Agriculture, Excellence Center in Animal Science, Ferdowsi University of Mashhad, Mashhad, Iran, [2]Department of Animal Sciences, College of Agriculture, Isfahan University of Technology, Isfahan, Iran.*

The objective of this study was to investigate the effect of feeding pistachio by-products (PBP) as a replacement for alfalfa hay (AH) on populations of bacteria involved in rumen biohydrogenation in Baluchi sheep. Four Baluchi sheep (41 ± 1.3 kg BW) fitted with ruminal cannulas were assigned at random to 4 experimental diets in a 4 × 4 Latin square design. Treatments consisted of feeding the following diets: (1) control (0% PBP), (2) 12% PBP, (3) 24% PBP, and (4) 36% PBP. The basal diet was 36% DM alfalfa hay, 16% DM wheat straw, 20% DM barley grain, 0.3% DM sunflower oil. The experiment consisted of 4 periods. Each period lasted 20 d, comprising 16 d of adaptation to the experimental diet followed by 4 d for sampling. Bacterial populations were assessed by DNA extraction of samples of rumen liquor followed by rt-PCR analysis. All data were analyzed using the PROC MIXED procedure of SAS. Among the total ruminal bacterial community, the relative abundance of *Butyrivibrio fibrisolvens* and *Butyrivibrio proteoclasticus* were not affected by the treatments (Table 1). This finding suggests that dietary PBP at levels up to 36% DM had no effects on relative abundance of bacteria involved in rumen biohydrogenation.

Table 1. Populations of biohydrogenating bacteria[1] (percentage of total bacteria) in Baluchi male sheep fed different levels of pistachio by-product

	Pistachio by-product level					*P*-value		
Bacteria	0%	12%	24%	36%	SEM	Treatment	Linear	Quadratic
B. fibrisolvens	1.001	1.764	0.955	0.909	0.318	0.591	0.537	0.354

W125 Effects of pistachio by-products as a replacement for alfalfa hay in the diet of sheep on ruminal fermentation. M. H. Ghaffari[1], A. M. Tahmasbi[1], M. Khorvash[2], S. A. H. Ghaffari[1], and S. Kargar*[2], *[1]Faculty of Agriculture, Excellence Center in Animal Science, Ferdowsi University of Mashhad, Mashhad, Iran, [2]Department of Animal Sciences, College of Agriculture, Isfahan University of Technology, Isfahan, Iran.*

The objective of this study was to investigate the effect of feeding pistachio by-products (PBP) as a replacement for alfalfa hay (AH) on ruminal fermentation in sheep. Four Baluchi sheep (41 ± 1.3 kg BW) were assigned at random to 4 experimental diets in a 4 × 4 Latin square design. Treatments consisted of feeding the following diets: (1) control (0% PBP), (2) 12% PBP, (3) 24% PBP, and (4) 36% PBP. The basal diet was 36% DM alfalfa hay, 16% DM wheat straw, 20% DM barley grain. The experiment consisted of 4 periods. Each period lasted 20 d, comprising 16 d of adaptation and 4 d for sampling. All data were analyzed as a 4 × 4 Latin square design using the PROC MIXED procedure of SAS. Results of ruminal fermentation parameters are presented in Table 1. Treatments had no effect on ruminal pH, while rumen ammonia-N concentration decreased linearly ($P < 0.05$) with increasing PBP levels up to 36% of DM. Reduction in the ruminal ammonia-N concentration with the feeding of PBP in the diet may have resulted from tannins (2.46% DM) bound to proteins, decreased proteolysis and subsequently lowered ammonia-N concentration in rumen fluid. Feeding of 36% PBP in the diet reduced ($P < 0.05$) total VFA and acetate concentrations, while the concentrations of propionate, butyrate and acetate to propionate ratio were similar to across all treatments. Reductions in the VFA concentration might be related to the lower microbial fermentation in presence of tannins in PBP.

Table 1. Ruminal fermentation parameters in sheep fed different levels of pistachio by-product meal (PBP)

	Treatments					*P*-value
Rumen parameter	0PBP	12PBP	24PBP	36PBP	SEM	Linear
Rumen pH	6.31	6.33	6.26	6.38	0.06	0.541
Rumen NH_3-N (mg/dL)	19.41[a]	17.46[ab]	16.31[b]	15.18[b]	0.78	0.003
Total VFA (mmol/100 mol)	103.30[a]	104.63[a]	103.01[ab]	100.33[b]	0.87	0.024
Individual VFA (mmol/100 mol)						
Acetate	70.93[a]	69.71[a]	69.44 [a]	66.99[b]	0.70	0.004
Propionate	21.14	23.79	22.35	22.25	0.91	0.653

Key Words: Baluchi sheep, pistachio by-product

W126 Substitution of ground corn with different levels of coarsely ground wheat in the diets of dairy cows on feed intake, nutrient digestion, microbial N supply, and plasma metabolite profiles. Y. Guo*, Y. Zou, S. Li, Z. Cao, X. Xu, and Z. Yang, *State Key Laboratory of Animal Nutrition, College of Animal Science and Technology, China Agricultural University, Beijing, China.*

The effects of increasing concentrations of coarsely ground wheat (CGW, 3-mm screen, geometric mean particle sizes: 1,139μm) substituted for ground corn (GC, 3.5-mm screen, geometric mean particle sizes: 666μm) on feed intake, nutrient digestion, microbial N supply and plasma metabolites were evaluated using 8 multiparous Holstein cows (569 ± 47 kg of BW, 84 ± 17 DIM) in a duplicated 4 × 4 Latin square design with 21-d periods. The 4 diets contained 0, 9.6, 19.2, and 28.8% CGW and 27.9, 19.2, 9.6, and 0% GC (DM basis), respectively. The cows were fed a TMR, with a 47:53 forage to concentrate ratio, where forage was 27% corn silage, 14% alfalfa hay, and 6% Chinese wild rye. Increasing CGW in the diets resulted in a quadratic response ($P = 0.07$) in feed intake with numerically greater intake at 9.6 and19.2% of diet DM. Apparent digestibility of CP and starch were not affected by dietary treatments; however, apparent digestibility of NDF and ADF decreased significantly ($P < 0.01$) when cows were fed 28.8% CGW diets. Apparent digestibility of DM ($P = 0.02$) and OM ($P = 0.01$) decreased linearly with increasing CGW in the diets. The appropriate amount of CGW can promote microbial N supply, and the optimal value is in 9.6% CGW diets; however, the calculated absorption of purine derivatives ($P = 0.04$) and intestinal flow of microbial N ($P = 0.02$) decreased significantly when cows were fed 28.8% CGW diets. With increasing the level of dietary CGW, plasma BHBA ($P = 0.07$), cholesterol ($P < 0.01$), and triglycerides ($P = 0.06$) decreased linearly, whereas plasma glucose ($P = 0.08$) and insulin ($P = 0.02$) increased linearly at 6h after morning feeding. These data indicate that CGW is a suitable replacement for CG in dairy cow diets when fed up to 19.2% of diet DM; however, the substitution percentage should not be too high, a great amount of CGW in the diets may increase the risk of digestive disturbance, depress microbial N supply, perturbs the patterns of plasma metabolites in lactating dairy cows.

Key Words: dairy cow, nutrient digestibility, wheat

W127 Particle size distribution of corn can predict starch degradability in rumen. Y. Zou*, Z. Yang, S. Li, and Z. Cao, *State Key Laboratory of Animal Nutrition, College of Animal Science and Technology, China Agricultural University, Beijing, China.*

A study using 5 Holstein cows with ruminal cannulas were conducted to evaluate the degradation mechanisms of different particles, and to establish the relationship between ruminal degradation dynamics and particle size distribution. The particle size of corn grain was prepared to pass 5 sieves: 6000, 2360, 600, 450, and 300 μm. All nylon bags containing the tested corn were placed in rumen simultaneously, and 2 bags of each cow were removed at each time point after 2, 4, 8, 12, 24, and 48 h of incubation. In general, in situ disappearance and degradation curves of DM and starch were linearly ($P < 0.05$) increased from grounded (300 μm) to coarsely rolled (6000 μm) corn because of destruction of crystallization of corn. R^2 varied from 0.6790 ($P = 0.086$) to 0.9344 ($P = 0.008$) of DM and from 0.7467 ($P = 0.059$) to 0.9908 ($P < 0.001$) of starch disappearance, and for degradable variables varied from 0.6188 ($P = 0.115$) to 0.9010 ($P = 0.014$) of DM and from 0.6243 ($P = 0.112$) to 0.9290 ($P = 0.008$) of starch, expect for starch degradability at 0 h ($R^2 = 0.3113$, $P = 0.328$). Overall, a simple way for evaluating degradation characteristics of mixed particle corn in feed was established, dynamic degradability and degradation variables can be predicted using the product of corresponding value of each particle calculated in the linear formula and the percentages of corn on each screen of a standard test sieve.

Table 1. Dry matter and starch degradation variables of corn kernel with 5 different particle sizes incubated in situ

W128 Ruminal fermentation kinetics of finishing feedlot beef diets with increasing levels of whole cottonseed. V. N. Gouvea*[1], J. T. Neves Neto[2], D. B. Galvani[3], M. V. C. Ferraz Junior[1], J. A. Faleiro Neto[1], M. V. Bieh[4], J. J. R. Fernandes[2], and A. V. Pires[4], *[1]University of São Paulo, Pirassununga, SP, Brazil, [2]Federal University of Goiás, Goiânia, GO, SP, Brazil, [3]EMBRAPA Goats and Sheep, Sobral, CE, Brazil, [4]University of São Paulo, Piracicaba, SP, Brazil.*

Whole cottonseed (WC) is the primary by-product included in Brazilian finishing feedlot beef diets. Because a high level of WC in the diet can impair animal performance, the objective of this study was to evaluate the in vitro fermentation kinetics of diets containing 0, 8, 16, 24, or 32% of WC (DM basis). Diets were composed of 0.85 concentrate and 0.15 of forage (corn silage), being formulated to meet protein and energy requirements of Nellore bulls (2.2% of N and 80% TDN, respectively). Samples of each diet (0.8 g) were weighed into 160 mL serum bottles, with 8 mL of inoculum and 72 mL of a buffer solution. Rumen inoculum was collected before the morning feeding from 2 Holstein cows fitted with permanent ruminal cannula and fed ad libitum a total mixed ration consisting of 0.30 commercial concentrate and 0.70 corn silage. Four bottles for each diet, plus 4 additional bottles containing buffered medium and rumen fluid inoculum only (blanks) were used. As the bottles were filled they were immediately closed with rubber stoppers, shaken and placed in the incubator at 39°C. The volume of gas produced was recorded at 2, 4, 6, 8, 10, 12, 15, 18, 21, 24, 36, 48, 72, and 96 h of incubation using the pressure reading technique. To estimate kinetic parameters of gas production (GP) data were fitted to the model $G = A[1-\exp^{-c(t-L)}]$, where: G (ml) is the cumulative gas production at time t; A (ml) is asymptotic gas production; c (/h) is the fractional rate of gas production; and L (h) is the lag time. Increasing WC level in the diet linearly increased ($P < 0.001$) the fractional rate of gas production (0.048, 0.052, 0.053, 0.058, and 0.064/h). Discrete lag time also linearly increased (3.69, 3.79, 4.08, 4.42, 4.95 h; $P < 0.05$), while the asymptotic gas production decreased ($P < 0.05$) when the level of WC was greater than 8% in the diet (333.80, 353.65, 333.28,

320.03 and 323.55 mL/g DM), probably due to great contents of ether extract (17.5%) and lignin (13.0%) in the WC. Including WC in feedlot finishing diets for beef cattle at levels greater than 8% can impair ruminal fermentation.

Key Words: by-product, gas production, lag time

W129 Animal performance and fractional volatile fatty acid absorption rate through the rumen wall in lactating cows receiving a corn straw or mixed forage diet. X. X. Weng[2,3], J. Q. Wang*[1,2], D. P. Bu[2], Y. D. Zhang[2], and F. D. Li[3], *[1]Agronomy College of Heilongjiang August First Land Reclamation University, Da qing, Heilongjiang, China, [2]State Key Laboratory of Animal Nutrition, Institute of Animal Science, Chinese Academy of Agricultural Sciences, Beijing, China, [3]College of Animal Science and Technology, Gansu Agricultural University, Lanzhou, China.*

Objective of this experiment was to investigate effects of 2 types of forage diets on animal performance and fractional absorption rate of volatile fatty acids (VFA) through the rumen wall. Ten primiparous, rumen-cannulated Holstein dairy cows in late-lactation were randomly assigned to mixed forage diet (MF, forage: concentrate = 60: 40) with Chinese wildrye, alfalfa hay and corn silage as the forage source or corn straw diet (CS, forage: concentrate = 40: 60) with corn straw as the forage source. Cows were fed their respective diet for 58 d, following which n-valeric acid and Co-EDTA were used as markers for measuring ruminal VFA absorption and passage rates. Rumen fluid was collected from ventral sac of the rumen. Feed intake, body weight and milk production were monitored. Milk fat, protein, lactose and total solids were analyzed by near-infrared analysis. Results showed that dry matter intake was not affected ($P > 0.05$) by treatments, averaging 19.78 kg/d. Cows fed MF diet produced more 4% FCM ($P < 0.05$), milk fat ($P < 0.05$) and total solids ($P < 0.10$). Ruminal ammonia concentration was significantly higher in CS treatment ($P < 0.01$). Mixed forage treatment markedly increased rumen acetate concentration and acetate: propionate ratio ($P < 0.05$). Cows fed CS diet tended to have higher molar proportions of propionate and isobutyrate ($P < 0.10$). Fractional rates of total VFA absorption and passage from the rumen were not affected by dietary treatments, averaging 14.78 and 13.64%/h, respectively. However, cows fed MF diet had higher ($P < 0.05$) estimated clearance rate of acetate, as well as total VFA passage rate (mol/h). These results suggest that cows fed MF diet improve yields of 4% FCM, milk fat and total solids. Lower rumen ammonia concentration indicated a more efficient utilization of feed nitrogen in MF diet compared with CS diet. Dietary treatments did not affect fractional rate of VFA absorption in late lactating cows.

Key Words: animal performance, forage source, VFA absorption rate

W130 The use of Propolis in calf feeding: Effect on fecal score, health score and feed consumption behavior. P. Peravian*, K. Rezayazdi, G. Nehzati, and M. Dehghan-Bonadaki, *University of Tehran, Tehran, Iran.*

Forty female Holstein calves with 41 ± 1 kg birth weight were assigned to a completely randomized design with 4 treatments and 10 replicates (calves) in each treatment from 14 until 65 d of age. Treatments were (1) Control (without monensin in starter and without Propolis in milk), (2) starter without monensin and 500 ppm soluble Propolis powder in milk, (3) starter without monensin and 1000 ppm soluble Propolis powder in milk, and (4) monensin in starter and without Propolis in milk. During the experiment calves were inhabited in individual boxes and had free access to water and starter. The starter was formulated according to NRC 2001.To decrease the stress of weaning, calves stayed in their boxes after weaning for 9 d. Fecal score (fluidity score, 1 = normal, 2 = soft, 3 = runny 4 = watery) and health score (cough score: 1 = normal, 2 = induced single cough, 3 = induced repeated cough, 4 = repeated spontaneous cough, and nasal score: 1 = normal, 2 = unilateral cloudy discharge, 3 = bilateral cloudy discharge, 4 = copious bilateral discharge) were measured daily. dry matter intake behavior (time of feeding, ruminating, resting) was measured at the middle of the experiment. Means of fecal score (1.29, 1.21, 1.26, 1.22) ($P = 0.3$), nasal score (1.18, 1.19, 1.18, 1.17) and cough score (1.18, 1.19, 1.18, 1.17) ($P = 0.6$) for treatments 1–4 respectively, were not different among treatments. The times spent on feeding (147, 154, 154,180 min/d), ruminating (397, 370, 343, 376 min/d), resting (706, 660, 620, 637 min/d) were not influenced by treatments ($P = 0.7$). The results showed that Propolis in milk or monensin in starter did not affect fecal score, health score and feed consumption behavior of Holstein female calves.

Key Words: fecal score, Holstein female calf, Propolis

W131 Effects of three different diets on productive performance and archenteric pH values of dairy cows at late lactation. J. N. Li[1,2], D. P. Bu[1], J. Q. Wang*[1], P. Sun[1], F. D. Li[2], C. F. Qin[1], and P. Zhang[1], *[1]State Key Laboratory of Animal Nutrition, Institute of Animal Science, Chinese Academy of Agricultural Sciences, Beijing, China, [2]College of Animal Science and Technology, Gansu Agricultural University, Lanzhou, Gansu, China.*

This study was to investigate the effects of 3 different types of diets on productive performance and archenteric pH values in late lactation dairy cows. Fifteen primiparous, permanently ruminally and duodenally fistulated Holstein cows at late lactation (DIM = 293 ± 5.34) were randomly assigned to 3 treatments (n = 5) mainly differing in forage: MF diet (alfalfa hay, Chinese wildrye, corn silage, soybean meal), CSA (corn straw, soybean meal), CSB (corn straw, cottonseed meal, corn gluten lipid, high protein corn meal). CP, NDF and NE_L in 3 diets were 18.02, 16.90 and 16.30%; 61.43, 56.73 and 57.06%; 1.48, 1.54 and 1.52 Mcal/kg, respectively. Dry matter intake and milk yield were recorded daily, body condition scoring (BCS) were conducted once weekly. Milk compositions were detected twice weekly, rumen and duodenum samples were collected with 2-h intervals and pH values were determined. Data were analyzed using the MIXED procedure (SAS 9.1). Compared with CSA treatment, cows fed MF diet had positive effect ($P < 0.05$) on composition of milk free fatty acid (FFA) (2.18 and 3.48%; $P < 0.05$), and tended to have negative effect on milk urea percentage (0.042 and 0.037%; $P = 0.09$). Cows in CSB group had higher FFA composition (2.18 and 2.76%; $P < 0.05$), somatic cell count (SCC) (155.43 and 179.16×10^3 mL^{-1}; $P < 0.05$) and lower density (1032.95 and 1031.93 g/L; $P < 0.05$) in milk compared with those in CSA group. There was no difference in other indexes of productive performance ($P > 0.05$). Compared with CSA treatment, the ruminal pH of MF group decreased at 1730 (6.80 and 6.25; $P < 0.01$), 1930 (6.44 and 6.10; $P < 0.01$), and CSB treatment decreased at 1730 (6.80 and 6.58; $P < 0.01$), and 2330 (5.92 and 6.06; $P < 0.05$). The population mean of duodenal pH in all treatments had no significant difference ($P > 0.05$). The results indicated that productive performance affected by forage patterns slightly, milk FFA composition, density and SCC of dairy cows at late lactation were influenced by different dietary protein sources. Ruminal and duodenal pH values were influenced by diet systems partly.

Key Words: archenteric pH, diet system, productive performance

W132 Influence of diets with different protein sources on productive performance and rumen microbial communities in dairy cattle. J. W. Zhao[1,2], D. P. Bu[1], J. Q. Wang*[1], S. G. Zhao[1], and C. F. Qin[1], *[1]State Key Laboratory of Animal Nutrition, Institute of Animal Science, Chinese Academy of Agricultural Sciences, Beijing, China, [2]College of Animal Science and Technology, Inner Mongolia University for the Nationalities, Tongliao, Inner Mongolia, China.*

The objective of this experiment was to study the effects of diets with different protein sources on productive performance and composition of rumen microbial community in dairy cows. Ten Holstein cows (primiparous, DIM 314 ± 16 d, BW 540 ± 50 kg) were assigned to 2 groups randomly and fed with soybean meal diet (soybean meal, 23.6% DM) or miscellaneous meal diet (soybean meal, 3.3% DM; cottonseed meal, 2.6% DM; DDGS, 9.3% DM; Corn gluten lipid, 9.9% DM; and corn high meal, 11.9% DM). The content of crude protein of 2 diets was 18.02% DM and 16.90% DM, respectively. Completely randomized design was conducted and feeding lasted for 60 d. Ruminal fluid samples were collected from 6 dairy cows with rumen canullas on d 30. Total DNA were extracted and analyzed by denaturing gradient gel electrophoresis (DGGE) with subsequent analysis on sequences and clusters. Results showed that diets with different protein sources had no effects on dry matter intake, body weight, milk production, standard milk production, milk fat, milk protein, lactose, fat/protein ratio, milk urea nitrogen and free fatty acid contents ($P > 0.05$). According to the above synthesis evaluation of performance indexes, soybean meal could be replaced by miscellaneous meal effectively. DGGE profiles of rumen microbial community from 2 groups showed that the quantity and optimal density of the DGGE bands which were analyzed with Quantity one were changed significantly. Shannon-Weiner index showed no difference ($P > 0.05$) between 2 groups. Sequences analysis in 2 groups showed that the uncultured bacteria belonged to the phylum of *Bacteroidetes*, *Firmicutes*, *Spirochaetes*, *Proteobacteria* and *Planctomycetes*. These results revealed that bacteria community structure from diets with different protein sources were unique but no difference existed in diversity of rumen bacteria.

Key Words: dairy cow, productive performance, rumen microbial

W133 Screening and analysis of dipeptidyl peptidase IV from microbial metagenomic library in the rumen of dairy cow. J. W. Zhao[1,2], J. Q. Wang*[1], S. G. Zhao[1], P. Sun[1], D. P. Bu[1], X. L. Hu[1], Y. F. Lu[1], D. D. Wang[1], and D. Jin[1], *[1]State Key Laboratory of Animal Nutrition, Institute of Animal Science, Chinese Academy of Agricultural Sciences, Beijing, China, [2]College of Animal Science and Technology, Inner Mongolia University for the Nationalities, Tongliao, Inner Mongolia, China.*

As the key enzyme of oligopeptides degradation, the study for sequence characteristics and enzymatic properties of dipeptidyl peptidases IV (DPP-IV) contribute to control the degrading of oligopeptides. Most of the DPP-IV sequences could not be obtained because limited culturable bacteria in the rumen. The purpose of this study was to reveal the characterization of DPP-IV sequences and enzymatic activity in the rumen of dairy cow by culturable-independent method. The dpp-IV degenerate primers were used to screen rumen microbial fosmid library including 17664 clones. The plasmids were extracted from the positive clones and digested by Hind III. The dpp-IV sequences were obtained by PCR, cloning and sequencing. The Fosmid end sequences and DPP-IV sequences of the positive clones were analyzed by blastx and blastp, respectively. The peptidase activity from the positive clones was measured using Gly-Pro-pNA as a substrate. Ten positive clones named DP1-DP10 containing dpp-IV fragment were obtained. 78% of the Fosmid end sequences could match with the known genes (similarity 44–94%). DPP-IV sequences contained N-conservative region (DWVYEEE) and C-catalytic domain (GWSYGG). DPP-IV sequences matched to *Cyclobacterium marinum* (43%), *Capnocytophaga* sp. (63%), *Prevotella ruminicola* 23 (66%) and *Solitalea canadensis* (50%). The activity of DP7 peptidase is highest (6.88 U/mg). Ten positive clones obtained from rumen microbial fosmid library had different sequence characteristics and peptidase activity. In the future, we will overexpress the DPP-IV in vitro, and characterize the enzyme kinetics.

Key Words: dipeptidyl peptidase IV, enzyme activity, fosmid library

W134 Adhesion molecules of the immune system of dairy cows fed with n-3 and n-6 fatty acid sources in the transition period and early lactation. L. C. Verdurico*, J. R. Gandra, R. D. Mingoti, R. V. Barletta, J. E. Freitas Junior, L. Oliveira, G. D. Calomeni, R. Gardinal, C. S. Takyia, T. H. Vendramini, and F. P. Renno, *Universidade de Sao Paulo, Pirassununga, Sao Paulo, Brazil.*

The aim of this study was to evaluate effect of omega 3 and omega 6 supplementation, on expression of adhesion molecules of Holstein cows during transition period and early lactation. Forty-eight Holstein cows were divided in 4 experimental groups in randomized design. Animals were assigned to receive one of 4 treatments: 1) control (C; n = 12), without fat sources in pre- and postpartum; 2) flaxseed (FS; n = 12), fed 60 and 80 g/kg of DM of flaxseed in pre and postpartum; 3) whole raw soybeans (WS; n = 12), fed 120 and 160 g/kg of DM of whole raw soybeans in pre and postpartum; 4) calcium salts of unsaturated fatty acids (CSFA; n = 12; Megalac-E), fed 24 and 32 g/kg of DM of calcium salts of unsaturated fatty acids in pre and postpartum. Experimental diets were fed from 35 d before the estimate calving until 84 d of lactation, formulated to meet nutritional requirements of each period. Blood samples were taken −21, −14, −7 d in relation to prediction of birth, at birth and +7, +14, +21, +42, +84 d postpartum. Data were analyzed using the PROC MIXED of SAS 9.1 with fixed dietary effect, time effect, interaction between diet and time. Data were analyzed by orthogonal contrasts C vs. WS+CSFA+FS (C1); FS vs. WS+CSFA (C2); and WS vs. CSFA (C3). Was measured expression of adhesion molecules (cluster of differentiation) CD4+, CD8+, CD25+ and CD62L. Cows fed the FS, WS and CSFA treatments had higher expression of adhesion molecules CD4+, CD8+, CD25+ and CD62L than those fed the C diet. However, cows fed WS and CSFA treatments had higher expression of adhesion molecules CD14+ than those cows fed the FS diet peripartum period (30.6 and 25.1 vs. 18.2% of positive cellules respectively). The inclusion of sources of fatty acids omega 3 and 6 in the diet of dairy cows improved the expression of adhesion molecules in the transition period.

Key Words: dairy cow, fat source, immune function

W135 Regulation of pancreatic amylase synthesis by leucine and phenylalanine is associated with the changes in mRNA abundance and/or phosphorylation of 4E-BP1. Z. Yu, K. Liu, Y. Liu, M. Xu, and J. Yao*, *College of Animal Science and Technology, Northwest A&F University, Yangling, Shaanxi, China.*

Insufficient pancreatic amylase secretion may be the critical limiting factor of low starch digestibility in the small intestine of ruminants. The present experiment, therefore, aimed to evaluate the regulating mechanism of duodenal leucine (Leu) and phenylalanine (Phe) to pancreatic enzyme activities. Twenty yearling ewe goats with duodenal catheters were used in a completely randomized design experiment. All goats

were fed the same diet twice daily at 0800 and 1800, and were randomly assigned to 4 treatments: duodenal infusion of water, 3 g/d Leu (3L), 9 g/d Leu (9L), and 2 g/d Phe (2P) for 21 d. On d 21, all goats were slaughtered for blood and pancreatic tissue sample collection. Pancreases were weighed, subsampled, frozen in liquid N_2, and stored at −80°C for the subsequent analysis. Pancreatic DNA concentration was reduced ($P < 0.05$) by 9L treatment. Pancreatic protein:DNA ratios increased markedly ($P < 0.05$) in 9L and 2P treatments. Both Leu and Phe infusions increased ($P < 0.05$) pancreatic amylase activity. Pancreatic trypsin activity (U/mg of protein) decreased ($P < 0.05$) when 2P was infused, while when expressed by per milligram DNA, pancreatic trypsin activity increased ($P < 0.05$) in 9L group. Pancreatic lipase activity (U/mg of DNA) was improved by 9L and 2P treatment. Amylase mRNA levels were higher ($P < 0.05$) in 9L and 2P groups. The Leu and Phe infusions had no effects ($P > 0.05$) on trypsin mRNA levels. Lipase mRNA levels were increased ($P < 0.05$) by 2P treatment. Leu infusions significantly stimulated ($P < 0.05$) phosphorylation of 4E-BP1, while no effects ($P > 0.05$) were observed when goats were infused Phe. Leu infusions also increased ($P < 0.05$) pancreatic free Leu concentration. Phe infusion trended to increase plasma CCK concentration ($0.05 < P < 0.10$). Leu and Phe infusions did not influence plasma insulin concentration ($P > 0.05$). These results indicate that cell size, not cell number, is critical for digestive enzyme production. Duodenal Leu and Phe infusions regulate pancreatic amylase expression mainly through transcriptional and/or translational events.

Key Words: amino acid, pancreatic amylase, regulation

W136 Microbial protein synthesis in sheep supplemented with extracts of *Salix babylonica* and exogenous enzymes. K. I. Valdes[1], A. Z. M. Salem*[1], M. Gonzalez-Ronquillo[1], R. Rojo[2], H. Gado[3], N. Rivero[1], and N. Odongo[4], *[1]Facultad de Medicina Veterinaria, Universidad Autonoma del Estado de Mexico, Mexico, [2]CU-UAEM Temascaltepec, Mexico, [3]Department of Animal Production, Faculty of Agriculture, Ain Shams University, Qalubia, Egypt, [4]Animal Production and Health Section, Joint FAO/IAEA Division of Nuclear Techniques in Food and Agriculture, International Atomic Energy Agency, Vienna, Austria.*

The aim of this study was to estimate microbial protein synthesis and urinary excretion of purine in lambs. In a completely randomized design, 16 male growing Suffolk lambs (27.5 ± 2.5 kg LW) were used, which were assigned to 4 treatments in individual pens. Treatments were: control (lambs were fed on 30% concentrate and 70% corn silage at 0700h and 1600h; SB: control diet supplemented with *Salix babylonica* extract (30 mL); EZ: control diet supplemented with 10 g exogenous enzymes of Zado and SBEZ: control diet supplemented with *Salix babylonica* extract and exogenous enzymes of Zado. Enzyme product of Zado is commercially available multi-enzyme feed additive in a powder form produced from *Ruminococcus flavefaciens* and manufactured by the Academy of Scientific Research and Technology in Cairo, Egypt. Average daily gain was increased ($P = 0.001$) with EZ, while dry matter intake was increased with SBEZ. Allantoin and xanthine concentrations were increased ($P < 0.001$) with SBEZ supplementation compared with the other treatments. Uric acid and total purine derivatives were increased ($P < 0.001$) with EZ addition in diets. The combination of the 2 additives increased ($P = 0.025$) allantoin-to-creatinine ratio compared with control diet. As a conclusion the addition of 10 g of exogenous enzymes of Zado or in combination with *Salix babylonica* extract in lamb's diet, increased the microbial protein synthesis.

Key Words: lamb, purine derivative, *Salix babylonica*

W137 Changes in the relative population size of target ruminal bacteria following a grain-induced challenge in beef cattle receiving viable and nonviable active dried yeast. R. Mohammed[1], D. Vyas*[1], A. Uwizeye[1], W. Z. Yang[1], K. A. Beauchemin[1], and N. Walker[2], *[1]Agriculture and Agri-Food Canada, Lethbridge, Alberta, Canada, [2]AB Vista, Marlborough, Wiltshire, UK.*

This study was conducted to characterize changes in the relative population size (RPS) of selected ruminal bacteria in cattle fed active dried yeast (*Saccharomyces cerevisiae*) following an induced ruminal acidosis. Six ruminally cannulated beef heifers fed a 50:50 forage:concentrate diet (DM basis) were used in a double 3 × 3 Latin square design. Treatments were control (Ctrl; no yeast), active dried yeast (ADY; 4 g providing 10^{10} cfu/g; AB Vista, UK), and killed dried yeast (KDY; 4 g autoclaved ADY). A day before acid challenge (d21), intakes were restricted to 50% of ad libitum intake. Acidosis was induced on d22 by adding barley grain (amount equivalent to 25% of DMI) directly into the rumen before feeding. Ruminal digesta was collected on d22 of each period at time 0 (before feeding), 3, 6, 9, 12, 24 h, and 168 h. Real-time PCR data from the liquid and solid ingesta were summed by cow at each time and reported as % (16S copies for time t relative to time 0). The RPS of *S. ruminantium* was greater ($P = 0.03$), and that of *R. flavefaciens* tended to be greater ($P = 0.06$), for heifers fed ADY and KDY compared with Ctrl. Treatment × time interactions were not significant. There was a time effect on the RPS of *S. ruminantium* reaching peak values 12 h post-challenge. The RPS of *F. succinogenes* decreased until 9 h post-challenge and recovered to the 0 h value by 168 h. The RPS of *S. ruminantium* ($r^2 = 0.62$; $P < 0.01$), *M. elsdenii* ($r^2 = 0.57$; $P < 0.01$) and S. bovis ($r^2 = 0.31$; $P = 0.03$) were positively related to lactate concentration, while RPS of *F. succinogenes* ($r^2 = 0.30$; $P = 0.03$) was negatively related to lactate. The RPS of *S. ruminantium* ($r^2 = 0.62$; $P < 0.01$) and *M. esldenii* ($r^2 = 0.38$; $P = 0.01$) were negatively related to ruminal pH while RPS of F. succinogenes ($r^2 = 0.43$; $P = 0.01$) and *R. flavefaciens* ($r^2 = 0.38$; $P = 0.01$) were positively related to pH. Feeding active dried yeast, regardless of its viability, during a period of acidosis can help increase the RPS of *S. ruminantium* that utilize lactic acid and *R. flavefaciens* that digest fiber.

Key Words: acid-challenge, active dry yeast, ruminal bacteria

W138 Effect of ensiling high moisture corn with aspen wood byproducts on in situ dry matter disappearance of the final ensiled product. E. Caldera*, J. J. Wagner, and T. E. Engle, *Colorado State University, Fort Collins.*

The objective of this study was to investigate the effect of ensiling high moisture corn (HMC) with aspen wood byproducts (bark, shavings, and saw dust) on in situ dry matter disappearance (DMD) of the final ensiled product. Treatments consisted of (1) 100% HMC; (2) 90% HMC, 10% bark; (3) 90% HMC, 10% shavings; (4) 90% HMC, 10% saw dust; (5) 100% bark; (6) 100% shavings; and (7) 100% saw dust; with 5 replications per treatment. All ratios were calculated for similar DM. Treatments were individually packed by placing each experimental silo (0.368 m × 0.302 m × 0.267 m) into a modified press. A torque wrench was used to apply the same packing pressure (2.76 kg·m) and densities across treatments. Prior to packing each silo, 50 kg of HMC was prepared by mixing water and dry rolled corn at a desired ratio (29.4% water to 70.40% dry rolled corn) then mixed with each aspen wood byproduct specific for each treatment. After 30 d of storage in a well-ventilated room at 25°C, silos were opened, weighed, and subsampled for DM determination. Following DM analysis, samples were ground through a 2 mm screen and composited. Two sets of in situ bags for each treatment (including blank bags) were prepared for 6 different time periods (0, 6, 12, 24, 48,

and 72 h; in triplicate) and placed in 2 fistulated steers maintained on a roughage based diet for 3 weeks before in situ incubation. Steers were then switched to a high concentrate diet for 3 weeks and the in situ incubation was repeated. Area under the curve (AUC) was calculated for each replicate within each treatment over the 72-h incubation time period. Using the DMD results from the 100% HMC, bark, shavings, and saw dust treatments, a predicted digestion curve was generated for treatments 2, 3, and 4. Predicted and actual AUC were compared for treatments 2, 3, and 4. In situ DMD AUC for predicted and actual digestion curves in roughage and concentrate fed steers were similar across treatments 2, 3, and 4. These data indicate that under conditions of this experiment, ensiling HMC with aspen wood byproducts had no effect on in situ DMD of the final mixture.

Key Words: ensiling, in situ, wood

W139 Neutrophil (PMN) expression of extracellular trap formation and immunometabolic genes in response to prepartal energy intake and postpartal intramammary lipopolysaccharide challenge in postpartal dairy cows. K. M. Moyes*[1], D. E. Graugnard[2], J. K. Drackley[2], M. J. Khan[2], M. Bionaz[2], and J. J. Loor[2], *[1]University of Maryland, College Park, [2]University of Illinois, Urbana.*

Our objectives were to determine the effect of intramammary (IM) LPS challenge during the postpartal period on the expression of key genes associated with extracellular trap formation and immunometabolic response in blood neutrophils (PMN) for cows fed control (CON; 1.34 Mcal/kg dry matter; n = 8) or excess energy (OVE; 1.62 kg/dry matter; n = 5) during the dry period (~45 d before expected calving date). All cows were fed a common lactation ration after parturition. At 7 d in milk, all cows received LPS (200 mg) into one rear mammary quarter. Blood PMN were isolated before (0 h) and after (12 h) after IM LPS challenge for gene expression analysis using real-time quantitative PCR (qPCR). The effect of time, diet and their interaction was analyzed using the MIXED procedure of SAS with repeated measures. Regardless of prepartal diet, intramammary (IM) LPS challenge increased the expression of genes associated with the immune response (i.e., SELL, STAT3 and SOD2). Diet altered gene expression where cows fed CON during the prepartal period had decreased expression of genes associated with inflammation (ALOX5; −8.8-fold change) and metabolism (PLA2GA4; −2.3-fold change) when compared with OVE cows. At 0 h, we observed a −2.5-fold change in expression of S100A9, a gene associated with extracellular trap formation, for CON when compared with OVE cows. At 12 h, NFKB1 expression, a key gene associated with the inflammatory response, decreased (−1.5-fold change) for CON when compared with OVE cows. Results suggest a downregulation of genes associated with extracellular trap formation and the immunometabolic response after postpartal IM LPS challenge in blood PMN from cows fed a controlled energy diet during the prepartum period.

Key Words: immune, metabolism, neutrophil

W140 The effect of feeding competition on pre- and postweaning performance of dairy calves. E. K. Miller-Cushon*[1], R. Bergeron[2], K. E. Leslie[3], G. J. Mason[4], and T. J. DeVries[1], *[1]Department of Animal and Poultry Science, University of Guelph, Kemptville Campus, Kemptville, ON, Canada, [2]Department of Animal and Poultry Science, University of Guelph, Campus d'Alfred, Alfred, ON, Canada, [3]Department of Population Medicine, University of Guelph, Guelph, ON, Canada, [4]Department of Animal and Poultry Science, University of Guelph, Guelph, ON, Canada.*

This study examined how reduced access to teats and feed buckets during the milk-feeding stage affects preweaning performance and postweaning response to competition for feed. Twenty Holstein bull calves were housed in pairs and provided milk replacer (MR) and starter ad libitum via either (1) 2 teats and 2 feed buckets/pen (non-competitive feeding; NCF), or (2) 1 teat and 1 feed bucket (competitive feeding; CF). Weaning occurred in wk 7 through incremental dilution of MR from 150 g/L to 0 g/L. Postweaning, calves were provided a complete pelleted diet and followed for 6 wk. In wk 8, 9, 12, and 13, all pens were fed noncompetitively via 2 feed buckets/pen. In wk 10 and 11, pens were fed competitively with 1 bucket/pen. Intake was recorded daily and calves were weighed 2×/wk. Data were analyzed in a repeated measures general linear mixed model. MR intake was subject to a treatment by week interaction ($P < 0.001$); NCF pens had initially greater intake (wk 2, 9.6 vs. 8.3 L/calf/d; SE = 0.6) and CF pens increased intake in later weeks (wk 5, 13.4 vs. 11.7 L/calf/d; SE = 0.3). Correspondingly, ADG evolved differently over time ($P = 0.003$), but BW was similar at weaning (103.6 kg; SE = 3.9; $P = 0.9$). Solid feed intake was greater for NCF pens before weaning (0.15 vs. 0.12 kg/d; SE = 0.01; $P = 0.009$) and similar during weaning (1.1 kg/d; SE = 0.04; $P = 0.9$). Postweaning, previously CF pens had greater intake than NCF when fed non-competitively ($P = 0.02$; in wk 8 and 9, 2.9 vs. 2.6 kg/d/calf, SE = 0.09, and wk 12 and 13, 4.9 vs. 4.5 kg/d/calf, SE = 0.1). During the competitive feeding period (wk 10 and 11), intake was subject to a treatment by day interaction ($P = 0.04$); previously NCF pens had initially lower intake but rapidly increased intake. Calves in previously CF pens tended to have greater ADG in noncompetitive weeks (1.4 vs. 1.2 kg/d; SE = 0.1; $P = 0.08$) and similar ADG in the competitive weeks (1.2 kg/d; SE = 0.1; $P = 0.5$). Final BW was similar between treatments (147.2 kg; SE = 4.5; $P = 0.8$). These results suggest that calves are able to adapt to moderate competition for feed in the milk-feeding stage and that prior exposure to competition influences response to feeding competition.

Key Words: dairy calf, competition, feeding

W141 Measurement of feeding motivation in limit-fed dairy heifers. A. M. Greter[1], T. F. Duffield[2], B. W. McBride[3], T. M. Widowski[3], and T. J. DeVries*[1], *[1]Dept. of Animal and Poultry Science, University of Guelph, Kemptville Campus, Kemptville, ON, Canada, [2]Dept. of Population Medicine, University of Guelph, Guelph, ON, Canada, [3]Dept. of Animal and Poultry Science, University of Guelph, Guelph, ON, Canada.*

The objective of this experiment was to determine whether, and how hard, limit-fed heifers were motivated to work, both immediately post-feeding and following a short-term period of feed deprivation, for parcels of a low-nutritive feedstuff (i.e., oat straw) to ameliorate health concerns and meet foraging needs. Ten Holstein heifers (291.6 ± 39.2 d of age, weighing 324.2 ± 61.2 kg) were exposed to each of 2 dietary treatments, in a random order, over 2 successive 26-d treatment periods (14-d adaptation and a 12-d data collection) using a crossover design. The treatments were (1) a high-forage control TMR (60% DM; C) and (2) a limit-fed, low-forage TMR (50% DM; LF) at 2.05% BW. During the data collection period, heifers were fed at 1100 h and then tested for feeding motivation using a push-door apparatus 3 h later (1400 h) and 21 h later (0800 h). Intakes and feeding behavior were recorded during the last 7 d of each period. Rumination was recorded during 3 d of each period. The amount of weight pushed as a % of BW and latency to access the push-door were recorded 3 times for each heifer at each time point on each treatment. Data were analyzed in a general linear mixed model. DMI was greater on the C treatment (12.9 vs. 7.2 kg/d; SE = 0.6; $P < 0.001$). Heifers on the C treatment spent more time feeding (209.3 vs. 82.4 min/d; SE = 6.2; $P < 0.001$) and ruminating (452.2 vs. 318.3 min/d; SE = 15.8; $P < 0.001$), as well as consumed their feed slower across the day (0.06 vs. 0.09 kg/min; SE = 0.004; $P = 0.001$) than heifers on the LF treatment. On the LF treatment heifers tended to pushed more weight at 3 h (4.5 vs. 1.9% of BW; SE = 1.0; $P = 0.09$) and did push more weight at 21 h (9.3 vs. 2.8% of BW; SE = 1.0; $P < 0.001$) after feed delivery. Latency to access the door was similar between treatments at 3 h (96.7 ± 45.0 s) and 21 h (113.8 ± 45.0 s) after feed delivery. In summary, heifers will work harder, spend less time feeding and ruminating, and consume feed faster when provided a low-forage, limit-fed ration compared with a high-forage, ad-libitum-fed ration, providing evidence that limit-fed animals are experiencing feelings of hunger and may not be physically or behaviorally satisfied.

Key Words: feeding behavior, limit feeding, motivation

W142 Do limit-fed heifers prefer supplementary long or short straw? A. M. Greter[1], T. F. Duffield[2], B. W. McBride[3], T. M. Widowski[3], and T. J. DeVries*[1], *[1]Dept. of Animal and Poultry Science, University of Guelph, Kemptville Campus, Kemptville, ON, Canada, [2]Dept. of Population Medicine, University of Guelph, Guelph, ON, Canada, [3]Dept. of Animal and Poultry Science, University of Guelph, Guelph, ON, Canada.*

The objective of this study was to determine whether limit-fed heifers will choose to consume long, rather than short, particles of a low-nutritive feedstuff to ameliorate rumen function and meet foraging needs. Ten Holstein heifers (261.6 ± 39.2 d of age, weighing 303.3 ± 56.2 kg) were exposed to each of 2 dietary treatments, in a random order, over 2 successive 7-d treatment periods (4-d adaptation period and a 3-d data collection period) using a crossover design. The treatments were (1) provision of long particle oat straw (85% of particles >8 mm; LS) and (2) provision of short particle oat straw (45% of particles >8 mm; SS). Both treatments were offered following consumption of a limit-fed, nutrient-dense TMR fed at 2.05% of BW. Following these 7-d periods of exposure to each type of straw (long and short), heifers were given access to both types during an additional 2-d preference period. Individual intakes, feeding and lying behavior were recorded during the last 3 d of each treatment period. Intake and behavior data were analyzed in a general linear mixed model. Preference ratio (LS consumed/total straw intake) was tested for a difference from 0.5 using a *t*-test. Dry matter intake of both the TMR (6.3 ± 0.4 kg/d) and straw (0.36 ± 0.06 kg/d) was similar between treatments. Heifers fed LS spent more time feeding (197.7 vs. 175.2 min/d; SE = 5.7; $P = 0.01$) than heifers fed SS due to the increase in time required to consume long particles in the LS (59.8 vs. 34.2 min/d; SE = 5.0; $P = 0.007$). Daily lying time (974.7 ± 11.4 min/d) and time spent standing without eating (278.9 ± 10.4 min/d) was similar between treatments. The preference period showed a strong preference ratio for LS rather than SS (preference ratio = 0.83; SE = 0.06; $P < 0.001$), with heifers consuming 0.43 ± 0.2 kg/d of LS and 0.07 ± 0.1 kg/d of SS. In conclusion, heifers will consume similar amounts of supplementary long or short straw if provided to them alongside of a limit-fed

TMR. Limit-fed heifers do, however, show a clear preference for LS when offered the choice, suggesting that they find LS to be more satisfactory for achieving rumen fill and/or meeting their behavioral foraging needs.

Key Words: feeding behavior, limit feeding, preference

W143 The effect of calving environment on the behavior, metabolism, and milk yield of Holstein heifers. S. Y. Morrison*, P. Ji, H. M. Gauthier, S. E. Williams, and H. M. Dann, *William H. Miner Agricultural Research Institute, Chazy, NY.*

This study determined the effect of the calving environment on periparturient behavior and its potential effect on behavior, blood metabolites, and milk yield of Holstein heifers during the first 21 DIM. Heifers (n = 54) were housed in a bedded pack enhanced with a 4.6x4.0 m calving blind during a 21-d close-up period and then were either moved when calving was imminent to an individual pen (IND; n = 24) or left in the pack (GRP; n = 30). After calving heifers were housed in a freestall pen, fed a TMR, and milked 3×/d. Calving, standing, and rumination behaviors were monitored using visual observations, video review, and data loggers. Calving difficulty (1: easy to 5: difficult) was recorded. Serum was analyzed for nonesterified fatty acids (NEFA) and β-hydroxybutyrate (BHBA) on 0, 7, 14, and 21 DIM. Data were analyzed as a completely randomized design using the MIXED procedure of SAS with repeated measures as appropriate. Twelve GRP heifers calved in the blind and 6 IND heifers were in the blind at the time they were moved to the individual pen. IND heifers were in the individual pen for 89 ± 10 min before calving. Labor was 98 and 124 min for GRP and IND heifers (SEM = 12 min; $P = 0.11$), respectively. Calf birth weight (38.0 ± 1.1 kg) and calving difficulty score (1.7 ± 0.2) were not affected by treatment ($P > 0.10$). During the 2 h before calving, treatment did not affect standing (49 ± 5 min; 3.2 ± 1.2 bouts; 21 ± 5 min/bout) or rumination (10 ± 2 min). During the 12 h after calving, treatment did not affect standing (504 ± 14 min; 11.5 ± 0.8 bouts; $P > 0.10$), but GRP heifers tended to spend more time ruminating (78 and 60 min; SEM = 7; $P = 0.07$). During the first 21 DIM, treatment did not affect ($P > 0.10$) NEFA (0.35 ± 0.02 mEq/L), BHBA (5.9 ± 1.0 mg/dL), standing (849 ± 16 min/d; 57 ± 1 min/bout), or milk (30.7 ± 1.3 kg/d). Daily rumination was greater for GRP than IND (367 and 324 min; SEM = 15; $P = 0.03$). The calving blind was used by 40% of GRP heifers at calving and may indicate a desire for seclusion at calving. Management decisions around parturition should be considered to minimize disruptions that may delay normal calving progress and resumption of rumination after calving.

Key Words: calving, behavior, cow

W144 Rumination and feeding behavior before and after calving. K. Schirmann*, N. Chapinal, L. A. Vickers, D. M. Weary, and M. A. G. von Keyserlingk, *Animal Welfare Program, Faculty of Land and Food Systems, The University of British Columbia, Vancouver, BC, Canada.*

The objectives of the current study were to describe the changes in rumination and feeding behavior around calving. Rumination time, feeding time and dry matter intake were monitored in 11 Holstein cows from 96 h before to 48 h after calving. Data were initially summarized in 2-h periods; these data were first averaged across cows and plotted to describe the pattern relative to time of calving. Ruminating and feeding started to decline approximately 4 and 8 h (respectively) before calving and increased in the 4 and 6 h (respectively) after calving. Data were then averaged within cow to form daily values relative to calving time; the period from 96 to 24 h before calving was averaged to calculate one baseline value per cow. These data were analyzed using the mixed models in SAS with day as a repeated measure and Dunnett's 2-tailed test was used as a post-hoc test to evaluate differences between baseline and subsequent days. Compared with baseline (baseline rumination time: 426.1 ± 26.5 min/d; baseline feeding time: 205.1 ± 13.2 min/d), cows spent 63 ± 30 min less time ruminating and 66 ± 16 min less time feeding during the day before calving. These behaviors remained lower than baseline the day after calving when, compared with baseline, cows spent 133 ± 35 min less time ruminating and 82 ± 18 min less time feeding. Cows also tended to decrease dry matter intake by 3.8 ± 1.9 kg DM the day before calving as compared with baseline (baseline: 15.7 ± 1.5 kg DM/d); dry matter intake returned to baseline values by the day after calving. In conclusion, time spent ruminating and time spent feeding show promise as tools to identify cows as they approach calving.

Key Words: welfare, parturition, dry matter intake

W146 Social constraints and motivation of dairy cows to work for access to pasture. A. C. Andressa[1,2], J. A. Fregonesi *[2], D. M. Weary[1], and M. A. G. von Keyserlingk[1], [1]*Univerisity of British Columbia, Vancouver, British Columbia, Canada,* [2]*Universidade Estadual de Londrina, Londrina, Paraná, Brazil.*

In social species such as cattle, motivation to access resources may depend upon the location and behavior of social partners. This study tested how the motivation of lactating dairy cows to access to pasture, varied with the presence of familiar and unfamiliar social partners. We used a total of 24 lactating dairy cows. Twelve Holstein cows were trained to push a weighted gate to access fresh TMR, and the other 12 cows formed the unfamiliar group. The weight started at 14 kg and was increased by 7 kg/d until cows were no longer willing to perform the task. Cows were then individually allowed to push the gate to access pasture for 3 d under each of 3 conditions: (1) familiar social group on pasture, with weight set at the maximum pushed for TMR + 7 kg; (2) unfamiliar group on pasture with weight set as in treatment (1); and (3) familiar social group on pasture, with weight set at the maximum pushed for TMR + 14 kg. The number of cows pushing the gate to have access to pasture was compared using Fisher's Exact test. Cows pushed on average a maximum of 36.6 ± 9.1 kg during the TMR test and 50.4 ± 8.8 kg in treatment (3). The number of cows accessing pasture was higher in treatment 1 versus 2 (6.5 ± 0.7 versus 1.0 ± 0.0; $P = 0.01$), but similar for Treatment 3 (4.5 ± 2.1; $P = 0.12$). The results indicate that motivation to access pasture is stronger when paired with access to familiar social companions.

Key Words: social behavior, operant test, welfare

W148 Combined wavelet and linear regression techniques to model cattle behavioral responses to changes in forage allowance. M. S. Gadberry*[1], W. Whitworth[2], and G. Montgomery[2], [1]*University of Arkansas, Cooperative Extension Service, Little Rock,* [2]*University of Arkansas, Southeast Research and Extension Center, Monticello.*

As forage availability diminishes, cattle compensate, in part, by increased grazing time. As a result, the visual cue of activity throughout the day may help delineate conditions whereby available forage negatively affects productivity. This study attempted to model dawn to dusk changes in grazing, lying, and indeterminate activity for varying amounts of available forage during summer months. Activity was visually assessed for 16 h at 1 h intervals for 3 (2010 and 2011) or 2 herds (2012) of predominately Beefmaster cows (nonlactating). To create variability in available forage without negatively influencing herd productivity, 3 (yr 1 and 2) or 2 (yr 3) pastures of different sizes were assigned to the study. Herd size was fixed at 20 cows within herd in yr 1 and 2 and 30 in yr 3. Each herd was assigned to a pasture, grazed for a 2-wk adaptation and observed during wk 3. At the conclusion of the observation wk, herds were re-assigned

pastures so all herds were grazed and observed on all pastures. Forage allowance (FA) ranged from 12.8 to 56.5 kg DM/100 kg BW. Proportional behavior responses to change in FA were transformed to Haar wavelet coefficients. ANOVA at the 2, 4, and 8 h scales indicated similar coefficient variability ($P > 0.10$) among FA allocations. Correlation between FA and individual wavelet coefficients was determined. Linear models to predict coefficients were constructed for the significant correlations that occurred for lying at level 1, position 1 and standing at level 0. The lying coefficient was predicted as 0.011944 × FA – 0.641426 ($r^2 = 0.47$); and the grazing coefficient was predicted as 0.009547 × FA – 0.847766 ($r^2 = 0.52$). Based on the predicted coefficients, from 600 to 900 h, lying activity increased as FA increased; however, from 1000 to 1300 h, lying activity decreased as FA increased then converged for 1400 to 2100 h. Prior to 1300 h, more cattle were predicted grazing as FA increased. Following 1300 h, the proportion of cattle grazing increased as FA decreased. These results indicate FA changes affect morning lying and afternoon grazing activity.

Key Words: grazing behavior, model, wavelet analysis

W149 Determinants of body temperature and feed intake in beef cattle during summer heat. A. K. Curtis*, B. Scharf, P. A. Eichen, M. S. Kerley, J. R. Russell, and D. E. Spiers, *Division of Animal Sciences, University of Missouri, Columbia.*

Heat stress in cattle has long been known to affects well-being and decrease performance. The challenge comes in determining reliable predictors of heat stress in the form of measurable, independent variables that indicate current and near-future changes in performance. A 42-d study, including 25 crossbred Angus (*Bos taurus*) steers with a body weight of 347 ± 29 SD kg, was conducted during summer 2011 to identify animal and environmental determinants of core body temperature (Tcore) and feed intake (FI). Animals were stratified by weight and housed among 5 different pens. Ambient temperature (Ta) during this period ranged from 17.3 to 40.7°C with a mean of 27.2°C. Steers were provided a feedlot diet and water ad libitum and Tcore was measured hourly using intrarumenal telemetric boluses (SmartStock, Pawnee, OK). Electronic ID tags (Allflex US Inc., Dallas-Fort Worth, TX) connected to a GrowSafe FI system (GrowSafe Systems Ltd., Airdrie, AB, Canada) provided FI. Data loggers (Hobo H8 Pro; Onset Computer, Bourne MA; accuracy: ±0.2°C and ±3% relative humidity) recorded ambient conditions in sun and shade, along with black globe temperature (BG). Temperature-Humidity Index (THI) was calculated for all combinations. Analysis of FI used the daily sum of animal values to determine population FI, whereas Tcore used hourly daylight (0700–1900) values. Both stepwise and multivariant linear and polynomial regression analyses (JMP statistical software; SAS Institute; Cary, NC) were used for 0 to 4-d delay evaluations. Best FI predictor, based on highest R^2 was mean THI using BG in the sun, with a 3-d delay ($R^2 = 0.24$, $P < 0.005$). Analysis of Tcore used group averages for each hour. Both regression analyses identified Ta alone with no delay as the best indicator of Tcore ($R^2 = 0.62$, $P < 0.005$). These results indicate that although air temperature alone may be the best predictor of core temperature in the heat, radiant heat load may be a better determinant of feed intake over time.

Key Words: heat stress, beef cattle, telemetry

W150 Influence of pen-shade on feedlot performance of Bos indicus growing heifers under hot weather conditions. J. A. Vazquez[1], B. J. Cervantes[2], A. Camacho[3], M. A. Espino[3], T. J. Heras[3], L. R. Flores[3], J. J. Lomeli[3], and R. Barajas*[3], *[1]CUALTOS, Universidad de Guadalajara, Tepatitlan, Jalisco, Mexico, [2]Ganadera Los Migueles, S.A. de C.V., Culiacan, Sinaloa, Mexico, [3]Facultad de Medicina Veterinaria y Zootecnia, Universidad Autonoma de Sinaloa, Culiacan, Sinaloa, Mexico.*

Pen-shade has shown to be beneficial to feedlot performance of cattle under hot weather conditions. Most experiments have been conducted using *Bos taurus* cattle. However, differences in heat tolerance and greater use of *Bos indicus* in hotter areas of the world suggest that we should focus on evaluating the utility of pen-shade use in these cattle as well. In this study 60 *Bos indicus* heifers (initial BW = 195.8 ± SD 2.936 kg) were used to evaluate the influence of pen-shade on feedlot performance of *Bos indicus* growing heifers under hot weather conditions. Heifer were weighed individually and blocked by Initial BW. Groups of 5 heifers were placed in each pen, and the pen constituted the experimental unit. In a complete randomized block design experiment, within a block, pens were randomly assigned to receive one of 2 types of allotment: (1) dirt-floor pens (6 × 12 m) without shade (Control); and (2) Control plus shade (Pen-shade). Shade was provided by a ceiling of 6 × 4 m of metal sheeting positioned 3.7 m over soil level. Cattle were weighed on d 1 and 84 when they finished the experiment. Feed intake was recorded daily. Samples of food (1 kg) were taken weekly for DM determination (110°C/24 h). Results were analyzed by ANOVA for a randomized complete block design. The daily variation ($P < 0.01$) of temperature and relative humidity is described for its mean ± SE observed values of 28.35 ± 1.32°C (maximum 40.5°C, minimum 21.1°C) and 76.0 ± 5.98%, respectively. Cumulative rain was 504 mm; air velocity 7.65 ± SE 2.59 km/h, and sun radiation of 872 ± SE115 W/m^2. Compared with heifers housed in the control pens, heifers housed in the pen-shade group had higher final weight (284.4 vs. 275.0 ± SE 2.113 kg; $P = 0.02$), superior average daily gain (1.05 vs. 0.94 ± SE 0.026 kg/d; $P = 0.02$), and a better feed efficiency (0.17 vs. 0.15 ± SE 0.003 kg of gain/kg of DMI; $P < 0.01$). Dry matter intake was not affected by treatments (6.25 vs. 6.23 ± SE 0.070 kg/d; $P = 0.84$). It is concluded, that provision of pen-shade contributes to improve the feedlot performance of *Bos indicus* growing heifers under hot weather conditions.

Key Words: *Bos indicus*, feedlot performance, hot weather

W151 Behavior of horses kept in large groups in a feedlot environment. J. H. Higginson Cutler*[1], M. Robertshaw[1], E. A. Pajor[2], L. J. Keeling[3], L. Burwash[4], C. Dewey[1], and D. B. Haley[1], *[1]University of Guelph, Guelph, ON, Canada, [2]University of Calgary, Calgary, AB, Canada, [3]Swedish University of Agricultural Sciences, Uppsala, Sweden, [4]Alberta Agriculture, Food and Rural Development, Airdrie, AB, Canada.*

Horses kept for meat production, a legal practice in Canada, are commonly kept in large social groups; however no data about the behavior or welfare of horses in these conditions is available in the literature. The objective of this study was to describe the general activity of horses kept in large groups under dirt dry-lot conditions in western Canada. Observations were made on 18 d spread evenly over a period of time from June 1 to August 19, 2010. Scan samples were completed every 10 min to count the number of horses performing various behaviors during the following blocks of time: 0700–0900, 1000–1200, 1300–1500, and 1600–1800h. Environmental conditions at the time of observations were also recorded. Two pens of horses grouped by age were observed. The number of animals in the pens ranged from 124 to 182 in one pen and 100–200 in the second pen. The proportion of animals performing each behavior divided by the number of animals in the pen was determined for each behavior. A mean (±SE) of 25.2 (±0.3)% of horses were eating, 1.1 (±0.02)% drinking, 11.9 (±0.4)% lying, 6.1 (±0.1)% moving, 46.4 (±0.6)% standing, 1.3 (±0.06)% playing, and 4.5 (±0.1)% grooming throughout the scan samples. Preliminary statistics examining the relationship between pen, weather (rain vs. no rain), time period, and date were analyzed using mixed models. The number of horses performing behaviors was affected by date of observation ($P < 0.05$). Rain altered the number of horses performing all behaviors ($P < 0.05$) except playing ($P = 0.35$), with lying, eating, drinking and

grooming decreasing during rain while standing increased. The number of horses performing certain behaviors was also altered by time of day, with grooming increasing throughout the day, play increasing until the final daily observation period, and lying decreasing throughout the day ($P < 0.05$). Knowledge gained regarding the behavior of horses housed in large social groups will allow for improved management practices to ensure appropriate resources are provided for these animals.

Key Words: equine, group size, behavior

W152 Barrow approachability to a novel object when selected for feed efficiency. J. Colpoys*[1], N. Gabler[1], A. Keating[1], S. Millman[2], J. Siegford[3], and A. Johnson[1], *[1]Animal Science, Iowa State University, Ames, [2]Veterinary Diagnostics and Production Animal Medicine, Iowa State University, Ames, [3]Animal Science, Michigan State University, East Lansing.*

The objective of this study was to determine if divergent selection for residual feed intake (RFI) influenced barrows' approach to a novel object, an orange traffic cone. Twenty low-RFI (high FE) and 20 high-RFI (low FE) barrows (BW 49 ± 9.2 kg) from 8th generation Yorkshire RFI selection lines were randomly selected and evaluated once over a 4-wk period using a novel object test (NOT). The NOT arena measured 4.9 m long × 2.4 m wide, with black corrugated plastic walls 1.2 m high. The arena floor was divided into 4 zones; zone 1 being the traffic cone while zone 4 was furthest from the traffic cone and was the point where the pig entered the arena. Between 1300 and 1700 h pigs were moved individually from their home pen and into a weigh scale for 1 min. Pigs then entered the NOT arena and were video recorded for 10 min. Video was then continuously scored by one observer for latency, duration, and total number of freezing postures (defined as whole body still for ≥ 3 s). Latency, duration, and total number of zone visits were also collected. Data were analyzed with PROC Glimmix and the experimental unit was the barrow. Latency to show the first freeze posture and total length of time freezing did not differ between selection lines ($P > 0.28$). However, low-RFI froze fewer times compared with high-RFI barrows ($P = 0.003$). Latency to enter zones: low-RFI barrows took longer entering zone 2 ($P = 0.02$), but did not differ entering zone 1 or 3 when compared with high-RFI barrows ($P > 0.17$). Duration of time within a zone: low-RFI barrows tended to spend less time in zone 3 compared with high-RFI barrows ($P = 0.09$). For all other zones there was no difference in time spent in the zones ($P > 0.36$). Number of visits: low-RFI barrows visited zones 3 and 4 less often compared with high-RFI barrows ($P < 0.02$). For all other zones there was no difference in number of visits ($P > 0.24$). These data suggest that differences exist in the response to a novel stressful situation between barrows of different RFI lines. Therefore, the ability of livestock to recognize and cope with stress may be related to RFI and feed efficiency.

Key Words: novel approach, residual feed intake, pig

W153 Influence of dietary flavors on sheep feeding behavior and nutrient digestibility. J. J. Villalba*[1], A. Mereu[2], and I. R. Ipharraguerre[2], *[1]Utah State University, Logan, [2]Lucta, S.A., Montornés del Vallés, Spain.*

A variety of flavored feeds may enhance intake relative to a monotonous diet. The aim of this study was to assess whether the feeding pattern displayed by sheep exposed to a monotonous ration is modified when the same ration is presented in a diversity of flavors and if such diversity influences nutrient digestibility. Twelve wethers (3 lambs/group/period) were housed in metabolic crates during 2 successive periods. One group of lambs [Diversity (D)] was fed simultaneously an unflavored TMR of alfalfa, barley, beet pulp, and urea (55:35:9:1) and the same ration supplemented (0.2%) with one of 2 flavors: 1) sweet, and 2) umami. The other group [Monotony (M)] received just the unflavored TMR. All animals were fed their respective rations ad libitum from 0800 to 1600. The first 20 d of each period were used for adaptation, and the last 6 d were used for sample collection. On d 20, intake was assessed every 30 min for 8 h (feeding pattern). Intake was estimated by subtracting the amounts of feed offered and refused. Intake values were matched with composited samples of feces to determine digestibility. The design of the experiment was a split-plot design with lambs nested within groups and period, day and time interval (feeding pattern) as repeated measures. On average, lambs in D tended to consume more feed than lambs in M ($P = 0.08$). Lambs in D showed greater intakes than M during 30 ($P = 0.006$), 60 ($P = 0.02$), 90 ($P = 0.02$), 120 ($P = 0.04$), and 180 min ($P = 0.07$) after offering the rations. Digestibility of CP ($P = 0.08$) tended to be lower for lambs in D than for lambs in M. Lambs in M and D digested the same amount of DM, NDF, ADF, and N ($P > 0.10$). Flavor diversity did not affect N retained, N retained/N consumed, or ruminal pH 1 h after feeding ($P > 0.10$). In conclusion, exposure to diverse flavors in the same ration has the potential to increase feed intake relative to monotonous rations due to changes in feeding patterns occurring within the first 180 min of feeding. This enhanced consumption likely contributed to the slight decline observed for DM and CP digestibility. The amount of nutrients digested, however, was not influenced by such a decline.

Key Words: flavor, behavior, intake

W154 Metabolic profile of sheep and their lambs in an artificial nursing system. L. H. Díaz-García*, L. P. López-Huitrado, A. Muro-Reyes, H. Gutiérrez-Bañuelos, and J. A. López-Román, *Universidad Autónoma de Zacatecas, Zacatecas, México.*

The artificial nursing system is a methodology that must be used in most sheep farms as it can help reduce the high mortality rates of lambs in the first days of life. The aim of this study was to evaluate seric blood concentrations of glucose (GL), triglycerides (TG; mg/dL) and total protein (TP) (gr/dL) in ewes (SH) and their lambs (LB) during artificial (AN) and natural nursing (NN). Samples were obtained by jugular venipuncture at 1, 8, 15 and 22 d (experimental period) after birth, and chemical profile obtained by spectrophotometry. We used 20 third-parity SH (10 per treatment) and their respective LB, divided into 2 treatments (Tx): artificial nursing (AN, n = 13; lambs did not nurse their dams) and natural nursing (NN, n = 12; lambs nursed their dams). Data were analyzed with PROCGLM, running an ANOVA to detect differences between Tx and animal type. Also, Pearson correlation coefficients (PROC CORR) were run to assess relations between variables. All data was computed by SAS statistical package. Data are shown on Table 1. No differences were found ($P > 0.05$) between Tx for SH in any of the variables evaluated. For LB, both GL and TG differs ($P < 0.001$ and < 0.05, respectively). It was concluded that the type of nursing does not influence the chemical blood parameters of sheep, and nonetheless GL and TG differs on lambs, both chemical variables are within normal ranges.

Table 1. Means (±SD) for each metabolite by treatment (artificial nursing, AN, and natural nursing, NN) and animal type (ewe, lamb)

	Ewe		Lamb	
Variable	AN	NN	AN	NN
Glucose	40.44 ± 17.79	40.66 ± 23.6	52.27 ± 26.8[b]	84.77 ± 29.28[a]
Triglycerides	26.13 ± 15.67	27.07 ± 13.2	68.01 ± 35.72[b]	89.16 ± 30.93[a]
Total protein	7.3 ± 1.39	6.82 ± 1.6	4.45 ± 1.62	5.05 ± 1.47

[abc]Different superscripts represent significant difference ($P < 0.05$) between treatments.

W155 Individual behavior of lambs confined in enriched environment. J. P. A. Lorenço[1], P. A. Bustos Mac-Lean*[1], N. Mora[1], J. M. Malheiros[2], T. Zunino[1], C. G. Titto[3], B. S. Lala[1], and F. A. F. Macedo[1], *[1]State University of Maringa, Maringa, PR, Brazil, [2]Faculty of Agriculture and Veterinary Sciences, Jaboticabal, SP, Brazil, [3]University of São Paulo, FZEA/USP, Pirassununga, SP, Brazil.*

This research aimed to investigate the influence of environmental enrichment with brushes on individual behavior of confined lambs. The project was lead at Maringá-PR, October to December 2012. Were used 6 Pantaneira lambs allotted in individual pens. The behavior was measure by the focal method on 6 separate days, 5 h in afternoon each day (which heat stress increases due to combination of high temperature air and relative humidity in tropical climates). The behavioral assessment divided the 2 treatments, and the first 3 observations without the object and the other 3 observations, put up a brush located in the region above the feeder. The activity patterns of the animals were recorded in an ethogram field every 5 min, and were noted the times of posture (standing or lying) and activities (eating, drinking, ruminating, idleness, brushing and other activities). Behavior data were analyzed by Student's *t*-test to compare means before and after introduction of environmental enrichment using SAS-STAT at a significance level of 0.05. The air temperature and relative humidity within the stall had a variation 25.7 to 35.2°C and 47 to 81%, respectively, causing heat stress to the animals. Table 1 shows that the frequency of the lying position and ruminating activity was significantly higher in the evaluation of lambs when there was enrichment in the pens and this behavior shows that the animals are under a high level of welfare. When lambs remain standing for long, they may be trying to lose heat to the environment. Thus, environmental enrichment alters the behavior of lambs in the hottest hours of the day and can be a tool to reduce stress in confined animals.

Table 1. Frequency of behaviors (means ± SE; %/5 h) observed in lambs with and without environmental enrichment

Behavior	Without brush	With brush
Posture		
Standing	41.4 ± 0.1[a]	32.2 ± 0.1[b]
Lying	58.6 ± 0.1[b]	67.8 ± 0.1[a]
Activity		
Eating	20.0 ± 0.1[a]	10.4 ± 0.1[b]
Drinking	2.3 ± 0.04[b]	3.8 ± 0.06[a]
Ruminating	11.8 ± 0.1[b]	18.4 ± 0.1[a]
Idleness	43.3 ± 0.1[a]	39.4 ± 0.1[b]
Brushing	0.0 ± 0.0[b]	11.8 ± 0.1[a]
Other	22.6 ± 0.1[a]	16.1 ± 0.1[b]

[a,b]Means followed by different small letters in column differ by *t*-test ($P < 0.05$).

Key Words: environmental enrichment, welfare, lambs

W156 Creation and persistence of conditioned aversion to grape leaves and sprouts for grazing sheep in vineyards. C. L. Manuelian[1], E. Albanell[1], M. Rovai[1], A. A. K. Salama[1,2], and G. Caja*[1], *[1]Group of Ruminant Research (G2R), Universitat Autonoma de Barcelona, Bellaterra, Spain, [2]Animal Production Research Institute, Dokki, Giza, Egypt.*

Sheep grazing is a sustainable and environmentally friendly alternative to the traditional vineyard weed control without using machinery and herbicides. However, vineyard grazing has its drawbacks; sheep are attracted by grape leaves and sprouts. Sheep grazing in vineyards usually damages vines, compromising grape quantity and quality. With this in mind, 2 midterm and consecutive experiments were conducted with 12 Manchega and 12 Lacaune ewes, consisting of Exp. 1: Aversion induction to grape leaves (novel food) and persistence evaluation under simulated grazing conditions; and Exp. 2: Descriptive study in a commercial vineyard. In Exp. 1, ewes were allocated into 4 groups (6 ewes/group and breed) in which grape leaves intake was measured after dosing lithium chloride (AV, 225 mg LiCl/kg BW) or water (C, control). Induced aversion was created after offering individually 100 g of grape leaves (var. Tempranillo) in pens for 30 min, and orally administering a single LiCl dose post-consumption; validation was done individually for 3 d. Aversion persistence on a simulated vineyard (2 kg leaves and sprouts var. Tempranillo in wood frames on a ryegrass prairie) was tested during 30 min in 11 sessions (d 5 to 375). Intake data was analyzed by a nonparametric Mann-Whitney U-test using SPSS v.19.0.0 of IBM. On average, C ewes avidly ate grape leaves whereas AV ewes fully refused them, either during validation in the pens (95.1 ± 1.9 vs. 0 g/d and ewe; $P < 0.001$) or in the simulated vineyard (1.47 ± 0.06 vs. 0 kg/group; $P < 0.001$). In Exp. 2, AV ewes were moved to a commercial vineyard (var. Merlot; Penedes county, Barcelona, Spain) and allowed to rotationally graze for 3 h/d during 10 d (d 401 to 410). Averted ewes reduced grass cover between vine lines by 70% but they started to bite grape leaves and sprouts when grass was scarce (d 403 to 410); no significant damage in the vines was visually appreciated. In conclusion, aversion to grape leaves and sprouts persisted in the AV ewes for 1 yr but, in practice, the use of a reinforcing LiCl dose after this time is recommended for assuring an effective aversion behavior in grazing sheep.

Key Words: aversion, grazing, sheep

W157 Feed management of psittacines in captivity using energy requirement equations. V. M. Pereira, T. S. G. Carvalho, V. D. L. Assis, F. M. O. B. Saad, and C. E. P. Saad*, *Federal University of Lavras, Lavras, Minas Gerais, Brazil.*

Captive birds have decreased energy requirement as a result of reduction in living space. Furthermore, ad libitum feeding can induce overweight and may favor the selection for fruits and the rejection of extruded feedstuffs. The selection of feeds by parrots can cause an imbalance of the diet and induce nutritional disorders. Selection also increases feed wastage, mainly of extruded feeds. Two Red Macaws (*Ara chloroptera*), three Blue Macaws (*Anodorhynchus hyacinthinus*), and three Purple Breast Parrots (*Amazona vinacea*) from the "Fundação Zoobotânica" Zoo, Belo Horizonte, Brazil, were used. Before the experiment birds were fed ad libitum. During the trial, birds were fed according to their energy requirement, calculated as body weight to the 0.75 power multiplied by (156 kcal/kg $BW^{0.75}$) for 28 days. The diet contained 70% of extruded dry feed (corn, wheat germ, soybean meal, egg powder, wheat bran, beet pulp, minerals and vitamins) and 30% of fruits (papaya, banana, orange, and apple). The birds were weighed initially and weekly until the end of the experiment and the initial and final weight compared by Student's t-test. Even with restricted feeding, the bird's weight showed no statistical differences ($P > 0.05$) between the initial and final weight. It can be concluded that using formulas based on energy requirements for maintenance do not affect the bird's body weight and contribute to avoid waste of food. Acknowledgment: Fundação Zoobotânica of Belo Horizonte city, CAPES and FAPEMIG.

W158 Comparison of pre-race behaviors of Thoroughbred race horses on finish order and finish type. A. McDuff*, K. William, J. Gregory, and C. E. Ferguson, *McNeese State University, Lake Charles, LA.*

This study compared various pre-race behaviors of Thoroughbred (TB) race horses (n = 1018) at Delta Downs (Vinton, LA) with their performance. The horses were evaluated based on their behavior by 4 experienced horse persons and the pre-race period was divided into 3 sections: pre-saddling (BSAD), which was the time the horse entered the saddling paddock until the saddling, saddling (SAD), which was the time from saddling until the jockeys prepared to mount the horse, and post-parade (POSTP), which consisted of the time the jockey mounted and rode the horse in the parade. The behavior was classified as calm, nervous, or ready and they were also scored numerically from 1 to 5 with 1 being only minimal movement and 5 being a horse that reared, flipped over or pawed several times during the each evaluation period. The horses received a separate behavior type and numerical score for BSAD, SAD and POSTP. Following completion of the race the horses finish order and method of finishing the race (running, tired, or pulled-up) was recorded. Statistically evaluations were performed in SAS and chi-squared analysis was performed to determine statistical differences. Horse scored as nervous during BSAD were more likely ($P < 0.001$) to finish the race tired (68%) compared calm or ready horses (34% and 35%), respectively. Being nervous during BSAD significantly ($P < 0.006$) decreased the horses chances of finishing first to third (17%) compared with calm or ready horses (36% and 38%), respectively. More ($P < 0.0001$) horses that were nervous during SAD finished tired (63%) compared with calm or ready horses (31% and 36%), respectively. Also, horses that were nervous during POSTP were more likely ($P < 0.004$) to run tired (59%) compared with calm or ready horses (34% and 35%), respectively. The BSAD, SAD and POSTP behavior score did not affect finish type ($P < 0.4$, $P < 0.14$, $P < 0.76$) or the percent finishing fourth or better ($P < 0.18$, $P < 0.56$, $P < 0.26$), respectively. Horses with no chain or it used as a regular lead shank were more likely ($P < 0.01$) to run first to fourth (64%) compared with horses with a chain used over their nose or in their lip (47%).

Key Words: horse racing, Thoroughbred, behavior

W159 Alleviation of pain associated with disbudding. A. Mathias*, J. Gilliam, D. Stein, and M. Calvo-Lorenzo, *Oklahoma State University, Stillwater.*

Disbudding, the removal of the horn buds of a calf, is a necessary management procedure because it eliminates costs associated with horns and improves safety. However, disbudding is known to cause pain and distress in calves. Extra-label use of some pharmaceuticals allows for some of the alleviation of the pain and distress, but it is not the best way. A FDA-approved pharmaceutical would be the best option to alleviate the pain and distress, however one does not exist. Therefore, pharmaceuticals are often used extra-label to alleviate pain and distress. This study evaluates the effectiveness ethyl alcohol (EtOH) to produce a cornual nerve block, when the area surrounding the horn is numb. To test this, calves were given 1 of 4 treatments: 5 mL saline solution (SAL), solution mixture of 2.5 mL 2% Lidocaine and 2.5 mL 75% EtOH (MIX), or 5 mL 75% EtOH (ALC). The calves were needle pricked in the area surrounding the horn bud at 5, 10, 15, 20, 30, and 60 min after the treatment on d 1 to determine the onset of the cornual nerve block. To test the duration of the cornual nerve block they were pricked once daily from d 2 - 14. The behavioral response to the prick test was evaluated as either "blocked" or "not blocked." "Blocked" was defined as no movement in response to the prick test, and "not blocked" was defined as pulling on halter, throwing head back, backing away from handler, or falling down. The study found that SAL calves exhibited "not blocked" behaviors at all needle pricking time points; all other treatments exhibited initial "blocked" behaviors at 5 min post-treatment. The study also found that the MIX and ALC treatments were effective at maintaining a cornual nerve block for 2 weeks when needle pricked daily from d 2–14. These results indicate there is potential in utilizing EtOH as a form of non-restricted pain relief for disbudding calves, which would be beneficial for management practices on farms today. Future research incorporating the removal of the horn buds after EtOH administration will further evaluate the effectiveness of EtOH as a cornual nerve block.

Key Words: dehorning, calf, ethyl alcohol

W160 Factors affecting neonatal dairy calf mortality in a hot-arid environment. E. L. Lopez Rodriguez*, M. Mellado, F. G. Veliz, M. A. de Santiago MIRAMONTES, and J. E. Garcia, *Autonomous Agrarian University Antonio Narro, Torreon, Coahuila, Mexico.*

A field study involving 7734 Holstein calves from 8 large intensive dairy herds in northern Mexico (26° N; 24.2°C mean annual temperature; same location) was conducted to determine some factors affecting early postnatal (one to 21-d of age) dairy calf mortality, and to assess its association with climatic conditions. The effects of season of birth, size of dairy operation, birth type (single or twin), sex of calves, and temperature-humidity index (THI) shortly before, during or shortly after calving were analyzed by the GENMOD procedure of SAS. The total mortality incidence was 14%. Mortality of calves was altered by the THI during birth, with a decreased ($P < 0.05$) mortality rate from 16 to 12% when THI was 81 or higher. Mortality levels were 4 percentage point higher ($P < 0.05$) in winter than all other seasons. Single-born calves had fewer deaths (14%) than twin-born calves (19%). The mortality rate was higher ($P < 0.05$) in male than in female calves (17 vs. 12%). Calves that were born in dairy operations > 1800 cows had a greater risk of dying than calves born in smaller dairies (16 vs. 13%). Both respiration rate (74.4 ± 15.6 vs. 67.8 ± 16.3; means ± SD) and heart rate (119.2 ± 19.6 vs. 113.9 ± 17.0; means ± SD) were higher ($P < 0.05$) in calves born in winter than in summer. Rectal temperature was not altered by high ambient temperature and panting was not observed in calves during high ambient temperature. It was concluded that in this particular zone characterized by an intense heat load for the most part of the year, calf mortality was not linked to high ambient temperature around calving. Instead, survival of calves was negatively affected by winter weather. Thus, efforts to protect calves from cold weather would alleviate calf losses.

Key Words: calf, mortality, climate

W161 GALNT13, a positional candidate gene on bovine chromosome 2 for heifer pregnancy, is only expressed in nervous tissue. J. N. LaMastro*[1], W. A. Khan[1,2], S. O. Peters[2,3], O. O. Ajayi[1],

M. De Donato[1,4], W. Bai[1,5], and I.G. Imumorin[1], *[1]Cornell University, Ithaca, NY, [2]University of Veterinary and Animal Sciences, Lahore, Pakistan, [3]Berry College, Mt. Berry, GA, [4]Universidad de Oriente, Cumana, Sucre, Venezuela, [5]Shenyang Agricultural University, Shenyang, China.*

Genetic improvement programs for reproductive traits have been much slower to develop than improvement programs for growth and carcass traits for reasons including low heritability of fertility traits. In our previous study, a Bayesian based association mapping combined with alignment to differentially expressed hypothalamic transcriptome from RNA-seq data helped to identify candidate genes that may be responsible for the variation in heifer pregnancy on bovine chromosome 2. One of these candidates is uridine diphospho N-acetylgalactosaminyltransferase 13 (GALNT13), belonging to a family of enzymes involved in mucin-type O-glycosylation of serine and threonine residues of polypeptide acceptors. Bovine GALNT13 has 11 exons with mixed structures in its secondary structures predicted using the GORIV tool showing that it possesses the glycosyltransferase and ricin domains. We analyzed expression of bovine GALNT13 using reverse transcriptase-PCR amplification of 290 bp from exon 1. Like its murine and human counterpart, bovine GALNT13 is expressed in brain and spinal cord and not in liver, heart, kidney and lymph node. Our results appear to support previous studies in mouse that GALNT13 is a major enzyme responsible for the synthesis of O-glycan residues in neurons, which is consistent with being expressed only in nervous tissue.

Key Words: GALNT13, bovine, brain

W162 Combining ruminally protected choline and flaxseed in cattle diets to increase assimilation of n-3 fatty acids from the diet . C. P. Weiss*, C. L. Van Bibber-Krueger, K. A. Miller, C. A. Alvarado-Gilis, and J. S. Drouillard, *Kansas State University, Manhattan.*

Crossbred heifers (n = 108; initial BW = 285 ± 13.6 kg) were used in a randomized complete block experiment with a 2 × 2 factorial treatments arrangement to evaluate effects of ruminally-protected choline and ground flaxseed on changes in plasma concentrations of long-chain fatty acids, glucose, and L-lactate. Heifers were stratified by initial BW and allocated randomly, within strata, to 36 feedlot pens with 3 heifers/pen (9 pens/treatment). Factors consisted of level of ruminally-protected choline (C) fed at 0 or 113 g/d (Robert Morgan Inc.) and level of an extruded mixture of flaxseed, wheat middlings, vitamins, and minerals (F) fed at 0 or 10% of diet DM (Great O3 Premium Feed). Heifers were fed a basal diet (DM basis) of 25% corn silage, 15% alfalfa, 25% wet corn gluten feed, steam-flaked corn, and supplement. Cattle were fed their respective diets ad libitum at 1600 h daily. On d 0 and 14 of the study, cattle were weighed, blood was sampled via jugular venipuncture and centrifuged to recover plasma. Plasma glucose and L-lactate were measured using a YSI 2100D analyzer and fatty acid methyl esters (FAMEs) were measured by gas chromatography. Data were analyzed as a mixed model with choline, flaxseed, day, and all interactions as fixed effects, weight block as a random effect, and pen as the experimental unit. There were no significant interactions between C and F for performance or blood constituents ($P > 0.05$). Feeding C tended to improve gain efficiency (0.284 vs. 0. 313) for 0 and 113 g/d feeding levels, respectively; $P = 0.06$); but did not affect ADG, DMI, or blood constituents ($P > 0.10$). Gain, DM intake, gain efficiency, and plasma glucose and lactate were unaffected by feeding F ($P > 0.10$), but plasma concentrations of α-linolenic acid were greater for cattle fed F compared with those without ($P < 0.01$). Ruminally protected choline yielded efficiency responses comparable to those observed in previous studies. The Great O3 feed used in this study increased plasma concentrations of n-3 fatty acids, but including choline provided no further improvement in assimilation of dietary fats.

Key Words: FAME, glucose, lactate

W163 Kyphosis induced by maternal vitamin D intake is not explained by a reduction in vertebrae body mineral content of pigs at birth or weaning. L. M. Vanderwerff*, L. A. Rortvedt-Amundson, and T. D. Crenshaw, *University of Wisconsin, Madison.*

Kyphosis, an idiopathic disease characterized by abnormal outward spinal curvature, commonly affects the 14th to 16th thoracic vertebrae. In recent experiments kyphosis was induced in young pigs produced by sows fed diets with no supplemental vitamin D_3 (D) throughout gestation and lactation. The current objective was to assess variation in mineral content of regions along spinal columns of pigs produced by gilts fed diets varying in D. Regions were examined to determine if a reduction in percent ash (%ash) predisposed specific vertebrae to conformational deformities associated with kyphosis. Spinal columns were collected from pigs at birth (d 0, n = 12) and weaning (d 25, n = 15). Gilts that produced the pigs were fed diets containing 0, 325, or 1,750 IU D/kg from breeding through lactation. After euthanasia, the spinal column was removed and vertebrae bodies were dissected, then extracted with ether and ashed. Data from individual vertebral bodies were grouped into regions (n = 3/region) and numbered 1 to 7 consecutively from the 1st rib through the last lumbar vertebra. Regions of 3 adjacent vertebrae were selected based on the definition of kyphosis. Differences due to maternal diets were not detected in vertebrae % ash of pigs at birth (44.4, 43.6, and 44.8%) or weaning (37.4, 37.1, and 39.9%). Vertebrae % ash decreased ($P < 0.05$) from d 0 to d 25 (44.3 vs. 38.1%) but these differences varied by region within the vertebral column (age X region interaction, $P < 0.01$) as shown below. The 6% decrease in % ash with age was due to a 4-fold increase in bone organic matrix (0.11 vs. 0.49 g) that exceeded the 3-fold increase in bone mineral (0.09 vs. 0.31 g). At d 0, the % ash was essentially constant across regions but at d 25, % ash increased, especially in the more distal regions. At d 25, % ash values in regions associated with kyphosis were greater, implying that kyphosis may result from an overgrowth of organic matrix not from a lack of matrix mineralization.

Table 1. Ash (%) values of different vertebral regions

	Vertebral region (3 vertebrae/region)							Pooled
Age, d	1	2	3	4	5	6	7	SEM
0	43.8	43.8	44.1	44.3	44.2	45.0	44.9	0.07
25	36.5	37.3	37.6	38.4	39.0	39.5	38.5	0.08

Key Words: bone ash, bone matrix, vitamin D

W164 Effect of sex, pen density and season on feedlot performance. J. H. Moss*, C. L. Maxwell, and C. R. Krehbiel, *Department of Animal Science, Oklahoma State University, Stillwater.*

There are a variety of factors that can affect feedlot performance for both steers and heifers. The objective of this study was to quantify factors that affect DMI, ADG, and efficiency of cattle during the finishing phase. Factors that were evaluated were sex and season of cattle closeout. Trial data from 2003 to 2012, including initial BW, final BW, DMI, ADG, G:F, from the Willard Sparks Beef Research Center was compiled and analyzed. The data set consisted of 933 pens, 647 pens of steers (3,706 steers) and 286 of heifers (1,800 heifers). The effect of sex was analyzed using PROC MIXED (SAS 9.3, Cary, NC), initial

BW was used as a covariate when necessary ($P < 0.05$) to determine the difference in performance and efficiency between steers and heifers. Steers consumed 14.5% more feed (10.29 vs. 8.99, kg/d), gained 16.9% faster (1.66 vs. 1.42, kg/d), and were 3.2% more efficient than heifers (0.162 vs. 0.157; $P < 0.01$). Season was evaluated to determine the effect of seasonal variation on performance. Season was divided into 4, 3 mo periods 1(Jan-Mar), 2(Apr-Jun), 3(Jul-Sep), 4(Oct-Dec). Cattle finished in season 4 consumed 5% more feed (10.02 vs. 9.54 kg/d; $P < 0.01$) compared with the other 3 seasons. Cattle in seasons 2 and 4 had a 5.2% improvement in ADG compared with season 1 (1.61 vs. 1.53 kg/d) and an 11.0% improvement in ADG compared with season 3 (1.61 vs. 1.45; $P < 0.01$). Cattle in season 2 and 4 were 4.1% more efficient than cattle in season 1 and 3 (0.164 vs. 0.157, $P < 0.01$). A strong positive correlation existed between initial and DMI for heifers ($r^2 = 0.54$; $P < 0.01$), as well as steers ($r^2 = 0.40$; $P < 0.01$). Using PROC REG, dry matter intake for this data using only initial BW was estimated by the equation DMI, kg/d = 6.75 + (initial BW, kg*0.162) ($P < 0.01$). Actual DMI was positively correlated to predicted DMI (Eq.7–2, NRC, 2000; $r^2 = 0.40$, $P < 0.01$). The results of this study indicates that steers have increased DMI, ADG, and feed efficiency during the finishing period compared with heifers, and that cattle closed out in the spring and fall of the year experience improved feedlot performance compared with cattle closed out in the winter and summer.

Key Words: sex, season, feedlot performance

W165 Phosphorus status of grazing beef cattle in Virginia's Chesapeake Bay watershed. S. J. Neil*, D. D. Harmon, and M. A. McCann, *Virginia Polytechnic Institute and State University, Blacksburg.*

Phosphorus loads in the Chesapeake Bay are a focus of environmental concern. Animal agriculture's contribution to this problem has been documented and efforts are focused on mitigating the issue. Major research and extension efforts have focused on concentrated animal feeding operations (mainly dairy and poultry); however, 400,000 beef cows are located in Virginia's Chesapeake Bay watershed counties. The objective of this study was to document phosphorus (P) supplementation in free choice minerals, soil test P, forage P and manure P levels of grazing beef cows in Virginia's Chesapeake Bay watershed. Producers could submit more than one set of samples if a full complement of samples was collected and the samples represented another land area or herd. Thirty-four producers from 2 counties cooperated with sample collection (n = 80) and completed a questionnaire related to their management practices. Soil test P values were characterized as low (14%), medium (29%), high (27%) and very high (13%) based on Virginia Cooperative Extension Soil Test guidelines. Phosphorus content of pasture forage grab samples (mean = 0.36%, SD = 0.10) was correlated to soil phosphorus levels (r = 0.42), but manure total P was lowly related (r = 0.05) to soil P values. Forage P levels were compared with Beef Cattle NRC (2001) P requirements for a 545-kg cow (peak milk, 13.6 kg/d). All forage samples were sufficient in P content to meet a dry cow's requirements, 98% met the requirements for late gestation and 87% met the peak lactation P requirement. Farm mineral supplements were categorized into 4 levels of P content (0, 1.0–2.5, 3.0–5.0 and >6.0%). Forage P content did not affect mineral selection by producers. The mean forage P content for the 4 mineral categories were 0.27, 0.37, 0.37 and 0.46%, respectively. Manure TP increased as mineral P content increased, 0.54, 0.65, 0.80 and 0.88% respectively. All farms surveyed required little or no phosphorus supplementation in regard to cow nutrient requirements. Sixty-five percent of participating cattlemen were receptive to modifying their P supplementation based on forage test results while only 6% were opposed to any modification.

Key Words: phosphorus, beef cattle

W166 Effect of anabolic implants on adrenal cortisol synthesis in beef cattle. K. A. Branham*[1], J. O. Ellison[1], B. I. Gomez[1], A. D. Stapp[1], C. A. Gifford[1], C. R. Kreihbel[1], B. C. Bernhard[1], C. L. Maxwell[1], D. M. Hallford[2], and J. A. Hernandez Gifford[1], *[1]Oklahoma State University, Stillwater, [2]New Mexico State University, Las Cruces.*

Implantation of anabolic steroids to increase growth rate in beef cattle affects adrenal glucocorticoid production. The mechanism by which trenbolone acetate and estrogen reduce cortisol (C) biosynthesis in heifers is not clear. The objective of this study was to determine serum C concentrations and adrenal steroidogenic enzyme mRNA levels in heifers implanted with Revalor 200. On d 0 of a 90-d finishing phase, 187 predominantly Angus heifers were randomly assigned to 3 treatments: non-implanted controls (con); Revalor 200 implant for 90 d of finishing phase (early); or Revalor 200 for last 30 d of finishing phase (late). On d 0, BW was 363, 359, and 361 kg for con, early and late treatments, respectively. At d 60, BW for early implanted heifers (458 kg) was greater ($P < 0.01$) than con (439 kg) and late implanted (436 kg) heifers. Final BW (d 90) was greater in early (519 kg) and late (510 kg) implanted heifers compared with con (492 kg). In a subset of heifers (n = 49) peripheral blood was collected to quantify serum C concentrations at d 0, 30, 60 and 90. Serum C was similar among groups at d 0 ($P = 0.65$); however, at d 30 heifers receiving implants had a marked reduction ($P < 0.01$) in serum C concentrations (31 ng/mL) compared with con (47 ng/mL) and late (48 ng/mL). At d 90, con heifers had a serum C value of 43 ng/mL compared with 25 ng/mL in both early and late implanted heifers ($P < 0.01$). At harvest (d 90) adrenal tissue was collected (n = 6/group) for mRNA analysis of steroidogenic enzymes cytochrome P450, family 21, subfamily A, polypeptide 2, cytochrome P450, family 11, subfamily B, polypeptide 1 and melanocortin 2 receptor. Despite decreased serum C in implanted heifers, no difference among treatments was detected for expression of the steroidogenic enzymes or the ACTH receptor in adrenal glands indicating other components of the hypothalamic-pituitary-adrenal axis are responsible for the observed decrease in serum C.

Key Words: adrenal, cortisol, implant

W167 Expression of WNT signaling transcripts at specific stages of follicle development in bovine granulosa cells. A. J. Potts*[1], A. D. Stapp[1], B. I. Gómez[1], K. B. Parker[1], C. A. Gifford[1], D. M. Hallford[2], and J. A. Hernandez Gifford[1], *[1]Oklahoma State University, Stillwater, [2]New Mexico State University, Las Cruces.*

Follicular maturation is a dynamic process requiring input from pituitary gonadotropins and ovarian derived factors. Members of the wingless-type mammary tumor virus integration-site (WNT) signaling pathway have been recognized to be differentially expressed and hormonally regulated in rodent ovaries, and we recently reported that WNT2 is regulated by FSH in bovine granulosa cells. However, the role and expression of WNT signaling molecules in ovarian follicle development in cattle is unknown. Therefore, the objective of this study is to characterize components of the WNT signaling pathway at specific stages of follicular development by real-time PCR. To identify gene expression changes in bovine folliculogenesis, granulosa cells and follicular fluid were collected from ovary pairs containing a stage III CL (d 11 to 17 of an estrous cycle). Granulosa cells were isolated from small (1 to 5 mm; n = 4) and

large (8 to 22 mm; n = 4) follicles, and the corresponding CL (n = 3). Intra-follicular estradiol and progesterone concentrations were used to identify large dominant follicles (estradiol:progesterone >1). Real-time PCR quantification of select WNT family members was evaluated at distinct stages of development. Compared with small follicle granulosa cells, expression of the WNT transcriptional co-factor, CTNNB1 was similar in large dominant follicles ($P = 0.95$) but was decreased in the CL ($P = 0.06$). Expression of WNT ligands also demonstrated stage specific regulation as WNT2B was reduced in large dominant follicles ($P = 0.02$) but similar in CL ($P = 0.53$) compared with small follicles. A comparable pattern of expression was demonstrated for WNT5A as small follicles had greater expression compared with large follicles ($P < 0.01$) and was similar to CL ($P = 0.37$). However, WNT2 mRNA expression was unchanged throughout follicle maturation ($P = 0.47$). Previous work in our laboratory demonstrated WNT3A is antagonistic to FSH signaling in cultures of primary rat granulosa cells. Results from the current experiment indicate that WNT signaling molecules may be inhibitory to follicle development and luteinization in cattle.

Key Words: folliculogenesis, ovary, WNT

W168 Solubility of copper sulfate and three sources of dicopper chloride trihydroxide. C. S. Park* and B. G. Kim, *Konkuk University, Seoul, Republic of Korea.*

Copper sulfate ($CuSO_4$) and dicopper chloride trihydroxide (dCCTH) are widely used as Cu sources in swine diets. The objective of this study was to determine the solubility of Cu in $CuSO_4$, and 3 sources of dCCTH consisted of α-form (dCCTH-α), β-form (dCCTH-β), or a mixture of α and β-form (dCCTH-α·β) at different pH and an in vitro digestion procedure using a shaking incubator at 39°C. In Exp. 1, $CuSO_4$, dCCTH-α, dCCTH-β, and dCCTH-α·β were incubated in buffer at pH 2.0, 3.0, 4.8, and 6.8 for 4 h. Copper sulfate was completely dissolved within 15 min except at pH 6.8. At pH 2.0, solubility of Cu in dCCTH-α and dCCTH-α·β was greater (42.5 and 34.9 vs. 17.2%; $P < 0.05$) than dCCTH-β at 15 min and Cu in all dCCTH was completely dissolved at 4 h. In pH 3.0 and 4.8 buffers, all sources of dCCTH were dissolved at less than 22% and 3%, respectively, when incubated for 4 h. Copper in dCCTH sources was not dissolved at pH 6.8. Exp. 2 was conducted to determine the solubility of Cu in the same Cu sources as in Exp. 1 using an in vitro digestion assay simulating digestion procedures of pigs. All sources of Cu were completely dissolved at pH 2.0 when incubated for 2 h in a phosphate buffer. In Exp. 3, the 5 diets consisted of a control diet and diets supplemented with 250 ppm of Cu as $CuSO_4$, dCCTH-α, dCCTH-β, or dCCTH-α·β were prepared to determine the solubility of Cu during an 3-step in vitro digestion assay. Solubility of Cu in diets supplemented with $CuSO_4$ and dCCTH sources was greater ($P < 0.05$) than the control diet in step 1 and 2. These results indicate that solubility of $CuSO_4$ and dCCTH is affected considerably by pH of digesta. Among dCCTH sources, the solubility of Cu in dCCTH-α is greater than in other dCCTH sources at pH 2.0.

Key Words: in vitro digestion, swine, trace mineral

W169 Effects of poor maternal nutrition on GH, IGF-I, insulin, and leptin concentrations in pregnant ewes. M. E. Forella*, K. N. Peck, M. L. Hoffman, A. R. Fox, K. E. Govoni, and S. A. Zinn, *Department of Animal Science, University of Connecticut, Storrs.*

Maternal hormones affect fetal growth and development through their effect on nutrient partitioning and placental development. Maternal diet is one factor regulating maternal hormone concentrations. We hypothesized that during gestation, diet alters concentrations of maternal metabolic hormones. Pregnant ewes (n = 36; 12/treatment) were individually fed 1 of 3 diets [100% (CON), 140% (OVER), or 60% (RES) NRC requirements] from wk 5 of gestation until parturition. Weekly blood samples (20 mL) were obtained via jugular venipuncture and BW was measured. Concentrations of GH, IGF-I and leptin were determined by RIA. Insulin was determined by ELISA. Data were analyzed using ANOVA. By the end of gestation (wk 20), RES ewes (89.3 ± 3.6) were lighter ($P < 0.01$) and OVER ewes (119.7 ± 3.6 kg) were heavier ($P < 0.1$) than CON ewes (112.9 ± 3.6 kg). However, compared with CON ewes (0.27 ± 0.01 kg), ADG was increased ($P < 0.01$) in OVER ewes (0.35 ± 0.01 kg) and decreased ($P < 0.01$) in RES ewes (0.12 ± 0.01 kg). Concentrations of GH were greater ($P < 0.01$) in RES ewes (6.4 ± 0.6 ng/mL) than CON ewes (3.2 ± 0.6 ng/mL) and OVER ewes (2.3 ± 0.6 ng/mL). Average concentrations of IGF-I were greater ($P < 0.1$) in OVER ewes (197.7 ± 14.5 ng/mL) compared with CON (163 ± 14.5 ng/mL) and RES (146.35 ± 14.5 ng/mL) ewes, but there was no difference between CON and RES ewes ($P < 0.42$). Average concentrations of insulin were greater ($P < 0.01$) in OVER ewes (0.61 ± 0.7 ng/mL) than RES (0.31 ± 0.7 ng/mL) and CON (0.32 ± 0.7 ng/mL) ewes. Leptin averaged 2.3 ± 1.4, 1.5 ± 1.4, and 4.3 ± 1.4 ng/mL in CON, RES, and OVER ewes, respectively, but there were no differences in leptin due to diet ($P > 0.32$). In conclusion, poor maternal diet during gestation affects circulating concentrations of GH, IGF-I, and insulin, and this may contribute to developmental changes in the fetus.

Key Words: insulin, maternal diet, somatotropic axis

W170 In vitro fermentation of high forage substrate with addition of direct fed microbials and/or monensin. K. E. Roberts*, K. M. Anderson, N. M. Kenney, K. R. McLeod, and E. S. Vanzant, *University of Kentucky, Lexington.*

This study was conducted to determine in vitro ruminal fermentation characteristics with addition of direct fed microbials (DFM) and/or monensin (MON) to a high forage TMR. ANKOM RFS fermentation vessels received either 50 µg lactose (control) or 50 µg DFM containing 50,000 cfu lactic acid bacteria (LifeProducts 10G) whereas MON was applied in the feed of the inoculum donor steers. Four ruminally cannulated steers received a high forage diet either with (n = 2) or without (n = 2) 440 mg/hd/d MON. Rumen fluid for each pair of steers was combined before inoculating fermentation vessels. Gas production was measured in each vessel for 24 h. At termination, fluid samples were collected from each vessel for measurement of VFA, ammonia, and pH. The best-fit model of 10 gas production models evaluated was used to quantify gas production parameters for individual vessels. Data were analyzed with the GLM procedure of SAS with a model appropriate for a completely randomized design with treatments arranged in a 2 × 2 factorial structure. Treatments did not influence ($P > 0.10$) total VFA concentrations (m*M*) or gas production (mL). Gas production rates were decreased slightly ($P = 0.06$; 0.236 mL/min and 0.224 mL/min ± 0.004) by DFM and were unaffected by MON ($P = 0.89$). Interactions between DFM and MON were detected ($P \leq 0.08$) for NH3 concentration and molar proportions of all VFA except propionate. In the absence of MON, DFM had no influence ($P > 0.10$) on any of these variables. With MON, acetate proportion was decreased ($P < 0.06$; 56.8 vs. 53.7 ± 1.10%) by DFM, whereas molar proportions of the remaining VFA (except propionate) were increased ($P < 0.10$; 11.9 vs. 13.2 ± 0.43%; 4.4 vs. 5.2 ± 0.28%; 2.1 vs. 2.4 ± 0.09%; 4.7 vs. 5.5 ± 0.28%; for butyrate, valerate, isobutyrate, and isovalerate) by DFM, as was NH3 concentration (1.6 vs. 2.8 ± 0.43 m*M*). Although MON decreased pH slightly ($P < 0.01$; 6.86 vs. 6.73 ± 0.015), DFM had no effect ($P = 0.30$) on pH. Results indicate that the effects of DFM on VFA profiles and ammonia concentrations with in vitro fermentation of a high forage substrate were dependent on the presence of MON.

Key Words: direct-fed microbial, VFA, gas production

W171 Effects of poor maternal nutrition on gene expression in bone marrow stromal cells from lambs. D. M. Kaelin*, S. Neupane, M. L. Hoffman, K. N. Peck, S. A. Zinn, and K. E. Govoni, *University of Connecticut, Storrs.*

Poor maternal nutrition can reduce growth rate, reduce bone development, and increase fat deposition in offspring. Bone marrow stromal cells (BMSC) are multipotent stem cells that can differentiate into several cell types including osteoblasts and adipocytes. Poor maternal nutrition may commit these cells to the adipocyte lineage, contributing to increased adipose tissue and reduced bone; however the mechanisms are not well established. We hypothesized that poor maternal nutrition would alter gene expression in BMSC. Pregnant ewes (n = 24) were randomly assigned to a diet of 100% (CON), 60% (RES), or 120% (OVER) of NRC requirements beginning at d 114 ± 10 of gestation. Within 24 h of birth, lambs were euthanized (n = 3/treatment), BMSC were isolated from the femur, cultured until 80% confluent, and RNA was extracted using TriReagent and ethanol precipitation. Real-time reverse transcriptase (RT)-PCR was used to determine mRNA expression. Data were analyzed by ANOVA. We did not observe an effect of treatment on markers of adipogenesis [CCAAT-enhancer binding protein (CEPB)-α, proliferation-activation receptor (PPAR)-γ, Pref-1; $P \geq 0.29$]. Maternal diet did not affect runt-related transcription factor (Runx)2 ($P \geq 0.45$), a key transcription factor in osteoblast differentiation, as well as various transcription factors involved in osteoblast development [dickkopf-related protein (DKK)2, low density lipoprotein receptor-related protein (Lrp)4, Lrp5, glycogen synthase kinase (GSK)-β and β-Catenin; $P \geq 0.3$]. mRNA expression of T-box (Tbx)-3, a key transcription factor in development and osteoblast function, tended ($P = 0.1$) to be reduced 1.6 ± 0.2-fold in RES. Expression of P2Y14 receptor, a key factor in lineage commitment of BMSC, was reduced 3.8 ± 0.1-fold in OVER ($P = 0.03$). Expression of CEBP-β was reduced 2.0 ± 0.1 and 2.2 ± 0.1-fold in RES and OVER, respectively ($P \leq 0.02$). In conclusion, poor maternal nutrition during gestation alters the expression genes involved in the commitment of BMSC to osteoblast and adipocytes cell lineage, which may contribute to altered body mass and composition of offspring.

Key Words: maternal nutrition, bone marrow stromal cells, sheep

W172 Effects of maternal dietary yeast supplementation on foal growth and development. E. R. Share*, J. M. Reddish, and K. Cole, *Department of Animal Sciences, The Ohio State University, Columbus.*

Dietary yeast supplementation in horses has been reported to influence nutrient digestibility and milk production in mares. Altering the nutrient composition of the milk from mares may influence the growth of their foals. The objective of this study was to determine if dietary yeast supplementation of the maternal diets would influence foal growth and development. Eight Quarter Horse mares (14.5 ± 7.5yr) were randomly assigned to one of 2 groups: Yeast or Control. All mares received 0.5% BW of a 16% CP pelleted concentrate, with water and mixed grass hay ad libitum. Mares in the yeast treatment group were fed a targeted dose of 1 g/ 45.4 kg of BW per day of a live culture of *Saccharomyces cerevisiae* for a period of 180 d. Growth measurements (body weight, body length, heart girth, wither and hip height, upper and lower leg length, and front/rear cannon bone circumference) were taken on d 0, 7, 14, 21, 28, 35, 42, 49, 56, 70, 84, 98, 112, 126, 140, 154 and 168. Data were analyzed using the PROC Mixed procedure of SAS. Average daily gain (ADG) of the foals was not influenced by the addition of yeast to the maternal diets. Hip height and wither height were highly correlated (r = 0.99). Although upper leg length and wither height were highly correlated (r = 0.93), lower leg length and wither height were not (r = 0.72). No significant differences in foal growth and development due to dietary yeast supplementation of the

Key Words: foal, growth, yeast

W173 Effects of poor maternal nutrition during gestation on gene expression in renal adipose tissue of lambs. A. M. Bush*, M. L. Hoffman, K. N. Peck, S. A. Zinn, and K. E. Govoni, *Department of Animal Science, University of Connecticut, Storrs.*

Poor maternal nutrition impairs postnatal growth and development of the animal, particularly decreasing carcass quality with an increase in fat deposition. We hypothesized that poor maternal nutrition would alter expression of key genes involved in adipogenesis in lambs. Thirty-six multiparous Dorset (n = 25), Shropshire (n = 7), and Southdown (n = 4) ewes were individually housed and fed either 100% (CON), 60% (RES), or 140% (OVER) of requirements for ewes pregnant with twin lambs (NRC, 1985) starting at d 31 ± 1.3 of gestation. Lambs were euthanized within 24 h after birth (n = 18) and perirenal adipose tissue was collected immediately and snap frozen in liquid nitrogen. Gene expression was determined by RNA extraction using Tri-Reagent, an RNeasy Mini Kit, and real-time reverse transcriptase-PCR. Data were analyzed using ANOVA with significance considered as $P \leq 0.05$. To determine if maternal diet affected markers of adipogenesis, we quantified expression of peroxisome proliferator-activated receptor gamma (PPAR-γ) and CCAAT/enhancer binding protein β (CEBP-β). We did not observe a change in expression of either gene in lambs born to RES and OVER ewes relative to controls at birth ($P \geq 0.27$). In addition, we did not observe an effect of maternal diet on glucose transporter type 4 (GLUT-4), a marker of nutrient uptake, in RES and OVER lambs relative to controls at birth ($P = 0.17$). Maternal diet did not effect adiponectin (ADIPOQ), a marker of energy homeostasis, in RES and OVER groups relative to controls ($P = 0.07$). These findings suggest that during fetal development, poor maternal nutrition does not alter expression of key markers of adipogenesis. Further analysis is needed to determine if poor maternal nutrition alters gene expression in adipose tissue at later stages of development when fat accretion is more rapid.

Key Words: maternal nutrition, adipose tissue, sheep

W174 Uterine flux of estrone sulfate in an ovine maternal nutrient restriction model during melatonin supplementation. L. J. Grossner*[1], L. E. Camacho[2], D. M. Hallford[3], K. A. Vonnahme[2], and C. O. Lemley[1], *[1]Mississippi State University, Mississippi State, [2]North Dakota State University, Fargo, [3]New Mexico State University, Las Cruces.*

Previous data from our laboratories showed an increase in uteroplacental secretion of progesterone and estradiol 17β in nutrient restricted vs. adequate fed ewes. The current objectives were to examine the effects of dietary melatonin supplementation and nutritional plane on uteroplacental estrone sulfate flux and placental protein expression of steroidogenic acute regulatory protein (StAR) and aromatase. From d 50 to 130 of gestation, 31 primiparous ewes received 100% (ADQ) or 60% (RES) of nutrient requirements and were supplemented with 5 mg of melatonin per day (MEL) or no melatonin (CON). At d 130, uterine artery blood flow (BF) was determined under general anesthesia. Blood samples were collected from maternal saphenous artery, gravid uterine vein, umbilical artery, and umbilical vein. Estrone sulfate was not detected in the umbilical vein or umbilical artery samples (concentration ≤0.01 ng/mL). Uterine flux of estrone sulfate was calculated as maternal arterial-venous difference × uterine BF. Maternal artery estrone sulfate was increased ($P < 0.01$)

in RES (5.3 ± 1.4 ng/mL) vs. ADQ (0.7 ± 0.3 ng/mL) ewes. Similarly, uterine vein estrone sulfate was increased ($P < 0.05$) in RES (5.1 ± 1.5 ng/mL) vs. ADQ (1.5 ± 0.7 ng/mL) ewes. Maternal arterial-venous difference of estrone sulfate was increased ($P = 0.01$) in CON-RES (1.9 ± 1.0 ng/mL) vs. CON-ADQ (−1.1 ± 1.0 ng/mL), while MEL-RES (−2.1 ± 1.0 ng/mL) was not different ($P > 0.50$) from CON-ADQ. Uterine flux of estrone sulfate was decreased ($P < 0.01$) in MEL-RES (−3.4 ± 1.4 μg/min) vs. CON-RES (2.2 ± 1.4 μg/min), while neither was different ($P \geq 0.07$) from CON-ADQ (−1.5 ± 1.5 μg/min). Placental StAR protein expression was increased ($P < 0.05$) in RES vs. ADQ ewes at d 130, while placental aromatase protein was not different ($P > 0.60$) across all treatment groups. Maternal nutrient restriction interacted with dietary melatonin supplementation to alter uterine flux of estrone sulfate. Moreover, the previously observed increase in steroid secretion from nutrient restricted dams is associated with an increase in placental StAR protein.

Key Words: estrone sulfate, melatonin, uterine flux

W175 Reproductive indices of quail hatching eggs under semi-intensive management system. O. T. F. Abanikannda, A. M. Adeyeye*, A. O. Leigh, and A. A. Olubunmi, *Lagos State University, Ojo, Lagos, Nigeria.*

The supply of day old chicks is very important for successful hatchery operations and the future of quail production, breeding and management. This is predicated not only on the number produced but also the fertility and hatchability of the eggs. Fertility and hatchability are 2 major indices for assessing reproductive performance which are mostly sensitive to environmental and genetic influences. This study was aimed at assessing the fertility and hatchability of quail eggs under semi-intensive management. A total of 985 eggs were sourced from a quail farm in the Savannah region of Nigeria. The breeders were kept in cages and were freely pen-mated with a sex ratio of one male to 5 female birds. Eggs were cleaned, labeled, measured, fumigated, incubated and classified as fertile or not fertile after incubation. Measurements included egg weight, length, width, vertical and horizontal circumferences, while computed indices were egg density, surface area and volume (Table 1). All statistical analyses (exploratory, correlation and logistic fit) were done with JMP$^{(R)}$ software. Fertility was 74.92%, while hatchability was 67.82% in the entire study but 90.51% within the fertile eggs group. There was no statistical significance ($P > 0.05$) in mean of all variables in the 2 groups (fertile and not fertile) and a further logistic fit of the 2 groups based on the measures was not significant ($P > 0.05$). In a similar way, hatchability was not significantly influenced by the pre-hatch measures of the eggs. It can be concluded from the study that physical characteristics of the eggs as reflected by the measured variables and indices was not the significant factor in the determination of the fertility and hatchability of the eggs.

Table 1. Descriptive statistics of measured variables

Variable	Fertile	Not fertile
Sample size (no.)	738	247
Egg weight (g)	9.90 ± 0.03	9.93 ± 0.06
Egg length (mm)	30.46 ± 0.05	30.62 ± 0.09
Egg width (mm)	24.54 ± 0.04	24.49 ± 0.04
Horizontal circumference	8.37 ± 0.02	8.34 ± 0.02
Vertical circumference	9.25 ± 0.02	9.23 ± 0.03
Egg density	1.05 ± 0.01	1.05 ± 0.01
Egg surface area	22.61 ± 0.06	22.66 ± 0.10
Egg volume	10.33 ± 0.05	10.34 ± 0.07

Key Words: fertility, hatchability, logistic fit

W176 Effects of maternal 25-hydroxycholecalciferol (25OHD3) supplementation on fetal bone development in pigs. K. K. McFadden*[1], M. L. Hoffman[1], J. D. Starkey[2], J. D. Coffey[2], E. A. Hines[2], C. W. Starkey[2], and K. E. Govoni[1], *[1]University of Connecticut, Storrs, [2]Texas Tech University, Lubbock.*

Lameness in pigs is often due to poor bone development and creates a major health issue for the swine industry. The majority of bone development occurs during fetal and early postnatal development and vitamin D is required for proper bone development. It has been shown in swine that 25OHD3, a metabolite of vitamin D, is more bioavailable than vitamin D_3. We hypothesized that providing vitamin D as 25OHD3 to pregnant gilts would increase markers of bone formation in the bones of fetuses. Forty PIC Camborough-22 gilts were randomly assigned to one of 2 corn-soybean meal-based diets. The control diet contained 2,500 IU of vitamin D_3 per kg of diet. The experimental diet contained 500 IU D_3 per kg of diet plus 50 μg of Rovimix Hy-D (DSM Nutritional Products Ltd., Basel, Switzerland) the 25OHD3 form. Beginning 43 d before gestation, gilts were fed 2.7 kg of their assigned diet once a day until 90 d of gestation. At d 90 ± 1 femurs from the 2 median BW fetuses per gilt (1 male and 1 female) were collected (n = 22: control; n = 28: 25OHD3). mRNA was extracted from the mid-diaphysis for gene expression analysis using real time-reverse transcriptase (RT)-PCR. Data were analyzed using ANOVA with significance considered at $P \leq 0.05$. Specifically, we evaluated mRNA expression of markers of bone formation [osteocalcin, alkaline phosphatase (ALP), and type I collagen], as well as, vitamin D receptor, parathyroid hormone receptor (PTHR), and fibroblast growth factor-23 (FGF-23), molecules critical for bone development and known to interact with the vitamin D pathway. We did not observe an effect of maternal 25OHD3 supplementation on the expression of any of the genes evaluated ($P = 0.32$). In addition, we did not observe an effect of gender ($P = 0.25$) or a treatment × gender interaction ($P = 0.46$). These data suggest that maternal supplementation with 25OHD3 does not alter the expression of these genes at this time during fetal development (90 d of gestation). Further studies are needed to determine if maternal vitamin D supplementation will affect markers of bone formation later during fetal development and postnatal growth.

Key Words: vitamin D, swine, bone

W177 Pituitary genomic expression profiles of steers are altered by grazing of high (HE) versus low (LE) endophyte-infected pastures. R. M. Hegge*, J. A. Boling, and J. C. Matthews, *University of Kentucky, Lexington.*

Consumption of ergot alkaloids in endophyte-infected tall fescue induces a distinct set of physiological and whole-animal performance parameters collectively known as "fescue toxicosis." It is estimated that fescue toxicosis-associated animal performance losses cost cattle farmers about $1 billion annually. Many of these parameters, such as decreased fertility and milk production are consistent with impairment of pituitary functions. The goal of this study was to test the overall hypothesis that consumption of endophyte-infected tall fescue would alter pituitary genomic expression profiles, including genes involved with prolactin (PRL) metabolism, a known marker of fescue toxicosis. Total RNA was extracted from pituitaries of 16 Angus-cross steers (BW = 266 ± 10.9 kg) that had been randomly assigned (n = 8) to graze either HE or LE pastures for 89 d, and for which serum PRL levels of HE steers was only 10% of LE steers (JAS, 2009, 87:748–760). RNA was subjected to microarray analysis using a custom platform (WT Btau 4.0 Array, Affymetrix). Raw expression intensity values were adjusted using Robust Multichip Averaging and then normalized using the GeneChips and Media Polish Summarization algorithms (Partek). Pearson (linear)

Correlation Analysis revealed a high (>0.98) correlation among all chips. ANOVA testing found differential ($P \leq 0.001$) expression of 592 RNA transcripts in HE vs. LE pituitaries. Hierarchical clustering analysis (Partek) of differentially-expressed genes revealed that each animal segregated within its respective treatment group. Bioinformatic analysis identified decreased (17 to 63%) expression in HE steers of genes for prolactin signaling and regulation of lactotroph, gonadotroph, and thyrotroph proliferation (GPR101, DRD2, PCSK1, PRL, PRLR), and altered expression of another 13 genes for gonadotropin releasing hormone-mediated signaling. In conclusion, steers grazing HE pastures had altered pituitary genomic profiles, in a manner consistent with reduced blood PRL and altered whole-body metabolism, hallmarks of fescue toxicosis.

Key Words: pituitary, gene expression, ergot alkaloid

W178 Excess estrus in meat goats: 1-year summary. B. A. Schulte*, L. S. Wilbers, J. D. Caldwell, C. Clifford-Rathert, and A. K. Wurst, *Lincoln University, Jefferson City, MO.*

Excess estrus (EE) occurs when animals exhibit behavioral estrus, or standing heat, after conception. Excess estrus can occur frequently in some domestic farm animals; however, information regarding its frequency in goats is limited. The causes and effects of EE on the reproductive cycle and pregnancy in goats have not previously been studied. The objective of this project was to determine the frequency of EE in meat goats. Hormone profiles of estradiol-17β (E_2) and progesterone (P_4) during pregnancy and quantity of embryonic and fetal losses (near d 25, 40, 60, and 110) were recorded to determine if does displaying EE were more prone to reproductive dysfunction. In winter 2011, ultrasonographic examination was used to determine pregnancy in 132 bred Boer and Boer-cross does. One vasectomized buck fitted with a marking harness was placed with does following breeding to detect does displaying EE (EE does). Does were checked for breeding marks daily. Results of this study indicate that of 105 does confirmed pregnant, 21 (20%) showed EE at least once during pregnancy. Concentrations of E_2 and P_4 were lower in EE does compared with does not displaying EE near d 25 of pregnancy (5.9 vs. 7.3 pg/mL; 7.5 vs. 10.8 ng/mL, respectively). Concentrations of P_4 remained lower in EE does through d 40 (8.7 vs. 10.2 ng/mL) and tended ($P = 0.07$) to remain lower through d 60 (10.2 vs. 11.9 ng/mL) of pregnancy. On a percentage basis, fetal and embryonic losses were greater in EE does (29% vs. 15%); however, there was not enough animals to determine significance. Of does kidding, kidding rate of EE does compared with does that did not show EE was not different (1.6 vs. 1.5 kids/doe, respectively; $P = 0.72$).These results suggest that EE may occur in a significant portion of pregnant meat goats and may be associated with differences in embryonic and/or fetal losses of these animals. This project was supported by USDA-NIFA Cooperative agreement.

Key Words: goat, estrus, behavior

W179 Physicochemical analyzes of Longissimus dorsi muscle for checking the quality of meat from cattle Nellore (*Bos indicus*) selected for production. J. M. Malheiros*[1], W. A. Baldassini[2], L. A. L. Chardulo[3], J. A. V. Silva[2], and L. G. Albuquerque[1], *[1]UNESP-FCAV, Jaboticabal, SP, Brazil, [2]UNESP-FMVZ, Botucatu, SP, Brazil, [3]UNESP-IB, Botucatu, SP, Brazil.*

Tenderness is a major quality attribute of beef that affects consumer satisfaction, consumption habits and retail preferences. Hence, breeding programs that focus on meat tenderness are important for Brazil given the prevalence of *Bos indicus* breeds in the cattle industry [1]. The present work aims to determine traits in meat quality in Longissimus dorsi muscle of Nellore cattle from 10 farms in 5 Brazilian states that currently are selecting for meat tenderness traits in their breeding programs including analysis shear force (SF), rib eye area (REA), fat thickness (FT), myofibrillar fragmentation index (MFI) and total lipids (TL). The results of the analysis in this study show verified average and standard deviation for each analysis and the correlation of this with the value of shear force. It is the average value and standard deviation of 4.3 ± 1.25 for SF analysis, which confirms the tenderness of the meat in question since it did not exceed the limit accepted for the meat to be considered tender, ie, 4.5 kg [2]. The MFI value found was heavily influenced by postmortem, where the meat showed satisfactory average 63.19 ± 16.26 denoting high tenderness of the analyzed meat, as Culler et al. (1978) [3] values above 60 to qualify as tender flesh. It has been shown a significant correlation ($P < 0.01$) between SF and MFI, as these characteristics are inversely proportional. It has also been found significant correlations ($P < 0.05$) for the analysis of REA (65.49 ± 7.98) and TL (0.76 ± 0.36). For FT (5.26 ± 3.2) there was not a significant correlation ($P < 0.05$) with SF. Therefore, the use of physical and chemical analysis and correlations with shear force, can be used as a tool in verifying the quality of beef, mainly for Nellore (*Bos indicus*), showing a herd with a deficit for such.

Key Words: meat tenderness, myofibrillar fragmentation index, shear force

W180 Bioanalytical methods for calcium proteomic study on tenderness Longissimus muscle of Nellore cattle (*Bos indicus*). W. A. Baldassini[1], J. M. Malheiros*[2], L. A. L. Chardulo[2], J. A. V. Silva[2], L. G. Albuquerque[2], and P. M. Padilha[3], *[1]UNESP/FMVZ, Sao Paulo State University, Botucatu, Brazil, [2]UNESP/FCAV, Sao Paulo State University, Jaboticabal, Brazil, [3]SUNESP/IB, Sao Paulo State University, Botucatu, Brazil.*

The calpain system is a complex of proteases activated by calcium as the μ-calpain and m-calpain and its endogenous inhibitor, the calpastatin and are related to proteolysis and meat tenderness [1]. This study examines the separation of skeletal muscle proteins by 2D-PAGE and performing the identification of calcium ions in the protein spots by x-ray fluorescence (SR-XRF) for the 20 Nellore cattle (*Bos indicus*) contrasting meat tenderness: tough (TO) and tender (TE) meat animals. A third group (PI) with Piedmontese cattle (*Bos taurus*) was used as a comparative model of meat tenderness degree. The 3 groups were selected according by the rib eye area and backfat as well the shear force values [2]. The resolution of the gels (matching > 50%) and the image analysis between groups TO, TE and PI showed a correlation between gels of (n = 3) 82%, 54% and 53%, respectively. The average numbers of protein spots in repetitions gels were 176 ± 22, 172 ± 31 and 204 ± 33 for the groups TO, TE and PI, respectively. This standard deviation below 20% can be regarded as a good indication of the proteins fractionation by 2D-PAGE [3]. In the study images of the gels were estimated correlations between protein spots for the groups. The correlation between the spots of the protein was varied in the different groups TE and PI (R > 0.85) as well the gels of the TO and PI groups (R > 0.73). In the qualitative assessment of calcium ions by SR-XRF were randomly chosen 60 protein spots from the experimental groups, with molar weight (MW) between 20 and 97 kDa [4]. There was higher detection (56%) of calcium by SR-XRF in protein spots TE group, a factor that may be indicative of proteolytic activity in meat after slaughter. The 2D-PAGE in the evaluation study of the calpain system was effective in the fractionation of proteins present in Longissimus muscle. The correlations obtained in the 2D gels indicated that the procedures for extraction of total protein were

efficient and preserved the metal-protein structure. However, it was possible to make a detection of calcium in protein spots by SR-XRF with MW between 20 and 97 kDa.

Key Words: calpain system, 2D-PAGE, shear force

W181 The effects of selecting for the myostatin F94L polymorphism on reproductive traits in pubertal heifers. E. D. Forbes*[1], O. L. Swanson[2], A. K. McNeel[3], R. G. Tait Jr.[3], T. P. L. Smith[3], G. L. Bennett[3], T. A. Hoagland[1], S. A. Zinn[1], C. A. Lents[3], G. A. Perry[2], and R. A. Cushman[3], *[1]University of Connecticut, Storrs, [2]South Dakota State University, Brookings, [3]US Meat Animal Research Center, Clay Center, NE.*

The myostatin F94L polymorphism influences carcass traits in steers; however, the influence of this polymorphism on female reproductive performance should be characterized as part of using it for marker assisted selection. Results from USMARC indicate that heifers that are homozygous for the L allele (L) reach puberty later than heifers that are homozygous for the F allele (F, wild-type), but no one has investigated the influence of this polymorphism on reproductive function in pubertal heifers. We hypothesized that reproductive function would be decreased in heifers that were L. Homozygous heifers that were pubertal (n = 5/genotype) were synchronized with 2 shots of PFG2a given 11 d apart and observed every 4 h for behavioral estrus with the aid of estrus detection patches. Heifers were slaughtered on d 4 after estrus, and the uterus, ovaries, and anterior pituitary were collected, measured, and weighed. A representative piece of one ovary was fixed for histological evaluation, and a sample of subcutaneous adipose was collected and frozen to measure relative levels of chemerin mRNA, a marker of adiposity. Follicular fluid was aspirated from all small follicles (1–5 mm), pooled within heifer, and frozen. Data were analyzed using a MIXED model with genotype as a fixed effect. Heifers that were F had lighter birth weights than heifers that were L ($P = 0.04$), but there was no difference in weaning weight, slaughter weight, or chemerin mRNA levels in the adipose. Heifers that were L exhibited behavioral estrus 14 h sooner after PGF2a than heifers that were F ($P = 0.06$). There was no difference in reproductive organ measurements or numbers of follicles in the ovaries between genotypes. Follicular fluid estradiol concentrations tended to be greater in L heifers than F heifers ($P = 0.10$). Reproductive tract development is not altered in heifers homozygous for the L allele, although they reach puberty later. A shorter time from PGF2a to estrus indicates that timing of insemination in timed-AI protocols may need to be altered for L heifers. USDA is an equal opportunity provider and employer.

Key Words: heifer, myostatin, puberty

W182 Epidemiology of synchronization programs for breeding management in US dairy herds. A. H. Souza*[1,2], P. A. Carvalho[1], R. D. Shaver[1], M. C. Wiltbank[1], and V. Cabrera[1], *[1]Department of Dairy Science, University of Wisconsin, Madison, [2]Ceva Sante Animale, Libourne, France.*

The aim of this study was to evaluate the use of synchronization programs in US dairy herds. Reproductive records from DHIA (AGSource, Agritech, and DRMS) were analyzed. The final data set included artificial insemination records from 2008 to 2012 and restricted to AI-breedings with confirmed pregnancy outcome. Only herds reporting at least 30 breedings in the last 12 mo were included. A total of 1,142,821 breeding records from 40 states were available for the 1st analysis. Breeding codes were classified within herd into either AI-to-estrus (EAI) or synchronized-AI (SAI) based on weekly insemination profile for each herd. Within-herd, synchronized breedings were assumed when more than 30% of the breedings happened on the same day of the week, remaining breedings for the same herd were considered non-synchronized. Overall, 29.9% of the breedings happened after the use of synchronization programs, with great variation throughout states. The leading states in terms of proportion of SAI that reported more than 5,000 breedings were SD = 56%, WI = 46%, IA = 43%, OH = 40%, MI = 32%, NY = 29%, PA = 27%, MN = 24%, VA = 23%, and SC = 23%. Out of all SAI breedings, 78% happened on Thursdays and Fridays. There were no significant differences in conception results between SAI (32.6%) and EAI (33.4%), with no interactions with breeding month. Herd size information was available for a further data set from WI herds with 207,506 breedings. Findings in regards to herd size and use of SAI at 1st AI in herds in WI are shown in Table 1, which indicates that SAI is used in most 1st postpartum AIs and larger herds seem to use more SAI at 1st AI and have lower days to 1st AI without compromising conception outcomes. In summary, these results indicate that most dairy herds in US use synchronization strategically as part of their breeding program. Supported by Accelerated Genetics.

Table 1.

Herd size	ME305 (kg)	SAI – 1st AI (%)	DIM at 1st AI (d)	P/AI at 1st AI (%)
<300 (n = 54,199 AI)	13,104[a]	47.4[a]	80.2[a]	36.5[a]
300-1000 (n = 89,336 AI)	14,082[b]	66.4[b]	76.0[ab]	35.5[a]
>1000 (n = 63,971 AI)	14,527[c]	75.3[c]	72.0[b]	35.1[a]

Key Words: dairy farm, timed AI, synchronization

W183 Effects of different stall type and bedding materials on lactation length, milk yield and some health problems in dairy herds. N. K. Kara*[1], A. Galiç[2], and M. Koyuncu[1], *[1]Uludag University, Bursa, Turkey, [2]Akdeniz University, Antalya, Turkey.*

This study was carried out to determine effects of 2 different stall types and 3 different bedding materials on lactation length, milk yield and some health problems in dairy herds. 477 lactation cows in 37 herds in Bursa were examined. Mean of lactation length (day) and milk yield of cows in the same herd was calculated to determine the effects. A *t*-test was used to compare the means of free-stall or tie-stall herds, and one-way ANOVA was used to compare the means of herds with concrete, sand or rubber bedding. To test the association between stall type or bedding material and some health problems, Chi-squared test was used. According to the results, a significant difference was determined between 2 stall types, in terms of milk yield ($P < 0.01$), while mean of milk yield and lactation length of herds with rubber bedding were found higher than the others ($P < 0.01$). The associations between stall type and repeat breeding, dystocia and retained placenta were found to be significant ($P < 0.01$, $P < 0.01$ and $P < 0.05$, respectively). Also, it was found that repeat breeding and clinical mastitis were associated with bedding material ($P < 0.05$ and $P < 0.01$, respectively). The results of the present study indicate that by providing suitable stall type with better bedding materials, animals can be kept healthy, expenditures on medical treatments can be minimized and consequently profitability can be increased.

Key Words: bedding material, stall type, lactation length

W184 Genetic and phenotypic trends for milk yield in Holstein populations in Mexico. H. O. Toledo[1], F. J. Ruiz[2], C. G. Vazquez[1], J. M. Berruecos[1], and M. A. Elzo*[3], *[1]Universidad Nacional Autonoma de Mexico, Ciudad de Mexico, DF, Mexico, [2]INIFAP, Queretaro, Queretaro, Mexico, [3]University of Florida, Gainesville.*

The objectives were to evaluate genetic and phenotypic trends from 2007 to 2011 for milk yield in 3 Holstein populations representing 14% of the milk production in Mexico. Data consisted of first-lactation milk yields adjusted to 305 d, adult equivalent and 2 milkings/d. Records were from the Holstein Association of Mexico (HAM; n = 43,668), the National Bank of Dairy Information (NBDI; n = 120,217), and the National Breeding Program of Mexico (NBPM; n = 163,885) which included records from HAM and NBDI. Best Linear Unbiased Predictions of breeding values (BV) were computed with ASREML using a mixed animal model. Fixed effects were herd-year-season. Random effects were animal and residual. Weighted and unweighted yearly means of sire BV were computed for HAM, NBDI, and NBPM. Weights were numbers of daughters per sire per year. Weighted yearly means of sire BV in NBPM were also computed by country of origin (USA, Canada, México, Other). Lastly, yearly means of cow BV and phenotypic values (PV) were obtained for HAM, NBDI, and NBPM. The mean BV and PV of cows for milk yield in the HAM, NBDI, and NBPM populations increased between 2007 (BV = 108.4 ± 5.7 kg; PV = 217.3 ± 25.4 kg) and 2011 (BV = 242.9 ± 3.3 kg; PV = 486.3 ± 14.0 kg). Differences between yearly means indicated that cow BV from HAM tended to be higher than cow BV from NBDI (from 32.2 kg in 2009 to 47.2 kg in 2010). Holstein sires from the US tended to have substantially higher yearly mean BV for milk yield (from 722.4 kg in 2008 to 991.3 kg in 2010) than Holstein sires from Mexico. Breeders from HAM tended to choose sires with higher BV for milk yield (401.9 ± 15.1 kg) than those from NBDI (396.5 ± 11.0 kg). However, differences in weighted yearly means (from 221.9 kg in 2008 to 101.8 kg in 2010) suggested that NBDI breeders used sires with higher BV for milk yield more frequently than HAM breeders. Greater utilization of sires with increasingly higher BV for milk yield allowed dairy breeders in Mexico to consistently increase cow genetic and phenotypic means from 2007 to 2011.

Key Words: genetic trend, phenotypic trend, milk yield

W185 Genetic parameter estimates for rump traits and teat length in a multibreed dairy cattle population in Thailand. B. Wongprom[1], S. Koonawootrittriron[1], M. A. Elzo*[2], and T. Suwanasopee[1],

[1]*Kasetsart University, Bangkok, Thailand,* [2]*University of Florida, Gainesville.*

Hip width (HW, cm), pin width (PW, cm), hip to pin length (HP, cm), hip height (HH, cm) and teat length (TL, cm) of cows are important for reproduction and production efficiency of a dairy business. Most dairy cattle in Thailand and other Asian tropical countries are multibreed where Holstein is a major component breed (mean = 87%; SD = 9%) and both purebred and crossbred animals are regularly selected as parents of the next generation. The objective of this study was to estimate genetic parameters for rump traits (HW, PW, HP and HH) and TL of dairy cattle in a multibreed dairy population in Thailand. The data set consisted of pedigree and phenotypic information for HW, PW, HP, HH, and TL from 868 cows located in 122 farms across Thailand. The data were analyzed using a multiple-trait animal model that accounted for the fixed effects of herd, Holstein fraction, and age of cow, and the random effects of animal and residual. An average information-restricted maximum likelihood procedure was used to estimate variance components. Estimates of variance components were subsequently used to compute heritabilities and genetic correlations. Means and SD were 55.13 cm and 4.91 cm for HW, 18.49 cm and 2.40 cm for PW, 51.74 cm and 3.27 cm for HP, 134.07 cm and 5.52 cm for HH, and 5.07 cm and 1.43 cm for TL. Heritability estimates were high for HW (0.42 ± 0.10), medium for PW (0.23 ± 0.09) and HP (0.25 ± 0.10), and low for HH (0.11 ± 0.08) and TL (0.12 ± 0.09). Most genetic correlations ranged from medium (0.35 ± 0.28 between HP and PW) to high (0.91 ± 0.45 between PW and HH). The only low correlations were between TL and PW (0.14 ± 0.39) and between TL and HH (0.19 ± 0.54). These estimates of heritability and genetic correlations indicated that it would be feasible to develop a genetic improvement program for rump traits and teat length in this multibreed population.

Key Words: dairy, genetic parameter, type trait

W186 Genotype by environment interaction effect on lactation pattern and milk production traits in an Ethiopian dairy cattle population. G. Gebreyohannes[1], S. Koonawootrittriron[1], M. A. Elzo*[2], and T. Suwanasopee[1], [1]*Kasetsart University, Bangkok, Thailand,* [2]*University of Florida, Gainesville.*

The objective of this study was to evaluate the effect of genotype by environment interaction (GEI) on lactation pattern and milk production traits in an Ethiopian multibreed dairy cattle population. The analyses used 4,488 lactation milk records of 1,320 cows born from 254 sires and 896 dams collected in 2 research centers (Bako and Holetta) from 1979 to 2010. Breeds present in the population were Horro, Boran, Friesian, Simmental and Jersey. Traits were lactation milk yield (LY), initial milk yield (IY), peak milk yield (PY), average milk yield per day (YD), lactation length (LL) and days to peak (DP). The effect of GEI was tested using a fixed linear model that considered herd-year-season, parity, environment (Bako and Holetta), breed and the interaction between breed and environment as fixed effects, and residual as a random effect. Lactation length was considered as a covariate for the analysis of LY. Least squares means (LSM) were compared among subclasses of each factor. All factors in the model affected LY, IY, PY, YD and LL ($P < 0001$). The effects of breed and breed by environment interaction on DP were not significant. All traits had significantly ($P < 0001$) higher LSM values in Holetta than Bako. Friesian crossbred cows in Holetta had significantly higher LSM for LY (2111.9 ± 16.87 kg), IY (9.2 ± 0.08 kg), PY (11.6 ± 0.08 kg) and YD (6.6 ± 0.05 kg) than Simmental and Jersey crosses. The LSM for LY, PY and YD were significantly ($P < 0.0001$) higher for Friesian and Simmental than for Jersey crossbreds in Bako. However, the LSM IY and LL were not significantly ($P > 0.05$) different among Friesian, Simmental and Jersey crossbred cows. The LSM of LY, IY, PY, YD and LL for Boran and Horro were not different in both environments. In Holetta, the Jersey and Simmental were not significantly different for the LY, IY, PY and YD. Thus, Friesian sires can be recommended for crossbreeding with Boran or Horro in Holetta, and Friesian, Simmental and Jersey sires in Bako.

Key Words: dairy cattle, genotype by environment interaction, multibreed

W187 Impact of sire by region interaction on first-lactation traits of dairy cows raised under tropical conditions in Thailand. P. Yodklaew[1], S. Koonawootrittriron[1], M. A. Elzo*[2], and T. Suwanasopee[1], [1]*Kasetsart University, Bangkok, Thailand,* [2]*University of Florida, Gainesville.*

Initial yield (IY), peak yield (PY), days to peak yield (DP) and persistency (PS) are traits associated with milk yield (MY) in dairy cattle. Daughters of the same sire could have different lactation curve traits (IY, PY, DP, and PS) and MY in different regions. Thus, the objective of this study was to investigate the effect of sire-by-region interaction on first-lactation traits in 3 regions of Thailand. The data set contained 27,276 monthly test-day records from 2,431 first-lactation cows raised in 294 farms located in Central, Northeastern and Southern Thailand. Wood's gamma function was used to estimate IY, PY, DP, PS, and MY for individual cows using their monthly test-day records. A fixed linear model was used to avoid sire-by-region interactions due to unequal numbers of daughters per region. The fixed linear model included herd-year-season, calving age, Holstein fraction, and interaction between sire and region as fixed effects, and residual as a random effect. Sires were ranked in each region using their least squares means and correlations between sire rankings across regions were computed. Herd-year-season affected ($P < 0.001$) all lactation traits and calving age only influenced PY ($P = 0.02$). Holstein fraction had no effect on any trait and sire-by-region interaction had an effect only on PY and MY ($P < 0.001$). Correlations between sire rankings in the Central and Northeastern regions, Central and Southern regions, and Northeastern and Southern regions were low or close to zero for PY (−0.01 to 0.05) and MY (0.03 to 0.29). These results suggested that sires would affect their daughter's first-lactation PY and MY differently if they were located in different regions of Thailand. Thus, sires would need to be selected based on their genetic superiority in each region to optimize genetic improvement for milk production in this Thai population.

W188 Optimal age at first calving for US dairy cattle. J. B. Cole, J. L. Hutchison*, D. M. Bickhart, and D. J. Null, *Animal Improvement Programs Laboratory, Agricultural Research Service, USDA, Beltsville, MD.*

Heifer rearing is a major expense for the US dairy industry that accounts for 15 to 20% of the total cost of producing milk. Selecting for an optimal age at first calving (AFC) in US dairy cattle could reduce these costs while still providing animals with high lifetime yields. Records from 9,502,802 Holstein (HO), 611,939 Jersey (JE), and 46,580 Brown Swiss (BS) cows with first calvings from January 1, 1997 to present were selected for analysis. A linear model included the fixed effects of herd-year of calving, year-state-month of calving, and AFC, grouped into 50-d intervals. The traits analyzed included, milk yield, composition, and persistency; fertility; and longevity. Contrary to current age adjustment factors, the highest first-lactation milk yield occurred at an AFC between 651 to 700 d (21 to 23 mo) for HO, resulting in an increase in milk production of 58 kg compared with animals with an AFC between 701 to 750 d (23 to 25 mo). Similarly, fat, protein, and persistency of milk in HO showed an increase of 1.86 kg, 2.08 kg, and 0.05, respectively, for the same AFC

interval. For JE, the highest yields occurred at 601 to 650 d (20 to 21 mo), with increases of 129 kg, 5.18 kg, 4.45 kg, and 0.12 for milk, fat, protein, and persistency of milk, respectively. The greatest yields for BS occurred between 701 to 750 d, although they did not differ from the yields of the 651 to 700 d or 751 to 800 d groups. Heifers from all breeds calving between 601 to 750 d showed an increase in heifer and cow conception rates compared with those calving later. Lifetime traits (up to 5 parities) showed the same optimal HO AFC, with differences between 651 to 700 d and 701 to 750 d of +589 kg, +21.14 kg, +18.23 kg, +11 d, and +0.90 d for milk, fat, protein, days in milk, and days open. For JE, differences between 601 to 650 d and 701 to 750 d were +1397 kg, +64.21 kg, +50.03 kg, +33 d, and +0.72 d, respectively. These results show that the optimal AFC is actually 75 to 130 d less than the breed averages published in 2010, suggesting that a reduction in AFC may improve profitability and fertility in HO and JE cattle.

Key Words: age at first calving, milk production, fertility

W189 Evaluation of genetic advance of production traits in Shenxing dairy farm from 2002 to 2012. G. Yao[1], H. Liming[2], L. Guanglei*[1,2], Z. Changbin[1], and F. Fengshou[1], *[1]Shanghai Dairy Breeding Center Co., Ltd., Shanghai, China, [2]State Key Laboratory of Dairy Biotechnology, Shanghai Bright Holstan Co., Ltd., Shanghai, China.*

Genetic trends of milk, fat and protein yield (305 d, 1st lactation) from the Shenxing dairy farm in Shanghai were evaluated for genetic trend by best linear unbiased prediction. Original data consisted of 13,548 production records between 2002 and 2012 were obtained from Dairy Herd Improvement (DHI) project of Shanghai Dairy Breeding Center. Generation interval from sire to daughter was 6.48 years and from dam to daughter was 5.84 years, with an average of 6.16 years. Heritability of milk, fat and protein yield was calculated by half-sister correlation analysis. Heritability estimates were 0.27, 0.16 and 0.14 for milk, fat, and protein yield. Average genetic trend for milk yield was about 71 kg per year over 11 years, an increase about 0.84% per year (60 to 67 kg per year in the first 6 years, about 0.71 to 0.79% of average genetic progress; about 70 to 86 kg in the later 5 years, approximately 0.82% to 1.01% of average genetic change). Average genetic advance of fat and protein yield were about 2.1 kg and 1.1 kg per year, the average genetic progress were about 0.45% to 0.82% in fat yield and 0.37% to 0.56% in protein yield. Our results showed that the genetic level of yield traits in Shanghai Holstein herd have increased in the past 11 years, and that meant the improvement project of Shanghai Holstein herd is effective.

Key Words: genetic advance, generation interval, heritability

W190 Genetic parameters for test-day milk, fat, protein and mozzarella yield using random regression models in buffaloes. N. Hurtado-Lugo*[1,2], R. Aspilcuelta[1], G. M.F. de Camargo[1], M. Cerón[2], and H. Tonhati[1], *[1]State University of São Paulo, Faculty of Agriculture and Veterinary Sciences, Jaboticabal, São Paulo, Brazil, [2]University of Antioquia, Medellín, Antioquia, Colombia.*

Buffalo milk is used mainly for the production of milk derivatives due to the compositional and physicochemical quality of its components. Random regression models (RRM) can be applied to test-day milk yield as an alternative to standard procedures used for the genetic evaluation of longitudinal traits in dairy cattle. We aim was to estimate covariance functions for additive genetic and permanent environmental effects and, subsequently, genetic parameters for milk (MY), fat (FY) protein (PY) yields and mozzarella cheese production(MP) in buffaloes from Colombia using RRM with orthogonal Legendre polynomials (LP). Data of test-day MY, FY, PY and MP of 1884 first lactation buffaloes were analyzed. They were daughters of 228 sires from 14 herds in Colombia with calving between 1995 and 2011. For test-day, 10 mo classes of lactation days were considered. Herd-year test day was used as a contemporary group. The random effects in the model included: additive genetic effect, permanent environment and residual and the fixed effects of contemporary group, buffalo age at calving (linear and quadratic effect) and mean lactation curve of the population modeled by LP of 3rd order. The residual variances were modeled with homogeneous structures and many heterogeneous classes. The variance components were estimated using the statistical package WOMBAT. According to the REML test, the best model for MY was with 4 classes of residual variances, considering LP of 3rd and 5th order for additive genetic and permanent environment effects respectively. For FY, PY and MP, the best model was with 4 classes of residual variances, considering LP of 3rd and 4th order for additive genetic and permanent environment effect respectively. The heritability estimates for MY, FY, PY and MP varied from 0.38 to 0.05, from 0.67 to 0.11, from 0.50 to 0.07 and from 0.50 to 0.11, respectively. In general, the RRM were adequate do describe the genetic variation in test-day of MY, FY, PY and MP in Colombian buffaloes.

Key Words: animal model, heritability, mozzarella

W191 Rate of genetic progress and breeding values in commercial dairy herds using young versus daughter proven sires. C. D. Dechow*[1] and G. W. Rogers[2], *[1]Penn State University, University Park, [2]Geno Global Ltd., Hamar, Norway.*

The objective of this study was to evaluate the rate of genetic progress and breeding values (BV) of cows in commercial dairy herds using young sires (YS) with genomic BV versus daughter proven sires (PS). Genotypes were simulated at 1000 loci for a nucleus herd of 1000 animals (500 bulls and 500 cows) born each year and a commercial herd with 500 cows born annually. Allele effects were −1 or 1 for all loci and accuracy was 100% for initial scenarios as BV was obtained by summing allele effects across loci. Young bulls and cows were selected beginning at 2 years of age and ending at 3, versus a range of 6 to 7 years for PS. Young sires and dams from the top 10% of BV were selected for the nucleus herd. Sires for commercial cows were selected from the top 10%, 25%, or 100% of the nucleus population. Thirty years of selection were simulated and results among scenarios were compared for years 11 to 30. The average generation interval for the nucleus herd was 2.22 years and the actual genetic progress of 0.75 additive genetic standard deviations per year was close to expectations from the genetic progress formula (0.79). The rate of genetic progress in commercial herds (0.73 to 0.77) was nearly identical to progress in the nucleus herd regardless of whether YS or PS were selected. The BV of cows in PS scenarios lagged behind cows in YS scenarios by 4 years when selection intensity was identical between YS and PS, which was equivalent to the difference in generation interval. The lag was reduced to 1.5 years when the top 10% of PS were selected versus the top 100% of YS. Scenarios were considered where accuracy was reduced by adding a random noise term to the BV before making selection decisions. Higher accuracy for PS further reduced the lag between YS and PS scenarios. It was concluded that the rate of genetic progress in commercial herds may not differ for YS versus PS selection strategies, but that average BV at a specific point in time will vary depending on differences in generation interval, selection intensity, and accuracy. Genetic progress predictions may need to consider interdependencies among selection pathways.

Key Words: genomic, genetic progress

W192 Evaluation of sources of variation and estimation of productive parameters using multi-trait animal models in dairy buffaloes in Pakistan. S. M. Suhail*[1,2], M. S. Qureshi[2], I. Ahmed[2], H. Akbar[1], M. J. Khan[1], and J. J. Loor[1], *[1]University of Illinois, Urbana, [2]KPK Agricultural University, Peshawar, Pakistan.*

Buffalo is the major source of milk production in Asia. Production performance of buffaloes raised at 3 state farms of Pakistan was studied using complete milk records from 5,026 lactations. Economic traits including lactation yield (LY), standard 305-d yield (SY), peak daily milk yield (PY), average daily milk yield (DY) and lactation length (LL) were studied. A general linear model (GLM) procedure was used to study the effect of herd, year, season of calving and sire nested into herd, parity and age at puberty × season of calving on production traits. Birth weight, square of birth weight, lactation length, calving interval, age at puberty and age at first calving were used as covariates. Average LY was 2,076 ± 4.94 (1,524 to 3,723 kg) while SY was 2,200 ± 5.93 kg (1,540 to 3,852 kg). PY and DY averaged 9.9 ± 0.05 and 7.1 ± 0.02, respectively. Mean LL was 294 ± 0.49 (181 to 435 d). Herd, sire nested into herd and parity had a significant effect on lactation yield, while the effects of year, season of calving, year × season and age at puberty × season were nonsignificant. Among covariates, birth weight and lactation length had a significant effect on lactation yield. Similarly, standard 305-d milk yield was significantly affected by sire within herd and parity. Among covariates birth weight, square of birth weight, lactation length and calving interval affected the SY. Year and season of calving and their interaction affected PY. Among covariates the length of lactation affected the PY. Herd, sire within herd and parity significantly affected DY. Among covariates, birth weight, square of birth weight and lactation length affected the DY. Lactation length was affected by herd, sire nested into herd and parity. Standard 305 d milk yield was affected positively by birth weight while increasing parity increased milk yield up to third parity. It is concluded that the milk production ability of dairy buffaloes improves by increasing the birth weight and maturity, while keeping the calving interval shorter and the parity up to third lactation.

Key Words: lactation, animal model, dairy buffalo

W193 Development of a Monte Carlo simulation model to quantify genetic progress from an emerging in vitro fertilized embryo transfer dairy reproduction system. K. Kaniyamattam*, J. Schneider, and A. De Vries, *University of Florida, Gainesville.*

Objective of this study was to develop a Markov chain Monte Carlo simulation model to quantify genetic progress from an emerging in vitro fertilized (IVF) embryo transfer dairy reproduction system. The hypothesis is that IVF coupled with genomic testing of calves will rapidly accelerate the genetic gain from the female side. The model simulated individual dairy young stock and cows day by day for 20 years into the future. Individual animal performance was modeled using functions for feed intake, milk production, reproduction, body weight, risk of culling and genetic merit. The model was parameterized to represent an average US Holstein dairy herd. Phenotypic milk production was dependent on genetic merit. All heifer calves born were assumed to be genomically tested and ranked based on a Net Merit index, drawn from a normal distribution. A fixed cow herd size was assumed. The extra heifer calves were sold and the bull calves were sold within 2 weeks after birth. The top 5% of heifers from 10 mo of age to 5 mo of pregnancy were used as oocyte donors. The donor list was updated each month. Oocytes were collected from each donor 4 times per month. The collected oocytes were in vitro fertilized. On average there were 5 transferable embryos per collection. All open eligible heifers and cows were observed for estrus 3 d after giving prostaglandin. It was assumed that only 66% of eligible animals came into estrus. The recipients were randomly chosen. The recipients on d 6, 7, 8 of the estrus cycle were transferred with a d 7 embryo. Surplus embryos were frozen if there were not enough recipients available and AI was used if there were not enough embryos (fresh or frozen) available. The model was developed in JAVA. Preliminary results showed an increase in Net Merit of $30 per year based on selection on the female side. The model will be further used for evaluations and sensitivity analyses of management factors that affect genetic progress and profitability of this reproduction system such as genomic testing strategy and selection of recipients.

Key Words: in vitro fertilization, embryo transfer, genetic gain

W194 Heritability estimates of performance and health traits of Holstein calves. M. Mousa*[1,2], A. Seykora[2], H. Chester-Jones[3], D. Ziegler[3], and J. Cole[4], *[1]Department of Animal Production, Faculty of Agriculture, Assiut University, Assiut, Egypt, [2]Department of Animal Science, University of Minnesota, Saint Paul, [3]University of Minnesota, SORC, Waseca, [4]Animal Improvement Programs Laboratory, ARS-USDA, Beltsville, MD.*

The objective of this study was to estimate heritabilities of performance and health traits of Holstein calves. These traits were available on 6,390 AI sire-identified Holstein heifer calves reared at University of Minnesota, SROC facility. Calves were picked-up at 2 - 4 d old from 3 Minnesota commercial dairy farms during the period April 2003 to May 2012. Calves were removed from the data set if they were in sire progeny groups of less than 2, leaving 6,189 observations for analyses. Performance traits were BW (W56) and hip height (HH56) at 56d of age, BW (LBW) and hip height (LHH) at approximately 200d of age, daily gains in the nursery from arrival to weaning at 56d of age (WADG) and from arrival to 200d of age (LADG). Health traits were coded relative to number of incidences that required treatment during the first 56d of age (0, 1, 2 treatment incidences). The Proc MIXED procedure of SAS 9.1 was used to estimate variance components with sire fitted as a random variable. Significant fixed effects ($P < 0.01$) in the model were year of birth, month of birth, year of birth × month of birth, arrival BW and serum protein level fit as a covariate. Performance traits were moderately heritable, with estimates ranging from 0.25 to 0.37. Health traits had low heritabilities, ranging from 0.01 to 0.06. Results suggest that calf performance and health can be improved genetically.

Table 1. Performance and health traits

Performance trait	Average	SD	Sire variance	Residual	Heritability
W56 (kg)	74	9.38	2.5447	35.9814	0.26
HH56 (cm)	90	3.29	0.3357	5.128	0.25
LBW (kg)	206	21.90	29.9901	285.46	0.37
LHH (cm)	114	3.66	0.8692	8.9867	0.35
WADG (kg/d)	0.62	0.13	0.0008	0.0115	0.26
LADG (kg/d)	0.86	0.09	0.0004	0.0056	0.29

	Incidence occurrence (%)					
Health trait	0	1	2	Sire variance	Residual	Heritability
Scours	49.78	50.05	0.17	0.0034	0.2417	0.06
Respiratory	99.48	0.51	0.01	0.0005	0.0485	0.04
Navel	99.57	0.38	0.05	0.0002	0.0592	0.01

Key Words: heritability estimate, performance and health traits, Holstein calf

Breeding and Genetics: Applications and Methods in Animal Breeding—Pigs, Poultry, Sheep, and Horses

W195 Genetic analysis of the stayability for running of Thoroughbred horses. J. A. V. Silva*, L. H. Kato, A. M. Maiorano, R. A. Curi, and M. D. S. Mota, *Faculdade de Medicina Veterinaria e Zootecnia, UNESP, Botucatu, Sao Paulo, Brasil.*

Stayability is an economically relevant trait; it is directly associated with profitability of the production system by its relationship to specific costs or with efficiency. In this work, stayability is analyzed in racehorses and defined as stayability for running up to 4 years old (STAY4) and up to 6 years old (STAY6). Inclusion of this trait in genetic evaluation programs may permit selection of stallions that will have offspring with a greater probability of remaining productive (running) for a longer period of time. The objectives of the current study were to assess the feasibility of using stayability for running traits to improve the genetic potential of Thoroughbred horses and to examine the genetic relationship between STAY4 and STAY6. Stayability was considered to be a categorical trait and defined as whether a horse (male or female) that remained running up to the age of 4 (STAY4) and 6 (STAY6) yr of age, given that the opportunity to participate in races was provided. Data was gathered for 23,009 and 20,005 animals for STAY4 and STAY6, respectively, born from 1989 onward with performances between 1992 and 2010 analyzed using 2 trait animal threshold model based on Gibbs sampling algorithm. The matrix relationship included 35,422 animals until 6th generation. 60% and 17% were scored 1 for STAY4 and STAY6, respectively. Animals with stayability for running until evaluated ages were scored as 1, and those that failed were scored as 0. Analysis included fixed effects of breeder, breeding season, age at first competition and the linear covariate, the number of races to ages studied, in addition to the random animal effect. The sex and race distance effects were not include in the model because these were not significant. Heritability estimates for STAY4 and STAY6 were 0.12 ± 0.03 and 0.13 ± 0.03, respectively. The genetic and residual correlation estimates between the 2 traits were 0.48 ± 0.18 and 0.92 ± 0.03, respectively. Based on the results of this study, STAY can be used for selection of stallions for horse racing. Competition data provide a good tool for measuring the stayability for running in horses.

Key Words: heritability, genetic correlation, residual correlation

W196 Population parameters in Quarter Horses in Brazil. M. D. S. Mota, R. A. Curi, G. L. Pereira, A. C. Verdugo, and J. A. V. Silva*, *Faculdade de Medicina Veterinaria e Zootecnia, UNESP, Botucatu, Sao Paulo, Brasil.*

The Quarter Horse was first bred in Brazil from horses imported from the King Ranch in Texas, United States. Since the founding of the Brazilian Association of Quarter Horse Breeders (ABQM) in 1969, there have been approximately 360,000 animals and just over 61,000 breeders, owners and associated in ABQM. In 2012, breeders conducted auctions involving 5,372 horses at an average price of US$15,000. The objective of this study was to estimate population parameters of Quarter Horses registered by ABQM. We considered 122,355 animals born from 1950 to 2009. Of this total, 5,397 (4.41%) were inbred, with an average inbreeding coefficient of 8.56% and a maximum of 37.5%. To study the probability of origin of genes, we established a reference population of 56,329 animals born between 1980 and 2009. The number of founders (animals with unknown ancestors in the pedigree) was 5,479, while the effective number of founders reached 669.5. The difference between these 2 values indicates that not all horses' founders contributed equivalently to the population. The evaluation of the effective number of ancestors indicates that the 100 main breed males account for 30.13% of the genetic diversity of the population reference, while the top 10 account for approximately 7.5%.

Key Words: genetic diversity, inbreeding, pedigree

W197 Understanding the impact of frozen semen on swine production systems. D. Gonzalez-Pena*, N. V.L. Serão, R. Knox, and S. L. Rodriguez-Zas, *University of Illinois at Urbana-Champaign, Urbana.*
